Dynamics may be divided into two distinct parts: the mathematical consideration of motion, without reference to any connexion with its cause, and the experimental investigation of the connexion between pressure and the motion produced by it, together with the mathematical exhibition of the laws under which the second is a consequence of the first. The former branch is purely mathematical, and will be further treated under the head **MOTION, RELATIVE**; the latter will be found, as to its experimental part, under **MOTION, LAWS OF**; and as to the mathematical part, under **FORCES, IMPRESSED AND EFFECTIVE, and VIRTUAL VELOCITIES, PRINCIPLE OF.** We need not suggest that such articles as **FORCE, GRAVITATION, ATTRACTION, PERCUSSION, FRICTION, &c. &c.** contain the details of matters connected with the general term dynamics. The history of dynamics is particularly connected with the names of Galileo, Huyghens, Newton, D'Alembert, and Lagrange. See also on this point **MECHANICS**, the general term under which statics and dynamics are included.

DYNAMOMETER (measurer of power), a term which has been applied to an instrument which measures any thing to which the name of power has been given, whether that of an animal, or (to take a very different instance) of a telescope. We have also seen the incorrect term *dynameter*.

DYNO'MENE, a genus of brachyurous crustaceans belonging to the division *Notopoda*, founded by Latreille.

Character.—*Ocular pedicles* longer than those of *Dromia*. *Shell* wide, nearly heart-shaped and truncated posteriorly, hairy or bearded. *Two posterior feet* only dorsal, and much smaller than the others.

Example, *Dynomene hispida*, the only species known to M. Latreille. Locality, Isle of France.

Dynomene hispida.

DYRRA'CHIUM. [**DURAZZO.**]

DY'SENTERY (*Δυσεντερία*, *Dysentery*, from *δύς*, with difficulty, and *έντερον*, intestine; *difficultas intestinorum*, bloody flux), a disease in which there is difficulty and pain in passing the stools, which consist of mucus and blood, containing little or no faeculent matter, and generally attended with fever. The desire to evacuate the bowels is frequent and urgent; but the effort is accompanied with severe pain, and is often altogether ineffectual, constituting the affection called tenesmus. What scanty stools are passed consist, as has been stated, of mucus mixed with blood, or of pure blood in considerable quantity; and if any faeculent matter be present, it is commonly in the form of round and hard balls called scybala. There is always gripping pain in the abdomen. More or less fever is invariably present. The seat of the disease is chiefly in the large intestines: the disease itself consists essentially of inflammation of the mucous membrane.

The forms of this disease, the causes which produce it, the circumstances under which it prevails, the pathological conditions on which its essential characters depend, and its degrees of intensity, are infinitely various; and these modifying influences cause it to assume at different seasons, in different climates, and in different constitutions, the most diversified aspects. It is sometimes a primary, sometimes a consecutive, and sometimes a symptomatic disease. It is now sporadic, now endemic, and occasionally both endemic and epidemic. It is sometimes inflammatory and sthenic, at other times typhoid and asthenic, at one time acute, and at another chronic. These differences are attended with essential differences in the nature of the disease, which not only communicate to it different external aspects, dependent on different internal conditions, but which require totally different remedies.

In the acute form of dysentery, when purely inflammatory, and when mild in character, constipation commonly precedes for some days the attack of diarrhoea. The liquid and frequent stools which at length succeed to this state

of constipation soon become streaked with blood; the gripping pains which accompany the evacuations, and the straining and tenesmus which follow them, are often attended with distinct chills. The stools may be from eight or ten to sixteen or twenty in the twenty-four hours. The pulse is commonly quick and small, the tongue loaded, and the appetite little impaired.

When the attack is more severe, it is generally attended at the very commencement with diarrhoea, often accompanied with nausea and vomiting, quickly succeeded by scanty, mucous, or gelatinous stools, streaked with blood, preceded by tormina, and followed by tenesmus. The pain in the course of the large intestines may be either severe, or it may not be urgent, but rather a sense of heat and aching than acute pain. Pain, however, is always induced by full pressure over the tract of the colon; and if, in any particular part of this tract, there be urgent pain, some degree of fulness may generally be perceived there. The progress of the disease is indicated by the increasing severity of all the symptoms, and more especially by the increasing frequency of the stools, by the increasing tormina and tenesmus, and the augmentation of the general febrile symptoms. It is not uncommon for from twenty to forty efforts at stool to be made in the twenty-four hours, with the effect of passing only a very small quantity of mucus and blood. In all cases the evacuations are exceedingly offensive; in the worst they are of a cadaverous odour, and the clots of blood are sometimes mixed with pieces of coagulated lymph or fibrin.

In hot climates the disease is still more intense. The heat, the tormina, and the tenesmus, are more urgent and distressing; the thirst becomes excessive, the urine scanty or altogether suppressed, the stools slimy, streaked with blood, and attended with *prolapsus ani*, or watery and ichorous, 'resembling the washings of raw beef, in which float particles or even large shreds of coagulable lymph, thrown off from the acutely-inflamed surface.' In these cases the prostration of strength is extreme, and is increased by most distressing and exhausting vomiting. When, as sometimes happens in this form of the disease, portions of the mucous coat of the intestine slough away, the countenance of the patient is sunk and cadaverous, and the odour of the stools, and in some degree, indeed, of the whole body, is putrid.

In the asthenic form of dysentery, the tormina, tenesmus, and mucous and bloody stools are attended with great depression of all the organic functions, and extreme prostration of strength. The local dysenteric symptoms, exceedingly urgent from the commencement, are rapidly followed by fever of a low nervous or typhoid type. This form of the disease often prevails as an epidemic; and under circumstances favourable to their accumulation and concentration, exhalations from the stools of the sick seem capable of producing dysentery in persons directly exposed to them, previously in a state of sound health. These forms of the disease are very apt to occur in hot seasons and in hot climates, where great numbers of persons are collected together in close and ill-ventilated apartments, in damp and unhealthy situations, as in barracks, garrisons, camps, crowded ships, &c. It is this form of dysentery which rages among the poor in seasons of scarcity, which sometimes destroys whole armies in countries laid waste by war, and which so constantly, in besieged towns, anticipates the havoc of the sword.

The duration of dysentery is as various as its types. It may prove fatal in a few days or hours, or last for weeks and even months, and ultimately destroy life by inflammation and gangrene of the bowels. In some cases the disease ceases spontaneously, the frequency of the stools, the gripping and the tenesmus gradually diminishing, while natural stools return; but in other cases the disease with moderate symptoms continues long, and ends in protracted and exhausting diarrhoea.

The causes which predispose to dysentery appear to be long-continued exposure to a high temperature, or alternations of heat and cold; hence the disease is generally most prevalent in summer or autumn, after considerable heats have prevailed for some time, and especially after very warm and at the same time very dry states of the weather. It is certainly more frequent, as well as much more severe, in hot than in cold or even in temperate climates. All observation and experience show that a powerful predisposition to the disease is formed by the habitual use of a high and stimulating diet, and especially by indulgence in spi-

rituous liquors, by excessive fatigue; and by all causes which enfeeble the constitution in general, at the same time that they over excite the alimentary canal in particular.

The exciting causes are long-continued exposure to intense heat, or to sudden and great alternations from heat to cold; exhalations from vegetable and animal matters in a state of decomposition, as from marsh, stagnant, river or sea water, from animalculæ and minute insects, or from the flesh of deceased animals; noxious exhalations from the bodies of persons crowded together in close and confined situations, and more especially, as would appear, from the discharges from the bowels of persons labouring under dysentery; scanty and bad food, consisting more especially of vegetable or animal matter in a state of decay, as tainted meat, stale fish, unwholesome bread, unripe rice, &c.

The inflammatory affection of the mucous membrane of the large intestine in which dysentery essentially consists, passes, in the severe forms of the disease, into ulceration and even gangrene. On the examination of the large intestine in fatal cases after death, there is often found effusion of coagulable lymph, ulcers of various forms, and patches more or less extensive of mortification. In the most malignant varieties the internal surface of the whole alimentary canal is of a livid, purple, or dark colour, with patches of excoriation, ulceration, and gangrene.

In the acute form of dysentery, when the fever is high, the pain intense, and the inflammation active, blood-letting from the arm is indispensable, which must be repeated to the subdual of the acute inflammatory symptoms. After a moderate general blood-letting, however, the local abstraction of blood by leeching or cupping is more efficacious; the number and the repetition of the leeches must of course depend on the urgency of the pain and the strength of the patient. The employment of purgative remedies in dysentery requires the greatest discrimination and caution. If the colon be distended with feculent matter which it cannot discharge, no remedies will succeed until this accumulation is removed; if, on the contrary, there have been already frequent and copious discharges of feculent matter, the administration of purgatives is absurd, for all purgatives are irritants, and the diseased membrane is already in a state of intense excitement. The practitioner should therefore carefully examine the state of the bowels with regard to their fullness or emptiness of fecal matter, and their actual state in this respect can almost always be ascertained with a great degree of certainty if due pains be taken to discover it. If there be reason to suppose that there is any accumulation of feces, the mildest purgatives should be given, of which the best is castor oil, and this should be cautiously repeated until the irritating matter is wholly removed. Great relief is at the same time afforded to the distressing tormina and tenesmus by emollient and opiate enemata injected in very small quantities. After the subdual of the inflammatory state by blood-letting, and the evacuation of the accumulated feces by mild purgatives, the great object is to soothe the irritated membrane by opiates, on the judicious employment of which, and the skilful combination and alternation of this class of remedies with mild purgatives, the successful treatment of ordinary dysentery mainly depends. The acute forms of dysentery in hot climates require a prompt and decided combination of remedies, the best selection and administration of which it is impossible to discuss here. The asthenic forms with typhoid symptoms need a guarded yet active treatment, nearly the same as that which is proper to typhus fever with abdominal affection. [FEVER.]

DYSPEPSIA (*Δυσπεψία*, *dyspepsia*). *Indigestion*, the difficult and imperfect conversion of the food into nutriment. Digestion is a part of the great function of nutrition; its ultimate object is to convert the aliment into blood. Between the articles taken as food and the nutrient fluid of the body—the blood, there is no obvious analogy, and there is a wide difference in nature. Hence the function of digestion consists of a succession of stages, at each of which the food undergoes a specific change. Each change is effected by a peculiar process, for the accomplishment of which a special apparatus is provided. Of these processes the chief are mastication, deglutition, chymification, chylification, and fæcation. The delicacy and complexity of the apparatus by which each of these processes is carried on has been already shown. [DIGESTION.] The healthy condition and the natural action of every individual organ belonging to the portion of the

apparatus proper to each of these processes is necessary to the sound state of the function of digestion. It is easy therefore to see by how many causes it may be disturbed; in how many different organs the source of the disturbance may have its seat, of how varied a nature the disturbance may be, and how greatly the disturbance of the digestive function may derange the other functions of the body.

In the history of the human family there is no known community of human beings in any country, and no age of human life, in which the first necessity of existence, that of taking food for the nourishment of the body, is not the cause of disease and death to great numbers, and of uneasiness, nay, sometimes even of intense pain to far greater numbers. Why is this? Why is the digestive process more productive of suffering, disease, and death in man than in the lower animals of a similar structure, in which the function, considered in a physiological point of view, is scarcely at all less complex? The correct answer to this question would include a clear account of the causes of dyspepsia, and would suggest the appropriate remedies for the disease.

Digestion being an organic function, when this function is healthfully performed, for reasons which have been fully developed, it is unattended with consciousness. The first effect of the disturbance of this function is to render the patient not only conscious, but painfully conscious, that he has a stomach. A sense of nausea, sometimes, when the affection is severe, even vomiting, an obscure feeling of uneasiness, fullness, distension, weight in the region of the stomach, occasionally amounting to pain, and even severe pain, flatulence, eructation, a sensation of sinking, and lastly, a loss of appetite, constitute the train of uneasy sensations which, coming on after the reception of food, indicate disordered digestion, and which take the place of the feelings of refreshment and exhilaration which result from healthy digestion.

When these uneasy sensations are occasioned by a disordered state of the stomach, it is easy to understand, from the exposition already given of the structure and function of this organ [DIAGNOSIS], that the disorder may consist in a derangement either of its secreting arteries, or its mucous glands, or its organic nerves, or its muscular fibres, inducing a deficient secretion of the gastric juice, a deficient secretion of mucus, a diminished or increased irritability of the muscular fibres, by which the motions of the stomach are disturbed. If the gastric juice be deficient, the first step in the digestive process cannot take place, the food cannot be dissolved; if the mucus be excessive, the contact of the gastric juice with the food may be prevented: if the muscular fibres of the stomach are torpid or too irritable, the food may be detained too long or too short a time in the stomach.

The causes of dyspepsia are either those which act directly and immediately upon the stomach itself, or those which act upon the whole body or upon particular parts of it, but which still affect the stomach principally and almost solely.

Of the first kind are noxious, irritating, and indigestible substances taken into the stomach as articles of food or drink, such as tainted meat, decayed vegetables, unripe fruit, very acid matters, ardent spirits, &c.; and even wholesome food taken too frequently or in too large a quantity, especially when its nature is very nutritious, as when it consists principally of animal matter, or when a large quantity of nutriment is presented to the stomach in a very concentrated form, or is rendered too stimulating by being highly seasoned; the abuse of fermented and spirituous liquors, which is one of the most frequent causes of dyspepsia in its severest and most fatal forms; and large quantities of fluids, habitually taken at too high a temperature, as very hot tea, coffee, or soup.

Of the second kind, or the causes which act upon the whole body or upon particular parts and functions of it, are—want of pure air; hence the frequency of dyspepsia in large and crowded cities, and more especially in narrow and confined lanes and alleys, in the dirty and ill-ventilated houses of the poor. Want of exercise: from physical inactivity all the organs of the body languish, but the stomach first and most. Intense study or close application to business too long continued, implying both want of air and want of exercise. Mental emotion, more especially the depressing passions, fear, grief, vexation, dis-

appointment, anxiety and hope deferred. Exposure to the influence of cold and moisture. In persons with weak stomachs and delicate skins, a cold damp day, more especially suddenly succeeding a hot day, often produces a severe attack of dyspepsia. Hence it is that dyspeptic complaints are so prevalent when cold and damp weather first sets in. Cold is a sedative to the nervous system, as heat is an excitant; and the depressing effects of cold seem to be peculiarly manifested in the nerves of the stomach. Excessive discharges from the body, as flooding, leucorrhœa, large bleedings from the arm, profuse and long-continued sweating, and above all protracted suckling. It is a common practice among the poor in this country to suckle their children too long. A feeble woman is often seen with a strong child at her breast a year and a half or two years old. The effect upon the constitution of the mother is most pernicious. Emaciation, sharpness of the features, with a peculiar expression in the countenance of languor and exhaustion, a sense of sinking at the pit of the stomach, dimness of sight, giddiness, spectra of different kinds dancing before the eyes, headache, with a small, quick, and sometimes almost imperceptible pulse, and total loss of appetite, are the peculiar characters of this variety of dyspepsia.

The state of dyspepsia is most frequently a state merely of disordered function, without any appreciable change of structure in any of the tissues of the stomach. But all the symptoms of dyspepsia are produced in their intensest degree when they arise from some organic disease of the stomach. Of these the most frequent is inflammation of its mucous coat. This inflammation may be either acute or subacute. When acute, the nature of the malady is indicated by characters so striking that it cannot be overlooked; but the subacute form often exists for a long period quite unsuspected, producing violent and obstinate dyspepsia, which is often greatly aggravated by the remedies employed to remove the complaint. The diagnostic sign of this form of the disease is tenderness on pressure in the epigastric region. In scirrhus of the pylorus and ulceration of the mucous glands of the stomach, organic disease not of unfrequent occurrence, there is superadded to the ordinary signs of dyspepsia a peculiar train of symptoms scarcely to be overlooked or mistaken.

But dyspepsia is often the result of disease situated not in the stomach, but in some other organ. The stomach has been justly called the centre of sympathies, and there is scarcely any disorder of the body which does not affect the functions of the stomach in a greater or less degree. The organs the diseases of which are most apt to produce disorder of the stomach are the liver, the spleen, the uterus, the kidney, the bronchi, and the skin. In this secondary form of dyspepsia, the disease cannot be removed unless the seat of the primary affection, and the true nature of that affection, be ascertained.

The stomach is the organ in which chymification is effected. Chylification is accomplished in the duodenum, and completed in the jejunum, ilium, and mesenteric glands; and the highly important part of the digestive process, that which consists in eliminating and carrying out of the system the non-nutrient portion of the aliment, is performed by the large intestines. Each of these organs may be the primary seat of disease, giving rise to the ordinary symptoms of dyspepsia; but to these there will generally be superadded peculiar signs pointing out the real seat of the malady, signs almost always to be observed if carefully looked for, and the detection of which is of the utmost importance in the treatment of the disease.

The indications of cure are to avoid or remove the remote causes, to remove the symptoms which especially contribute to aggravate and continue the disease, and to restore the healthy tone of the disordered organs. There is no drug, no class of medicines, no one mode of treatment capable of removing dyspepsia when present, or of preventing its recurrence. This can only be done by a careful study of the exact cause of the disease in every individual case, and the precise seat and nature of the affection. The mode of treatment must be modified in strict accordance with these circumstances; and no mode of treatment will be attended with success of which the appropriate regulation of the diet and exercise does not form an essential part.

E.

E occupies the fifth place in the Hebrew alphabet and those derived from it. The vowels, when arranged according to their physical affinity, would lie in the series *i, e, a, o, u* [ALPHABET], and accordingly the vowel *e* is frequently interchanged with its neighbours *i* and *a*. It is occasionally convertible with *o* and *u*.

1. *E* is interchanged with *i*. Thus in Latin the old datives *heri, mani, ruri, musai*, afterwards took the forms *here, mane, rura, musae*; and the words *magis, videris, tristis*, when they appeared without an *s*, were written *mage, videre, triste*. The same interchange appears in the declension of the adjective *is, ea, id*, and the conjugation of the verbs *eo* and *queo*.

2. *E* in Latin often corresponds to *oi* in French. Thus many Latin infinitives in *ere* reappear in French with the termination *oir*, as *habere, debere; avoir, devoir*. The Latin past imperfect has the suffix *eba*, which passed through the forms *eva* and *ea* to *ois* and *oi*. Thus from *habebam* were deduced *aveva, aveu, avois*, and lastly *avois*. This final *s* does not appear in the oldest forms of the French language. Other instances of the change of *o* into *oi* may be seen in the Latin adjectives and other words in *ensis* or *estis*, which in French have the suffix *ois*, as *Vien-nensis, Viennois; mensis, mois*.

3. *E* Latin into *ie* French, as *mel, bene, ped; miel, bien, pied*.

4. *E* into *a*. This is well marked in the dialects of the Greek *σοφία*, Ionic; *σοφια*, Doric, &c. Hence the Latins have often an *a* where the common dialect of the Greek had *e*, as *μηχανη, πλαγη*; Lat. *machina, plaga*. Both forms often coexist in Latin, as *tristitia* and *tristitie*. The *a* is often changed into *e* in Latin, if a prefix is added, particularly if two consonants follow the vowel, as *factus, confectus; pars, expers; castus, incestus; ars, iners*.

5. *E* into *o*. Especially in Greek, as *λεγω, λογος; νιμω, νομος*. The Latin language prefers the *o*, as *ιμεω, vomo; πεπω, coquo; νος, nopus*. This change is particularly common in words beginning with a *w*, or with what was pronounced as a *w*, the Latin *v*. Thus *vester, velim, vorto, veto*, were once written *voster, volim, vorto, voto*. Even in our own language *worm* (vermis, Lat.), and *work* (ἔργον, Gr.), are now pronounced as if written with an *e*. The Greek even interchanges a long *o* with a long *e*, as *παρρη, ἀπαρρη, ἐκπαρρη*.

6. *E* Greek is changed into *u* in Latin before an *l*, as *Σικελος, Siculus*.

E (in music), the third note or degree of the diatonic scale, answering to the *mi* of the Italians and French.

EADMER, or **EDMER**, the friend and historian of Archbishop Anselm, lived in the twelfth century, but we have no information respecting his parents, or the particular time and place of his nativity. He received a learned education, was a monk of Canterbury, and became the bosom friend and inseparable companion of two archbishops of that see, St. Anselm and his successor Ralph. To the former of these he was appointed spiritual director by the pope. In 1120, by the desire of Alexander I. of Scotland, he was elected bishop of St. Andrews: but on the day of his election a dispute arose between the king and him respecting his consecration. Eadmer wished to be consecrated by the archbishop of Canterbury, who, he contended, was the primate of all Britain; while Alexander contended that the see of Canterbury had no pre-eminence over that of St. Andrews. Eadmer finally abandoned his bishopric and returned to England, where he was kindly received by the archbishop and clergy of Canterbury, who yet thought him too precipitate in leaving his bishopric. Eadmer at last wrote a long and submissive letter to the king of Scotland, but without producing the desired effect. Wharton fixes his death in 1124, the very year in which the bishopric of St. Andrews was filled up. Eadmer is now best known for his history of the affairs of England in his own time, from 1066 to 1122, in which he has inserted many original papers, and preserved many facts which are no where else to be found. His style is regular and good, and his work more free from legendary tales than is usual with the works of his time. The best edition is that by Selden, intitled

'Eadmeri Monachi Cantuariensis Historiæ Novorum, sive sui Sæculi, Libri Sex,' fol., London, 1623. His life of St. Anselm was first printed in 12mo, at Antwerp, in 1551, under the title of 'Fratris Eadmeri Angli de Vita D. Anselmi Archiepiscopi Cantuariensis, Libri duo.' Several others of his works, with the 'Historia Novorum,' were edited by the congregation of St. Maur at the end of Father Gerberon's editions of the works of St. Anselm, fol., Par., 1675 and 1721. His Lives of St. Wilfrid, St. Oswald, St. Dunstan, &c., with that of St. Anselm, were inserted by Wharton in his Anglia Sacra. (Tanner, *Bibl. Brit. Hib.*; Præf. ad *Opera S. Anselmi* ut supr.; Chalmers's *Biogr. Dict.*)

EAGLE. [FALCONIDÆ.]

EAGLE (constellation). [AQUILA.]

EAGLE (coin). [MONEY.]

EAGLE, Roman Standard. The eagle, as a symbol of empire, is often seen on antient coins and medals, and on none more frequently than on those of the Ptolemies of Egypt and the Seleucids of Syria. As an ensign of standard, borne upon a spear, it was used by the Persians in the time of the younger Cyrus. (Xenoph. *Anab.* l. 10.)

Pliny (*Hist. Nat.* li. x. c. 4, edit. Hardouin, tom. i. p. 549) says that, till the time of C. Marius, the Romans used five different animals for standards—the wolf, the minotaur, the horse, the boar, and the eagle—but that in Marius's second consulate they adopted the eagle as the sole ensign for their legions.

The eagle used by the Romans as a standard was of gold or silver: the latter metal, we are told by Pliny, was most frequently used, as the more glittering, and of course more readily seen. It was borne, like the Persian eagle, on the summit of a spear, and was of the size of a pigeon, with its wings displayed. It sometimes rested upon a cross bar on the top of the spear, and sometimes upon shields piled up. On the reverses of some of the coins of Augustus and Galba, in second brass, the legionary eagle is represented holding the thunderbolt in its talons. The small size of the eagle often contributed to its concealment, when the legion to which it belonged was defeated. The name of the legion was usually engraved upon it. Tacitus, in his *Annals* l. i. 60. relates the finding of the eagle of the nineteenth legion by Germanicus, which had been lost in the massacre of Varus.

Cicero (*Catilin.* i. c. 24) says that Catiline had a silver eagle in his house as his tutelary divinity, which was also his standard in war.

A Roman eagle in steel, found at Silchester, presumed to have been a legionary eagle, was exhibited to the Society of Antiquaries in 1788 by the then bishop of Carlisle.

The reader will see a great deal of learning displayed upon this and the standard of the cohorts in M. Le Beau's 'Quatorzième Mémoire sur la Légion Romaine; Des Enseignes.' Mem. de l'Académie des Inscriptions. tom. xxxv. 4to. Par. 1770, pp. 277-308.

EAGLE-WOOD, one of those substances of which the name, from similarity of sound in a foreign language, has been converted into another having no reference to its original signification. It is a highly fragrant wood, much esteemed by Asiatics for burning as incense, and known in Europe by its present designation ever since the Portuguese visited and imported the substance direct from the Malayan islands and the kingdom of Siam, where it has always been abundant, and long established as an article of commerce. The Malayan name is *agila*, whence the wood was called *pao-d'agila* by the Portuguese, and has since been converted into *pao-d'aguila*, and *pao-d'aquila*, bois-d'aigle, eagle-wood, and agel-hout.

From the Malayan *agila* has probably been derived the Sanscrit *agara*, whence we have the Hindu *agur*, if not from the more familiar appellation of *garoo*, by which eagle-wood is also known in the Malayan Archipelago. In Persian works on Materia Medica in use in India, we learn from Dr. Royle (*Illustr. of Himal. Bot.*, &c.) that several kinds of fragrant wood are described under the Arabic name *aod* (*haud* and *ud* of Garcias), and that he himself obtained three kinds in the bazaars of India, called *aod-i-hinder*, *aod-i-chinese*, and *aod-i-kimares* (evidently the al-cemicum of Arabian authors), and that with the above Hindu a Greek

synonyme, *agallochee*, is also given, and more especially applied to *sod-i-kimaree*, which is also called *aod-i-bukhoor*, incense-wood. As *agallochee* is no doubt a corruption of the *agallochum* of Dioscorides, described by him as a fragrant wood from India and Arabia, it is interesting to find that the translators from the Greek into the Arabic of the school of Bagdad settled these synonyms at a time when they must have been well acquainted, from their profession and position, with the substances to which both the Greek and Arabic names were applied. Serapion and Avicenna describe several kinds of this fragrant wood, and the latter under both *agalugen* or *aghaloojee*, and *aod*, which in the Latin version is translated *Xyloaloe*, a name that was applied by the later Greek medical writers to *agallochum*, whence we have *lignum aloes*, *lign-aloe*, and *aloes-wood*, the origin of which it is difficult, if not impossible, to ascertain, unless we suppose it to be a corruption of *agila*; for the bitter, scentless, spongy-textured stems of the genus *aloe* could not afford any substitute for this fragrant wood, or be thought to yield it, at least by the Arabs, who were well acquainted with, and accurately describe *aloes*, and the place, Socotra, where the best kind is found. Though Dioscorides notices only one, which some supposed to be the Tarum of Pliny, several kinds of *agallochum* are described by Serapion and Avicenna, which, as it is not possible at present to identify, it is unnecessary to notice, and therefore we shall refer only to the three kinds which have been traced to the trees yielding them, by naturalists who have visited the countries where these are indigenous.

An *Aguila brava* (wild) is mentioned by Garcias as produced near Cape Comorin, in the southern part of the Indian peninsula, and in the island of Ceylon; but the tree yielding this wood has not been ascertained. Rumphius (*Herb. Amb.* ii. p. 40), describes two kinds of *agallochum spurium*, found in Borneo and Sumatra, one of which he calls *Garu Tejampaca*, which is described as having leaves and flowers resembling those of the celebrated *champa*, *Michelia champaca*, and may be a species of the same genus. A third kind of spurious *agallochum*, differing much from the others as well as from the genuine, he describes in another part of his work, ii. p. 240, as the produce of his *Arbor excecans*, so called from the acridity of its juice blinding people, and which is the *Excecaria agallocha* of Linnaeus. Considering that Rumphius, in originally describing this tree, has said 'Lignum hoc tantum cum agallocha similitudinem,' and as affording a substitute for that substance, it is not surprising that it should be frequently quoted as the tree which yields the genuine *agallochum*, or *aloes-wood*. Fée (*Hist. Nat. Pharm.*) states that he had seen a genuine specimen of the wood of this tree, and that its fragrance cannot be compared with the *agallochum* of Loureiro. Dr. Roxburgh mentions that the wood-cutters of the Delta of the Ganges, though well acquainted with the highly acrid and very dangerous milky juice of this tree (there called *geria*), do not mention *agallochum* of any kind being found in this tree.

Of the two kinds of *agallochum* which are most valued, and both considered genuine, one is distinguished by the name of Calambac, and the other as the *Garu of Malacca*.

The first, called *calambac*, and *agallochum primum* by Rumphius, appears, as far as hitherto known, to be a native of Cochin China only, growing on the mountains of that country in about 13° of N. lat., near the great river Lavum, which may be the Meikeng flowing between Cochin China and the Laos. This tree was named *Aloexylum agallochum* by Loureiro, *Fl. Coch. Chinensis*, p. 327, and placed by him in Decandria Monogynia, and described as a lofty tree with erect stem and branches, long lanceolate shining leaves, terminal bunches of flowers, with a woody, falcate, one-seeded pod for its fruit, whence it is referred by De Candolle to the natural family of Leguminosae. Loureiro states that the wood of this tree is white and inodorous, and that its fragrance is the result of disease, when the oily portions thicken into resin in the central parts of the tree, and that no part of the tree is milky or poisonous, but that paper is made from its bark in Cochin China, as in Japan from that of the mulberry.

The next kind of *agallochum* is that commonly called *garu*, and to which the name of eagle-wood is more frequently applied, and which has long been an article of export from Malacca and the kingdom of Siam. Specimens of the tree which yield this were first obtained by M. Sonnerat in his second voyage to India, from which probably have been given the figure and description by Lamarck.

(*Enc. Méth.*, i. p. 49, Illustr. t. 376.) The plant he named *Aquilaria Malaccensis*. This, the *Garu de Malacca*, was introduced by Dr. Roxburgh into the Botanic Garden of Calcutta, and was not to be distinguished from specimens of a tree called *ugoon*, which is a native of the mountainous tracts east and south-east from Silhet, between 24° and 25° of N. lat., which flowers in April, and ripens its seed in August, and which he says there can be little or no doubt furnishes the real Calambac or *Agallochum* of the ancients; adding, that there seems more reason to think that it was carried to China from our eastern frontier, than to suppose it was carried from Cochin China, or any other country in the vicinity of China, where it has always been in great demand. Small quantities are sometimes imported into Calcutta by sea, from the eastward; but such is always deemed inferior to that of Silhet. (*Fl. Ind.* ii. p. 423.) As the Malacca plant had not flowered, Dr. Roxburgh was unable to decide that they were positively the same with those from Silhet, and therefore named these *Aquilaria agallocha*, as another species of the same genus. By this name it has been figured in Royle's *Illustr.* i. 36, f. 1, from a drawing by Dr. Hamilton of a plant which he called *Agallochum officinarum*, and which he found near Goalpara, on the eastern frontier of Bengal. This drawing is illustrated with dissections by Dr. Lindley. To the above-quoted work, and the latter's 'Natural System of Botany,' we refer for the botanical details and the characters of the family of *Aquilariaceae*, to which this genus gives its name. The fragrant nature of genuine *agila* or eagle-wood is well known, and that it has from very early periods been employed both by the natives of India and of China as incense. Mr. Finlayson, in his visit to Siam, says, that the consumption of this highly odoriferous wood is very considerable in Siam, but that the greatest part is exported to China. In the latter, it is used in a very economical manner; the wood being reduced to a fine powder and mixed with a gummy substance is laid over a small slip of wood, about the size of bull-rush, so as to form a pretty thick coating. This is lighted, and gives out a feeble but grateful perfume. French authors inform us that the eagle-wood was burned as a perfume by Napoleon in the imperial palace.

We cannot conclude this subject without inquiring whether the substances of which we have been treating are the lign-aloes of Scripture, *ahaloth*, masc. *ahel*, whose plural is *ahalim*. It would be impossible to do justice to the subject in a small compass, or without referring to the numerous dissertations which have been written on it; but it may be observed, that these might have been much shortened, if the authors had been naturalists, or intimately acquainted with the natural history and usages of eastern countries; such information would at least have prevented any species of *aloe* being considered or figured as the far-famed and fragrant lign-aloe from a mere similarity in sound. In the present instance, the difficulty is increased by the supposed necessity of reconciling the different passages in which lign-aloes are mentioned, as in *Numbers*, xxiv. 6, where it is mentioned as a tree planted; but in the three other passages, *Prov.* vii. 17, *Psalms* xiv. 9, and *Canticles*, iv. 14, it is enumerated with the most fragrant products of the East, as cinnamon, cassia, calamus, camphor, frankincense, myrrh, spikenard, and saffron. Here we may observe, that a substance which was indigenous in a country was not likely to have been an article also of commerce from a far country in those early times; and that therefore, as it is disputed whether the word shall be translated *tents* or *lign-aloes*, the word may perhaps be used in a poetical sense, as it is thought to be by some commentators. In the three passages, it may be noted, that, except sandal-wood, there is no other substance which could be so well enumerated with those with which it is found in connexion as the *agila* wood of the East, whether we consider its high price, delicate perfume, or the long time in which it has been held in high estimation, while the similarity of its name is at the same time remarkable.

EAGRE. [Borr.]

E.A.R. Many animals unquestionably enjoy the faculty of hearing to a limited extent, which are found, upon examination, to be unprovided with organs exclusively appropriated to the concentration and transmission of sound. In fact, the sense of hearing is, strictly speaking, only a refinement of the sense of touch. The impressions with which it is conversant arise wholly [Acoustics] from peculiar undulations of the particles of ordinary matter, propagated in obedience to its ordinary laws through the medium of

which the animal lives, and impinging more or less immediately upon a sensitive part; they have no necessary dependence, like those of sight, upon the agency of the more subtle fluids; nor have they any connexion, like those of smell and taste, with what may be called the *chemical* properties of matter. If to these considerations it be added that the vibratile substances which are commonly found to inclose the sensorium are not ill qualified to participate in the undulations of the surrounding medium, and carry them onwards to the internal seat of perception, the reader will be prepared to learn that the only *essential* part of the organ of hearing is a *nerve*, not materially different from those of common sensation, lodged at a sufficient depth to be secured from external injury, and sufficiently sensitive to be affected by these delicate impulses. This is called the *acoustic* or *auditory* nerve.

It is probable that even the lowest animals provided with a nervous system are able to perceive the notices thus conveyed of external objects, and turn them to account in the degree necessary for their security and comfort. But to meet the increasing wants and minister to the multiplied faculties of the more complete animals, various subsidiary parts are found to be added in something like a regular succession as we advance upwards in the scale, each lower grade possessing the rudiments of some additional provision more fully developed in the next above, till the organ reaches its greatest amplification and final perfection in man and the other mammalia. The particular use of many of these subsidiary parts has not yet been explained. We know in general that they must increase the force and vividness of the impression; that they afford indications of its direction, and the means of appreciating minute shades of difference in its kind and degree, and in the frequency of its repetition; that some of them add to the security of the organ without impairing its delicacy; and that others serve to adjust its position and to adapt it to various changes in the state of the atmosphere. It would be superfluous, in a work addressed to the general reader, and limited in space, to trace these gradual and complicated changes: we must content ourselves with noticing some of the most important of them, and then pass on to the description of the organ as it exists in man: advising the curious inquirer, after he has made himself acquainted with the details of that organ and with the classification of animals by Cuvier, an outline of which is given in a former part of this work [ANATOMY, COMPARATIVE], to consult the admirable essay on this subject by Professor Grant, in the third part of his 'Outlines of Comparative Anatomy,' where he will find a comprehensive and masterly summary of all that is known on the subject, from which we should be inclined to quote largely here, were space allowed and selection easy.

The *Radiata* (star-fish, sponges, &c.), which constitute the lowest, and in point of variety and number by far the most comprehensive division of Cuvier, appear to be universally unprovided with an organ of hearing: many of them have no nervous system, and are therefore probably altogether devoid of the sense.

The *Articulata*, which form the next division, are all furnished with a nervous system, and it is likely that they all enjoy the sense of hearing. Indeed, some of them are able to express their feelings and wants to their fellows by means of peculiar sounds, of which the cricket and queen bee are well-known examples. We find accordingly, that in many of the more perfect species the extremity of the acoustic nerve is expanded upon a simple kind of auditory instrument consisting of a whitish membranous bag of fluid, placed within the head in a somewhat larger cavity, the space between them being also occupied by fluid. This cavity is situated near the outer feelers, or *antennæ*. When the animal lives in water, it is commonly complete; if in air, there is a round external opening closed by a thin, tense and transparent membrane, showing the white colour within, to which the bag adheres, and which receives, concentrates, and transmits the sonorous vibrations of the surrounding medium. This kind of arrangement seems to be necessary, among other reasons, for the purpose of indicating the direction of the sound, which is probably made known in part by the clearer vibration of the membrane when turned in that direction, and in part by a comparison of the impressions on the two sides; for this organ, like all others which bring the animal into relation with the outer world (as distinguished from *ital* organs), is always double and symmetrical. It may be observed that the nerve dis-

tributed to the membranous bag just described is given on by that which supplies the antenna with its exquisite sense of touch: some have thought, but perhaps erroneously, that the faculty of hearing resides in the antennæ themselves.

The parts we have enumerated are all found, with others, in the higher animals, and may be considered as the most essential parts of an organ of distinct hearing. The cavity is called the *vestibule*; the soft membranous bag of fluid is the *vestibular sac*; the round external opening is called, from its shape in man and most other animals, the *fenestra ovalis*; the fluids within and without the sac are called respectively the *endo-lymph* and *peri-lymph*, (*ἔνδον* within, *περί* around); the latter, being analogous to the fluid discovered by Cotugno in the internal ear of mammalia is sometimes called, after his name, the *liquor Coturni*.

The principal tribes of the *Articulata* ascertained to possess organs of this kind are the air-breathing *insects* of the orders *Hymenoptera* (bees), *Orthoptera* (grasshoppers), and *Coleoptera* (beetles); the *Arachnida* (spiders), and the *Decapodous crustacea*, such as the lobster and crab. In the common black beetle they are very conspicuous, appearing externally in the form of round white points on the head, a little nearer the middle line, and somewhat higher than the base of the long outer antennæ. In the lobster they are contained in a small nipple-like prominence or *papilla* upon the under part of the moveable base of the antennæ, looking downwards and forwards. This papilla consists of a substance harder and more brittle and probably more vibratile than the rest of the shell.

The *Mollusca*, though placed higher in the scale of animals by Cuvier, do not afford so many examples of animals possessing a distinct organ of hearing as the *Articulata*. Such as have been discovered all belong to the order of the *Cephalopods* with two *branchiæ*, or gills, which approach more nearly to the true fishes in their structure than the other mollusks.

In the *Sepia*, or cuttle-fish, which belongs to this order, and which may be taken as a type of the rest, there is a protuberance under the elastic gristly integument at the back part of the head which contains the ear. It consists of a pair of symmetrical vestibules, each containing an oval *sac* filled and surrounded with fluid. On the interior surface of this sac the acoustic nerve is expanded in the form of a white mucous pulp. The sac is supported in the perilymph not only by an adhesion to the inner side of the parietes of the vestibule at the entrance of the nerve, but also by a fine net-work of fibrils which pass from its outer surface to numerous prominent points on the inner surface of the vestibule. There is no *fenestra ovalis*, or membrane, as in the lobster and the air-breathing insects, but the sac contains a small loose bony or chalky concretion, called an *otolith* (*ὠτὶς-λίθος*, the ear, and *λίθος*, a stone), which answers the same purpose, namely, to indicate the degree and direction of sound; for just as we estimate a weight by poising it in the hand, or, if it be suspended, by gently pushing it from us—thus measuring in our minds the muscular tension necessary to support it, or the force required to overcome its inertia, and conscious of the direction in which we exert our muscles—so, conversely (the weight and inertia of the *lapillus* always remaining the same), the degree and direction of a vibratory force affecting it from without through the medium of the integuments, the parietes of the vestibule, and the fluids within, may be estimated by a consciousness on the part of the animal of the nature of the stress on the sensitive membranes and fibrils which support it, which by their elasticity restrain and redress the slight movements impressed upon it. This should be borne in mind; for, as we shall see further on, it is in some degree by the exertion of the *muscular sense*, as Sir Charles Bell has called that by which we judge of weight and tension, that the human ear is enabled to estimate the intensity of sound. Other curious particulars as to the function of otoliths might be enlarged upon; but we have said enough to explain, as we think, the most important of them; and to correct the misstatements of authors who tell us that they are intended to *increase* the intensity of the vibrations of sound: they appear to us rather calculated to diminish it, as the board floating in the bucket of the water-carrier tends to prevent the fluid from dashing over the side. They undoubtedly play an important part in the organ of hearing, especially in the larger fishes, where they are more numerous, and attain a considerable size;

but it is difficult to conceive that they are possessed of any *intensative* power.

The *vertebrated* classes of the animal kingdom, comprising the true fish, reptiles, birds, and the mammalia, are all provided with acoustic organs, which are very various in their degrees of complexity, but much exceed in that respect the comparatively simple organs of the inferior divisions.

* In the cartilaginous fishes, such as the ray and the shark, the vestibule is deeply imbedded in the elastic walls of the back part of the cranium, near its junction with the spine. The fenestra ovalis, closed by a tense transparent membrane, faces upwards, backwards, and towards the middle line. The membrane is placed obliquely at the bottom of a more superficial, flattened, tubular cavity, which terminates beneath the integument in a kind of forked extremity, and may be considered as a rudiment of the *tympanum*, or middle ear, of the higher vertebrata, with its eustachian tube. The inner surface of the membrane is turned towards three *sacculi*, one of which is much larger than the rest, arranged at the opposite side of the cavity of the vestibule, and containing each an otolith. The sacs are filled with a thick gelatinous endolymph, which adheres to the lapilli, and serves, with minute filaments such as those in the *sepia*, to steady them. The vestibule is filled with a limpid aqueous perilymph, traversed in all directions by a fine cellular network, by means of which its contents are supported in their relative situations. Besides the fenestra ovalis, other perforations lead out of the vestibule into three arched cylindrical canals of considerable diameter and dimensions, the diverging curves of which take a wide circuit within the cranial cartilage, and terminate at both ends in this central cavity. These passages, from their situation and form, are called the anterior, posterior, and horizontal *semicircular canals*. Within the canals, in which the vestibular perilymph freely circulates, there are three similarly curved but more slender membranous elastic tubes: they are nowhere in contact with the sides of the canals, but are suspended in the midst of them by means of the cellular network above mentioned. They all swell out at one end like a flask (*ampulla*) as they enter the vestibule, after which the anterior and horizontal tubes separately enter a common pouch or *sinus*; into this their other ends likewise open by a conduit common to both. The posterior tube, which is the largest and longest, after forming its ampulla, resumes its former calibre, and passing along the floor of the vestibule under the largest *sac*, to which it is connected by the net-work, returns into itself, thus completing a separate circuit.

The fluid contents of the several membranous cavities do not communicate with each other or with the vestibular perilymph; though, as they lie in close apposition, their vibrations are mutually interchangeable.

The acoustic nerve is distributed in two principal branches only to the sacs and the ampullæ; chiefly to the latter, to which it gives a white colour. The filaments form a fine net-work on the outside of the ampullæ, and then piercing their parietes, are raised up within into a kind of crescentic screen, in order probably that they may be more exposed to the impulse of the vibrations descending along the aqueous endolymph of the semicircular tubes. All the parts we have described are transparent, except the opaque ampullæ and the solid cretaceous otoliths. We have been particular in our account of these membranous parts, which are found with little essential variation in all the superior animals, man included, because in the cartilaginous fishes they admit of more easy examination from their great size and firmer texture, and from the softness of the cartilage that encloses them. In man and the mammalia, they are not only much smaller and more delicate, but encased in the hardest bone in the body, from which it is almost impossible to separate them with sufficient accuracy to be certain that the description is correct.

In some cartilaginous fishes, as the sturgeon, the fenestra ovalis is not closed by a membrane, but by a round button-like piece of semi-transparent cartilage, called an *operculum*, or lid.†

The parts are similar in the osseous fishes, except that they have generally no fenestra ovalis.

In serpents there is but one sacculus containing chalky

* Scarpa de Audit.

† This is also found in the aquatic salamander, which, as concerns the organ of hearing, may be considered as the link between fish and reptiles, resembling the latter in the arrangement of the labyrinth, but being unprovided with a tympanum or a columella.

matter, and all the semicircular tubes communicate with a central membranous sinus, which the anterior and posterior tubes enter by a common trunk. The fenestra ovalis is closed, not as in fishes by a membrane, but by the expanded trumpet-shaped extremity of a slender bone (*ossiculum* or *columella*) attached at the other extremity by a ligament to the outer end of the intermaxillary bone.

Nearly the same arrangement of the *internal ear* prevails in the four-footed reptiles (turtle, crocodile, frog, lizard); but a new and important step is here made towards the ultimate perfection of the organ by the development of an air-cavity, called the *tympanum* or ear-drum, between the vestibule and the surface of the head. This addition, which, as we said, first becomes more than a mere rudiment in the four-footed reptiles, permits the vestibule to be placed with equal advantage at a comparatively greater depth, and therefore in greater security; but it has more important uses in rendering the sound more clear, and facilitating in several ways (to be presently explained) its communication to the auditory nerve. Like the musical instrument from which it takes its name, the tympanum is provided with a membrane tightly stretched upon the margin of a round opening in the outer part of its bony or cartilaginous wall; and has an open vent or passage called after the anatomist who discovered it, the *Eustachian tube*, leading forwards from the cavity to the throat or back part of the nostrils, by means of which the air within it is adjusted to the variable state of the atmospheric pressure without. If the animal be amphibious, as many of the four-footed reptiles are, the membrana tympani is still covered entirely by integument, sometimes, as in the crocodile, by a movable flap of the scaly hard skin, which can be raised up when the animal is out of the water: more frequently however the membrane lies entirely beneath the skin, here thinner than elsewhere on the head, as in the tortoise. The *lacerta agilis*, or basking lizard, alone, which lives entirely on the land, has the membrane naked to the air. In this class of animals the columella is not directed forwards to the angle of the jaw as in serpents, but is attached by a cartilaginous extremity to the centre of the membrana tympani, and thus conveys the collected effect of its vibrations directly to the fenestra ovalis: the effect of this arrangement in rendering the impression of sound more definite must be obvious. In some species the cartilaginous portion of the columella is joined to the bony portion at an acute angle, like the letter V, which adds an elasticity to the mechanism very serviceable as a protection to the delicate parts within the fenestra ovalis from the injury they might otherwise sustain by a blow or undue pressure upon the membrana tympani. This is the case with the lizard mentioned above, in which there is also a rudiment of the muscle which serves in the higher animals to tighten the membrane; a circumstance which makes this elbow in the columella a still more essential provision against sudden changes in the distance between the centre of the membrane and the fenestra ovalis. It is worthy of remark that in one class of serpents, the *cæcilia* (blindworms), the ear is as complete as in any of the four-footed terrestrial reptiles; possessing a tympanum with its membranes, a Eustachian tube, and a columella bent to an angle. This departure from the usual rule in serpents appears to be one of those compensations so frequently met with in the animal kingdom, the organ of sight in the *cæcilia* being imperfectly developed.

In birds, besides a greater nicety and tenuity in the conformation of the parts hitherto described, the ear is furnished with two additional provisions, both probably of great consequence to the perfection of the organ. The first is a short *meatus auditorius externus*, or outer passage, which removes the delicate membrane of the tympanum to some depth from the surface of the head, and thus places it more securely, and at the same time, to greater advantage for observing the direction of sound. The other additional provision in birds is an appendage to the mechanism of the internal ear. This is a small conical cavity in the bone, somewhat curved, with a double spiral ridge winding round the interior, and enclosing a cartilaginous structure so corresponding in form with the ridge as to divide the cavity into two partitions. These communicate with another at the apex, and with the vestibule and tympanum respectively, at their other ends. The cavity is termed the *cochlea*, from its resemblance to a spiral shell; the partition communicating with the internal ear is the *scala* (winding stair) of the vestibule; the other is the *scala tympani*; the open-

ing from the latter into the tympanum is called the *foramen rotundum*; it is closed by a membrane to exclude the air of that cavity while it permits the transit of vibration to or from the vestibular perilymph within; for that fluid, passing up the cochlea by the scala vestibuli, descends the scala tympani, and bathes the inner surface of the membrane of the fenestra rotunda. The cartilaginous *newel* is kept in its place like the semicircular tubes by retiform filaments, and is supplied with a separate branch of the acoustic nerve, which ramifies and expands on its surface. The *lapilli*, which seem to be chiefly a provision for hearing under water, and are therefore large and solid in aquatic and amphibious animals, appear in birds only as fine crystallized grains of chalk in the *utricle*, or sinus of the vestibule, rendering the endolymph somewhat turbid. The columella is straight, and the membrana tympani pressed outwards by it is consequently convex. There is a crescentic fold of skin extending upwards from the superior margin of the meatus externus, sometimes furnished, as in the horned owl, with a fringe of feathers which can be spread at pleasure like a fan to catch the sound. This fold of skin is a rudiment of the *concha*, or outer ear, of the mammalia.

As we have already said, it is only in this last-mentioned class of animals that the ear reaches its complete development. It is nearly the same in all of them; the difference being only in the comparative size and shape of the component parts of the organ, and not in their essential structure, number, or arrangement.

We shall therefore describe the organ in one species only.

There is every reason to suppose that in hearing, as in sight, man has no superiority over many of the lower animals except what arises from that intellectual supremacy which enables him to discriminate and compare his sensations more justly than they can do. Indeed, it is certain that in the mere perception of sounds he is inferior to most of the mammalia, and probably to birds; and if the musical faculty should seem to imply a greater perfection of the organ, the error, for such we believe it to be, may perhaps disappear upon reflection. We therefore select the human ear as the type of the organ in mammalia, not because it is in any respect more complete than the rest, but as the most interesting. The same description, of the more important parts at least, might be applied, nearly word for word, to all.

The parts now to be described fall naturally under a three-fold division into the internal, middle, and external ear.

1. The internal ear, comprising the acoustic nerve, vestibule, and labyrinth, is deeply placed in the interior of the head, within the most compact and hardest of the bones, denominated from that circumstance the *petrous* or rocky portion of the temporal bone. This wedge-like or triangular projection passes obliquely inward and forward in the direction of the outer tube of the ear, forming a strongly-marked knobby ridge within the cranium, in the basis or floor of that cavity. Near the inner point, which nearly meets its fellow on the other side, and upon its posterior declivity, there is a large trumpet-like hole (*meatus auditorius internus*) into which the seventh cerebral nerve enters from the *medulla oblongata*. [BRAIN, NERVE.] The meatus passes in a direction outwards, and therefore obliquely, into the petrous portion for half an inch, and then terminates abruptly in two *foveæ*, or pits: from the upper of these goes a winding canal through the substance of the bone, which is the course of the motor nerve of the face (the *portio dura* of the seventh pair), which, here separating from the auditory nerve, or *portio mollis*, we need not follow. The latter, splitting into several sets of filaments, finds its way through small sieve-like openings at the bottom of the lower fovea into the internal ear, and is here distributed in three separate portions to the cochlea, the ampullæ of the semicircular tubes, and the *utricle*, or vestibular sac. The cochlea is more complicated than in birds; it consists of a spiral canal in the bone, gradually diminishing as it ascends to a point, wound round a central hollow pillar of bone, called the *modiolus*, or *newel*. From its inner surface, that, namely, which may be considered as a groove in the modiolus, a thin and spongy lamella of bone projects rather more than half across the canal, ascending in a similar spiral. From the edge of this lamella, (called the *lamina spiralis*) a membrane passes to the outer surface of the canal, where it is attached; thus completing the separation of the canal into two *scale*, or winding partitions, which unite at the summit, and open (as before), the lower and

narrower into the vestibule, the superior and larger into the tympanum; each *scala* taking two turns and a half round the modiolus in ascending from the base of the cochlea to the cupola, or inverted cup-shaped cavity at the summit, placed over the funneus (*infundibulum*) into which the top of the modiolus expands. The cochlea is on a level with the vestibule and anterior to it, the base being turned towards the meatus internus; the summit looking outwards and a little downwards, is turned towards the sudden bend of the wide canal in the petrous portion of the temporal bone by which the internal carotid artery enters the cavity of the head. It is the close neighbourhood of this artery as it passes through the compact bone that occasions the rushing sound of the pulse to be heard when the ear is placed upon a pillow, or the attention is led to dwell upon what passes within, by deafness arising from some cause not affecting the parts essential to hearing. The modiolus is hollow to some distance from the base. Up this tubular cavity rises the large cochlear branch of the acoustic nerve, giving off lateral filaments through minute openings arranged spirally, which pass through the light spongy bone, and emerge from different points on the spiral floors and sides of the *scale*, where they ramify in a delicate pulpy expansion upon the membranous tubes which line the spiral osseous canals: the rest of the cochlear nerve passes through capillary perforations in the cul-de-sac of the tubular cavity; and ascending in the substance of the central pillar of the modiolus, is distributed through the bone in a similar way to the upper turns of the cochlea and the *infundibulum*. The two other branches of the acoustic nerve are distributed to the vestibular sac, which lies in a round depression or pit in the barrel-shaped cavity of the vestibule, and to the ampullæ of the semicircular tubes. The latter all meet in a membranous sinus, or *utricle*, which occupies another distinct pit of the vestibule, called, from its shape, the elliptic fovea, much according to the arrangement already described in other animals. The principal opening from the vestibule is the fenestra ovalis, situated on the outer side towards the tympanum, which is closed by a membrane; at the lower and front part there is another opening into the scala vestibuli of the cochlea. There are five at its posterior and outer side, which lead into the semicircular canals, of which the superior and posterior enter the vestibule by a common foramen. The sac and utricle each contain a cretaceous deposit, which, in some of the lower mammalia, has the consistence of soft chalk. The cochlea and semicircular canals, from their complexity, are termed the *labyrinth*. With respect to the object of their peculiar arrangement, not even a probable conjecture has been hazarded. Yet they appear with surprising uniformity in all the mammalia, and some of them, as we have seen, in the more numerous tribes of birds, reptiles, and fishes. The bony canals of the labyrinth and vestibule are stated to be invested within by a delicate periosteum, the surface of which towards the perilymph is thought to be of the nature of a serous membrane, and to secrete that fluid.

Fig. 1.

Fig. 1. Magnified view of the osseous labyrinth and vestibule as they would appear if the solid bone in which they are imbedded were removed, with the *oscula auditus* in situ. a, ampulla of the posterior semicircular canal; b, common tube by which this and the superior canal enter the vestibule; c, posterior canal; d, external canal; e, superior canal; f, cochlea; g, its cupola; h, fenestra ovalis covered by the stapes; k, fenestra rotunda; l, valvulus; m, incus; n, vestibule.

The deafness which arises from causes which affect the fenestra ovalis, or the nerves and canals within the vestibule and labyrinth, is seldom or never cured; and it is unfortunately very common. There is a very easy way by which the nature of the case may be often sufficiently tested. If the internal ear be affected, especially the nerves of it, the ticking of a watch pressed against the teeth or the outer part of the head on that side, will be very obscurely distinguished. If not, the sound can be easily heard, as the solid bones interposed between the sonorous body and the nerve are excellent conductors of vibration.

2. The middle ear comprises the cavity of the *tympanum* with its contents; the cells in the bony prominence behind the ear, called the *mastoid process*, with which the tympanum communicates; and the Eustachian tube, or passage leading from the tympanum into the upper and back part of the throat, where it opens in the form of an expanded slit on each side behind the posterior nares.

The tympanum is an irregular cavity scooped in the petrous portion of the temporal bone between the vestibule and the external meatus. The principal entrances to it are the fenestra ovalis and the round or somewhat oval opening at the bottom of the external passage upon which the membrana tympani is stretched. Between these there is extended a chain of three small bones, obliquely articulated to each other with perfect joints, so placed that the chain somewhat resembles in figure the letter Z.

These bones are called respectively the *stapes* (stirrup), the *incus* (anvil), and *malleus* (hammer), from some similarity in form to those implements. The base of the stapes is applied to the fenestra ovalis, exactly fitting it, and is attached firmly to its membrane. The extremity of the longer leg of the incus is articulated to the head of the stapes, and there is a minute bone between them of the size of a small shot, which is generally considered to be only a process of the incus. It is however called from its spherical shape the *os orbiculare*, and is sometimes reckoned as a fourth bone. (Fig. 3, o.) The shorter leg of the incus (Fig. 2, c,) rests against the bony parietes of the tympanum at the back part, near the mastoid cells. Upon the hollowed cavity in the head of the incus (Fig. 2, a) the lateral depression of the head of the malleus (Fig. 2, k) is articulated, and moves easily; the long handle of the latter is attached by its extremity (Fig. 2, h) to the middle of the membrana tympani, as well as by a portion of the side of the handle, which lies close to and parallel with the membrane. The long slender process of the malleus called the *processus gracilis* (Fig. 2, g) lies in a slit passing to the articulation of the jaw called the *glenoid fissure*.

Fig. 2. Magnified view of the ossicula auditus. M, malleus; I, incus; S, stapes; o, shape of the fenestra ovalis; a, cavity of the incus, which is articulated to the malleus; d, longer process of the incus with the os orbiculare attached at b; c, its shorter process; e, head of the malleus; f, its short process, or prominent point for the attachment of the tensor tympani; h, the depression which articulates with the incus; g, processus gracilis of the malleus; h, its handle, or manubrium.

Fig. 3.

Fig. 3. The same bones of their natural size. m, malleus; i, incus; s, stapes; o, orbiculare.

The use of these bones is undoubtedly to transmit the vibrations of the membrana tympani to the membrane of the fenestra ovalis, and thence to the internal ear. But they have another use which would be incompatible with a single bone passing between those membranes, as in birds and

most reptiles; this is to permit the membrana tympani to be drawn into a conical shape so as to tighten it, and adapt it either to resist the impulse of too loud a sound, or favour a more acute or gentle one. The muscle which chiefly effects this object, called the *tensor tympani* (Fig. 4, a), is attached near the head of the malleus to a point projecting from it. (Fig. 2, f.) Other muscles, to steady and antagonize its action, called the *laxator major* and *minor tympani* are also attached to the malleus, the former (Fig. 4, b) to the processus gracilis, the latter (Fig. 4, c) to the handle of

Fig. 4. Muscles attached to the ossicula auditus. a, tensor tympani; b, laxator major; c, laxator minor; d, stapideus.

the bone. A further description of the directions and outer attachments of these minute muscles would be tedious and unintelligible to the general reader. No muscle is attached to the incus, but a small one of great importance is inserted into the neck of the stapes, called the *stapideus*; the effect of this is to counteract the obliquity of traction or tilting of the stapes, which would otherwise ensue from the movements of the other bones; by this means the motion of the stapes is directed either immediately to or from the fenestra ovalis, the membrane of which is also further preserved from injury by the oblique arrangement of the joints of these minute bones, by means of which, although the membrane of the tympanum oscillates through a considerable space in passing from tension to relaxation, that of the fenestra is moved to a much smaller extent. It is to be observed that the same action which draws the membrana tympani into a cone thrusts the base of the stapes farther into the fenestra ovalis.

These small muscles are not under the dominion of the will, being supplied with nerves in a way peculiarly interesting to a physiologist, and acting automatically in correspondence with the impressions on the auditory nerve. Yet the instinctive consciousness we have of the degree of their contractions in adjusting the tension of the membrana tympani to circumstances, is probably one of our chief means of estimating the intensity of sounds.

The fenestra ovalis is situated nearly opposite the membrana tympani, on the upper edge of a prominence called the *promontory*; it faces outwards and a little downwards; and beneath it, concealed by the promontory, is the foramen rotundum, closed by a membrane, and leading into the cochlea by the scala tympani. The object of this last opening is disputed: some think it conveys in part the vibrations of the air of the tympanum to the internal ear; but it seems more reasonable to suppose, with Sir C. Bell, that the end it chiefly serves is to give vent and freedom to those of the fluids pent up in the unyielding bony canals of the labyrinth. Besides these openings from the tympanum, there are others which lead into the mastoid cells behind it; these are also filled with air, and are supposed to contribute to the distinctness of the tympanic vibrations. There is also an opening from the tympanum forwards into the Eustachian tube. This canal is nearly two inches long the first part of its course from the tympanum is bony: it then becomes cartilaginous, and widens as it approaches the throat, the mucous membrane of which lines it, and thence passing into the tympanum, spreads over the surface of the whole cavity, investing the ossicula and its other contents, as well as the mastoid cells. From this circumstance arises the tendency of the inflammation of cold or sore throat to extend into the tympanum, producing temporary deafness, ear-ache, and sometimes mischief of a more permanent kind. From the deafness which accompanies the closure of the Eustachian tube by that or other causes, the importance of its functions in renewing and giving vent to the air within the tympanum may be appreciated. Besides the foramina already mentioned, there are others through which nerves and vessels enter the tympanum. We have not space to describe them: we shall only mention that one of the nerves, called the *chorda tympani*, originally connected with the *portio dura* of the seventh nerve, after traversing the petrous

bone in a circuitous course, enters the cavity of the tympanum, and passing quite across it, is transmitted through the glenoid fissure to a salivary gland under the lower jaw. The object of this singular but uniform course of the chorda tympani is not well understood.

Deafness arising from closure of the Eustachian tube has been sometimes cured by dilating that canal by instruments passed for that purpose into its outer expanded extremity through the nostrils, or from the back of the throat; or by injecting fluids into it by means of a syringe with a small curved pipe. This latter plan has also been successful in curing deafness arising from chronic inflammation, or morbid secretion within the tympanum. Suppuration within that cavity, or in the mastoid cells, sometimes results from high inflammation, and has been attended with fatal consequences by spreading to the bones of the cranium, or along the nerves to the brain, or its membranes. Cases of this kind generally originate, as we have already stated, in cold with sore throat, and are found to occur chiefly in scrofulous habits.

Fig. 5.

Fig. 5. This is not to be considered as a correct delineation of the organ, being intended only as a diagram, to give a general idea of the relative situations of the several parts. a, superior semi-circular canal; b, posterior ditto; c, external ditto; d, scala tympani of the cochlea opened, to show r, the fenestra rotunda, entering the tympanum under the promontory; e, Eustachian tube; f, membrana tympani; g, vestibule, not laid open; m, meatus auditorius externus; n, meatus internus, terminating in two foramina.

3. The external ear consists of the *meatus auditorius externus* (fig. 5, m) and *concha*. The former, commencing from the *membrana tympani*, is an osseous canal in the first part of its course in the adult, and then becomes nothing more than a tubular continuation of the expanded cartilage of the *concha*, or outer appendage of the ear. It is lined throughout with a delicate skin, covered by thin cuticle, which also covers the outer surface of the membrane. Beneath the skin, and opening through it on the surface, are numerous glandular follicles which secrete the ear-wax or *cerumen*. In the fœtus and new-born infant there is hardly any appearance of this tube; the membrane of the tympanum being close to the surface of the head, stretched upon the inner margin of a bony ring (*annulus auditorius*) which afterwards increases in length and becomes a tube. In the adult the length of the whole tube may be nearly an inch; but from the obliquity of the membrane, which faces a little downwards, it is longer below than above. Its direction from the membrane is outwards and a little backwards, and it is slightly convex upwards, and rather narrower in the middle than elsewhere. The last mentioned peculiarity is the reason why it is so much easier to introduce beads and other round bodies (as children are apt to do) than to get them out. This however must always be done as soon as possible when such an accident happens; for the presence of the foreign body sometimes excites great inflammation and swelling, and may lead to very serious consequences. The most easy method and the least painful is to direct a strong stream of warm water into the tube with a syringe, which commonly succeeds immediately if resorted to before there is much swelling. Other means will readily suggest themselves; but if resorted to, they should be very tenderly used, for the part is extremely sensitive, especially the membrane itself, to rough contact. The wax, which is very bitter, P. C., No. 561.

serves to prevent the entrance of insects and to keep the skin soft. When secreted too abundantly, it is often a cause of deafness, and should be removed as a foreign body by means of a syringe and a solution of soap in warm water. The commonest kind of ear-ache is that caused by inflammation of this passage, and is generally followed by a copious and fœtid secretion poured out by the ceruminous follicles. If this last long, deafness is sometimes the result from thickening of the membrane, and has been removed, as well as that arising from closure of the Eustachian tube, by puncturing the membrane. This part is sometimes ruptured by the spasmodic action of the tensor muscle caused by loud sounds, or by driving air up the Eustachian tube in a forcible expiration, as in blowing the nose violently. This accident is not followed by the degree of deafness that might be expected, unless the stapes becomes displaced from the fenestra ovalis: the other ossicula may be lost with comparative impunity for obvious reasons.

Fig. 6.

Fig. 6. View of the *pinna*, or *auricle*. The cartilaginous prominences are, a, helix; b, anti-helix; d, tragus; e, anti-tragus; the lobe or lobulus, g, contains no cartilage, being composed only of skin and a fatty cellular tissue. The depressions are c, the scapha or scaphoid (boat-like) fossa; and f, the concha, a term often used to denote the whole appendage of which it is the most important part.

The *concha*, or *pinna*, or *auricle* (for by all these names the outer appendage of the ear is known), consists of several pieces of elastic cartilage expanded in a form more or less resembling an ear-trumpet in different animals. In man it serves the purpose of collecting the sonorous vibrations and directing them into the meatus externus much less perfectly than in many other animals, which are also provided with muscles for directing it to the source of sound, which in man are but rudimentary. It is marked with various prominences and hollows, of which the names are given in the figure. It does not seem necessary to describe them more particularly. The cartilages are bound by ligaments to the neighbouring prominences of bone, and are covered by a smooth and closely adherent skin.

It may be observed that the aquatic mammalia (whales, porpoises, &c.) are unprovided with this part of the organ; and have a very narrow but long and curved meatus externus, passing obliquely into the surface of the head, and in some instances capable of being closed by a flap of movable skin to exclude the water. In these animals also the cochlea is imperfect, the *scala* making but one turn and a half round the modiolus.

(*Scarpa, de Auditu*; Soemmering, ditto; Breschet, ditto; Blainville, *Comp. Anat.*; Bell's *Anatomy*; Grant's *Outlines*.)

EAR-RING; a ring hung from a hole, perforated for that purpose through the ear, sometimes set with pendant jewels, pearls, or other precious stones. The word is Anglo-Saxon, *ear-hring*. Ornaments of this sort, large or small, have been worn in almost all countries by women, from the earliest ages; but more rarely by the men. Montfaucon says that the men, in many instances, wore them as amulets. In the Latin of the middle age ear-rings are termed *pendentes*, from the more common form of the ornaments usually attached to the ring itself. Sir Richard Hoare, in his *antient Wiltshire*, describes the ear-rings of a British female found in one of the barrows of that county.

EARL.—The title of count or earl, in Latin *comes*, is the most antient and widely spread of the subordinate or subject titles. This dignity exists under various names in almost every country in Europe. By the English it is called *earl*, a name derived to us from the ealdorman of the Anglo-Saxons and the *eorle* of the Danes. By the French it is called *comte*, by the Spaniards *conde*, and by the Germans *graf*, under which generic title are included several distinct degrees of rank,—landgraves, or counts of provinces, palsgraves, or counts palatine, of which there are two sorts, markgraves, or counts of marches, or frontiers, (whence marchio, or marquess), burghgraves, or counts of cities, counts of the empire, counts of territories, and several others. [COUNT; BARON.]

As to the English earls,—after the battle of Hastings, William the Conqueror, as it is well known, recompensed his followers with grants of the lands of the Saxon nobles who had fallen in the battle, to be held of himself as strict feuds; and having annexed the feudal title of earl to the counties of the Saxon earls (with whom the title was only official), he granted them to his principal captains.

These earldoms were of three kinds, all of which were by tenure. The first and highest was where the dignity was annexed to the seisin or possession of a whole county, with 'jura regalia.' In this case the county became a county palatine, or principality, and the person created earl of it acquired royal jurisdiction and seigniorship. In short, a county palatine was a perfect feudal kingdom in itself, but held of a superior lord. The counties of Chester, Pembroke, Hexham, and Lancaster, and the bishopric of Durham, have, at different times, been made counties palatine; but it does not appear that the title of earl palatine was given to the most antient and distinguished of them, viz., the earl of Chester, before the time of Henry II., surnamed Fitz-Empress, when the title of palatine was probably introduced from the empire. The earls of Chester created barons and held parliaments, and had their justiciaries, chancellors, and barons of their exchequer. This county palatine reverted to the crown in the reign of Henry III. The second kind of earls were those whom the king created earls of a county, with civil and criminal jurisdiction, with a grant of the third part of the profits of the county court, but without giving them actual seisin of the county. The third kind was where the king erected a large tract of land into a county, and granted it with civil and criminal jurisdiction to be held *per servitium unius comitatûs*.

Under the early Norman kings, all earls, as well as barons, held their titles by the tenure of their counties and baronies; and the grant, or even purchase, with the licence of the sovereign of an earldom or a barony, would confer the title on the grantee or purchaser; but with the solitary exception of the earldom of Arundel, earldoms by tenure have long since disappeared, and in late times the title has been conferred by letters patent under the great seal. Earls have now no local jurisdiction, power or revenue, as a consequence of their title, which is no longer confined to the names of counties or even of places; for several earls, as Earl Spencer, Earl Grey, and others, have chosen their own names, instead of local titles.

The coronet of an English earl is of gold surmounted with pearls, which are placed at the extremity of raised points or rays, placed alternately with foliage. The form of their creation, which has latterly been superseded by the creation by letters patent, was by the king's girding on the sword of the intended earl, and placing his cap and coronet on his head and his mantle on his shoulders. The king styles all earls, as well as the other ranks of the higher nobility or peerage, his cousins. An earl is entitled right honourable, and takes precedence next after marquesses, and before all viscounts and barons. When a marquess has an earldom, his eldest son is called earl by courtesy; but notwithstanding this titular rank, he is only a commoner, unless he be summoned to the House of Lords by such title. So the eldest sons of dukes are called earls where their fathers have an earldom but no marquise, as the duke of Norfolk, &c.

EARL MARSHAL OF ENGLAND, one of the great officers of state, who marshals and orders all great ceremonies, takes cognizance of all matters relating to honour, arms, and pedigree, and directs the proclamation of peace and war. The *curia militaris*, or court of chivalry, was formerly under his jurisdiction, and he is still the head of

the heralds' office, or college of arms. Till the reign of Richard II., the possessors of this office were styled simply Marshals of England: the title of Earl Marshal was bestowed by that king in 1386 on Thomas Lord Mowbray, Earl of Nottingham. The office is now hereditary in the family of Howard, and is enjoyed by the duke of Norfolk. (Chamberlaine's *State of England*, Dallaway's *Inquiries into the Origin and Progress of Heraldry in England*, 4to., Glouc. 1793, pp. 93-95.)

EARSHELL. [HALIOTIDÆ.]

EARTH (Astronomy). In the language of astronomers, the earth is rarely treated as a planet. All the phenomena connected with its motion are seen in the apparent motion of the SUN, to which article we therefore refer.

EARTH, CONTROVERSY ON THE MOTION OF THE. [MOTION OF THE EARTH.]

EARTH, DENSITY OF THE. The fundamental experiment of Cavendish for the determination of this astronomical element being likely to be shortly repeated, it is advisable to defer this article: see therefore WEIGHT OF THE EARTH.

EARTH, FIGURE OF THE. [GEODESY.]

EARTH. The old chemists imagined that all material substances were ultimately resolvable into four simple bodies, viz. air, fire, water, and earth, which were therefore called the four elements. This term is still occasionally employed in a more restricted sense, as when mention is made of *earthy* salts, &c. It is now universally admitted, that the bodies called earths are compounds of oxygen and a base, and in fact that they are mostly metallic oxides. The principal earths are alumina [ALUMINUM], barytes [BARIUM], glucina [GLUCINUM], lime [CALCIUM], magnesia [MAGNESIUM], silica [SILICIUM], strontia [STRONTIUM], yttria [YTTRIUM], zirconia [ZIRCONIUM].

EARTH-NUTS are either the fruit of certain plants which bury it below the ground after the flowering is past, as the *Arachis hypogæa*, *Lathyrus amphicarpos*, and others, or else the subterranean tubercles of fleshy-rooted plants, such as *Bulbocastanum*, *Cyclamen*, *Lathyrus tuberosus*, *Apios tuberosa*, and the like.

EARTHENWARE. The art of moulding earthen vessels for domestic use appears to have been practised in the earliest ages, and undoubtedly has been known among the rudest nations. The most antient records allude to the potter's wheel, and we have proof that great skill had been acquired in the manufacture of porcelain of a superior quality in China and in Japan at a very remote date. The little figures, covered with a fine deep-blue glaze, which are deposited with Egyptian mummies, and numerous jars, some specimens of which may be seen in the British Museum, show that in Egypt likewise the art was antiently practised; and indeed we see in Egyptian paintings representations of vessels (presumed to be earthen) which closely resemble those made in Egypt at present, and also the representations of the manufacturing process itself. (*Library of Entertaining Knowledge*, Egypt, ii. 179.) [COOLERS.] It has been supposed that the Britons understood the potter's art before the Roman occupation of this island, since urns of earthenware have been found in barrows in different parts of the kingdom; but other writers affirm, though we believe without proof, that our ancestors were in those days supplied with such articles by the Phœnicians. Vestiges of considerable Roman potteries have been discovered in many parts of this island, particularly in Staffordshire; and there is an interesting account by Governor Pownall (*Archæologia*, 5th vol., p. 282, &c.) of the discovery of numerous vessels of pottery which were fished up in the Queen's Channel, near Margate. It was for some time supposed that a Roman trading vessel, freighted with pottery, had been wrecked at this place; but on a more particular examination of the spot, called by the fishermen Puddingpan Sand, Roman bricks cemented together, apparently the ruins of a building, were likewise discovered, and on farther investigation it was found that an island existed formerly on this spot on which there had been a large pottery established by the Romans. Many of the earthen pans were recovered in a perfect state, and several of them had the name of Attilianus neatly impressed upon them. The island has long since disappeared, but specimens of the manufacture carried on there were frequently drawn up during the last century in the nets of the Kentish fishermen.

In newly-discovered countries it has been found that the use of earthen vessels is familiar among people otherwise

little acquainted with the arts of civilised life. Vases have been found among the aboriginal Indians on the Mosquito shore which were preserved as memorials of antiquity; and there is strong evidence for believing that these vessels were the manufacture of the country in which they were found, since the remains of ancient potteries have been discovered at a considerable distance up the Black River on that coast. In the United States of North America also fragments of pottery made by the native Indians have often been discovered.

Although earthenware may be considered as a general term applicable to all utensils composed of earthen materials, it is usual to distinguish such utensils more particularly into three different kinds; namely,—pottery, earthenware, and porcelain. Under the first of these terms are classed the brown stone-ware made into jugs, &c., the red pans and pots in common use, porous vessels, &c. [POTTERY.] Porcelain is distinguished from earthenware as being a semi-vitrified compound, in which one portion remains infusible at the greatest heat to which it can be exposed, while the other portion vitrifies at a certain heat, and thus intimately combines with and envelops the infusible part, producing a smooth, compact, shining, and semi-transparent substance, well known as the characteristic of true porcelain. [PORCELAIN.] At present our notice will be confined to earthenware as used in its distinctive meaning.

Until the beginning of the eighteenth century the manufacture of earthenware in this country was confined to a few objects of the coarsest description, and till nearly the close of the same century, the porcelain of China was still in common use on the tables of the wealthy, the home manufacture being confined to articles of the commonest domestic use. Earthenware was likewise largely imported from Holland, and superior kinds from Germany and France. English earthenware and porcelain are now not only brought into general use in this country, to the exclusion of all foreign goods, but earthenware is also largely exported to almost every part of the known world, and even to those countries where the art was previously prosecuted. M. Faujas de Saint Fond observes on this subject—'Its excellent workmanship, its solidity, the advantage which it possesses of sustaining the action of fire, its fine glaze impenetrable to acids, the beauty and convenience of its form, and the cheapness of its price, have given rise to a commerce so active and so universal, that in travelling from Paris to Petersburg, from Amsterdam to the furthest part of Sweden, and from Dunkirk to the extremity of the south of France, one is served at every inn upon English ware. Spain, Portugal, and Italy are supplied with it; and vessels are loaded with it for the East Indies, the West Indies, and the continent of America.' England is mainly indebted to Mr. Wedgwood for the extraordinary improvement and rapid extension of this branch of industry. Before his time our potteries produced only inferior fabrics, easily broken or injured, and totally devoid of taste as to form and ornaments. Wedgwood's success was not the result of any fortunate discovery accidentally made, but was due to patient investigation and unremitting efforts. He called upon a higher class of men than had usually been employed in this manufacture to assist in his labours, and in prosecuting his experiments he was guided by sound scientific principles. The early and signal success which crowned his first exertions only served as an additional motive for continuing his pursuit. One of the principal inventions of Mr. Wedgwood was his *table ware*, known at present as *queen's ware*, in consequence of the patronage of the queen, who commanded it to be thus designated. It is characterised as a dense and durable substance, covered with a brilliant glaze, and capable of bearing uninjured sudden alternations of heat and cold. From its first introduction, it was manufactured at so cheap a rate as to render it an article within the reach of all. Soon after, embellishments were introduced which very little enhanced the cost of the article; first, a coloured edge, or painted border was added to the queen's ware, and, lastly, printed patterns covering the whole surface, which at first exhibited very little taste, but by degrees reached the perfection which the art has now attained. Mr. Wedgwood's more beautiful inventions were—a *terra cotta*, which could be made to resemble porphyry, granite, Egyptian pebble, and other beautiful stones of the silicious or crystalline kind: a black porcelainous biscuit, very much resembling basalt in its properties, and therefore called *ba-*

scuites: a white and a cane-coloured porcelain biscuit, both smooth and of a wax-like appearance; and another white porcelainous biscuit, distinguished as jasper, having in general all the properties of the basaltes, with a very important addition, the capability of receiving through its whole substance from the admixture of metallic oxides, the same colours as those oxides communicate to glass or enamel in fusion. This peculiar property renders it applicable to the production of cameos and all subjects required to be shown in bas-relief, as the ground can be made of any colour while the raised figures are of the purest white. Mr. Wedgwood likewise invented a *porcelain biscuit* nearly as hard as agate, which will resist the action of all corrosive substances, and is consequently peculiarly well adapted for mortars in the chemist's laboratory.

The principal ingredients employed in the composition of all kinds of pottery are clay and flint. The nature of the clay used in the manufacture is of great importance, and so also is the combining of it with a due proportion of flint. The clay principally used in the English potteries is obtained from Dorsetshire and Devonshire; that from the former county is brought from the Isle of Purbeck, and is considered superior to the Devonshire clay. It is of two kinds, distinguished as brown clay and blue clay. The clay from Devonshire is likewise of two distinct qualities, and known as black clay and cracking clay. All these clays are of good working quality, and burn extremely white, being free from any impregnation of iron: the blue clay is considered the best. Another description of clay, superior to either of the former, was first discovered in Cornwall by Mr. Cook worthy, in 1768, and is commonly denominated China clay, because similar in its properties to the porcelain earth of China. It is very white and unctuous, and on investigation has been found to be formed by the gradual disintegration of the felspar of granite. This Cornwall clay is prepared on the spot where it occurs. The partially decomposed granite is broken into small pieces, and thrown into a running stream, where the argillaceous parts are washed off and held suspended in the water, while the mica and quartz being heavier remain at the bottom. At the end of the stream the water is stopped by a dam, and the pure clay gradually subsides. When the whole has separated itself from the water, the latter is drawn off and the solid matter dug out in blocks, which are placed in a situation exposed to a free current of air, and when sufficiently dry are packed in casks for shipment in the state of a fine smooth white powder. Mr. Wedgwood found by analysis that this substance contains sixty parts of alumina and twenty parts of silica; it is infusible,* and remains unaltered in the greatest heat of a porcelain furnace. The price of this material is much higher than that of the other English clay; but in the making of porcelain it is indispensable, and it is also used in some of the finer kinds of earthenware.

Preparation.—In the preparation of the clay some labour is required, before it is in a fit state to be combined with the flint. It is first mixed with very pure water to the consistence of cream: this work is called *blunging*, and in large establishments is performed by means of machinery. The result is a smooth pulp, which is then passed through a series of sieves of increasing degrees of fineness, till at length it is perfectly fitted to enter into the composition of the ware. If the clay were moulded and dried without the addition of any other body it would certainly crack, as the evaporation of the water with which it is mixed, in order to render it sufficiently plastic for the potter's wheel, would cause it to shrink in the proportion of one part in twelve in drying. In combination with silicious earth in proper proportions, it bears the action of fire without cracking, while the silica materially improves the whiteness of the ware.

The flints are prepared by being burnt in a kiln, and removed while red-hot from the kiln and thrown into cold water. By this operation their attraction of aggregation is lessened, and the labour of grinding them is much facilitated. They are then broken and ground to a very fine powder in a mill constructed for the purpose, the original of which was invented by Brindley. A quantity of water is thrown into the mill with the flints, by which the process is quickened and the health of the workmen is preserved, the finer particles of flint being thus prevented from flying off and mixing with the atmosphere which the workmen inhale.

* The fumble quality of felspar is owing to the presence of about an eighth part of potash. This alkali is separated by decomposition, and thus the felspar being deprived of it becomes infusible, as is the case with this China clay.

The flints, when reduced to powder, are transferred from the mill into another vessel, where more water is added, and the whole is violently agitated by mechanical means; the finer parts are in consequence held in suspension above, and in this state are passed into a reservoir, while the grosser particles are left behind at the bottom of the vat. After subsidence, the supernatant water is drawn off from the reservoir, and the pulverized flint is in a fit state for use. It is considered of a proper fluidity for mixing with the clay when a pint weighs 32 oz., while an equal measure of the diluted clay should weigh 24 oz. The proportions in which the clay and flint are mixed vary with the quality of the clay, with the nature of the ware to be produced, and also with the practice of each manufacturer. Parkes, in his 'Essay on the Making of Earthenware,' &c., though his knowledge was obtained by a residence of some years at the seat of manufacture, does not give any precise information on the subject, but states that flint forms a fourth, a fifth, or a sixth part by weight of the prepared paste. The dilutions of clay and flint being brought together in suitable proportions, are intimately mixed by agitation, and passed, while in a state of semi-fluidity, through different sieves, whereby the whole becomes a smooth homogeneous mass. This mixture, technically called *slip*, is then very carefully evaporated, the mass being frequently stirred and turned over lest a part should become improperly hardened while the remainder continues too fluid. When the clay or paste is removed from the *slip-kiln*, it is well incorporated together by beating it with wooden mallets, in order to expel the air which it contains. The next operation is cutting it into small pieces, which are thrown together again with all the strength of the workmen; and this process is continued until the mass is considered in a complete state of consistence. When in this state it should be allowed to remain for a considerable period before being used, since it becomes more intimately united by time than by any mechanical means.

The paste, when taken for use, undergoes the process of *slapping*, which is similar in its effect to the last operation, and should incorporate the whole mass so completely, that wherever it is cut, it should exhibit a perfectly smooth and uniformly close appearance. The clay, being thus prepared, is now in a fit state for forming into ware. The processes for this purpose are of three different kinds—throwing, pressing, and casting, which are respectively employed according to the form of the article required.

The operation of throwing is performed upon a machine called a potter's lathe, and is used in shaping vessels which have a circular form. By this means the *thrower* moulds the clay into the form which he desires; and when finished to his satisfaction, he removes his work to a board or shelf, where it is left to dry partially; and when in a particular state of hardness, called the *green state*, well known to the operator, the vessel is in proper order for being further smoothed and shaped in the *turning-lathe*, and for being furnished with handles, spouts, or any other addition. The turning-lathe is similar to that used by the turner in wood, and by means of it rings, rims, &c. are formed on the vessels. For making dishes, plates, and other similar shallow vessels, a plaster mould is used, which is placed on the block at the top of the upright spindle of the lathe, and the workman continues the process in nearly a similar manner as in throwing. When sufficiently dry to be taken from the mould, the edges are pared with a sharp knife, and the vessels are placed in piles and left to harden, preparatory to their being baked.

A machine called an *engine-lathe*, which has a horizontal movement backwards and forwards, in addition to the rotary motion, is used in giving to earthenware a milled edge. Handles, spouts, &c. are fixed on the vessels as soon as they are taken out of the turning-lathe. They are affixed by means of slip, with which the parts designed to come in contact are moistened: in a short time, when dry, the union of the parts is found to be perfect. Handles, &c. are made by pressure in a small metallic cylinder, which has an aperture in the centre of its bottom, to which plugs of various shaped orifices are fitted. There is likewise a piston, so fixed as to be worked by a screw up and down the cylinder. The cylinder, being filled with clay, the piston is inserted, and forces the clay through the orifice at the bottom, and consequently gives it the same form as the aperture through which it was pressed. Being then cut into lengths and bent to the desired shape, the clay is ready,

when sufficiently dry, to be joined to the vessel. For ornamental spouts, small ornaments, and other appendages of the like nature, the clay is pressed in moulds, the particular mode of doing which may be readily conceived.

When the vessels are sufficiently dry they have to be submitted to the action of fire. For this purpose they are placed in deep boxes called *seggars*, made of a mixture of fire-clay and old ground seggars, and capable of sustaining the most intense degree of heat without being fused. The seggars are of various sizes, shapes, and depths, adapted to the different pieces which they are to contain. In no case is one piece placed in or on another in the seggar, and all is so arranged that the heat may be equally applied to every part of each. The seggars, with their contents, are then disposed in the oven in such a way that the heat may be distributed fairly throughout: they are built one layer on the top of another until they reach nearly to the top of the oven, each seggar forming a cover to the one beneath it, and the upper seggar in each pile being always empty. The oven is of a cylindrical form, and very similar to the common kilns used for burning tiles. The process of baking usually lasts from forty-eight to fifty hours, during which time the heat is gradually increased, as it would be injurious to the ware to apply a very high degree at first. To ascertain when the baking has been carried far enough, the workman uses tests of common Staffordshire fire-clay, the pyrometer of Wedgwood having been long laid aside. [PYROMETER.] When the appearance is considered satisfactory the firing is discontinued, and the oven is suffered gradually to cool during twenty-four or thirty hours before the contents are taken out. The ware in this state is called *biscuit*. The glaze is now applied; the pieces are again placed in seggars, and conveyed to the glass-oven, where heat is applied to them of sufficient intenseness to fuse the glaze; but the heat must by no means be so great as that to which the *biscuit* has previously been exposed, as the glaze would crack or peel off if the vessels were liable to any further shrinking.

The glaze generally used for common kinds of earthen ware is a compound of litharge and ground flints, in the proportion of ten pounds of the first to four pounds of the latter. This method of glazing is however highly objectionable on account of its injurious effects on the health of the workman, while the lead being soluble by acids, makes a most pernicious glaze for vessels which are used for containing many articles of prepared food. Glazes for porcelain and the finer kinds of earthenware are generally made with white lead, ground flints, ground flint-glass, and common salt. But almost every manufacturer uses a peculiar glaze of his own, the manner of making which he keeps in as much mystery as possible. Some glazes are made without the admixture of any lead, and in the whole of the better glazes this ingredient enters in so small a quantity as not to be injurious. The manner of applying the glaze is, to reduce the ingredients to powder, mix them with water to the consistence of cream, and then merely dip the pieces into the preparation and withdraw them immediately, taking care that all the parts have been wetted with the glaze.

When the earthenware is to be printed it undergoes this process previously to glazing. It is thus performed:—the landscape or pattern is engraved upon copper, and the desired colour being mixed with linseed-oil, is laid on the plate, and impressions are taken off on tissue-paper, in the manner usually employed by copper-plate printers. The paper, wet with the colour, has then all the blank parts cut away, leaving only the pattern entire, which is applied lightly to the ware when in the state of biscuit. It is then rubbed with a piece of woollen cloth, and rolled tightly in the form of a cylinder, till the colour is pressed sufficiently into the ware. In this state the whole is left for an hour, when it is placed in a cistern of water, so that the paper becomes sufficiently moistened to peel off readily, having transferred to the biscuit the colour and impression which it had received from the copper-plate. When the pieces thus printed are sufficiently dry they are placed in an oven and exposed to a gentle heat, in order to dissipate the oil: they are then in a fit state to receive the glaze. Till within the last few years, blue produced from the oxide of cobalt was the only colour employed, but at present many other colours are printed with equal facility.

The art of painting on earthenware more particularly applies to porcelain: the description of the colours used, which are all metallic oxides, and the manner of applying

them, therefore more properly belong to the article under that head, as well as the method of gilding porcelain. Gold and silver *lustre ware* is commonly of an inferior quality. The metallic oxides used for this purpose are intimately mixed with some essential oil, and then brushed entirely over the surface of the vessel: the heat of the enamelling oven dissipates the oxygen, and restores the oxides to their metallic state, but with their brilliancy somewhat diminished.

The principal seat of the manufacture of earthenware in England is in Staffordshire, about a mile from the borders of Cheshire. This district, known as 'The Potteries,' extends through a distance of more than seven miles, in which there are towns and villages so thickly built and so close to each other that to a stranger the whole appears one large straggling town. There are likewise extensive manufactures of earthenware and porcelain in Yorkshire, and Worcestershire. There are establishments for making the commoner kinds of ware in many parts of the kingdom. In the evidence given by Mr. Wedgwood before a committee of the Privy Council in 1785, it is stated that the manufacturing part alone in the Potteries and their immediate vicinity gives bread to 15,000 or 20,000 people; yet this is but a small part when compared with the whole number of those who depend upon it. A very great number of persons are employed in raising the raw material and the coals for fuel, in the conveyance of these materials to the Potteries, and in the re-conveyance of the finished goods to every part of England and to the different ports where they are shipped for foreign consumption.

The number of pieces of earthenware of English manufacture exported, and the real value of the same in each year, from 1831 to 1835, were as follows:—

| | Pieces. | Value. |
|------|------------|----------|
| 1831 | 37,028,897 | £461,090 |
| 1832 | 43,265,283 | 490,787 |
| 1833 | 46,258,549 | 496,963 |
| 1834 | 44,015,623 | 493,382 |
| 1835 | 45,893,446 | 540,421 |

Shipments of these goods are made to every country with which Great Britain has any trading relations. The exports in 1835 were sent to various quarters in the following proportions:—

| | Pieces. | Value. |
|---|------------|---------|
| Northern Europe, chiefly to Germany and the Netherlands | 7,214,515 | £65,716 |
| Southern Europe, chiefly Portugal, Spain, and Italy | 3,293,870 | 42,726 |
| Africa | 855,695 | 10,160 |
| Asia, chiefly East India Company's territories, islands of the Indian Seas, and New South Wales | 2,534,811 | 30,563 |
| United States of America | 17,527,271 | 246,220 |
| Other parts of North America, chiefly British colonies | 6,706,156 | 74,183 |
| Brazil | 5,369,103 | 42,123 |
| Other States of South and Central America | 2,059,943 | 24,537 |
| Guernsey, Jersey, Alderney, &c. | 332,082 | 4,193 |

Pieces . 45,893,446 £540,421

EARTHQUAKES are the most terrific of all natural phenomena. The solid surface of the globe is put in motion by them, and assumes an appearance which in some cases may be compared with the sea when agitated by the wind.

The least dangerous of these phenomena are those which by the Creoles of South America are called *Tremblores*, a term which may be translated by *tremors*. The surface of the earth is put in a trembling motion, by which such objects as are not well supported are thrown to the ground, and even walls are split, but the damage does not extend farther. Life is safe, and property but slightly injured. These tremors are by far the most common kind of earthquakes, and occur in some countries of South America, especially in Chile, almost every day, at least in certain seasons.

The *terremotos* of the Creoles, or proper earthquakes, give to the surface either horizontal oscillations, not dissimilar to the waves of an agitated sea, or they consist in violent perpendicular upliftings, so that it would seem as if repeated explosions were exerting their force against the roof of a subterranean cavern, threatening to burst it open and to blow into the air every thing placed over it. By these earthquakes walls are overthrown, and fissures are

produced in the ground. The latter are frequently more than a foot in width, and sometimes water gushes out of them like a fountain.

Nothing makes such an awful impression on the senses as an earthquake. The earth is violently convulsed, heaving up and down in a manner hardly conceivable by those who have not witnessed it. The tottering buildings, the crashing of the timbers of the roofs, and the falling of the tiles, completely distract the senses. Fear drives men from their houses; but they do not always find safety out of doors. No person can stand without support: people cling to one another, to trees, or to posts. Some throw themselves on the ground; but the motion of the earth is so violent that they are obliged to stretch out their arms on each side to prevent themselves from being tossed over. Animals are equally alarmed. They stand with their legs spread out and their heads down, trembling violently. The air itself seems to participate in the convulsion, for the birds fly about wildly. Meanwhile the sea retires from the shore; but after a few minutes it returns in a high wave, which advances like a watery wall with incredible velocity, and covers all those tracts which are not more than fifty feet above high-water mark. It rushes back with equal velocity. This motion of the sea is repeated as long as the shocks of the earthquake are violent. Vessels sailing along a coast convulsed by an earthquake feel also a motion quite different from that produced by gales or currents. The loss of life by earthquakes is sometimes considerable. It is chiefly produced by the falling of the buildings when the shock is so unexpected that the inhabitants have not time to escape. In some cases the overflowing of the sea has been fatal to a great number of persons. People have also been swallowed up by the fissures caused by earthquakes.

Earthquakes are generally preceded and sometimes attended by a subterranean noise, which is compared by some to that of a very heavy artillery waggon rolling quickly over a stone pavement at a distance; by others, to the echo of distant thunder in a mountainous country. It is worthy of remark that this noise is sometimes heard without any earthquake taking place, as in 1784 at Guanajuato, in Mexico, and that it has been as audible in places situated at a considerable distance from the seat of the earthquake as in those which experienced the shocks. There are also several cases on record in which the earthquakes have not been attended by such subterranean noise.

Considerable changes may be produced on the surface of the globe by earthquakes. It is said that by the earthquake of 1783 in Calabria some mountains changed their relative positions to one another; but this fact is not well established. It is, however, beyond all doubt that the coast of Chile has undergone a considerable change by earthquakes during the last fifteen years. In 1822 the coast, north of Valparaiso, to the extent of fifty miles, was raised nearly three feet above its former level; in some places the rocks on the shore were raised four feet. In 1825 the island of S. Maria (near 37° S. lat.) was upheaved nine feet, so that the southern port of this island has almost been destroyed, and the soundings round the island have diminished a fathom and a half every where.

The single shocks of an earthquake last from a few seconds to two or three minutes. Sometimes they follow one another at short intervals. It is remarkable that generally either the first or one of the first shocks is the most violent, and that they afterwards gradually decrease in force. Sometimes they return for several days, and even weeks; and in some places, as at Copiapó, in Chile, they are of daily occurrence.

Earthquakes are sometimes experienced over an immense tract of country. The last earthquake in Chile (in 1835) was felt at all places between the Island of Chiloe (40° S. lat.) and Copiapó (27° S. lat.); consequently over thirteen degrees of latitude. It extended from the Island of Juan Fernandez to the town of Mendoza, on the east side of the range of the Andes, over ten degrees of longitude. But when earthquakes extend over such an immense tract of country, some districts are always convulsed with greater violence, and these may be considered as the centre of the earthquake. The farther a place is removed from these centres, the less violent, as a general rule, are the shocks.

We know little, or rather nothing, of the origin or cause of earthquakes. It may, however, be considered as certain that they are due to the same agency which produces volcanic eruptions. These eruptions are frequently preceded

by earthquakes; and whenever, in places situated near active volcanoes, it is observed that no smoke issues from their craters, the inhabitants begin to fear the approach of an earthquake.

It is not quite certain whether or not there is any connexion between the state of the atmosphere and the phenomena of earthquakes. It is not improbable that such is the case with the slighter shocks, the *trembores*. They commonly occur, or at least are by far most frequent, at the time of the changes of the seasons, in Guatemala as well as in Chile. But the more violent concussions seem to be quite independent of the seasons, and they occur both in calm and cloudless weather and in storms and during rain. In some instances they have been preceded by luminous meteors.

Antient authors, especially Thucydides, frequently mention earthquakes; but only in general terms. Yet we learn enough from these slight notices to show that they were often equal in violence to those which in modern times have convulsed the continent of Europe and Asia. (Thucyd. i. 101; iii. 89; v. 50; viii. 41.) No detailed description of an earthquake in Europe or in the old continent exists before that which, on the 1st of November, 1755, almost destroyed the city of Lisbon. This is the most destructive earthquake which has ever occurred in Europe. The number of persons that perished by it is stated to have been 30,000. In February and March, 1783, the north-eastern part of Sicily and the southern portion of Calabria were convulsed by repeated and very violent shocks, which overthrew the town of Messina, and killed many thousands of its inhabitants, as well as many persons in Calabria. The last considerable earthquake in Europe extended over the middle of the kingdom of Naples, and was most destructive in the districts lying along the declivities of Mount Matese. (41° 30' N. lat.) The number of persons who perished by it amounted to 3274, besides 1615 who were wounded.

On the first day of the present year (1837) the countries along the eastern extremity of the Mediterranean, especially Syria, were violently agitated by an earthquake. The towns of Damascus, Acre, Tyre, and Sidon, suffered great damage, and Tiberias and Safet were entirely destroyed. It is stated that about 6000 lives were lost.

America is more subject to earthquakes than any portion of the Old Continent, but they are only strongly felt between 20° N. lat. and 40° S. lat.; and it is not the whole country included between these latitudes that is visited by them, but only the table-lands of the Mexican isthmus, the Andes, and the countries bordering on them, and those which are adjacent to the Caribbean Sea. Mention of earthquakes in these countries occurs in the Spanish historians of the Conquest; but it would seem as if the earthquakes were less destructive formerly than in the last century. In 1717 the town of Guatemala was greatly damaged by an earthquake on the 29th of September; and on the 29th of June, 1773, the town was almost entirely destroyed. Caracas was destroyed by an earthquake on the 26th of March, 1812, when upwards of 12,000 of its inhabitants were buried in the ruins; and the same town experienced, in 1826, another earthquake, which was hardly less destructive. Bogotá experienced a very severe shock in 1827. On the table-land of Quito violent earthquakes are frequent. In 1698, on the 20th of June, Lacatunga and Hambato were destroyed; and on the 4th of February, 1797, the town of Quito was greatly damaged, and Riobamba levelled to the ground. Not less than 40,000 persons are stated to have perished by this last earthquake on the table-land. Lima and the countries about it are likewise subject to frequent and violent earthquakes. The town of Lima was almost entirely destroyed on the 20th October, 1687, and again on the 28th October, 1746. In this latter catastrophe the port of Callao was inundated by the sea, and the whole population perished. Arequipa has had its share of earthquakes; but the last violent one occurred in 1725. Copiapó was destroyed on the 11th of April, 1819, and again in 1822. By this last earthquake, which happened on the 19th of November, the town of Valparaiso was levelled to the ground. Santiago has suffered largely from the destructive effects of the earthquakes so frequent in Chile: on the 8th of July, 1730, it sustained great damages. But no place in Chile has so frequently been destroyed as Concepcion. It was first destroyed by the united effects of repeated shocks and the inundation of the sea in 1730, and again in the same manner in 1751. After this the town

was rebuilt on another site; but this new town and its port of Talcahuano were entirely demolished on the 20th of February, 1835. A most graphic description of this dreadful earthquake is given in the 'London Geographical Journal,' vol. vi. p. 319, &c., to which we are much indebted for several valuable facts and remarks. The inundation of the sea during this calamity may be compared with the narrative of a similar event recorded by Thucydides (iii. 89).

E A R W I G. [FORNICULIDÆ.]

EASEL (derived by some from the Teutonic *assel*, or *esel*, an ass), the wooden frame, furnished with a set of moveable pegs, or more convenient sliding ledge, on which pictures are placed while being painted, and which raises or lowers them according to the artist's convenience. Its antiquity is manifest, from its appearance in pictures discovered in Hierculaneum.

EASEMENT (from the French words *aiss*, *aisement*, ease), is defined by the old law writers as a service or convenience which one neighbour hath of another by charter or prescription without profit; as a way through his ground, a sink, or the like. It includes rights of common, ways, water-courses, antient lights, and various other franchises, issuing out of corporeal hereditaments, and sometimes, though inaccurately, applied to rights of common. (Kitchin; Woodd. Lect.)

At the common law these privileges (which can only be created and transferred by deed) might be claimed either under an immemorial custom or by prescription; but 20 years uninterrupted and unexplained enjoyment of an easement formerly constituted sufficient evidence for a jury to presume that it originated in a grant by deed; except in the city of London, where the presumption of a grant from 20 years' possession of windows was excluded by the custom which required that there should exist 'some written instrument or record of an agreement.' Nonuser during the same period was also considered an extinguishment of the right, as raising a presumption that it had been released.

By the recent statute 2nd and 3rd William IV., cap. 71, several important alterations have been made with regard to this description of property: 40 years' enjoyment of any way or other easement, or any water-course, and 20 years uninterrupted 'access and use of any light to and for any dwelling-house,' &c., now constitute an indefeasible title in the occupier, unless he enjoys 'by some consent or agreement expressly given or made for that purpose by deed or writing.' The same statute also enacts that non-user for the like number of years (according to the description of the particular right) shall preclude a litigating party from establishing his claim to it.

The easements of the English correspond to the Servitudes of the Roman and the Servitudes of the French law. The servitudes were a class of rights which gave rise to numerous complicated questions. Those of road, water, light, drains, were the principal. (*Dig. lib. viii. De Servitutibus*; *Code Civil des Français*, liv. ii. tit. 4, *Des Servitudes*.)

EAST, the point of the compass which is in a direction at right-angles to that of north and south, and which is towards the *right* hand of a spectator who faces the north. The distinction between east and west must ultimately be derived from a reference to the human body; for we can only define a spectator's *right* hand by saying that it is the hand which is not upon the same side as the heart.

EAST INDIA COMPANY This association originated from the subscriptions, trifling in amount, of a few private individuals. It gradually became a commercial body with gigantic means, and next, by the force of unforeseen circumstances, assumed the form of a sovereign power, while those by whom it was directed continued in their individual capacities to be without power or political influence; thus presenting an anomaly without a parallel in the history of the world.

The company was first formed in London in 1599, when its capital, amounting to 30,000*l.*, was divided into 101 shares. At the end of the next year the adventurers obtained a charter from the crown, under which they enjoyed certain privileges, and were formed into a corporation for fifteen years under the title of 'The Governor and Company of Merchants of London trading to the East Indies.' Under this charter the management of the company's affairs was intrusted to 24 members of a committee chosen by the proprietors from among their own body, and this committee was renewed by election every year.

The first adventure of the association was commenced in 1601. In the month of May of that year, five ships, with cargoes of merchandise and bullion, sailed from Torbay to India. The result was encouraging, and between 1603 and 1613 eight other voyages were performed, all of which were highly profitable, with the exception of the one undertaken in the year 1607. In the other years the clear profits of the trade varied from 100 to 200 per cent. upon the capital employed. At this time the trading of the company was not confined to the joint stock of the corporation, but other adventurers were admitted, who subscribed the sums required to complete the lading of the ships, and received back the amount, together with their share of the profits, at the termination of every voyage.

The charter of the company was renewed for an indefinite period in 1609, subject to dissolution on the part of the government upon giving three years' notice to that effect. In 1611 the company obtained permission from the Mogul to establish factories at Surat, Ahmedabad, Cambaya, and Goga, in consideration of which permission it agreed to pay to that sovereign an export duty upon all its shipments at the rate of $\frac{3}{4}$ per cent.

After 1612 subscriptions were no longer taken from individuals in aid of the joint-stock capital, which was raised to 420,000*l.*, and in 1617-18 a new fund of 1,600,000*l.* was subscribed. This last capital, although managed by the same directors, was kept wholly distinct from the former stock, and the profits resulting from it were separately accounted for to the subscribers.

The functions of government were first exercised by the company in 1624, when authority was given to it by the king to punish its servants abroad either by civil or by martial law, and this authority was unlimited in extent, embracing even the power of taking life. Under the peculiar circumstances of the case the granting of such a power might perhaps be necessary in order to prevent the grossest disorder in distant settlements, where no authority more regular was established; but this necessity proves only the impropriety on the part of the government of permitting the formation of settlements without at the same time making provision for the regular administration of justice.

The success which attended its commercial operations naturally induced a desire for their extension. In 1632 a third capital, amounting to 420,700*l.*, was raised, and its management, although confided to the same directors, was also kept distinct from that of the first and second subscriptions.

There is some obscurity in the early annals of the company, which makes it uncertain whether the capitals here severally mentioned were considered as permanent investments or were returned to the subscribers at the termination of each different adventure.

A rival association, formed in 1636, succeeded in obtaining from the king, who accepted a share in the adventure, a license to trade with India, notwithstanding the remonstrances of the chartered body, of whose rights this was deemed an infringement. Promises indeed were given that the license should be withdrawn, but these promises were never fulfilled, and after carrying on their trade for several years in a spirit of rivalry which was fatal to their prosperity, the two bodies united in 1650, and thenceforward carried on their operations under the title of 'The United Joint Stock.' Two years after this arrangement was made the Company obtained from the Mogul, through the influence of a medical gentleman, Mr. Boughton, who had performed some cures at the Imperial Court, the grant of a license for carrying on an unlimited trade throughout the province of Bengal without payment of duties: for this privilege the very inadequate payment of 3000 rupees (375*l.*) was made by the Company.

Some proprietors of the Company's stock becoming dissatisfied with the management of the directors, obtained from Cromwell in 1655 permission to send trading vessels to India, and nominated a committee of management from their own body, for which they assumed the title of 'The Merchant Adventurers.' The evils to both parties of this rivalry soon became apparent, and in about two years from the commencement of their operations the Merchant Adventurers threw their separate funds into the general stock under the management of the directors. On this occasion a new subscription was raised to the amount of 786,900*l.* In April, 1661, a new charter was granted to the Company, in which all its former privileges were con-

firmed, and the further authority was given to make peace or war with or against any princes and people 'not being Christians;' and to seize all unlicensed persons (Europeans) who should be found within the limits to which its trade extended, and to send them to England.

The settlement at Madras, on the Coromandel coast, was made about 1648, to facilitate the investments in piece-goods, then a chief object in the trade with India; and in 1668 the Company obtained a further settlement on the western coast of the peninsula by the cession in its favour of the Island of Bombay, made by Charles II., into whose hands it had come as part of the marriage portion of the Princess Catherine of Portugal. Bombay had been in possession of the English government during only a very few years, and its cession to the Company was only made because the expense which it occasioned was far beyond the revenue which it could be made to produce to the crown. The grant declares that the island is 'to be held of the king in free and common soccage, as of the manor of East Greenwich, on the payment of the annual rent of 10*l.* in gold on the 30th of September in each year.' At the same time the Company was authorized to exercise all the powers necessary for the defence and government of the island.

The first occasion on which the Company was brought into hostile collision with any of the native powers of India occurred in the beginning of 1664, when Sevajee, the founder of the Maharatta States, found occasion, in the prosecution of his plans, to attack the city of Surat. On this occasion the native inhabitants fled; but the members of the British factory, aided by the crews of the ships in the harbour, made a successful resistance, and forced Sevajee to retire. To show his satisfaction at the conduct of the Europeans upon this occasion, the Mogul accompanied the expression of his thanks with an extension of the trading privileges enjoyed by the Company. Another attack made upon Surat by the Maharattas in 1670 was repelled with equal success.

The right given to the Company by the charter of 1661 of seizing unlicensed persons within the limits above mentioned, and sending them to England, was soon exercised in a manner which produced a very serious dispute, in 1666, between the two houses of parliament. A merchant, named Skinner, had gone in a ship loaded with merchandise to the Island of Barella, off the north-east coast of Sumatra, which he had bought from the king of Jambee, and upon which he had made a settlement. His ship and the island, with all the property thereon, were seized by the Company, upon which Mr. Skinner made complaint to the government, and by his importunities caused the matter to be referred first to a committee of the privy council, and next to the House of Peers. It is difficult to understand the grounds for this last proceeding, or how the House of Peers could act judicially upon any case not brought before them by appeal from a court of law. Having awarded a compensation of 5000*l.* to Mr. Skinner for his losses, the affair was taken up by the House of Commons, who sent Mr. Skinner to the Tower, and passed a resolution declaring that any person who should proceed to execute the decision of the House of Lords was a betrayer of the rights and liberties of the Commons of England, and an infringer of the privileges of their house. These contentions proceeded to such a height, and were renewed so often, that the king adjourned the parliament in consequence seven times before he was able to induce the houses, by personal interference and persuasion used to influential members of both, to erase from their journals all their votes and resolutions relating to the subject. Mr. Skinner ultimately failed to procure any redress or compensation for his losses.

For several years following the junction with the Merchant Adventurers the trade of the Company was carried on uninterrupted by any serious rivalry, and with considerable success. Sir Josiah Child, who was one of the directors of the Company, in his *Discourses on Trade*, published in 1667, represents that trade as the most beneficial branch of English commerce, employing from 25 to 30 sail of the finest merchant ships in the kingdom, each manned with from 60 to 100 seamen,* and supplying us with saltpetre, pepper, indigo, calicoes, and drugs, besides materials for export to Turkey, France, Spain, Italy, and Guinea,

* To show how imperfectly these matters were understood at that time, it may be mentioned that in a tract published in 1615, entitled 'The Trade's Increase,' and which was greatly esteemed, complaint is made of the decay of the English navigation, which is ascribed to the great consumption of mariners in the East India trade.

without which a profitable trade with those countries could not be carried on. According to this representation, the trade of England must at that time have been insignificant indeed when compared with its amount in more modern times. In 1677-78 the whole adventure of the Company to India was 7 ships, with an investment of 352,000*l*. In 1678-79 the number of ships was 8, and the amount employed 393,950*l*. In 1679-80 there were despatched 10 ships with cargoes valued at 461,700*l*. In 1680-81, 11 ships, with the value of 596,000*l*.; and in 1681-82 there were 17 ships employed, and the investment amounted to 740,000*l*.

It was probably the indication of its profitableness afforded by the augmentation of the trade in the later years of the series just quoted, added to the great increase of commercial capital in the nation, that caused the formation of a project for establishing a rival company in 1682-83, but which failed to obtain the sanction of the government. As one means for discouraging similar attempts in future, the Company ceased to give any detailed statements concerning the amount of the trade, and for several years we have no knowledge as to the tonnage and amount of money to which it gave employment. Such an expedient was not likely to answer the end proposed. The veil of mystery thrown around their proceedings caused the public to entertain an exaggerated opinion concerning them, and tempted many private adventurers to set the regulations of the Company at defiance, and to despatch ships to trade where, according to the general belief, such great profits were to be obtained. These *interlopers*, as they were called, were seized by the Company's officers wherever they could be found, and under the pretext of piracy or some other crimes, they were taken before the Company's tribunals. Sentence of death was passed upon several, and the Company boasted much of the clemency that was shown in staying execution until the king's pleasure could be known; keeping the parties meanwhile in close confinement.

A new charter, to have effect for twenty-one years, was granted in 1693, in which it was stipulated that the joint-stock of the Company, then 756,000*l*., should be raised to 1,500,000*l*., and that every year the corporation should export British produce and manufactures to the value of 100,000*l*. at least. The power of the crown to grant the exclusive privileges given by this charter was questioned by the House of Commons, which passed a declaratory resolution to the effect 'that it is the right of all Englishmen to trade to the East Indies, or any part of the world, unless prohibited by act of parliament.' To obtain a charter thus at variance with the feelings of the people, it is known that bribery to a great extent was practised. The books of the Company, which were examined by order of the House of Commons, proved, indeed, that such practices were by no means new; that for many years bribes had been regularly given to men in power; and that in the year in which the charter was obtained nearly 90,000*l*. was distributed in this manner. The Duke of Leeds, who was charged with receiving 5000*l*., was impeached by the Commons; and it is said that the prorogation of parliament which occurred immediately afterwards was caused by the tracing of the sum of 10,000*l*. to a much higher quarter.

As might be expected, the resolution of the House of Commons just recited, unnoticed as it was on the part of the crown, acted as an encouragement to new adventurers, many of whom, acting individually, began to trade with India; but a still more formidable rival arose in a powerful association of merchants, whose means enabled them to outbid the old Company for the favour of the government. The necessities of the crown being at that time great, the Company offered as the price of the confirmation of its charter the loan of 700,000*l*., at 4 per cent. interest; but the associated merchants offering to lend 2,000,000*l*. at 8 per cent. interest, this offer was preferred, and an act was passed incorporating the association by the name of 'The General Society,' and authorizing the subscribers to trade with India, each one to the amount of his subscription, while such as desired to trade in combination might do so to the amount of their aggregate subscriptions. The old Company was allowed to trade for three years, and further to subscribe towards the stock of the General Society, of which latter privilege it availed itself to the amount of 315,000*l*. Those members of the General Society who preferred to trade upon a joint-stock soon after obtained another charter of incorporation, under the title of 'The English Company trading to the East Indies.' Their subscribed

capital, which formed part of that of 'The General Society, being all lent to the government, their trade was by that means greatly crippled, and did not equal in amount that carried on by the old Company, which body procured an act of parliament continuing its corporate rights, and entitling the members to trade on their own account in respect of the stock which they held in the General Society.

The commercial and political inconvenience that attended the working of these rival corporations was soon made apparent, and great efforts were made to bring about their union. The king himself strongly recommended such a course to both parties; but such was the spirit of hostility by which each was actuated, that whenever any advance towards accommodation was made by one, the other immediately drew back, and it was not until January, 1702, that the general terms of union were adjusted and mutually approved. The principal points embraced in this arrangement were, that of the court of twenty-four directors, twelve individuals should be chosen by the subscribers of each of the companies; that the directors should every year determine the amount of the exports, one half of which should be furnished by each company; that seven years should be allowed for winding up the separate concerns of each company, during which time each should appoint and employ separate factors in India; but that at the end of the seven years one great joint-stock should be formed by the complete union of the funds of both companies, which thenceforward were to be wholly subject to the absolute management of the same directors in England, and the same officers in India. An indenture, to which the queen was made a party, was drawn up to give efficacy to this arrangement: this indenture was passed under the great seal of the kingdom, and the two companies took the common name which has been continued to the present day, of 'The United Company of Merchants trading to the East Indies.'

That part of this arrangement which provided for the independent management of the affairs of each company in India during seven years was the occasion of many serious disagreements, which however gave place to a feeling of common danger. The necessities of the government induced it to call upon the Company for a loan of 1,200,000*l*. without interest, and it was impossible for it to raise the necessary funds unless their disputes were previously settled, while there was danger lest some other association might be formed which should take advantage of the wants of the government to obtain privileges at the expense of the existing corporation. Under this feeling, both parties agreed to refer their differences to the arbitration of Lord Godolphin, then lord high treasurer of England, whose award, dated in September, 1708, was made the foundation of the Act, 6 Anne, chap. 17, which is the foundation of the privileges long enjoyed by the United East India Company. Under this act, the Company advanced the sum required (1,200,000*l*.) without interest, to government. This sum, added to the former loan of 2,000,000*l*. at 8*l*. per cent., made the debt of the government 3,200,000*l*., and the interest equal to 5*l*. per cent. upon the whole sum. The charter which under the old indenture might have been terminated in 1711, was continued until the expiration of a notice of three years, which could not be given earlier than March, 1726, and further until the money borrowed by the government should be repaid. The Company was empowered to add the 1,200,000*l*. to its capital, and to raise 1,500,000*l*. either by bonds under its common seal or by contributions from its members.

Having thus briefly sketched the history of the various bodies which, after successive unions and arrangements, came, in 1708, to form the body which has since performed so important a part in the history of the world under the title of the United East India Company, it is necessary now to give some account of its constitution and government, and to trace that part of its history which has carried it from conquest to conquest, and made it in fact one of the greatest sovereign powers of the present times.

The capital stock of the Company, which, in 1708, amounted to £ 3,200,000 was increased, under successive acts of parliament, as follows —

| | | | |
|---------|---|---|-----------|
| In 1786 | . | . | 800,000 |
| 1789 | . | . | 1,000,000 |
| 1794 | . | . | 1,000,000 |

Making its present capital £ 6,000,000

Upon which sum dividends are paid: the later subscriptions were made at rates considerably above par, so that the money actually paid into the Company's treasury on that account has been 7,780,000*l*.

The home government of the Company consists of—

- 1st. The Court of Proprietors.
- 2nd. The Court of Directors; and
- 3rd. The Board of Control, the origin and functions of which body will be hereafter explained.

The Court of Proprietors elect the directors of the Company, declare the amount of dividend, and make bye-laws, which are binding upon the directors for the management of the Company in all respects which are not especially regulated by act of parliament. The votes of the proprietors are given according to the amount of stock which they possess. The lowest sum which entitles a proprietor to vote is 1000*l*. of stock; 3000*l*. stock entitles to two votes; 6000*l*. to three votes; and 10,000*l*. to four votes, which is the largest number of votes that can be given by any one proprietor. At the time of the last parliamentary inquiry into the concerns of the Company, it was stated that the number of proprietors entitled to vote was 1976: of this number 54 were entitled each to four votes; 50 had each three; 370 had two votes; and 1502 had single votes.

The Court of Directors consists of 24 proprietors elected out of the general body. The qualification for a seat in the direction is the possession of 2000*l*. stock. Six of the directors go out of office every year; they retire in rotation, so that the term of office for each is four years from the time of election. The directors who vacate their seats may be re-elected, and generally are so, after being out of office for one year. The chairman and deputy chairman are elected from among their own body by the directors, thirteen of whom must be present to form a court.

The power of the directors is great: they appoint the governor-general of India and the governors of the several presidencies; but as these appointments are all subject to the approval of the crown, they may be said to rest virtually with the government. The directors have the absolute and uncontrolled power of recalling any of these functionaries. All subordinate appointments are made by the directors, but as a matter of courtesy a certain proportion of this patronage is placed at the disposal of the President of the Board of Control.

The Board of Control was established by the act of parliament passed in August, 1784, and which is known as Mr. Pitt's India Bill. This board was originally composed of six privy councillors, nominated by the king; and besides these, the chancellor of the exchequer and the principal secretaries of state are, by virtue of their offices, members of the board. It is no longer necessary to select the members from among privy councillors. In practice the senior member, or president, ordinarily conducts the business, and on rare occasions only calls upon his colleagues for assistance. It is the duty of this board to superintend the territorial or political concerns of the Company; to inspect all letters passing to and from India between the directors and their servants or agents which have any connexion with territorial management or political relations; to alter or amend, or to keep back, the despatches prepared by the directors, and, in urgent cases, to transmit orders to the functionaries in India without the concurrence of the directors. In all cases where the proceedings of the directors have the concurrence of the Board of Control, the court of proprietors has no longer the right of interference. The salaries of the president and other officers of the Board, as well as the general expenses of the establishment, are defrayed by the East India Company. With the powers thus described, the president of the Board of Control has been correctly described as 'a secretary of state for the affairs of India, governing by means of the court of directors as its instrument in all matters of a political nature,' which, since the last renewal of the charter in 1833, includes all the functions of the company, the right of trading having by that act been taken away.

The act 6 Anne, c. 17, already mentioned, conferred upon the company the exclusive privilege, as regarded English subjects, of trading to all places eastward of the Cape of Good Hope to the Straits of Magalhaens; and these privileges, with some unimportant modifications, which it is not necessary to explain, were confirmed by successive acts of parliament, and continued until 1814. By the act 53 Geo. III., c. 155, passed in 1813, the Company's charter was

P. C., No. 562.

renewed for twenty years, but received some important modifications, the trade to the whole of the Company's territories and to India generally being thrown open to British subjects under certain regulations; the trade between the United Kingdom and China was still reserved as a monopoly in the hands of the East India Company. It was also provided by the act of 1813 that the territorial and commercial accounts of the Company should be kept and arranged so as to exhibit the receipts and expenditure of each branch distinctly from those of the other branch. These accounts, made out in forms approved by government, the directors are obliged to lay before both houses of parliament in the month of May in every year, 'made up according to the latest advices that shall have been received, and with as much accuracy as the nature of the case will admit.' In imposing this obligation upon the directors, it would almost appear that the legislature must have had in view the course which, twenty years later, on the next occasion of renewing the charter, was actually pursued. The act of 1833, by which the charter was renewed for twenty years, takes away from the Company the right of trading either to its own territories or the dominions of any native power in India or in China, and throws the whole completely open to the enterprise of individual merchants. The progress of the Company's trade at different periods has not been regularly published. The investigations that have been made into its concerns by committees of the houses of parliament, when it has been necessary to renew its charter, have been the means of bringing to light some information upon this subject; but the returns called for on each of these occasions have generally had reference only to the period immediately preceding that in which the inquiry has been made. The committee of secrecy which sat in 1773 did indeed call for various statements embracing a considerable period of time; and it is from the report of this committee that the following particulars relating to the trade of the Company, in the forty years between 1732 and 1772, have been obtained. Dividing this term of forty years into decennary periods, the average result in each period was as follows:—

| | Exports of goods and bullion. | Bills of exchange paid. | Total cost of goods received. | Amount of sales of goods. |
|----------------------|-------------------------------|-------------------------|-------------------------------|---------------------------|
| 1733 to 1742 | £617,283 | £167,311 | £784,594 | £1,699,775 |
| 1743 .. 1752 | 886,938 | 196,160 | 1,083,098 | 2,058,862 |
| 1753 .. 1762 | 797,318 | 303,076 | 1,100,394 | 2,030,104 |
| 1763 .. 1772 | 667,600 | 323,422 | 991,022 | 2,298,768 |
| Average of 40 years. | | | | |
| 1733 .. 1772 | 742,285 | 247,492 | 989,777 | 2,171,877 |

It would appear from this statement that the trade must have been highly advantageous. The average annual profit upon the amount invested, as above shown, amounted, in the first decennary period, to 116 per cent.; in the second period to 96 per cent.; in the third period to 84 per cent.; in the fourth period to 132 per cent.; and embracing the whole forty years, the gross profit amounted to 119½ per cent. It must be borne in mind, however, that this was *gross* profit, and that the expenses of carrying on the trade according to the method employed of establishing factories were necessarily very great. In fact, they were such as to absorb the profits and to bring the Company considerably into debt: a result which it would be more correct to attribute to the political character of the Company than to its necessary commercial expenditure.

When compared with the commercial dealings of even individual merchants in modern times, the trade of the East India Company, as exhibited above, is insignificant. Small as it was, however, it afterwards experienced a considerable diminution, and in 1780, the entire value of the exports of goods and bullion amounted to only 401,166*l*., a large part of which must have consisted of military stores and supplies required by the various factories and establishments of the Company. The commutation plan of Mr. Pitt, under which the duty on tea was reduced to 12½ per cent. *ad valorem*, and which came into effect in September, 1784, caused a considerable augmentation of the Company's outward investments, in order to procure the quantity of tea needed for use in this kingdom. The sales of tea at the India House, which, in the three years preceding the commutation, averaged 5,721,655 lbs., rose in the three following years to the average of 16,054,603 lbs., at which quantity it remained nearly stationary for several years. Notwithstanding this circumstance, the value of the exports made

by the Company in each of the three years which preceded the renewal of the charter in 1793 did not exceed one million. Under the provisions of this new charter, the Company was bound to provide 3000 tons of shipping every year for the accommodation of private traders, and it is deserving of remark that under this apparently unimportant degree of competition the trade of the Company increased rapidly and greatly. During the last four years of its existence, from 1810-11 to 1813-14, the average annual exports of the Company were—

| | Goods. | Stores. | Total. |
|----------------------------------|-----------|---------|-----------|
| | £ | £ | £ |
| To the three Presidencies, Bata- | 723,083 | 897,481 | 1,119,514 |
| via, Prince of Wales's Island, | | | |
| St. Helena, and Beencoolen . | 1,023,065 | 2,786 | 1,025,851 |
| To China | 1,745,098 | 400,267 | 2,145,365 |

On the occasion of the next renewal of its charter, viz. in 1814, the Company was obliged to make a further cession of its exclusive privileges, and stipulating only for the continuance of its monopoly in the importation of tea into this country, to allow the unrestricted intercourse of British merchants with the whole of its Indian possessions. Under these circumstances the Company found it impossible to enter into competition with private traders, whose business was conducted with greater vigilance and economy than was possible on the part of a great company; its exports of merchandise to India fell off during the ten years from 600,000*l.* in 1814-15 to 275,000*l.* in 1823-24, and to 73,000*l.* in the following year, after which all such exportation of merchandise to India on the part of the Company may be said to have ceased. The shipments to China were still continued, and large quantities of stores were also sent to India for the supply of the army and other public establishments.

It will be seen from the following statement of the value of exports from this country from 1814 to 1832 to all places eastward of the Cape of Good Hope, except China, in which the shipments of the Company (which include stores) are distinguished from those of private traders, that while the trade of the Company was thus falling off, that of private merchants was carried to an amount much greater than had existed during the monopoly of the Company.

| | By the East India Company. | By Private Traders. | Total Value of Exports. |
|----------------|----------------------------|---------------------|-------------------------|
| 1814 | £826,558 | £1,048,132 | £1,874,690 |
| 1815 | 996,248 | 1,569,513 | 2,565,761 |
| 1816 | 633,546 | 1,965,909 | 2,589,455 |
| 1817 | 638,382 | 2,750,333 | 3,388,715 |
| 1818 | 553,385 | 3,018,779 | 3,572,164 |
| 1819 | 760,508 | 1,586,575 | 2,347,083 |
| 1820 | 971,096 | 2,066,815 | 3,037,911 |
| 1821 | 887,619 | 2,656,776 | 3,544,396 |
| 1822 | 606,089 | 2,838,354 | 3,444,443 |
| 1823 | 458,550 | 2,957,705 | 3,416,255 |
| 1824 | 654,783 | 2,841,795 | 3,496,578 |
| 1825 | 598,553 | 2,574,660 | 3,173,213 |
| 1826 | 990,964 | 2,480,588 | 3,471,552 |
| 1827 | 805,610 | 3,830,580 | 4,636,190 |
| 1828 | 488,601 | 3,979,072 | 4,467,673 |
| 1829 | 434,586 | 3,665,678 | 4,100,264 |
| 1830 | 195,394 | 3,891,917 | 4,087,311 |
| 1831 | 146,480 | 3,488,571 | 3,635,051 |
| 1832 | 149,193 | 3,601,093 | 3,750,286 |

The impossibility, as thus shown, of the Company's entering into competition with private merchants had a powerful influence with parliament when it was last called upon to legislate upon the affairs of India, and in the charter of 1833 not only was the monopoly of the China trade abolished, but the Company was restricted from carrying on any commercial operations whatever upon its own account, and was confined altogether to the territorial and political management of the vast empire which it has brought beneath its sway.

Having thus, as briefly as possible, traced the progress of the Company from its foundation to the close of its commercial existence, it remains to describe it in its far more important capacity as the possessor of an empire almost unexampled in extent, and containing a population of one hundred millions of subjects.

The commencement and early progress of the political power of the East India Company in India have already been described. [BENGAL.] It would extend this notice to an unreasonable length if we attempted to trace the successive wars and conquests which mark the annals of the Company; this, indeed, is the less needed because of the notices given in our account of the various provinces and states of India in which that information necessarily finds a place. All that it appears requisite to give under this head will be found in the following chronological table of the acquisitions of the British in India, in which are stated the powers from whom the territory has, from time to time, been acquired.

| Date. | Districts, &c. | Power from whom acquired. |
|-------|--|---------------------------|
| 1757 | Twenty-four Pergunahs | Nabob of Bengal |
| 1759 | Masulipatam, &c. | The Nizam |
| 1760 | Burdwan, Midnapore, and Chittagong | Nabob of Bengal |
| 1765 | Bengal, Bahar, &c. | The Mogul |
| .. | Company's Jaghire, near Madras | Nabob of Arcot |
| 1766 | Northern Circars | The Nizam |
| 1775 | Zamindary of Benares | Vizier of Oude |
| 1776 | Island of Salsette | The Maharattas |
| 1778 | Nagore | Rajah of Tanjore |
| .. | Guntow Circar | The Nizam |
| 1786 | Palo Penang | King of Quenda |
| 1792 | Malabar, Dundigul, Salem, Barramahal, &c. | Sultan of Mysore |
| 1799 | Coimbatore, Canara, Wynaad, &c. | Iditto |
| .. | Tanjore | Rajah of Tanjore |
| 1800 | Districts acquired by the Nizam in 1793 and 1799 from Sultan of Mysore | The Nizam |
| 1803 | The Carnatic | Nabob of the Carnatic |
| .. | Goruckpore, Lower Doab, Bareilly | Vizier of Oude |
| .. | Districts in Bundelcund | The Peishwa |
| 1804 | Cuttack and Balasore | Rajah of Berar |
| .. | Upper part of Doab, Delhi, &c. | Dowlat Rao Scindia |
| 1805 | Districts in Gujerat | The Guicowar |
| 1815 | Kumaon and part of the Terrale | Rajah of Nepal |
| 1817 | Saugur and Hattah Darwar, &c. | The Peishwa |
| .. | Ahmedabad Farm | The Guicowar |
| 1818 | Candesh | Holkar |
| .. | Ajmeer | Dowlat Rao Scindia |
| .. | Poonah, Concan, Southern Maharatta Country, &c. | The Peishwa |
| 1830 | Lands in Southern Concan | Rajah of Sahwuntwate |
| 1832 | Districts in Begapore and Ahmednaggar | The Nizam |
| 1834 | Singapore | Rajah of Johore |
| 1835 | Malacca | King of Holland |
| 1826 | Assam, Aracan, Tarai, &c. | King of Ava |
| .. | Districts on the Nerbudda, Patna, Sambhulpore, &c. | Rajah of Berar |

It has always been felt to be highly anomalous that an association of individuals, the subjects of a sovereign state, should wage wars, make conquests, and hold possession of territory in foreign countries, independent of the government to which they owe allegiance. At a very early period of the Company's territorial acquisitions, this feeling was acted upon by parliament. By the act 7 Geo. III., c. 57 (1767), it was provided, that the Company should be allowed to retain possession of the lands it had acquired in India for two years, in consideration of an annual payment to the country of 400,000*l.* This term was extended by the 9 Geo. III., c. 24, to February, 1774. The sums paid to the public under these acts amounted to 2,169,398*l.* The last of these payments, which should have been made in 1773, was not received until 1775, and could not then have been paid but for the receipt of 1,400,000*l.* which was lent to the Company by parliament. This loan was afterwards discharged, and the possession of its territory was from year to year continued to the Company until 1781, and was then further continued for a period to terminate upon three years' notice to be given after 1st March, 1791. Under this act the Company paid to the public 400,000*l.* in satisfaction of all claims then due. In 1793 the same privileges were extended until 1814, the Company engaging to pay to the public the sum of 500,000*l.* annually, *unless prevented by war expenditure*; but owing to the contests in which it was engaged throughout that period, two payments of 250,000*l.* each, made in 1793 and 1794, were all that the public received under this agreement.

The act of 1813, by which the charter was renewed for twenty years from 1814, continued the Company in the possession of its territory, without stipulating for any immediate payment to the public; it provided that the accounts of the Company, both in England and in India, should be so kept as to exhibit the territorial and political, distinct from the commercial, branch of its concerns, the territorial revenue being appropriated strictly to the expenses of government and the repayment of the territorial debt, while the commercial receipts and profits were alone applicable to commercial objects, and to the payment of dividends to the proprietors. The 59th section of the act provided that when the territorial debt should be reduced to 13,000,000*l.*

the territorial profits should be applied first to the repayment of any public funds that might have been created in this country for the use of the Company, and that they should be then paid into the public exchequer to accumulate until the deposits should amount to 12,000,000*l.*, which sum should be retained for securing the capital stock of the Company, and providing an annuity to the proprietors equal to the rate of dividend, 10½ per cent. per annum, which they then received. In the event of the accumulations going beyond 12,000,000*l.*, one-sixth only of the surplus was to go to the Company, and five-sixths to be the property of the public. By these provisions, the right of parliament to assume possession of the Company's territories and of the revenues derived from them is clearly established.

Throughout the whole of the territories held in absolute sovereignty by the East India Company, it exercises the right of ownership in the soil, not by retaining actual possession in its own hands, but by levying assessments, which have usually been so calculated as to yield the greatest amount of present rental that could be collected from the cultivators, very frequently 'all that could be raised without diminishing the number of the inhabitants or desolating the country.' Before the sway of the English in India, the lands were held by a class of men who cultivated the soil with their own hands, whose right of perpetual occupancy was never questioned, but who were subject to the demands of their several governments, demands unlimited as to the right of the sovereign, but limited in fact by custom, which was stronger than the sovereign power. Different systems, as regarded the mode of collecting the rent on the part of the government, existed in different parts of the country. In some places the rent, or rather the amount of the tax, was collected in one sum from each village, which kept up an establishment of officers, whose functions consisted in first proportioning according to the means of each, and in then levying the sum assessed among the cultivators. In other cases, government officers were appointed who received charge of several districts, and who were paid for their services by a per-centage upon the amount collected. These officers were known as Talookdars, or more commonly as Zamindars, and this system has from them acquired its name of the Zamindari system. It was usual formerly for the government to allow to the zamindar one-tenth of the amount of the collections, and to require the remaining nine-tenths to be paid into its treasury. In 1793, however, the Marquess Cornwallis, being then Governor General of India, formed the resolution of fixing the assessment, and placing the zamindars in the situation of proprietors, engaging not to raise at any time the amount of the assessments against them. This arrangement, known as the *permanent settlement*, has been established through a great part of the presidencies of Bengal and Madras, including also certain polygars in the south, and hill chiefs in the Northern Circars.

It was hoped that by this means the zamindars would have been induced to improve their estates, since the whole increased revenue resulting from such improvements would have been permanently theirs. Unfortunately the power thus confided to the landholder has been used principally as the means of oppressing the actual cultivators, the ryots, and in order to repair this evil, the Company has of late years become the purchaser of all estates thus held which have been brought to sale, and making its bargain direct with the ryots, the actual cultivators of the soil, with the view of abolishing the system of employing middle-men: this plan is known under the name of the *ryotwary system*.

The executive government of the Company's territories is administered at each of the presidencies by a governor and three councillors. The governor of Bengal is also the governor-general of India, and has a control over the governors of the other presidencies, and if he sees fit to proceed to either of those presidencies, he there assumes the chief authority. The governors and their councils have each in their district the power of making and enforcing laws, subject in some cases to the concurrence of the supreme court of judicature, and in all cases to the approval of the court of directors and the board of control. Two concurrent systems of judicature exist in India, viz.: the Company's courts and the king's or supreme courts. In the Company's courts there is a mixture of European and native judges. The jurisdiction of the king's courts extends over Europeans generally throughout India, and affects the native inhabitants only in and within a certain distance around

the several presidencies: it is in these courts alone that trial by jury is established. Every regulation made by the local governments affecting the rights of individuals must be registered by the king's court in order to give it validity.

The constitution, in other respects, of the East India Company is shown by the following brief analysis of the principal clauses of the act 3 and 4 William IV., c. 85, which received the royal assent, 28th August, 1833, and under which its concerns are at present administered:—

- Sec. 1.—The government of the British territories in India is continued in the hands of the Company until April, 1854. The real and personal property of the Company to be held in trust for the crown, for the service of India.
- 2.—The privileges and powers granted in 1813, and all other enactments concerning the Company not repugnant to this new act, are to continue in force until April, 1854.
- 3.—From 22nd April, 1834, the China and tea trade of the Company to cease.
- 4.—The Company to close its commercial concerns and to sell all its property not required for purposes of government.
- 9.—The debts and liabilities of the Company are charged on the revenues of India.
- 43.—The governor-general in council is empowered to legislate for India and for all persons, whether British or native, foreigners or others.
- 44.—If the laws thus made by the governor-general are disallowed by the authorities in England, they shall be annulled by the governor-general.
- 81.—Any natural-born subject of England may proceed by sea to any port or place within the limit of the Company's charter having a custom-house establishment, and may reside thereat, or pass through to other parts of the Company's territories to reside thereat.
- 86.—Lands within the Company's territories may be purchased and held by any persons where they are resident.
- 87.—No native nor any natural-born subject of his majesty resident in India, shall, by reason of his religion, place of birth, descent, or colour, be disabled from holding any office or employment under the government of the Company.
88. Slavery to be immediately mitigated, and abolished as soon as possible.

The alterations in the constitution and administration of the Company effected by this act of 1833 are calculated to exercise a very important influence upon the future condition of the inhabitants of India. So long as the Company was allowed to combine commercial pursuits with its political character, its power might always have been, and very frequently was exercised in a manner ruinous to private traders. The extensive scale upon which its purchases were made raised prices in the country of production, and tended to lower them in Europe, and as it was never known in what articles the investments of the Company were to be made, their competitors were always forced to act under apprehension of interference, that set all their calculations at defiance. Now that the trade has been allowed to take a more natural course, we may confidently expect that the usual good result will attend upon the employment of individual skill and enterprise, that greater regularity of prices will be experienced, and that production will be stimulated until the prices of India produce are brought within the compass of a larger number of European consumers than at present. The advantages to England of this state of things must be great. To use the emphatic words of Dr. Wallich, the superintendent of the Company's botanic gardens at Calcutta, "The Company's territories in India are productive of every article which can conduce to the happiness of man; and it only requires skill and ingenuity, and encouragement, both to the natives and to Europeans in India, to select every thing that can possibly be desired." On the other hand, the luxuries and conveniences of European production, which are suited to the tastes of the natives of India, are equally varied and numerous, and present experience warrants the belief that under a regular course of trade, the circle of our customers for these productions will be continually enlarged. The progress here described must be greatly accelerated by the provisions contained in the 81st and 86th sections of the act, which authorises the settle-

ment of Europeans in India and the purchase of lands by them. Previously to the passing of this act, the Company possessed the right of arbitrary deportation against Europeans without trial or reason assigned, and British-born subjects were not only restricted from purchasing lands, but were prohibited from even renting them. Under the 87th section, if fairly carried into execution, a greater inducement than had hitherto been offered, is held out to the natives of India to qualify themselves for advancement in the social scale; a circumstance from which the best moral effects upon their characters are expected to result.

The revenue of the Indian government is not confined to its collections from the land, but consists likewise of customs—duties, stamp-duties, subsidies, and tribute from certain native states, some local taxes, and the profits arising from the monopolies of salt and opium. The following is an abstract of the revenues and charges of the Indian government during each of the three years 1831-32 to 1833-34, the latest for which the accounts have yet been presented to parliament.

| | 1831-32. | 1832-33. | 1833-34. |
|---------------------------------------|------------|----------------------------|------------|
| REVENUES. | | | |
| Bengal | 9,474,084 | 9,487,778 | 8,844,341 |
| Madras | 3,332,155 | 2,969,956 | 3,335,323 |
| Bombay | 1,401,916 | 1,497,308 | 1,600,691 |
| Total revenues of India . . | 14,198,155 | 13,955,042 | 13,680,165 |
| CHARGES. | | | |
| Bengal | 7,535,170 | 7,687,328 | 7,018,449 |
| Madras | 3,339,261 | 3,174,347 | 3,358,996 |
| Bombay | 2,060,498 | 2,034,710 | 1,968,045 |
| Charges on account of St. Helena | 94,153 | 95,553 | 91,641 |
| Charges disbursed in England | 1,476,655 | 1,237,636 | 1,293,637 |
| Total charges of India . . | 14,405,736 | 14,219,374 | 13,630,767 |
| Deficiency | 207,581 | 264,332 | — |
| Surplus | — | — | 49,398 |

| | | Annual Amount of Interest. | |
| Public debts bearing Interest. | | | |
| Bengal | 31,508,574 | 1,609,844 | |
| Madras | 3,351,371 | 112,837 | |
| Bombay | 603,636 | 81,844 | |
| | 35,463,483 | 1,754,545 | |

The great extent of its territories, and the nature of the tenure by which they are held, oblige the Company to keep on foot a large standing army, which is necessarily accompanied by great expense. The most recent detailed account that has been given upon this subject has reference to the year 1830, in which year the total number of the military force employed at the three presidencies and subordinate settlements in India amounted to 224,444 men, and its expense to 9,474,481*l*. The different descriptions of force and the expense attending each were then as follows—

| | Total. | Expense. |
|---|---------|------------|
| Engineers—Officers, European and Natives, and Rank and File | 1084 | £83,873 |
| Artillery—European—Horse | 2560 | 199,141 |
| Foot | 7469 | 252,343 |
| Native—Horse | 1062 | 74,239 |
| Foot | 6294 | 100,740 |
| Cavalry—European—King's | 2577 | 172,588 |
| Native—Company's—Regular | 12,248 | 718,853 |
| Irregular | 4714 | 179,393 |
| Infantry—European—King's | 17,731 | 628,612 |
| Company's | 3634 | 122,400 |
| Native—Regular | 124,391 | 3,103,355 |
| Irregular | 24,306 | 270,712 |
| Invalids | 10,588 | |
| Pioneers | 3487 | 74,511 |
| Hospital | 1266 | |
| Expense of Medical Department | | 132,858 |
| Staff | 1033 | 488,490 |
| Commissariat | | 614,327 |
| Other Military charges . | | 2,258,046 |
| Total Force | 224,444 | |
| Total Expense | | £9,474,481 |

The distribution of this force on the 30th of April, 1830 was as follows:—

| | Bengal. | Madras. | Bombay. | Prince of Wales's Island. | St. Helena. | Total. |
|---------------------|---------|---------|---------|---------------------------|-------------|---------|
| Engineers | 869 | 80 | 185 | .. | .. | 1,084 |
| Artillery.—European | 4,403 | 2,778 | 2,425 | .. | 493 | 10,099 |
| Native | 3,539 | 2,773 | 1,044 | .. | .. | 7,356 |
| Cavalry.—European | 1,235 | 637 | 705 | .. | .. | 2,577 |
| Native | 9,211 | 4,934 | 2,817 | .. | .. | 16,962 |
| Infantry.—European | 8,350 | 8,168 | 4,404 | .. | 445 | 21,365 |
| Native | 80,482 | 42,868 | 23,347 | .. | .. | 148,697 |
| Invalids | 2,746 | 5,837 | 1,663 | .. | 92 | 10,588 |
| Pioneers | 851 | 1,718 | 918 | .. | .. | 3,487 |
| Hospital | 457 | 494 | 992 | 15 | 8 | 1,966 |
| Staff | 440 | 445 | 148 | .. | .. | 1,033 |
| | 112,583 | 70,730 | 40,148 | 15 | 968 | 224,444 |

EAST INDIES. The portion of the globe to which the name of India, or the East Indies, is given, is usually understood to comprehend the peninsula of Hindostan lying to the east of the river Indus, and thence eastward as far as the boundary of the Chinese empire, by which empire, and by Tartary, India is also bounded on the north. The East Indies include also the islands of the Indian Ocean which lie between Hindostan and Australia as far north as the Philippine Islands, and as far east as Papua, but without including either the Philippines or Papua.

EASTER, Anglo-Saxon *Eastre*, a moveable feast, held in commemoration of the Resurrection; being the most important and most antient in observance, it governs the whole of the other moveable feasts throughout the year. In the Greek and Latin churches it is called *Πασχα*, *Pascha*, originally derived from a Hebrew word signifying a passage, which was the name given to the great feast of the Passover, held by the Jews on the same day with that on which our Saviour held his paschal feast. The etymologies of the word Easter have been various. Bede says, it was derived from a goddess called *Eostre*, to whom the people used at this season to celebrate festivals; but the most obvious is the Anglo-Saxon *yet*, a storm, the time of Easter being subject to the continual recurrence of tempestuous weather.

That the observation of Easter is as antient as the time of the Apostles seems undoubted. In the second century, however, a controversy arose as to the exact time of its celebration. The Eastern churches kept it on the 14th day of the first Jewish month; the Western churches on the night which preceded the anniversary of our Saviour's resurrection. The inconvenience of the former was, that this festival was commonly held upon other days of the week than the first, or Sunday, which was undoubtedly the proper day. The disputants retained their respective customs till towards the middle of the fourth century, when the rule for the celebration of Easter was fixed by the Council of Nice, A.D. 325. It was ordered to be held on the Sunday which falls next after the first full moon following the 21st of March, or vernal equinox.

Brand, in his *Popular Antiquities*, has given a long enumeration of the sports and observances at Easter in former times, including a few superstitions. The mutual presentation of coloured eggs at this season from friends continues both in the East and in Russia. (See Dr. E. D. Clarke's *Travels*, vol. i., 4to., Cambr., 1810, p. 59.) *Lifting*, originally designed to represent our Saviour's resurrection, is also still practised on Easter Monday and Tuesday in England, in Lancashire and some other counties; on which days, as well as at Whitsuntide, the Londoners repair to the celebration of their popular gaieties at Greenwich fair. Tansey puddings and cakes were antiently eaten in England at Easter.

(Broughton's *Dict. of all Religions*, fol., London, 1756, p. 395; Brady's *Clavis Calendaria*, 8vo. London, 1812, vol. i., p. 269; Brand's *Popular Antiquities*, vol. i., p. 137-155.)

EASTER, Method of Finding. The importance of this question, in aiding historical reference, is confined to that definition of Easter Sunday which was finally adopted by the western church. It is as follows: the Sunday following the full moon which follows the 21st of March; if a full moon fall on the 21st of March, therefore, the next full moon is the paschal moon; and if the paschal moon fall on a Sunday, the next Sunday is Easter Sunday.

By common consent, it is not the real sun or the real

moon which is employed in finding Easter, but the fictitious sun and moon of astronomers, which move uniformly with the average motion of the real bodies. It must therefore never surprise any one to find the Easter of any year not agreeing with the above definition, since such a case might (and sometimes must) arise. Say, for instance, that the real opposition of the sun and moon took place at a minute before twelve o'clock at night, March 21, and that of the average sun and moon two minutes after the above. The consequence would be that, counting by the real bodies, the full moon in question would not be the paschal full moon, while that of the average bodies would be so. But the following rules will determine the Easter day of chronologists in any year of the Christian era, which is all that is required:—

First, ascertain the dominical letter, taking the second where there are two. [DOMINICAL LETTER]. Next, ascertain the golden number (year of the Metonic cycle) as follows: add one to the date of the year and divide by 19, the remainder (or if there be no remainder, 19 itself) is the golden number. The following table must then be used, in the manner to be immediately explained:—

| | O.S. | N.S. | | O.S. | N.S. |
|------------|------|------|-----------|------|------|
| March 21 C | 16 | 14 | April 9 A | 17 | 15 |
| 22 D | 5 | 3 | 10 B | 6 | 4 |
| 23 E | — | — | 11 C | — | — |
| 24 F | 13 | 11 | 12 D | 14 | 12 |
| 25 G | 2 | — | 13 E | 3 | 1 |
| 26 A | — | 19 | 14 F | — | — |
| 27 B | 10 | 8 | 15 G | 11 | 9 |
| 28 C | — | — | 16 A | — | — |
| 29 D | 18 | 16 | 17 B | 19 | 17 |
| 30 E | 7 | 5 | 18 C | 8 | 6 |
| 31 F | — | — | 19 D | — | — |
| April 1 G | 15 | 13 | 20 E | — | — |
| 2 A | 4 | 2 | 21 F | — | — |
| 3 B | — | — | 22 G | — | — |
| 4 C | 12 | 10 | 23 A | — | — |
| 5 D | 1 | — | 24 B | — | — |
| 6 E | — | 18 | 25 C | — | — |
| 7 F | 9 | 7 | | | |
| 8 G | — | — | | | |

O. S. means *old style*; N. S., *new style*.

Having the golden number, and the dominical letter, find out the golden number in the second or third column, according as old style or new style is meant; and look down the first column until the *next* occurrence of the dominical letter comes. Easter day is opposite. Thus the golden number being 13 and the dominical letter F, Easter day is March 31 in the old style, April 7 in the new style.

Example 1.—What was Easter day A.D. 1688 (old style)?

The dominical letters are A G. Take the second, G.

$$\begin{array}{r} 1688 \\ 1 \\ \hline 19)1689(88 \end{array}$$

rem. 17 the golden number.

Opposite to 17, under O. S., comes April 9 A, and the next G which occurs is opposite to April 15, which was therefore Easter day.

Example 2.—When will Easter day fall, A.D. 1841?

The dominical letter is C.

$$\begin{array}{r} 1841 \\ 1 \\ \hline 19)1842(96 \end{array}$$

rem. 18 the golden number.

Opposite to 18, under N. S., is April 6 E, and the next C is opposite to April 11, which is therefore Easter day.

The following table gives Easter day for every year from 1800 to 1999. Thus in 1873 Easter day is April 13 (a. 13); in 1973 it is April 22 (a. 22).

| | 18. | 19. | | 18. | 19. | | 18. | 19. |
|----|-------|-------|----|-------|-------|----|-------|-------|

EASTER ISLAND, an island in the eastern part of the Pacific Ocean, more than 2000 miles distant from the coast of South America, is situated between $75^{\circ} 5'$ and $75^{\circ} 12'$ S. lat., and between 109° and 110° W. long. It is about thirty or forty miles in circuit, with a stony and hilly surface, and an iron-bound shore. The hills appear to rise to the height of 1200 feet, according to Beechey. At the southernmost extremity of the island is an extinct volcano. Lava seems to form the principal component of the hills, which rise gradually and are covered with grass. The island has no safe anchorage, no wood for fuel, no fresh water, and no domestic animals, except a few fowls. The inhabitants live on yams, potatoes, and sugar-cane. In physiognomy, language, and manners, they resemble the inhabitants of the other groups of islands lying farther west. But it is remarkable, that on this island are found a number of colossal statues, some of which are fifteen or even eighteen feet high; they stand on platforms, which have been made with a considerable degree of art. Some conjecture that these monuments have been erected by a nation more numerous than its present inhabitants. Cook estimated the population at 600 or 700; but La Perouse thought that it amounted to 2000, and Beechey to 1230. (Cook, La Perouse, and Beechey.)

EAVES. [HOUSE.]

EBB. [TIDES.]

EBEL, JOHN GOTTFRIED, an esteemed writer on statistics and geology, born at Francfort on the Oder, October 6, 1764; died at Zürich, 1830. After completing his studies and taking his degree as doctor of medicine, he went to France, and became intimately acquainted with the Abbé Sieyès. In 1801 he went to Switzerland, and resided chiefly at Zürich. He travelled through Switzerland in all directions, and published some very valuable works on the natural history and statistics of the country. The most popular is his 'Guide to Travellers in Switzerland.' In his description of the mountaineers of Switzerland, he draws an interesting picture of the inhabitants of Appenzel and Glarus. His work on the geology of the Alps touches also on the structure of the globe in general, and contains valuable information on the geognostical relations of the Alps.

EBELING, CHRISTOPHER DANIEL, born 1741, at Garmissen in Hildesheim; died in 1817. He studied theology at Göttingen, and acquired great knowledge of the oriental languages, especially the Arabic, and was thoroughly acquainted not only with the classical literature of Greece and Rome, but also with that of modern Europe, particularly England. He published numerous translations, &c., but his chief work is his 'Geography and History of the United States of North America,' 7 vols. 8vo., which was justly considered as a masterpiece, not only in Europe, but still more in America itself. He was chosen a member of almost all the learned societies of the country, and the Congress voted him public thanks for his services. That part of his library which related to America, consisting of 3900 volumes, was purchased after his death by M. Israel

Thoredino, a friend of learning, at Boston, and presented to Harvard college. Ebeling was for thirty years professor of history and of the Greek language in the gymnasium at Hamburg. His industry was extraordinary. Besides the duties of his professorship and the composition of his chief work, he was for above twenty years keeper of the public library of the city, into which he introduced order and judicious arrangement, and composed a catalogue, which was much wanted. He besides contributed largely to numerous periodicals. He was of a most friendly, cheerful, and social disposition; and we must admire the wonderful patience and equanimity with which he bore for thirty years a hardness of hearing, which gradually increased to almost total deafness, so that a loud voice was scarcely perceptible to him even with the aid of an ear-trumpet.

EBENA/CEÆ, a natural order of monopetalous exogens with the following essential character:—Flowers either with separate sexes, or occasionally hermaphrodite. Calyx permanent, with from three to six divisions. Corolla monopetalous, regular, of a thick leathery texture, usually downy on the outside, with the same number of divisions as the calyx. Stamens twice or four times as numerous as the lobes of the corolla, adhering to its tube, and usually in two rows; sometimes adhering in pairs. Styles several. Fruit fleshy, superior, with only one pendulous seed in each cell. Embryo lying in much albumen, with large leafy cotyledons and a long taper radicle. The species consist entirely of bushes or trees, some of which are of large size; their leaves are alternate, with no stipules, and generally leathery and shining. *Diospyrus Ebenus*, and some others, yield the valuable timber called ebony. The fruit of *Diospyrus Kaki* is about as large as an apricot, and is dried as a sweetmeat by the Chinese. Most of the plants of this order are tropical; of the few found beyond the tropics, *Diospyrus Lotus* inhabits Africa and Switzerland, and *D. Virginiana*, the United States.

A branch of *Diospyrus Lotus* in fruit; 1, a flower; 2, a corolla, cut open; 3, the calyx and ovary; 4, a section of a ripe fruit, showing the seeds.

EBERSBACH, the largest village in the kingdom of Saxony, is situated in the eastern part of that kingdom, and in the circle of the Land, a subdivision of the province of Lusatia, in 51° 0' N. lat., and 14° 38' E. long. It is the centre of the linen manufacture of Saxony, is divided into Upper and Lower Ebersbach, has two churches, three schools, and about 700 houses, with upwards of 5000 inhabitants. There are more than 2000 looms in activity. It lies about nine miles north-west of Zittau.

EBIONITES, a sect of Christian Jews, which existed in Palestine and other parts of the East in the first and second centuries of our æra. Like the Nazarenes, with whom they have been often confounded, they continued to observe the precepts and ceremonies of the Mosaic law; they kept both the Sabbath and the Sunday, made their ablutions, used unleavened bread in the celebration of the eucharist, and moreover, abstained from eating flesh. Still they do not seem to have formed a distinct sect till after the second destruction of Jerusalem by Hadrian, when they became separated from the rest of the church by their dogmas as

well as by their external practices. Origen, Epiphanius, Eusebius, and other early fathers, distinguish two sorts of Ebionites, namely, those who denied the divinity of Jesus Christ, asserting that he was the son of Joseph and Mary, though endowed with a prophetic gift, and those who maintained that he was born of a virgin, but denied his pre-existence as God. The Ebionites in general acknowledged only one gospel, namely, the Hebrew one, which goes by the name of St. Matthew, and that one mutilated. They discarded the Acts of the Apostles, and especially the Epistles of St. Paul, whom they considered as an apostate from the old law. They had several apocryphal books; among others, a life of St. Peter. The earlier Ebionites lived a regular life, and many of them observed celibacy, which they held in great esteem. The later Ebionites became much more lax in their morals. The name of Ebionites is said by Eusebius, Origen, and Irenæus to be derived from a Hebrew word of contempt, meaning 'poor low people,' which the Jews applied to those of their countrymen who had embraced Christianity. Others have derived it from a philosopher of the name of Ebion, whose existence however is doubtful. Epiphanius speaks at length of the Ebionites, but he confounds them with other sects, and his account cannot be trusted. (Mosheim, *Institutes of Eccles. History*, with notes by Dr. Murdoch; Neander, *Kirchengeschichte*.)

EBOË, is the name given in the West Indies to the blacks imported from the coasts of the Bight of Benin, as distinct from the natives of the Gold Coast and other parts of Africa. 'In their complexion they are much yellower than the Gold Coast and Whidah Negroes; but it is a sickly hue, and their eyes appear as if suffused with bile, even while in perfect health. The conformation of the face in a great majority of them very much resembles that of the baboon.' (Edwards' *History of the West Indies*.) The Eboes are subject to great despondency and depression of spirits, which form a striking contrast to the frank and fearless temper of the Koromantyns, or Gold Coast Negroes. When the slave trade was still in vigour, the distinction between these two races was much attended to by the planters, who treated the Eboes with greater indulgence, in order to prevent their committing suicide, to which they were very prone. The Eboes practised circumcision and worshipped the guana. They were said to be cannibals in their native country.

EBONY is well known as a hard black-coloured wood, brought from the hot parts of the world. The Greek name is ébenos (ἔβερος), from which the Latin ébenus, and our word ebony have been immediately derived. It is first mentioned by Ezekiel, xxvii. 15, but in the plural, hobnem, where the men of Dedan are described as bringing to Tyre horns of ivory and ebony. The Persian name, abnoos, is that by which it is commonly known all over India; it is probable, therefore, that the name, like the wood itself, had an Eastern origin. From its hardness, durability, susceptibility of a fine polish, and colour, which has almost become another name for blackness, ebony has always been in high estimation, and in the present day is much used for mosaic work and ornamental inlayings, though cheaper woods dyed black are frequently substituted.

Herodotus (iii. 97) mentions ebony as part of the presents brought in considerable quantities to the king of Persia by the people of Ethiopia. Dioscorides describes two kinds, one Ethiopian, which was considered the best, and the other Indian, which was intermixed with whitish stripes and spotted; and hence commentators have disputed whether there were one or two kinds of ebony. But the fact is, that several trees yield this kind of wood, and all belong to the genus *Diospyrus*. Owing to the known geographical distribution of this genus, the ancients must have derived their ebony either from the peninsula of India and the island of Ceylon or by the coasting trade from Madagascar; for no species of *Diospyrus* has yet been discovered by botanists in the upper parts of Egypt or in Abyssinia, though it is not improbable that some may be found, as the climate is well suited to their existence.

The genus *Diospyros* (from dios and puros, which may be translated celestial food) has been so named from some of its species affording edible fruit. They all form large trees, with alternate, thick, often coriaceous leaves. The flowers are usually single and axillary, the male and female flowers separate or united. Calyx and corolla four-cleft, rarely five-cleft. Stamens often eight, but varying in different species. Germ superior, often eight-celled; cells one-seeded;

attachment superior. Styles three or four, rarely five, or one, and variously divided. Berry from one to twelve-seeded, often eight-seeded. Embryo inverse, and furnished with albumen. Male flower frequently with twin anthers. The species are found chiefly in the tropical parts both of Asia and America, as in the Malayan archipelago and peninsula, and in almost every part of India. One species extends southwards to New Holland; one, *D. Lotus*, to Switzerland, and *D. Virginiana* into the United States of America. As some are remarkable for the wood which they afford, and others on account of their fruit, it is necessary only to notice a few of each, though the whole require the labours of a monographist.

Diospyros Ebenus, the true ebony, and that which is considered to be of the best quality, is a large tree, a native of the Mauritius, Ceylon, and apparently also of Madagascar: for *D. lanceolata*, Poir., collected by Commerson in that island, is considered the same. The leaves are very smooth, short, petioled, alternate, bifarious, oblong in shape, the buds very hairy; male flowers sub-racemed, with about twenty anthers, the hermaphrodite solitary, octandrous. Large quantities of the ebony of this species have been sometimes imported into Europe.

D. Ebenaster. This is also a tree of considerable magnitude, a native of Ceylon, of which the leaves are coriaceous and smooth on both sides, and the buds smooth.

D. reticulata (Tessellaria, Poir.) is another elevated tree, a native of the Mauritius, of which the heart-wood forms ebony.

D. melanoxylon, described and figured by Rumph, iii. p. 9, Corom. Planta, 1 to 46, by Dr. Roxburgh, is the ebony tree of the Coromandel coast. It is found on the mountains of that coast as well as of Malabar, and in Ceylon. It grows to be very large, particularly the male tree, of which the wood is also most esteemed. The leaves, which are sub-opposite, oval, oblong, obtuse and villous, are deciduous in the cold season, the new ones appearing with the flowers in April and May; as in other species, it is only the centre of large trees that is black and valuable, and this varies in quantity according to the age of the tree. The outside wood, which is white and soft, time and insects soon destroy, leaving the black untouched. The ripe fruit is eaten by the natives, though rather astringent, as is also the bark. *D. tomentosa* and *Roylei* are other Indian species which yield ebony.

Several species of the genus bear fruit, which, though clammy and sub-astringent, is eaten by the natives of the countries where the trees are indigenous. We need name only the most celebrated, as *D. Lotus*, a native of Africa, and now common in the south of Europe, which bears a small yellow sweetish fruit about the size of a cherry, and which has by some been supposed to be the famous *Lotus* of the *Lotophagi*; but this is more likely to have been the jujube, called by botanists *Zizyphus Lotus*.

Diospyros Kaki is celebrated in China and Japan: specimens introduced into the Botanic Garden of Calcutta were found to be identical with others from Nepal. The fruit is described by Dr. Roxburgh as being tolerably pleasant. It is esteemed in China, where it attains the size of an orange, and is frequently sent to Europe in a dried state, and called the date-plum of China, and also keg-fig of Japan.

D. discolor of the Philippine Islands also bears a fruit which is esteemed, and called *Mabolo*.

D. Virginiana, the Persimmon tree, is indigenous in North America, especially in the middle and southern of the United States, where it attains a height of sixty feet, but it does not flourish beyond the 42° N. latitude. The fruit while green is excessively astringent, but when ripe, and especially after it has been touched by the frost, it is sweet and palatable. The fleshy part separated from the seeds is made into cakes, which are dried and preserved. A kind of cider has also been made from this fruit, and a spirituous liquor distilled from its fermented infusion.

D. glutinosa also affords a fruit which, though edible, is far from palatable, but more valuable as an article of commerce. The tree is middle sized, a native of the moist valleys amongst the mountains of the Circars, and all along the foot of the Himalaya to 30° N. latitude. Sir William Jones first mentioned what is well known throughout Bengal, that the astringent viscid mucus of the fruit is used for paying the bottoms of boats. The unripe fruit contains a large proportion of tannin, and its infusion is employed to steep fishing-nets in to make them more durable.

EBRO, IBERUS, a river of Spain, which rises near

Reinosa in Old Castile, at the foot of the Asturian mountains, flows in an east-south-east direction, and crosses the north part of Old Castile. Afterwards, on reaching the frontiers of Biscay, it inclines more to the south-east, and marks the boundary between Biscay and Navarra on its left and Castile on its right bank, passes by Miranda and Logroño, then enters Navarra, and divides the districts of Tudela and Cascante from the rest of that province. It then enters Aragon, which it divides into two nearly equal parts, one to the north-east and the other to the south-west of its course, flows by Zaragoza and Mequinenza, and below the latter town enters Catalonia, when it assumes a south-south-east direction, and passes by Tortosa, below which it enters the sea by two branches, the southernmost of which forms the port of Alfaques. [CATALONIA.] The whole course of the Ebro, with its numerous windings, is rather more than 400 miles. The valley of the Ebro, lying between the great Pyrenean chain and the highlands of Castile, forms a natural division between the northern provinces of Spain and the rest of the peninsula, and the course of the Ebro has therefore been often assumed as a military line in the wars of that country. Previous to the second Punic war, it formed the line of demarcation between the dominions of Carthage and those of Rome. It afterwards formed the boundary between the dominions of Charlemagne and his successors and those of the Moors. The French in their Spanish wars have repeatedly purposed to make the Ebro the boundary between France and Spain. The Ebro begins to be navigable for boats at Tudela in Navarra, but the navigation is often impeded by rapids and shoals. To avoid these, the imperial canal has been constructed, which begins at Fontelles near Tudela, and running parallel to and south of the river, rejoins it six miles below Zaragoza. It was intended to carry it as far as Tortosa. [ARAGON.]

The Ebro receives numerous affluents from the Pyrenean chain, the principal of which are as follows. The Aragon, which rises in the mountains of Navarra and enters the Ebro near Milagro. The Gallego, from the mountains of Jaca in Aragon, enters the Ebro nearly opposite Zaragoza. The Segre, swelled by its numerous affluents, the Chinca, the Noguera Pallaresa, Noguera Ribagorza, and others, draining a vast tract of country both in Aragon and Catalonia, enters the Ebro below Mequinenza on the borders of the two provinces. On its right bank the Ebro receives, above Zaragoza, the Jalon, joined by the Jiloca, coming from the central highlands between Aragon and Castile. The Guadalupe, which comes from the mountains of Teruel in S. Aragon, enters the Ebro above Mequinenza.

EBULLITION. [BOILING OF FLUIDS.]

EBURNA. [ENTOMOSTOMATA.]

ECBATANA (*Ἐκβάτανα*), the ancient capital of Media, founded by Deioces (Herod. i. 98). The genuine orthography of the word appears to be *Agbátana* (*Ἀγβάτανα*: see Steph. Byzant. v. *Ἀγβάτανα*), as it is now written in the text of Herodotus, and as we are informed by Stephanus, it was written by Ctesias. It appears in the 'Itinerary' of Isidore of Charax under the form of *Apobátana*. There was a city of the same name in Syria, of uncertain position (Herod. iii. 64), where Cambyzes died. [CAMBYSES.]

Ecbatana was situated, according to the testimony of ancient writers, in a plain at the foot of a lofty mountain called Orontes. Herodotus, who had probably seen the place, describes it as built on a conical kind of hill, and consisting of seven circular inclosures or walls, one within another, each wall being higher than that which surrounded it, and the innermost wall, which surrounded the palace, of course the highest of all. Ecbatana being a high and mountainous country, was a favourite residence of the Persian kings during summer, when the heat at Susa was almost insupportable.

Hamadan, which is on or near the site of Ecbatana, is near the parallel of 35° N. lat. and in 48° E. long., in a low plain at the foot of Mount Elwund. Elwund belongs to that mountain-chain which forms the last step in the ascent from the lowlands of Irak Arabi to the high table-land of Iran. [ASIA, p. 470.] 'During eight months in the year the climate of Hamadan is delightful; but in winter the cold is excessive, and fuel with difficulty procured. The plain is intersected by innumerable little streams, covered with gardens and villages, and the vegetation is the most luxurious I ever beheld.' (Kinneir's *Persia*, p. 126.) Kinneir says that the summit of Elwund is tipped with continual snow, and seldom obscured by clouds. Hamadan

has a large manufacture of leather, and also a considerable trade, owing to its position on the high road from Bagdad to Tehran and Ispahan. According to Kinneir, it has about 10,000 inhabitants. [Asia, pp. 469, 470.]

The site of Ecbatana has been a matter of dispute; but the dispute has arisen solely because those who have discussed the question either did not know the evidence on which the question must be decided, or did not understand it. The route of commerce between the low country in the neighbourhood of the antient Seleuceia and the modern Bagdad and the high table-land of Iran, is determined by the physical character of the country, and has continued the same from the earliest recorded history of those countries to the present day. The places marked in the 'Itinerary' of Isidore as lying between Seleuceia and Ecbatana are the places indicated by modern travellers as lying on the route between Bagdad and Hamadan. This question is fully discussed in the 4th No. of the 'Journal of Education.'

For further references as to the history of Ecbatana, in addition to those given in the 'Journal of Education,' the reader may consult Bähr's 'Ctesias,' p. 88; the note on Q. Curtius, v. c. 8, ed. Pitiscus, 1708; and Wesseling's note on Herod. i. 98.

ECCLSIASITES, or THE PREACHER, a canonical book of the Old Testament, placed after the Proverbs and before the Song of Solomon. The English title is adopted from that in the Greek Septuagint (*Ἐκκλησιαστής*, *Ecclēsiastes*), which is a translation of the Hebrew title *חֹהֵלֶת*, *Chohēleth*, that is, one who calls together or calls out to an assembly—a public declaimer. A review of the various learned interpretations of this term is given in Mr. Holden's work on Ecclesiastes, p. 31. Widely different opinions have been expressed by many biblical critics concerning the author, date, and design of this portion of the Bible. The Rev. G. Holden, in the preface to his learned 'Attempt to illustrate the Book of Ecclesiastes,' 8vo. 1822, observes that, 'In common with most other students, he has felt much perplexed by the many difficulties of this book; that of all the Hebrew Scriptures none present greater obstacles to the expositor; for besides the obscurities possessed in common with the others, it has some peculiar to itself; that, with respect to the nature of the author's argument, style, and design, the opinions of critics and commentators have diverged to incredible distances; and their labours serve rather to perplex than to assist the inquirer.' The general supposition that Ecclesiastes was written by Solomon is apparently warranted by the passages i. 1, 12, 16; ii. 4-9, which designate the author as the son of David, king of Israel, and the greatest possessor of wealth and wisdom in Jerusalem. However, it is not only doubted by some commentators, as Semler (*Apparatus in Vet. Test.*, p. 203), that Solomon is the author, but by many other critics and divines of the greatest learning and reputation it is declared to be a production of the age of or subsequent to the Babylonish captivity (600 B.C.), that is, 400 years after Solomon, who reigned 1000 B.C.: Zirkel and others date it as late as 130 B.C. (Grotius, *Prolegum. in Ecclesiastem*; Hermann von der Hardt, *De Libro Koheleth*; Van der Palm, *Diss. de Libro Ecclesiastem*; Doederlein, *Scholia in Ecclesiastem*; Professor Dathe, *Notæ in Ecclesiastem*; Zirkel, *Untersuchungen in Ecclesiastes*; and especially Jahn, *Introduct. ad V. Test.*; and Eichhorn, *Einleitung in das Alte Test.*, vol. iii.) The writers of the Talmud and Rabbi Kimchi attribute this book, as well as Proverbs and the Song, to King Hezekiah or the prophet Isaiah. Dr. Adam Clarke (*Preface to Ecclesiastes*, in his ed. of the Bible) asserts that the traditional notion entertained by the Jews and many Christian divines, as Jerome, Huet, Michaelis, &c., that Ecclesiastes was written by Solomon in his old age, after recovering from idolatry and sensuality, is an assumption which never has been nor can be proved to be true; for since it was 'when Solomon was old, that his heart was turned away after other gods by his 700 wives and 300 concubines' (1 Kings, ii. 3 and 4), and as he died about the age of sixty, the supposition of a final period of philosophical and pious contrition is not warranted by probability. 'The language,' says the same divine, 'puzzles me not a little; Chaldaisms, Syriasms, and Chaldee words are frequent, and the style is that of the authors who lived at or after the captivity.' Bishop Lowth remarks that the style is peculiar; the diction low, exceedingly obscure, loose, unconnected,

and resembling conversation. (*Praelect. 24.*) The greatest difficulty in expounding this book consists in ascertaining the proper principle of interpretation; for many passages understood literally seem to sanction a belief in the non-existence of a divine Providence (ii. 11, 'All things, time and chance, happen alike to the righteous and the wicked'); in annihilation or materialism (iii. 19, 'A man hath no pre-eminence over a beast: both die alike; and the dead (ix. 5) have no knowledge and no reward'); splenetic repining is apparently sanctioned (iv. 3, 'It is more fortunate not to be born than to be either living or dead'); so voluptuousness (ii. 24, viii. 15, &c., 'Man hath no better thing than to eat, to drink, and be merry'); which is contradicted, (vii. 3,) where sorrow is said to be better than laughter. To clear the author from the imputation of teaching erroneous and contradictory doctrines, and promoting sensuality and despair, it has been suggested that the treatise is a series of counter propositions, or objections and replies. With this view Mr. Holden has composed an elaborate paraphrase of the original text, and by qualifying and judiciously modifying the expressions and interweaving many ingenious explanations, has reduced the whole to consistency. The general opinion of the commentators, that the design of the book is to inquire about the supreme good*, and to show that it consists in religious wisdom, is adopted by Mr. Holden, with the idea also of its consisting of two divisions: the first, to verse 10 of chap. vi. being occupied in setting forth the vanity of all the labours and enjoyments of human life, the second in eulogizing religious wisdom and describing its nature and effects. The learned Desvœux, in his 'Philosophical and Critical Essay on Ecclesiastes,' 4to. 1760 having collected and discussed many fanciful opinions of other expositors with regard to the design of this book, suggests and maintains it to be 'to prove the immortality of the soul and a future state of restitution.' Dr. Graves adopted this opinion; but Mr. Holden rejects and refutes it, remarking that 'the doctrine of a future state is left in great darkness and obscurity, not only in Ecclesiastes, but in all the Hebrew Scriptures, in no passage of which it is announced as a necessary article of faith.' Various fanciful conjectures have been offered in commenting on the figurative language of the last chapter, descriptive of old age (See Holden, p. 161.) In addition to the works already mentioned, the following may be found useful for reference:—Greenaway's translation of Ecclesiastes; Hodgson's translation; Bishop Reynolds's 'Comment on Ecclesiastes'; Dr. Wardlaw's 'Lectures on Ecclesiastes.' For numerous others, see Watt's 'Bibliotheca Brit.'

ECCLIASTICUS, or THE WISDOM OF JESUS THE SON OF SIRAC, an apocryphal book of the Old Testament. It is stated to have been originally written in Syro-Chaldaic, by Jesus, the son of Sirac, a learned Jew, who travelled in pursuit of knowledge 130 years B.C. It was translated into Greek for the use of the Jews of Alexandria, by the grandson of the author, or rather compiler. For it is evidently a collection of fragments, written at different times and on various occasions, consisting of meditations and proverbs relating to religion, morals, and the general conduct of human life. But though it is manifest that no methodical plan or arrangement was observed in the composition, the commentators remark that the whole will admit of division into three parts. The first extends to the end of chap. 43, and is occupied in the commendation of wisdom and the statement of moral precepts. The second celebrates the virtues of the patriarchs and prophets of the Jews, and extends to the end of chapter 49. The third part is comprised in the 50th and concluding chapter, and consists of a prayer or hymn, exhorting mankind to the pursuit of wisdom. These meditations display much acuteness of thought, with propriety of diction, and occasionally poetical eloquence. They closely resemble the numerous other oriental proverbs, and especially the collection attributed to Solomon. In the western Christian church this book was highly esteemed the council of Carthage made it canonical, as the fifth book of Solomon, and the council of Trent confirmed the decision. It was also introduced by the early Protestant reformers into the liturgy of the church of England.

Addison, in the 68th number of the Spectator, observes, that were this collection issued under the name of Con-

* See, on the question of the summum bonum, Aristotle's 'Nicomachean Ethics'; Plato's 'Philebus'; Cicero, 'De Finibus'; Stoicism, 'Eclog. Ethic.'; St. Augustine, 'Givitas Dei'; Harris 'On Happiness.'

fucius, or one of the sages of Greece, it would be regarded as one of the most brilliant moral treatises ever published. The opinion which attributes it to Solomon is falsified by several allusions to the captivity, showing that some parts at least were written under the monarchs of Babylon (c. 47, &c.), 400 years subsequent to the reign of Solomon. The Greek fathers frequently cite the book of Ecclesiasticus as *ἡ ἱσχυὶς σοφίας*, the Wisdom of Jesus; *Παράπτερος σοφία*, the Excellent Wisdom; and *Λόγος*, the Rational Discourse. The Latin fathers named it Ecclesiasticus, or the Book of the Church, from its being then appointed to be read in churches. A Syriac and an Arabic version are extant. The Latin version, which is supposed to be of the first century, contains numerous words adopted from the Greek, but differs much from the present Greek text. (*Ecclesiasticus*, or the *Book of the Church*, by Luke Howard, F.R.S., 1827; Dalrymple, Lord Hailes, *Wisdom of Solomon*, or *Ecclesiasticus*, 1755; Sonntag, *Comment. de Jesu Siracide Ecclesiastico*, 4to., 1792; Bretschneider, *de lib. Jesu Siracide* (prolegom. pp. 10-32), dates the original compilation 180 B.C.; Horne's *Introduct. to the Bible*, vol. iv.)

ECCREMOCARPUS SCABER, a climbing Chilian half-shrubby plant belonging to the natural order Bignoniacæ, inhabiting thickets and hedges in its native country, and scrambling among the branches of bushes and small trees. It has an angular cinnamon-brown stem, with pale-green succulent branches; opposite pinnated trifoliate leaves, with obliquely cordate serrated leaflets, and a terminal tendril; horizontal racemes of tubular orange-scarlet obliquely ventricose flowers, the limb of whose corolla is narrow and five-lobed; and remarkable oval compressed pods covered all over with short tubercles, and opening into two thin convex valves, within which is placed a number of thin winged netted seeds. It is a handsome half-shrubby plant, which will live in the open air in the milder parts of England. By some it is called *Calampelis scabra*.

ECHARD, LAWRENCE. It is unknown when this author was born; but his translation of the 'Amphitryo' of Plautus was published in 1694. He was educated at Cambridge, and having taken orders, was presented to a living in Lincolnshire. In 1712 he became archdeacon of Stowe and prebendary of Lincoln. His historical works have long ceased to be read; but his translation of Terence is still frequently purchased by indolent schoolboys, who could not well buy a more unprofitable book. The characters of the elegant and refined Terence are made to utter all the vulgarisms and scurrilities of the eighteenth century: thus we have such expressions as 'the devil a person,' 'damnable roguery,' 'fools' paradise,' constantly before us. Sir Charles Sedley has left a version of Terence's 'Eunuch' somewhat in the same style; but he has had the good sense merely to take the plot of the classic, and represent the characters as modern Englishmen; whereas Echard has committed the palpable absurdity of putting his ribaldry in the mouths of Athenian citizens: and to crown all, has written a most self-complacent preface, wherein he acknowledges he could not have followed his author more closely without destroying his design 'of giving an easy comic style.' We should not have been so pointed in our remarks on this worthless book had we not been fully aware, that while classical studies form so considerable a branch of education, it is of the utmost importance that the young student should not acquire those incongruous and absurd notions which he cannot fail to imbibe from such works as Echard's 'Terence.'

ÉCHEVIN, the name given under the old French monarchy to the municipal magistrates of various cities and towns. At Paris there were four échevins and a prévôt des marchands, whose jurisdiction extended over the town and adjacent territory; in the other towns there was a maire and two or more échevins. In the south of France the same officers were called by other names, such as consuls in Languedoc and Dauphiné, capitouls at Toulouse, jurats at Bordeaux. The last name, that of jurats, is retained in some of the English municipalities. They tried minor suits, laid the local duties or octroi upon imports, had the inspection of the commercial revenues and expenditure, as well as the superintendence of the streets, roads, and markets, the repairs of public buildings, &c. The name échevins seems to have been derived from scabini, a Latin word of the middle ages, which was used in Italy under the Longobards, and in France, Flanders, and other

countries under the Carolingian dynasty. In Holland they are called schepens. The scabini were the assessors to the counts or missi dominici, appointed by the monarch to administer a province or district; and they were chosen among the local inhabitants. Afterwards, when charters were given to the communes, the municipal magistrates elected by the burgeses assumed also the name of scabini or échevins. (Ducange, *Glossarium*.)

ECHIDNA (Cuvier), *Tachyglossus* (Illiger), a genus of *Monotremes*, *Monotremata* (Geoffroy), the third tribe of the order *Edentata* (Cuvier's sixth order of Mammifera) none of which have any incisor teeth in either jaw.

The peculiar structure of the group, consisting of *Echidna* and *Ornithorhynchus*, will be treated of under the title **MONOTREMES**.

Echidna.

Dental formula 0

Skull of Echidna.

Muzzle elongated, slender, terminated by a small mouth furnished with an extensible tongue, similar to that of the *Ant-eaters* and *Pangolins*. No teeth, but the palate armed with many rows of small spines directed backwards. Feet short, very robust, and formed for digging, each armed with five long claws. Tail very short. Body covered with spines like that of the hedge-hog. Stomach ample and nearly globular; cæcum moderate. Leur verge se termine par quatre tubercules.

Of this curious genus, zoologists are agreed that only one species has been yet discovered, though two have been recorded; viz. *Echidna Hystrix* and *Echidna setosa*, the so-called two species being the same animal in the clothing of different seasons, or of different periods of age. This species is the *Myrmecophaga aculeata* and *Porcupine Ant-eater* of Shaw, *Ornithorhynchus aculeatus* of Home, *Echidna Hystrix* and *Echidna setosa* of G. Cuvier, *Echidna Australiensis* of Lesson, *Hedge-hog* of the colonists at Sidney.

Size, about that of the common hedge-hog. Spines dirty-white for the greatest part of their length, and black at their extremity. Hair of a chestnut colour, soft and silky, in such abundance, at a certain season, as to half cover the spines, whilst, at another, the hair entirely disappears.

Food.—Ants, which the animal captures with its extensile tongue.

Habits.—The habits of the Echidna in a state of nature are but little known. It digs for itself burrows, wherein it remains during the dry season, coming out of the earth only during the rains. It is supposed to be capable of supporting a long abstinence, and has intervals of suspended animation (engourdissements), which continue for eighty hours at a time, and recur frequently when the animal is kept in confinement. For protection, the animal is said to be able to roll itself up like a common hedge-hog.

But, if we know little of the natural habits of the Echidna, we are indebted to Lieutenant Breton, Corr. Memb. Zool. Soc., for an account of its manners in captivity, and for some suggestions which we hope will be attended to if this article should meet the eye of any one who may have it in his power to put them in practice. If they are carefully followed, we may yet see this most interesting quadruped in the gardens of the Zoological Society in the Regent's Park.

Lieut. Breton had an Echidna which lived with him for some time in New Holland, and survived a part of the voyage to England. The animal was captured by him on the Blue Mountains: it is now very uncommon in the colony of New South Wales. It burrows readily, but he does not know to what depth. Its strength he considers as exceeding, in proportion to its size, that of any other quadruped in existence.

Previous to embarkation, Lieutenant Breton fed his Echidna on ant eggs (pupæ) and milk, and when on board its diet consisted of egg chopped small, with liver and meat. It drank much water. Its mode of eating was very curious, the tongue being used at some times in the manner of that of the chameleon, and at others in that in which a mower

uses his scythe, the tongue being curved laterally, and the food, as it were, swept into the mouth: there seemed to be an adhesive substance on the tongue, by which the food was drawn in. The animal died suddenly off Cape Horn while the vessel was amidst the ice; perhaps in consequence of the cold, but not improbably on account of the eggs with which it was fed being extremely bad.

Lieutenant Breton concurs with MM. Quoy and Gaimard in thinking that there would be little difficulty in bringing the *Echidna* to Europe, and the following plan is suggested by him for effecting its importation.

Previously to embarkation the animal should be gradually weaned from its natural food (ants). This may be done by giving it occasionally ants and ant-eggs, but more generally milk, with eggs chopped very small, or egg alone. It should be kept on shipboard in a deep box, with strong bars over the top, and a door. The box or cage must be deep, because the animal constantly tries its utmost to escape; and, as it possesses very great strength, it is liable to injure itself in its exertions to force its way through the bars. Its excrements are so extremely fetid, that it cannot be kept altogether in a cabin, unless the cage be frequently cleaned. While this is being done, the *Echidna* may be allowed its liberty, but must be narrowly watched, or it will certainly go overboard. It is absolutely necessary that the eggs on which it is fed during the voyage should be as fresh as possible: they can be preserved in lime water. If milk is not to be procured, water must be supplied daily; and egg and liver, or fresh meat, cut small, should be given at least every alternate day. When the weather will permit, it should be fed once a day. Half an egg, boiled hard, and the liver of a fowl or other bird, will suffice for a meal. The animal should be kept warm, and should be well supplied with clean straw. It will be as well to nail two or three pieces of wood (battens) across the floor of the cage, to prevent the animal from slipping about when the ship is unsteady. (*Zool. Proc.*, 1834, Part 2.)

Localities.—Blue Mountains, &c., the environs of Port Jackson, and Van Diemen's Land.

Echidna hystrix.

ECHINADES. [ACHELOUS.]

ECHINASTRÆA. [MADREPHYLLIGÆ.]

ECHINIDÆ, a family of radiated animals, comprehending those marine animals popularly known by the name of sea-eggs, or sea-urchins (*oursins* of the French).

De Blainville makes the *Echinidea*, the second order of the class *Echinodermata*, and he thus defines the order.

Body oval or circular, regular, sustained by a solid *shell*, which is calcareous and composed of polygonal plates, disposed in radiated order in twenty rows, which are either equal, or alternately and regularly unequal. The shell supports upon proportionable mamillary projections stiff spines which are extremely variable in form, and is pierced by series of pores, forming by their assemblage a kind of ambulacra. It radiates more or less regularly from the summit to the base and gives exit to tentaculiform cirrhi.

Mouth armed or unarmed, pierced in a notch of the shell invariably on the lower side.

Vent always distinct, but offering many variations in its position.

Generative Orifices four or five in number, disposed round the dorsal summit.

Anatomy, Reproduction, &c.—Not completely known notwithstanding the labours of Réaumur, Klein, Cuvier, Lamarck, De Blainville, Gray, Delle Chiaje, Tiedemann, and Dr. Sharpey, to whose works we must refer the reader. We shall only here observe that the whole of the *Echinidæ* are probably hermaphrodites, and that consequently reproduction is carried on without the aid of a second individual: but this is uncertain. On the European coasts the *Echinidæ* are observed with their ovaries in a turgescient state in the spring, and we may thence conclude that the time of ovipositing is the summer; the places of deposit are most probably the fissures or cavities of rocks and aggregations of fucus, and the deposit itself is made in one mass. Nothing certain appears to be known as to the development of the eggs, the duration of that development, or of the length of the life of the animal.

Geographical Distribution.—In almost all seas, but more especially in those of warm climates, on rocky or sandy coasts, often free, sometimes sunk in the sand. The species are very numerous.

Habits.—All the *Echinidæ* are locomotive, though their locomotion, which is effected principally by means of their contractile tubular feet, and in a degree by their spines, is rather laborious. Some of the species, which repose on rocks, have a power of eroding the stone so as to make a nidus for themselves, which is generally not deep.

Food.—Animal probably and molecular in the edentulous species. Those whose mouth is armed with teeth are supposed to live on marine plants. Cavolini, at least, says as much of the sea-eggs (*oursins*), properly so called.

Utility to Man.—When the ovaries of some of the species are fully developed (*Echinus edulis*, for instance), they are collected as an article of food.

FOSSIL ECHINIDÆ.

There are few animal remains, with the exception of the shells of the testaceous mollusks, which are better preserved than those of the *Echinidæ*. They occur in a fossil state in almost incredible numbers, and are to be traced through all the formations, from the epoch of the transition series to the present time. Dr. Buckland remarks that he found, many years ago, fossil Echinidans in the carboniferous limestone of Ireland, near Donegal, and that they are rare in the transition formation, become more frequent in the muschel-kalk and lias, and abound throughout the oolitic and cretaceous formations*.

Their abundance may be, in some degree, accounted for by the habits of a great proportion of them, which lead them to bury themselves in the sand, &c., so that their preservation must for the most part be complete. The nature also of the shell and its structure are other causes of fossil durability, for it is almost spathose in parts, while the animal is yet alive. The peculiar fracture presented by the shell and spines is relied on by De Blainville as indicating the place of the *Echinidæ* in the natural series to be with the Encrinites, and not with those *Zoophytaria* which are near the *Pennatulæ*, as some zoologists have thought.

SYSTEMATIC DISTRIBUTION.

Breyn, Klein, Linnæus, Leske, Lamarck, Cuvier, Gray, Desmarest, Goldfuss, Von Buch, Agassiz, are the principal zoologists who have undertaken the classification of the *Echinidæ*. De Blainville observes that the relative position of the mouth and the vent, and above all, of the ambulacra, are the principal points on which most of these writers have rested; and as he considers that this mode of viewing the subject has led to approximations not very natural, he proposes a system based on the following grounds:—

1st. On the general form of the body of the animal, which, at first subradiated, becomes, by little and little, completely radiated in all the parts which constitute it.

2nd. Upon the position of the mouth, which, nearly terminal and transverse, or bilabiated, in the first species, becomes completely central and circular in the last.

3rd. On the arming of this mouth, which, completely null in a great proportion of the *Echinidæ*, is, on the contrary, very powerful in the rest.

4th. Finally, on the position of the vent, on the number of ovaries and their orifices, on the nature of the spines and the tubercles which support them, as well as on the disposition of the ambulacra.

Synoptical Table of the Genera, according to De Blainville.

| | | | |
|-------------------|------------------|---|----------------|
| Mouth | Subterminal | { | Spatangus. |
| | | | Ananchites. |
| | Without teeth | { | Nucleolites. |

| | Infra-lateral | { | Galerites. |
| | | | |
| | Central | { | Echinometra. |
| | | | Echinus. |
| | | | Cidaris. |

Sub-Family. 1.

Eccentrostomata.

Genera. *Spatangus*.

Body oval, more or less elongated, heart-shaped, wider before than behind, with a furrow more or less profound at the anterior extremity. *Shell* delicate, of little solidity, composed of large polygonal plates, not many in number. *Spines* short, flat, sessile and scattered. *Ambulacra* incomplete, only four in number. *Buccal notch* more or less anterior, transverse, bilabiated, circumscribing a mouth without teeth. *Vent* terminal, and rather above than below the border. *Genital pores* four in number, disposed in two pairs. The species are very numerous, and are subdivided by De Blainville and others into sections according to their shape, &c. The following is De Blainville's method.

a.

Species whose ambulacra are not petaloid, and form scarcely but two lines, a little broken or bent at their internal side, and which have a rather deep anterior furrow, and the mouth not much in front.

Example, *Spatangus arcuarius*.

De Blainville observes that Mr. Gray places *Spatangus Atropos* in this section; but the former thinks that it sensibly differs from those classed under it, and places it in the following section.

B.

Heart-shaped species, with five deep and straight dorsal furrows, in which the ambulacra are hidden.

Example, *Spatangus Atropos*.

γ.

Species whose ambulacra are petaloid, going from a centre, and which have an antero-dorsal furrow more or less deep, occupying the place of the fifth ambulacrum; the posterior pair shorter than the anterior.

This section is divided into subsections, according to the depth of the ambulacra.

Example of the first (*Spatangus*, Klein, Gray), *Spatangus purpureus*. Example of the second (*Ovum*, Van Phelsum, Gray), *Spatangus canaliferus*.

δ.

Species whose anterior furrow is much less deep, or nearly null, and whose ambulacra, more or less petaloid, to the number of four, occupy the greatest part of a sort of dorsal plate, circumscribed by a sinuous line without tubercles or spines. (Genus, *Brissus*, Klein, Gray.)

Example, *Spatangus pectoralis*.

ε.

Heart-shaped species, rather strongly widened and notched in front, with five distinct and truncated ambulacra. Example, *Spatangus gibbus*.

ζ.

Species whose anterior furrow is still distinct; whose ambulacra, to the number of four, are marginal, and sometimes complete, or reaching up to the mouth; and whose genital pores are five. This section is subdivided into two, according to the extent of the ambulacra, the first, (example, *Spatangus subglobosus*), with ambulacra only reaching the circumference; the second, (example,

Spatangus cordatus, *Ananchites cordatus*, Lam.,) with ambulacra reaching to the border.

Geographical distribution.—In almost all seas, including our own. Numerous in the Mediterranean.

Habits.—Not known, but they seem to live constantly burrowed in the sand.

Food.—De Blainville supposes that the *Spatangi* are nourished with the animal matters which are mingled with the sand; for their intestinal canal, which is thin as a spider's web, was always found by him full of fine sand.

FOSSIL SPATANGI.

The species are numerous in the chalk and cretaceous group, and occur in the oolitic group.

Ananchites. (Fossil only.)

Body oval in its longer diameter (from before backwards), rounded and a little wider, but without a furrow, anteriorly, subcarinated posteriorly, conical, elevated at its summit, which is mesial, entirely flat below, covered with a very few small scattered tubercles. *Ambulacra*, to the number of five, rather large, divergent, comprised between double lines of pores but little approximated, and scarcely overpassing the borders. *Mouth* and *vent* subterminal and inferior. De Blainville subdivides this genus into two sections: the first, with the ambulacra prolonged up to the borders (*Ananchites*, Lam.), example, *Ananchites ovatus*; the second, with the ambulacra prolonged up to the mouth (*Echinocorys*, Leske, Gray; *Galea*, *Galeola*, Klein), example, *Ananchites pustulosus*, *Echinocorytes pustulosus*, Leske. M. DeFrance enumerates 12 species: to these are to be added M. Risso's three species, *A. carinatus*, *A. rotundatus*, and *A. stella*, if they be distinct. De Blainville observes that Lamarck's *Ananchites ellipticus* most probably does not belong to this division, and that his *A. Corvum* belongs to the same division as the *Violet Spatangus* Goldfuss has described some new species.

Sub-Family II.

Paraecentrostomata Edentata.

Genera. *Nucleolites*. (Fossil only.)

Echinobrissus of Breyn and Gray, adding the *Cassidula*.

Body oval or heart-shaped, wider and with a large furrow behind, rather convex, the summit subcentral and moderately elevated above, somewhat concave below; covered with small, equal and scattered tubercles. *Ambulacra*, to the number of five, subpetaloid, open at the extremity, dorsal and marginal, and continued by as many furrows up to the mouth, which is inferior, subcentral, and anterior. *Vent* subcentral, above, in the furrow. *Genital pores* to the number of four. Example, *Nucleolites depressus*, *Spatangus depressus*, Leske, Klein; *Clypeus lobatus*, Fleming.

Locality, &c.—The species are tolerably numerous and are frequent in the chalk, but are also found in the beds anterior and posterior to it.

Echinoclypeus. (Fossil only.)

Body depressed or conical, circular or inclining to oval, with a furrow behind, convex and with a subcentral summit above, rather excavated below, formed of distinct plates and covered with very small equal tubercles. *Ambulacra* to the number of five, dorso-marginal, subpetaloid; the double rows of pores united by a transverse furrow. *Mouth* subcentral, a little more anterior, pentagonal, with five converging, ambulacriform furrows. *Vent* entirely above, behind the summit, and at the origin of the posterior furrow. *Genital pores* to the number of four.

De Blainville remarks that this generic section, established by Klein under the name of *Clypeus*, has been confounded by Lamarck with his *Galerites*, which belong to an entirely different division of the *Echinidae*; and he observes that they might much better be confounded with the *Nucleolites*, after the arrangement of DeFrance. He adds that he should not be surprised if the *Cassidulus scutella* belonged to this division.

Echinolampas, Gray. (*Echinanthus*? Leske.)

Body oval or circular, depressed, subconvex above, rather concave below, rounded and widened forward, rather narrowed towards the anal extremity, composed of great polygonal plates and covered with spines, probably very small. *Ambulacra*, to the number of five, subpetaliform, not closed at their extremity, and nearly approaching the border. *Mouth* round, subcentral, and nevertheless a little anterior. *Vent* entirely marginal, terminal. *Genital pores* four only in number. Example, *Echinolampas orientalis* (recent).

The form occurs fossil; see, for instance, *Trans. Geol. Soc. (Second Series)* i., tab. 3, fig. 3, 4, 5. (*Echinonæus Lampas*.)

Cassidulus.

Body oval, more or less depressed, composed of indistinct plates and covered with small spines. *Ambulacra* five, dorsal, rarely marginal. *Mouth* below, submedian, in a stelliform notch. *Vent* postero-dorsal, or above the border. *Genital pores* four.

De Blainville subdivides this genus into the following sections:—

a.

Species whose ambulacra form a dorsal star, and whose mouth is at the bottom of a stelliform impression. Example, *Cassidulus Lapis Cancræ*.

β.

Species whose ambulacra are prolonged to the border and not closed. Example, *Cassidulus Australis*.

γ.

Species whose ambulacra are not known to De Blainville. Example, *Cassidulus scutella*.

De Blainville observes that this genus (Lamarck's) is evidently artificial; for that the position of the vent cannot furnish any character of much importance. He remarks that there is but one recent species; the others, to the number of nine, according to DeFrance, are fossil, from the beds anterior to the chalk, and with some little doubt, from more recent formations. Goldfuss unites the genus with *Nucleolites*.

Fibularia.

Body globular, but rather higher than it is wide, ribbed, as it were, with about twenty ribs, formed probably by so many ranks of polygonal scales, and covered with very fine spines. *Ambulacra* five, very short, and not shut at the extremity. *Mouth* round, subcentral. *Vent* inferior and much approximated to the mouth. *Genital pores* unknown. Example, *Fibularia craniolaris*.

De Blainville observes that this genus was established by Van Phelsum and by Leske, under the denomination of *Echinocyamus*, adopted by Mr. Gray. De Blainville only leaves under it *F. craniolaris* and the seven or eight but little distinguished or indistinct species which Van Phelsum established, and probably the *C. trigona* of Lamarck, but he says that he has seen none of them; and he adds that, in the genus as defined by him, only living species have yet been found.

Echinoneus.

Body rounded or oval, generally excavated below, composed of plates often distinct and covered with small spines. *Ambulacra* five, large, complete, radiating from the dorsal centre to the mouth, and formed by ambulacral lines, which are very close and impressed. *Mouth* central or subcentral, without teeth, and pierced in a subtriangular hole of the shell. *Vent* towards the border below or even above, in a longitudinal and subsymmetrical hole of the shell. *Genital pores* four.

De Blainville subdivides the genus into the following sections:—

a.

Oval species, with the anal hole longitudinal and below. Example, *Echinoneus minor*.

β.

Circular species, with the vent below and round. (*Discoidea*, Gray.) Example, *Echinoneus subuculus*.

γ.

Oval species, with the vent entirely marginal, and the genital pores to the number of seven? Example, *Echinoneus ovalis*.

δ.

Circular species, which are depressed and have a margino-dorsal, nonsymmetrical anal opening. Example, *Echinoneus cassidularis*.

De Blainville observes that no *Echinoneus* with the anal opening below is known in a fossil state; so that in the genus, as defined by Lamarck, there are no fossil species according to DeFrance; but that in his (De Blainville's) method of arrangement there are many; and he remarks that Goldfuss figures four species from the chalk, but he adds a query whether they belong to this genus.

Sub-Family III.

Paracentrostomata Dentata.

Mouth subcentral, in a regular notch of the shell, and provided with teeth.

Genera. Echinocyamus.

Body depressed, oval, wider behind than before, a little excavated below, covered with rounded tubercles pierced at the summit and rather large in proportion, supported internally by five double inferior ribs, terminating round the buccal notch by as many simple apophyses. *Ambulacra* dorsal, not marginal, completely open at the extremity, a little enlarged, and forming a sort of cross with dilated branches. *Buccal opening* subcentral, regular, armed with five teeth as in *Clypeaster*. *Vent* below, between the mouth and the border. *Genital pores* four. Example, *Echinocyamus minutus*.

De Blainville states that he characterized this genus from a considerable number of individuals of a very small species found in the intestines of a turbot, and which occurs in great quantity in the sand of the coasts of the English Channel, according to Pallas, both on the French and English shores. He adds that, very probably, it is the *Fibularia ovulum* of Lamarck; and that, without doubt, *Fibularia Tarentina* belongs to this genus, as well as *Echinoneus Placenta* of Goldfuss.

Lagana, Gray. (*Echinodiscus*, Van Phelsum, Leske.)

Body depressed, circular or oval lengthwise, a little convex above, concave below, with an entire disk and borders, composed of plates but little distinct and covered with scattered spines. *Ambulacra* five, regular, petaloid, shut, or nearly so at the extremity, with the pores of each side united by a furrow. *Mouth* median in the middle of a hole, with converging furrows and furnished with teeth. *Vent* inferior, pierced in a regular hole, situated between the mouth and the border. *Genital pores* five. The genus is thus sub-divided by De Blainville:

a.

Circular species. Example, *Lagana orbicularis*.

β.

Oval species. Example, *Lagana ovalis*.

γ.

Polygonal species. Example, *Lagana decagona*.

The genus approximates to *Clypeaster*, under which Lamarck arranges the species.

Clypeaster.

Body much depressed, rounded and rather thick on the borders, sometimes incompletely orbicular or radiated, enlarged towards the anal extremity, composed of large and unequal plates, covered with very small, equal, scattered spines supported on very small tubercles pierced with a pore. *Ambulacra* constantly five in number, dorsal, petaloid, the two rows of pores of each branch united by a furrow. *Mouth* central or sub-central, at the bottom of a sort of tunnel, formed by five grooves and armed with five teeth. *Vent* terminal and marginal. *Genital pores* to the number of five.

Living species few. *Localities*, the seas of warm countries—in Asia and America.

Example, *Clypeaster rosaceus*.

Fossil species more numerous and generally from the tertiary beds. DeFrance enumerates eleven. Goldfuss figures ten new ones; but De Blainville adds a query whether they are all of this genus.

De Blainville states that this division of Echinidans was established by Breyn under the name of *Echinanthus*, which Mr. Gray has retained, and under that of *Echinorodon* by Van Phelsum.

Echinodiscus.

Body rounded, depressed, sub-quinquelobated (the posterior lobe a little notched in the median line), rather conical above, concave below, composed of plates in twenty rows, placed two and two. The *ambulacraires* narrower and covered with very small, fine, close-set spines. *Ambulacra* to the number of five, diverging by the complete separation of each double line of pores. *Mouth* median, round, towards which converge five straight and stelliform furrows. *Vent* marginal. *Genital pores* to the number of four. Example, *Echinus Parma*.

Locality of the species.—De Blainville observes that it was

generally believed that all the species were the inhabitants of warm climates; but he quotes Dr. Fleming for a statement that Professor Jameson had received *Echinodiscus placunaria* (*Scutella placunaria*, Lam.) from the Isle of Foulah, where it would, nevertheless, seem to be very rare.

De Blainville further remarks, that no fossil species have as yet been discovered, unless *Scutella lenticularis*, Lamarck, belongs to this genus, which he thinks probable. He considers that these *Echinidae* appear to form the passage to the Polygonal Asteridians.

Scutella. (*Mellita*, Klein; *Echinodiscus*, Leske.)

Body irregularly circular, wider behind, extremely depressed, borders nearly sharp-edged, sub-convex above, a little concave below, composed of large polygonal scales and covered with very small, uniform, and scattered spines. *Ambulacra* five, more or less petaliform, the two rows of pores of each branch united by transverse furrows, which makes them appear striated. *Mouth* median, round, furnished with teeth, and towards which converge five vasculariform furrows more or less ramified and sometimes bifid from the base. *Vent* always inferior and at some distance from the border. *Genital pores* four.

LIVING SPECIES.

a.

Species whose disk alone is perforated. Example, *Scutella hexapora*.

β.

Species whose disk and borders are perforated. Example, *Scutella tetrapora*.

γ.

Species whose border only is notched. Example, *Scutella aurita*.

δ.

Species whose disk and border are entire. Example, *Scutella integra*.

ε.

Species whose disk is perforated and their border multigitated. Example, *Scutella octodactyla*.

ζ.

Species whose disk is imperforate and the border multiradiated. (*Demi-soleils*.) Example, *Scutella dentata*.

Localities.—The living species whose habitat is known are foreign, and the South Seas appear to be their principal locality. Nevertheless, as De Blainville observes, we ought to remember that DeFrance, in the description of a fossil species, *Scutella Hispana*, says, that it bears great resemblance to a species that lives in the English Channel and which is found on the coasts in the department of Calvados. De Blainville adds, that he has not seen this species, and that it is the first time we find it stated that a *Scutella* exists in our seas. None of the English, Italian, or French authors whom he consulted mention it.

FOSSIL SPECIES.

Tolerably numerous and occurring generally in the *calcaire grossier* of Paris, Grignon, and the environs of Nice. None as yet recorded in any other beds than those posterior to the chalk.

Sub-family IV

Centrostomata.

Mouth quite central. *Summit* median. *Body* regularly oval or circular, covered with tubercles and mamillæ, and consequently with spines of two sorts. *Vent* variable, ordinarily medio-dorsal.

Genera. *Galerites* (Fossil only) *Conulus*, Klein; *Echinoconus*, De Blainv.

Body nearly regularly circular or polygonal, entirely flat below, convex and often conical with the summit median above, formed of very dissimilar plates and covered with tubercles of two kinds. *Ambulacra* complete, narrow, to the number of five or four, dorso-buccal. *Mouth* central and probably armed. *Vent* infero-marginal. *Genital pores* to the number of five.

a.

Species with four ambulacra and consequently with six series of plates. Example, *Galerites quadrifasciatus*.

β.

Species with five ambulacra. Example, *Galerites ungaris*.

γ.

Species with six ambulacra. Example, *Galerites sexfasciatus*.

The genus is often found silicified and in casts. The greater portion belong to the chalk and a small number to the beds anterior to the chalk. None have as yet been found in the more recent strata.

Echinometra. (Gray.)

Body thick, solid, transversely oval, a little depressed, convex, with the summit (which is median) flat above and arched below, covered with mamillated tubercles of two sorts and bearing diversiform, but always strong and large spines. *Ambulacra* five, enlarging themselves below. *Buccal opening* of the shell large, transverse, with very powerful auricles on its internal circumference. Five sharp *teeth* at the mouth, with a complicated apparatus, as in *Echinus*. *Vent* medio-superal or opposed to the mouth. *Genital pores* to the number of five. Example, *Echinometra atrata*.

Localities.—The seas of warm climates. Unknown in those of England and France.

No fossil species known.

Echinus.

Body in general very regularly circular or sub-polygonal, sometimes slightly transverse, composed of twenty radiated rows, alternately unequal, of polygonal plates bristled with diversiform spines of two kinds, and supported on imperforate mamillated tubercles. *Ambulacra* constantly to the number of five and complete. *Mouth* central, armed with five pointed teeth, supported upon a very complicated internal apparatus. *Vent* median, superior, or exactly opposite to the mouth. *Genital pores* to the number of five.

Food.—The food is generally believed to consist of mollusks and crustaceans. Tiedemann found in *E. Saxatilis* small univalve and bivalve shells entire among the excrements, as well as fragments of larger ones. Bosc is said to have witnessed an Echinus in the act of seizing and devouring a small crustacean. Dr. Sharpey usually found in the intestine of *E. esculentus* small morsels of sea-weed, for the most part encrusted with *fusstra*; and he says that the excrements, which are in the form of small round pellets about the size of peppercorns, consist chiefly of sandy matter with fragments of shells. But he adds that it would be difficult to say whether these are the remains of digested mollusca or merely a portion of the usual testaceous debris so abundant in sand and mud.

a.

Arbacia, Gray; *Echinocidaris*, Desmoulin.

Species perfectly regular, ordinarily depressed; area very unequal; ambulacraires very narrow, bordered by ambulacra nearly straight, and composed to the right and left of a double series of approximated pores; auricles divided and spatulate. Example, *Echinus pustulosus*.

β.

Regular species, more or less convex, but, for the rest, diversiform; area sub-equal, bordered by a double series of pores, forming at the exterior, denticulations more or less marked and each with three pairs of holes.

De Blainville subdivides this section into three, with still further subdivisions depending on the non-fissured or more or less fissured angles of the buccal opening of the shell, and other variations. He states that he has been able to study a great number of living species, and though many have been only known to him by means of the shell, he has been able, he says, to find constant specific characters 1st, in the proportion of the ambulacral and anambulacral areas; 2nd, in the number of lines of double pores which limit the ambulacra; 3rd, in the number of those double pores which form the festoons of these lines; 4th, in the form of the auricles, serving for the insertion of the muscles of the dental apparatus; 5th, in the disposition of the border of the buccal orifice. He states as a result, that though he has indicated nearly double the number of species pointed out by Lamarck, they are much more easily recognized.

Localities, Habits, &c.—The form is widely diffused, and

there are species in most European seas. The Mediterranean produces some very fine ones. They live free at the bottom of the sea at considerable depths, or on the rocks of the coast in the midst of fuci. They lay an immense quantity of eggs.

FOSSIL ECHINI.

Desmarest distinguishes thirteen species from the beds anterior and posterior to the chalk. Risso gives one new from the environs of Nice, and Goldfuss nine from Germany.

Cidaris.

Body circular, regular, more or less elevated or depressed, composed of polygonal plates, covered with mamillated tubercles constantly perforated at the summit, and supporting spines of two kinds: one very long and sharp, the others short and nearly squamous. *Ambulacra* complete, to the number of five. *Mouth* below, central, furnished with five pointed teeth. *Vent* superior and central. *Genital pores* to the number of five.

a.

Subspheroidal species, more elevated than wide, with very narrow ambulacral areæ; the lines of double pores sinuous. (*The Turbans*.) Example, *Cidaris imperialis*.

β.

Orbicular species, depressed; ambulacral areæ less narrow, bordered by straight ambulacra; spines ordinarily fistulous. (*Diadema*, Gray.) Example, *Cidaris Diadema*.

γ.

Orbicular species, very depressed; interambulacral areæ equalling the half of the others, and bordered by straight and very large ambulacra. (*Astropyga*, Gray.) Example, *Cidaris radiata*.

Localities.—Seas of the southern hemisphere. Two species already known in the seas of Britain and France, one on the coasts of Scotland, rare; the other very common in the Mediterranean.

FOSSIL SPECIES.

Cidaris occurs in a fossil state in the chalk and the anterior beds. Deffrance mentions three, but hardly characterizes them. Risso adds two new ones; Fleming four; and Goldfuss has figured and characterized nineteen.

Mr. Gray (*Proceedings of the Zoological Society*, 1835) divides the genus *Echinus*, as restricted by Lamarck and modern authors, into what he considers four natural genera, adapted to facilitate the distinction of the species of this extensive group. He regards this distinction as of the more importance, inasmuch as some of the characters which had been used for this purpose, such as the number of the *tesserae* and of the pores in the *ambulacra*, have been found to be inconstant; the number of these increasing, as they are now known to do, with the age of the specimens. The following is Mr. Gray's subdivision:—Genus 1. *Arbacia*. This corresponds with section A of M. de Blainville. Example, *Arbacia pustulosa* (*Echinus pustulosus*, Lam.) Genus 2. *Salenia*, only known in a fossil state, and hitherto confounded with *Cidaris*; but its tubercles are not pierced. Example, *Salenia scutiger* (*Cidaris scutiger*, Munst.) Genus 3. *Echinus* containing sections B*, C, E, and G of De Blainville. Mr. Gray divides it into two sections:—1. The species with narrower ambulacra and with the pores moderate and approximated, which is subdivided into those with a *subintegral mouth* (type, *Echinus esculentus*) and those with the *mouth deeply incised*. (Example, *Echinus excavatus*, Lam.) 2. The species with wide ambulacra; the pores separated by small tubercles; the mouth five-incised. Example, *Echinus ventricosus*, Lam. Genus 4. *Echinometra*, containing sections B*, D, and F of De Blainville, as well as the *Echinometra* of that author. In this genus Mr. Gray observes the ambulacral plates may be considered as being composed of five or more doubly-pierced pieces, which form an arched line round the outer edge of the *tessera*, with a single pair of pores at its lower inner angle. Mr. Gray stated that he had formerly separated from the *Echini* some of the species of this genus, which are peculiar for their oblong form, and that the genus so proposed by him had been adopted by M. de Blainville; but a much more extended examination had convinced Mr. Gray that individuals of the same species vary from roundish to oblong; and therefore, having observed many round species agreeing with the oblong ones

in the peculiar character of the *ambulacra*, he has united them to the former under the same name. Mr. Gray remarked, as throwing doubt on the bilaterality of the *Echini*, that the spongy ovarian plates which that gentleman regarded as the mark of the hinder part of the *Echinida*, is always placed on one side or the other of the longer axis of the oblong species. See also Mr. Gray's paper on the genera of these animals in the 'Annals of Philosophy;' and Dr. Sharpey's article 'Echinodermata' in the 'Cyclopædia of Anatomy and Physiology.'

ECHINOBRISUS. [ECHINIDÆ, p. 259.]

ECHINOCACTUS, a genus of Cactaceous plants, with the stem of an ovate or spheroidal form, the sides being divided into many ribs, upon whose projecting angles are stationed at short intervals little spiny stars, which are the rudiments of leaves, and from whose centre the flowers appear. The latter consist of numerous sepals collected into a tube, an equally large number of petals, numerous stamens, and a filiform style divided into many lobes at the point. The species are very remarkable for the singular forms of their stems, and for the curious manner in which their spines are arranged. They are often moreover conspicuous for the beauty of their large flowers. The genus is extremely near *Cereus*, from which, according to De Candolle, it only differs in having the sepals and petals distinct from each other, not united into a tube. But as *Cereus triangularis* has its sepals distinct, and all the *Echinocacti* have more or less of a tube, we consider it better to limit the latter to such species as have a depressed or spheroidal form. With such a limitation the *Echinocactus Eyriesii*, one of the most beautiful of plants, will really belong to the genus *Echinocactus*, of which it has all the habit; otherwise it would be a *Cereus*, to which its stems bear but little resemblance. Most of the species are natives of Mexico and the West Indies. A few are found in Brazil.

Echinocactus Eyriesii.

ECHINOCLYPEUS. [ECHINIDÆ, p. 259.]

ECHINOCYNUS. [ECHINIDÆ, p. 261.]

ECHINOCORYS. [ECHINIDÆ, p. 259.]

ECHINOCYAMUS. [ECHINIDÆ, p. 260.]

ECHINODERMATA. Lamarck made his *Radiatares Echinodermes* consist of three sections. 1st, the *Stellirideans* (star-fishes), including *Comatula*, *Euryale*, *Ophiura*, and *Asterias*; 2nd, the *Echinida*; and 3rd, the *Fistulida*, comprehending *Actinia*, *Holothuria*, *Fistularia*, *Priapulus*, and *Sepunculus*.

Cuvier's *Echinodermes* form his first class of zoophytes, and this class is divided into two orders, viz., 1st, the *Pedunculated Echinodermes*, containing the great genus *Asterias* and its subgenera the *Encrinurites*, the *Echinida*, and *Holothuria*; and 2nd, the *Footless Echinodermes*, consisting of *Molpadia*, *Minyas*, *Priapulus*, the *Lithodermes*, *Sipunculus*, *Bonellia*, and *Thalassema*, with its subgenera *Echiurus* and *Sternaspia*.

De Blainville's *Echinodermata* are placed as his first

class of *Actinozoa*, and are divided into three orders: 1st, *Holothuridea*; 2nd, *Echinidea* [ECHINIDÆ]; 3rd, *Stelle-ridea*, embracing the *Encrinites* as well as the *Free Star-fishes*, &c.

The *Echinodermata* belong to the *Cycloneurose* sub-kingdom.

ECHINOPORA. [MADREPHYLLICÆ.]

ECHINORODON. [ECHINIDÆ, p. 260.]

ECHINUS. [ECHINIDÆ, p. 261.]

ECHITES, a genus of twining Apocynaceous plants inhabiting tropical countries. They have handsome yellow or white corollas, and are moreover remarkable for the singular fruit, which consists of two divaricating woody pod-like follicles containing a large number of silky seeds. They are dangerous lactescent plants of no known use.

E'CHIUM, an irregular-flowered genus of Boraginaceous plants, with handsome campanulate corollas. *Echium vulgare* is the most striking of our wild herbaceous plants; many species found at the Cape of Good Hope are shrubs.

ECHO. (*ἠχώ, ἦχος*, sound). When sonorous undulations are propagated from any origin through the elastic medium of the air, the spherical wave-like surface then generated conveys the sound through the circumjacent space, and moves from its origin and centre with a velocity of about 1125 feet in a second, at the ordinary atmospheric pressure and temperature; for the velocity of undulations propagated through elastic media depends only on their indices of elasticity and not on their intensity. [Acoustics.]

Suppose the point O to be the origin of a sound which in its progress encounters a plane obstacle NM; if this plane be sufficiently extended, a point M may be easily found which the sound will have just reached at the end of a given time. The waves which have previously reached the nearer points A, B, C, being precluded from advancing, are there reflected, that is, new spherical undulations *a'ab*, *b'bc*, *c'cd* are generated from A, B, C as centres, and their radii at the moment we have spoken of are respectively $Ab = OM - OA$, $Bc = OM - OB$, $Cd = OM - Oc$, and it is easily seen that all these spherical surfaces originating from A up to M and existing simultaneously, may be exactly enveloped by a single portion of a spherical surface of which the centre is placed in a position R corresponding to O in respect to its distance from NM, but at the opposite side of the obstacle; this spherical surface, of which the radius is RM, is the true returning wave at that moment, and being impressed on the auditory organs, so as to be distinguished from the original sound, is called the echo.

When a sound originates at a point O, and is reflected by a plane obstacle AC, the reflected pulsation of the air occupies

the space of a conical frustum *aACc* the vertex of the cone R being situated symmetrically with O at the opposite side of AC. In order that a person may hear the echo of his own sounds, it is therefore necessary that his situation may be at a point O' in a perpendicular to AC; and that a second person may hear the echo of the voice of another at O, he must be situated in the frustum *aACc*, so that the angles of incidence and reflection of the sound which reaches his ear may be equal; in both cases the distance from AC must be sufficiently great to distinguish between the original and the reflected sound.

Hence it follows, that wherever a person is situated, the echo of a single sound necessarily follows and cannot precede the original sound, for the two sides OA, *Aa* are greater than the third Oa through which the direct sound is propagated, and the velocities are in both cases alike.

However, the echo of a continued sound or note may be heard in the inverse order of time to that in which it was generated, provided the origin of the sound moves more rapidly towards the hearer than the rate at which sound travels. Thus a flash of lightning moving towards a person will produce a roll of thunder which, echoed by clouds, will be heard as it were backwards; but if the direction of the flash be such that the points of its current are nearly equidistant from the auditor, an instantaneous and intensely loud clap will be substituted for a continued roll.

The murmuring sound produced by the discharge of great guns is the succession of echoes from the particles of vapour floating in the atmosphere, and when the discharge is effected under a dense cloud, the echoes are stronger and better reflected, and a noise resembling a thunder-roll may then be heard. The whizzing of a bullet is attributed to its impinging in a state of rapid rotation on particles of vapour.

The time intervening between the primitive sound and its echo has sometimes been employed in determining the distance from the observer to the reflecting object, allowing 571 feet for each intermediate second of time; but like all methods dependent more on individual judgment than mechanical measurement, this process must be liable to considerable irregularities.

When several objects reflect sound, the number of echoes is greatly multiplied, not only from the primary echoes of each, but also from secondary and tertiary echoes by second and third reflections of returning waves against the reverberatory obstacles: each re-echo consists of only portions or frusta of the preceding; their intensities therefore diminish, and they gradually die away upon the ear, in the same manner that the images become obscure and by degrees imperceptible in consequence of the diminution of light when we look between two opposite and parallel plane mirrors.

The first echo heard in such circumstances is by no means necessarily the loudest. Taking any ellipse of which one focus is the origin of the sound and the other the place of the auditor, it is a well-known property of this curve that right lines drawn from the foci to any point in it make equal angles with the tangent at that point. Conceive now this ellipse to rotate round the line joining the foci so as to form a prolate spheroid, then sound emanating from one focus and reflected by a portion of the surface will be directed after reflection to the other, and its intensity will depend on the solid angle subtended at the focus by the reflecting body. Each echoing body may be conceived as a portion of such a spheroidal surface, taking a great axis major to comprehend the more distant bodies; and since the sum of the solid angles subtended by the more distant reflectors may be greater than those given by the nearer, the echo produced by them, though not reaching the ear as soon as that of the nearer, may, under such circumstances, be louder, bearing in mind in our estimate that this intensity has a source of diminution in the increase of distance. This case frequently occurs in places encompassed by chains of mountains, as the Killarney and Welsh lakes, &c.

When the succession of echoes from several bodies is sufficiently rapid, a continued sound or note may be produced, though the original sound was merely momentary; and when not sufficiently rapid for this purpose, a clamorous noise is produced, and hence Echo with her thousand tongues and babbling propensities has furnished matter for poetic imagination from Ovid to Shakspeare. As a single *ha* may be converted into an imitation of a stunning laugh, the romantic and echoing regions inhabited by the Scandinavian races materially assisted their untutored ima-

ginnings in attributing this appalling music to the aerial revelries of invisible hags or witches.

But when, as in the case of the electric fluid, the original cause of sound may be said to exist simultaneously through an extensive tract of an excited atmosphere, a sound perfectly continuous and majestic is produced in the thunder-roll, which may frequently be heard again echoed by neighbouring clouds, or awfully prolonged by repeated reflections from an amphitheatre of mountains.

A similar effect of rapidly repeated echoes may be perceived in the prolonged tread and ringing sounds which we hear when walking in stillness through long galleries, cloisters, and other narrow passages with parallel sides, particularly when the air is confined; but hangings and carpets, yielding to the impulse of the sonorous waves, or stifling them by a multitude of interior reflections, together with open windows or much furniture, diminish these effects to a great extent.

The distribution of sound in public edifices, so that the echoes may be most advantageously brought to strengthen the original sound, is a subject practically deserving of much attention. For some sensible observations on the errors of architects in this respect, we must refer to Sir J. Herschel's treatise on Sound. Certainly the unlucky error of placing the confessional in the cathedral of Girgenti in a focus conjugate to another and unenclosed part of the church, by which Echo was instrumental in informing a husband of the infidelity of his spouse, and the parabolic reflector of a late ingenious clergyman at Cambridge, which had the effect of completely stunning him, however impartially his voice was distributed to his congregation, are not inconveniences of such common occurrence as those contrivances by which a part of an audience in a church or theatre possesses a monopoly, while the remainder witness the ceremony or performance in dumb show.

A ludicrous anecdote, mentioned by Lord Bacon, of a Frenchman calling out Satan, and being answered Va-t'en, led him to assert that the letter S was not echoed, and this assertion has been copied by several cyclopedists. The fact is, that S being in a great measure a breathing, the distance necessary for the production of a distinct echo is too great to render it audible, owing to its small intensity; but when its echo is taken at a small distance, the effect is to increase the sound, and this very disagreeable prolongation is very perceptible in churches whenever persons in repeating the service make use of this letter. The whispering gallery of St. Paul's is another instance of this error, for a low whisper uttered at one end is conveyed by successive reflections along its curved roof, and being again concentrated at the other end, may be distinctly heard.

When the reflecting surfaces, instead of plane, are curved, as in caverns, grottos, rocks, or ruined buildings, the reflected sound will be most intense at the foci, or the points which would be most enlightened by reflection, if a luminous body were substituted in the place of the original source of sound.

Whatever may be the figure of the echoing surface, the total path traversed by a wave in a given time before and after reflection taken together is constant (and in different times is proportional to the time); therefore a small portion of a plane section of the echoing surface is common also to an ellipse having one focus at the origin of sound, the other in the returning wave, and the axis major equal to the space traversed by sound in a given time. Hence, first, the plane sections of the returning wave are the loci of the second foci of a series of ellipses, having a common focus and equal axes major, and all touching the section of the echoing surface; and, secondly, the figure of an obstacle necessary to produce a given wave will be found by taking the curve which touches a series of ellipses having their second foci in this wave surface and their first focus and axes major as before: this, strictly speaking, should however be confined to surfaces of revolution.

E/CIJA, a town of Andalusia, in the intendencia or province of Sevilla, situated on the river Genil, in a fine plain, on the high road from Sevilla to Cordova, about 55 miles north-east of the former city. Its ancient name was Astigis; the Romans afterwards gave it the name of Colonia Augusta Firma. The name of Ecija was given to it by the Moors (Miñano). Ecija has a population of 34,000 inhabitants, many churches and convents, several hospitals, and other public buildings, and a very fine promenade along the banks of the Genil, adorned with fountains and statues. It

is the residence of a corregidor and an alcalde mayor. The territory is rich in corn and olives; there are also some manufactories of woollens and linens. Ecija is the birth-place of Luis Velez de Guevara, a Spanish dramatist of the seventeenth century. There are several Roman inscriptions and a few other remains of antiquity.

ECKHEL, JOSEPH HILARY, an eminent antiquary and numismatist, was born at Entzersfeld, in Austria, January 13, 1737. His father, who was in the service of Coant Sinzendorf, sent him at a very early age to the Jesuits' College at Vienna, where, in 1751, he was enrolled in their society. He studied philosophy, mathematics, divinity, and the learned languages; but devoted himself chiefly to antiquities and medals. His skill in the latter induced the superiors of the college, a few years afterwards, to give him the place of keeper of their cabinet of medals and coins. In 1772 he went to Italy, where the grand duke of Tuscany, Leopold II., engaged him to arrange his collection; and on his return to Vienna, in 1774, he was appointed director of the Imperial Cabinet of Medals, and professor of antiquities. In 1775 he published his first work upon his favourite study, entitled 'Numi veteres Anecdoti ex Museis Cæsareo Vindobonensi, Florentino Magni Ducis Etruriæ, Graneliano nunc Cæsareo, Vitzaino, Festeticiano, Savorgnano Veneto, aliisque,' 4to Vienna. This was followed in 1776 by 'Catalogus Musei Cæsarei Vindobonensis Numorum Veterum, distributus in partes ii. quarum prior Monetam Urbium, Populorum, Regum, altera Romanorum complectitur,' 2 tom. folio, accompanied by eight plates of unedited coins. In 1786 he published his 'Sylloge Ima. numorum anecdotorum Thesauri Cæsarei,' 4to.; and his 'Descriptio Numorum Antiochiæ Syriæ, sive Specimen Artis criticæ Numariæ,' 4to., likewise printed at Vienna, the same year: and in 1787 produced a small elementary work on coins for the use of schools, in his native language, entitled 'Kurzgefasste Anfangsgründe zur alten Numismatik,' 8vo., Vien. This work has more recently been improved and published in France, under the title of 'Traité Élémentaire de Numismatique Grecque et Romaine, composé d'après celui d'Eckhel,' par Gerard Jacob, 2 tom. 8vo., Par. 1825. In 1788 Eckhel published a folio volume upon the gems of the Imperial Collection, 'Choix de Pierres gravées du Cabinet Imperial des Antiques, représentées en xl. Planches;' and in 1792 the first volume of his 'Doctrina Numorum Veterum,' Vienna, 4to.; the eighth and last volume of which was published in 1798. A supplement to it, with his portrait prefixed, has since appeared, 'Addenda ad Eckhelii Doctrinam Numorum Veterum ex ejusdem Autographo postumo,' 4to., Vindob., 1826. This work, which embraces the science of numismatics in general, has placed Eckhel at the head of all the writers upon ancient coins. He died, May 16th, 1798, at the house of his friend the Baron de Locella.

In his younger years Eckhel published three or four small pieces unconnected with numismatics: namely, two Latin odes on the nuptials of Joseph II., in 1765; another in German, in 1768, on the departure of Maria Carolina, archduchess of Austria, from Vienna; and two years afterwards an oration in German on the occasion of the emperor's visit to Italy, 'Rede auf die Reise Josephs II. in Italien,' 8vo., Wien, 1770. An 'Explication grammaticale des Prophéties d'Haggée,' by him, appeared in Millin's *Magasin Encyclopédique*, II^e année, tom. ii., p. 461.

(Saxii *Onomasticon*; Visconti's account of Eckhel in the *Biographie Universelle*, tom. xii., 8vo., Par. 1814, p. 463-467; and the 'Notitia Literaria de Vita et Scriptis J. H. Eckhel, translated from the French of Millin, prefixed to the 'Addenda ad Doctrinam Numorum Veterum'.)

ECKMÜHL or EGGMÜHL, a village on the Laber consisting of about sixteen houses, with a castle, and situated in the Bavarian circle of the Regen, in 48° 47' N. lat., and 12° 3' E. long. It owes its celebrity to the signal victory which the French and Bavarians, under the emperor Napoleon, gained over the Austrians, under the archduke Charles, on the 22nd April, 1809. In testimony of the skill and intrepidity which Marshal Davoust displayed on this occasion, Napoleon conferred the title of prince of Eckmühl upon him.

ECLECTICS, the name given to those philosophers who, without adopting any particular system or dogmatizing for themselves, professed to select (ἐκλεγειν) from other philosophical systems whatever they conceived most conformable to truth, and fitted those detached parts together so as

to form a new whole. The notion of such a union of jarring systems seems first to have originated with the Neoplatonists, who endeavoured to settle the dispute between themselves and the Peripatetics by the adoption of such parts of the doctrine of Aristotle as could be made to tally with their modification of the academic philosophy. This union of the Aristotelian and Platonic philosophies was attempted first by Potamo of Alexandria, whose principles were taken up and maintained by Ammonius Saccas. It may be doubted however if the title of Eclectics can be properly given to Potamo or Ammonius, the former of whom was in fact merely a Neoplatonist, and the latter rather jumbled together the different systems of Greek philosophy (with the exception of that of Epicurus) than selected the consistent parts of all of them. The most eminent of the followers of Ammonius were Plotinus, Porphyry, Jamblichus, Proclus, and Clemens Alexandrinus; and the ancient Eclecticism became at last little more than an attempt to reconcile Platonism with Christianity. The modern and more genuine school of Eclecticism sprung up in the seventeenth century, when Bacon and Descartes flourished. These philosophers refusing to acknowledge themselves members of any particular sect, or to adopt any principle on the mere authority of their predecessors, formed systems for themselves which admitted the doctrines of any other sect without distinction whenever those doctrines were not at variance with what their own investigation had taught them of the nature of things. But modern philosophers have since then formed themselves into new sects, and a new Eclecticism has consequently arisen in our own days, of which the originator was Hegel, and the present supporter Victor Cousin: this newest Eclecticism resembles that of the Alexandrian Platonists in being rather a union of systems than a selection from them, and though it has partisans on the continent, and especially at Berlin, it is not very likely that it will be soon taken up in this country, where persons who read or talk about metaphysics are generally attached to some particular sect of modern philosophy.

ECLIPSE (*ecleipsis*, *ἐκλειψις*), an astronomical phenomenon, being the disappearance of a heavenly body. This may happen in two distinct ways; either the disappearing body may be lost on account of another body coming between it and its source of light, and thus intercepting the light; or the disappearance of a body may be caused by another body coming between it and the spectator. These two sets of circumstances, though ending in the same species of phenomenon, are yet of a character so different that it will be advisable to consider the two in separate articles. We shall therefore here content ourselves with an enumeration of the various kinds of eclipses; leaving further detail, when necessary, to the articles which will be referred to.

Let us suppose a spherical body AB, which is luminous, and another CD, the smaller of the two, which is not luminous. Let us consider first the circular sections of these bodies made by the plane of the paper, and let common tangents be drawn to these sections, four in number, namely, AX, BY, AM, and BN. If the bodies be very distant from each other, in comparison with their bulk, then it will be sufficient for practical purposes to consider these common tangents as intersecting at A and B, and C and D, the opposite extremities of two parallel diameters. If the whole figure then revolve round the line joining the centre of the two circles, the spherical bodies will be reproduced, together with the conical envelopes by which it may be seen on what the phases of an eclipse depend.

The whole space generated by the revolution of YCDX is, in whole or in part, deprived of the light from AB. Within the space CDZ (or the cone generated by its revolution), the loss of light is total: a spectator situated within

that cone sees no part of AB, and a planet which receives its light from AB cannot, when in that cone, be visible in any part of space. This is even true at the point Z; but anywhere within the cone NZM, more or less of the border of AB is visible, and CD hides a portion of the middle of AB. If CD be small in comparison with AB, then the effect of CD to a spectator situated far off in NZM is only the appearance of a small dark spot upon the face of AB.

Within the spaces YCZN and MZDX, a part only of the face of AB is hidden from a spectator there situated, and part only of the light of AB is lost. On the lines CY or DX the spectator imagines the two bodies AB and CD to be in contact.

The eclipses in which the disappearance takes place by the removal of the light from the body are—

1. The eclipse of the moon. [MOON, ECLIPSE OF.]

2. The disappearance of a portion of Jupiter's surface, occasioned by one of its satellites passing between it and the sun. This is usually called the transit of the satellite's shadow over the disc of Jupiter. [JUPITER.]

3. The eclipses of Jupiter's satellites. [JUPITER.]

The eclipses in which the disappearance arises from the absolute interposition of another planet are—

1. The eclipse of the sun [SUN, ECLIPSE OF], meaning the eclipse of the sun by the moon.

2. The eclipse of the sun (that is, of a very small portion of the sun) by Mercury or by Venus, commonly called the transit of Mercury or Venus over the sun's disc. [MERCURY, TRANSIT OF; VENUS, TRANSIT OF.]

3. The occultation of a fixed star by the moon. [MOON.]

4. The eclipse of a portion of Jupiter by one of its own satellites, or transit of a satellite over the disc. [JUPITER.]

5. The eclipse of a satellite of Jupiter by Jupiter itself, or occultation of a satellite by the planet. [JUPITER.]

We have here mentioned such eclipses as are not unfrequent: the only additional phenomenon which we are aware of is the eclipse of a portion of the ring of Saturn by a satellite, or passage of a satellite over the ring, seen by Sir W. Herschel. The satellites of Saturn must suffer eclipses of the first kind by entering the shadows either of the planet or the ring, and of the second kind both from the planet and the ring; but these satellites are only seen with very good telescopes and under very favourable circumstances, so that their eclipses excite little public curiosity.

ECLIPTIC. [EQUATOR and ECLIPTIC.]

ECLOGUE. [BUCOLICS.]

ECONOMISTES. [POLITICAL ECONOMY.]

ECPHIMOTES (Fitzinger), a genus of Saurians, possessing the teeth and pores of the genus *Polychrus*, but with small scales on the body only. The tail, which is large, has great scales, which are pointed and carinated. The head is covered with plates. The form is a little short and flattened like that of some of the *Agamæ*, rather than like the slender shape of *Polychrus*. Example, *Ecphimotes tuberculatus* (*Agama tuberculata*, Spix; *Tropidurus torquatus*, Pr. Max.)

Description.—Ash-coloured, sprinkled with whitish blotches: a demi-collar of black on each side of the neck.

Locality. Brazil.

ECTOPISTES. [COLUMBIDÆ, vol. vii., p. 373.]

ECTOPISTINÆ. [COLUMBIDÆ, vol. vii., p. 373.]

ECUADOR is one of the three republics, which, before 1831, constituted the republic of Colombia, but since that time has become a separate government. It comprehends the antient kingdom of Quito, with the plains extending east of it between the Amazon river on the south, and the Uaupes, the principal branch of the Rio Negro, on the north. Its boundaries are not marked by natural objects, but follow mostly imaginary lines. A line beginning at Tabatinga, on the Amazon, and running due north, along the meridian of 70° 12', divides Ecuador from Brazil as far as 1° 10' N. lat., whence the boundary line runs on this parallel to the Rio Negro. The Rio Negro separates Ecuador from the republic of Venezuela, and the Uaupes forms in the whole length of its course the boundary between it and New Granada. Farther west this line extends over the mountain range in which the Rio Magdalena and the Rio Cauca originate, then passes over the northern ridges of the mountain-knot of Los Pastos, and terminates with the lower course of the Rio de los Patias, on the Pacific. The Pacific forms its western boundary. On the south, Ecuador is separated from Peru by a line beginning near

Tumbes, on the Bay of Guayaquil, and running in a south-south-east direction to the Rio Amazon, which it joins a short distance above S. Jaen de Bracamoros. From this point the Rio Amazon constitutes the boundary line between both republics.

Ecuador extends from 5° 50' S. lat. to 1° 19' N. lat., and from 69° 40' to 80° 40' W. long. Its surface is vaguely calculated at more than 537,000 square miles, or more than four times and a half the area of the British Islands.

About one-fourth of its surface is mountainous. The Andes enter the country between the Bay of Guayaquil and S. Jaen de Bracamoros, and thence run in a northern and north-eastern direction to the northern boundary. This chain forms in the southern and northern extremity two large mountain-knots, that of Loxa, between 5° 30' and 3° 15' S. lat., and that of Los Pastos, between 21° and 1° 13' N. lat. The first occupies, according to Humboldt, 11,650 square miles, and the second 8700. Between these two mountain-knots the Andes form an enormous mass of rocks, covering in width an extent of 70 or 80 miles. Both declivities are rather steep, but especially that towards the eastern plains. On both edges of this mass are lofty ranges running parallel to one another, and crowned by numerous summits, several of which rise above the line of perpetual congelation. The highest ridges of those ranges may be about fifty miles distant from one another; and between them extends a longitudinal valley, which measures from fifteen to twenty miles across, and extends nearly 300 miles in length. At two points transverse ridges unite the two ranges, and thus the great valley is divided into three smaller valleys. The most southern of these valleys, that of Cuenca, extends from 3° 15' to 2° 27' S. lat., with a mean elevation above the sea of about 7800 feet. Its waters join the Rio de S. Jago, a tributary of the Amazon. The summits of the ranges which surround it rise only to about 10,000 feet and nowhere attain the snow-line, except the range of Assuay (2° 27' to 2° 36' S. lat.), which separates the valley of Cuenca from that of Alausi and Hambato, and rises near the Ladera de Cadlud, on the great road, to 15,520 feet, and consequently approaches the snow-line. To the north of this transverse ridge extends the valley of Alausi and Hambato from 2° 27' to 36' S. lat. Its surface is somewhat higher than that of the preceding valley, and may be about 8000 feet above the sea. Its waters run off to the Marona and Pastaza, two tributaries of the Amazon. On the range east of this valley are the volcanoes of Sangay of Collanes and of Llangate, and on that on the east rises Chimborazo (21,420 feet above the sea), and the Carguairazo. The transverse ridge which separates this valley from that of Quito is called the Alto de Chisinche. It is only about 500 feet above the plains contiguous to it on the northern side, and is of inconsiderable width. At its western extremity stands the volcano of Cotopaxi, which attains a height of 18,880 feet, and at its eastern the Yliniza, which rises to 17,376 feet. This Alto de Chisinche forms the water-shed between the Pacific and Atlantic seas. The valley of Quito extends from 40' S. lat., to 20' N. lat. to the mountain-knot of Los Pastos. Its mean elevation above the sea is about 9600 feet. Its waters run off by the Rio Pita, which joins the Rio de las Esmeraldas, and thus flows into the Pacific. On the range standing east of this valley are the Antisana, 19,136 feet high, and the Cayambe Urcu, 19,548 feet high. The Cayambe Urcu is on the equator. On the western range are the Pichincha, 15,936 feet high, and the Cotacache, which rises to 16,448 feet. On the mountain-knot de los Pastos are several volcanoes, as those of Cumbal, Chiles, and Pasto. The elevated plains, which are inhabited, on that mountain region are 10,240 feet above the sea.

The country between the Andes and the Pacific is filled up with mountains of various elevations, which towards the shores sink down to hills. The shores themselves are high, but not of great elevation, except in a few places, as at Cape S. Lorenzo. The country along the river of Guayaquil forms an exception. Here a plain extends several miles in width, and is so low that part of it is covered by the inundations of the river in the rainy season, and part has been changed into a swamp.

The great plain east of the Andes is partly wooded and partly a savane; but in its present state it is of little importance, being only inhabited by the natives.

The principal river of Ecuador is the Amazon, which is here called Tungaregua. Where it leaves Peru, and begins

to form the boundary-line between the two republics, commence the series of cataracts and rapids with which it issues from the Andes. Near S. Jaen de Bracamoros is the Pongo de Rentemas, where the river, according to Humboldt, is only 1232 feet above the level of the sea. Lower down at the mouth of the Rio de Santiago, and between Santiago de las Montanes and Borja, is the rapid or Pongo of Manseriche, where the river is narrowed to about 150 feet, and for about seven or eight miles rushes down with incredible velocity. Below this Pongo the Amazon becomes navigable, and continues so to its mouth. [AMAZON.] Within the boundary of Ecuador, the Amazon receives the Marona, Pastaza, Tigre and Napo, which descend from the eastern declivities of the Andes. The Putumayo and the Yapura, which descend from the same range and in the same direction, fall into the Amazon within Brazil. The rivers which descend from the western side of the Andes have a comparatively short course. The most remarkable are the Rio de los Patias, Rio de las Esmeraldas, and the river of Guayaquil; but only the latter, so far as we can learn, is navigated by large vessels to the town of Guayaquil, and by river-boats about seventy or eighty miles higher.

The temperature must, of course, differ considerably in the elevated valleys which are surrounded by the high peaks of the Andes, and in the low countries on both sides of the range. In the valley of Quito the seasons are scarcely perceptible. The mean temperature of the day, all the year is round, is between 60° and 67°, and that of the night between 48° and 52° of Fahrenheit. The winds blow continually, but never with great violence. They generally come from the north or south, but occasionally shift to other quarters, without apparently depending in any degree on the seasons. During the whole morning, till one or two o'clock, the weather is generally delightful, and the sky serene and clear; but after this hour vapours begin to rise, and the whole sky is gradually covered with black clouds, which bring on dreadful tempests of thunder and lightning, followed by torrents of rain. At sunset the weather generally clears up, and the nights are as serene as the mornings. The rains sometimes continue all night, and occasionally, though rarely, three or four days in succession. At other times a few fine days, without rain, follow one another. The interval between September and May is called the winter; and the remainder of the year the summer. The winter is only distinguished by a somewhat greater quantity of rain, and the summer by a greater number of fine days. These valleys are also subject to frequent earthquakes, of which those of 1698 and 1797 were particularly destructive. In the last earthquake 40,000 inhabitants are stated to have perished in the valleys; and, it is said, that the climate of Quito has become much colder than it was formerly.

At Guayaquil and on the other valleys along the coast the mean temperature of the year varies between 78° and 82°. From December to April the heat rises to 95° and no more. In this season an unvarying calm prevails, and the rain continues day and night with short interruptions; it is accompanied with frequent and dreadful tempests of thunder and lightning. In the remainder of the year the heat is moderated by the south-western and west-south-western winds, which blow with considerable force from noon to five or six in the morning of the following day. The sky is always serene and bright, gentle showers being rarely known to fall. This season is stated to be very healthy.

The great plain extending along the Rio Amazon and its numerous tributaries has a hot climate. The mean temperature probably does not fall short of between 75° and 85°, and the heat sometimes rises to 95° and more. But every day at two o'clock a wind begins to blow with great force, and continues to sun-set. It always proceeds from the east, and is considered as the continuation of the trade-winds. Near the base of the Andes it frequently blows with the violence of a storm. In this region rain falls nearly every day, generally after noon, when the wind commences.

Agriculture varies with the elevation of the cultivated land above the level of the sea. Near the snow-line, which in this part of the Andes occurs at the height of 15,750 feet, the vegetation of the *Paramos* (flat tracts on the summit or the range, from 11,000 to 14,000 feet above the sea) is extremely scanty, consisting only of two or three species of plants. Districts situated at an elevation of 10,000 feet are covered with grass, which affords good sheep-walks; such are the plains in the mountain-knot of Pastos. The cul-

ture of European cerealia and fruits prevails between 10,000 and 4000 feet, especially in the great valley of the Andes, where excellent wheat is raised, with barley and Indian corn. Lucern is also extensively grown as fodder for beasts of burden. In those parts of the country which do not exceed in elevation 4000 feet above the sea the vegetables cultivated for food are chiefly sweet potatoes, mandiocca, yams and bananas, with rice, Indian corn, and some leguminous plants. The most common fruit-trees are cherimoyers, pine-apples, papayas, and anonas. There are also extensive plantations of sugar-cane, cotton, tobacco, and cocoa. Among the forest-trees is that which gives the cinchona bark. This tree is most frequent on the heights of the mountain-knot of Loxa, where it grows on the eastern declivities at an elevation of 6000 or 8000 feet above the level of the sea.

Sheep and cattle are reared in great numbers, the former especially in the valleys of the Andes, and on the higher declivities of the mountains. Horses, asses, and mules, are sufficiently numerous to be articles of export. In some districts, especially in the valleys along the coast, a considerable quantity of wax is collected; and still higher up are some spots where the cochineal insect is reared. Along the coast a murex is found which juice is used in dyeing purple.

Ecuador is less rich in the precious metals than the other countries of South America which comprehend a portion of the Andes. There are several mines of gold and silver, and a few are still worked; but the annual produce is not considerable. Lead and quicksilver occur in some places, and in others sulphur is prepared in considerable quantity. Salt is obtained from sea-water along the coast.

The population of Ecuador is composed of the descendants of Spaniards and of the aborigines. The proportion of both races is not stated, but it would appear that the aborigines constitute at least three-fourths of the population. Those Indians who inhabit the elevated valleys belong to the race of the Peruvians, and speak the Quichua language. They are mostly agriculturists, and cultivate their lands with much care. They apply themselves also to manufactures, and make coarse stuffs of wool and cotton. The Indians who inhabit the eastern plain are much lower in civilization. They cultivate only small pieces of ground, and apply themselves almost exclusively to fishing and hunting. The Jesuits had made considerable progress in bringing them over to Christianity and civilization; but as their successors did not pursue this object with equal zeal or success, the *missiones* decreased gradually in extent and population. The political events which have taken place since the year 1812 have driven the monks out of the country all the *missiones* are in ruins, and the Indians have returned to the forests, and lost all marks of civilization. The whole population was thought to amount in 1827 to 492,000, with the exception of the Indian braves of the plain. Three-fourths of the population are in the elevated valleys of the Andes.

When it formed a part of the republic of Colombia, Ecuador was divided into three departments. We cannot learn whether a new division of the territory has been made since its separation, and we shall therefore notice that which existed before.

1. The department of Ecuador or Quito extends along the coast from the mouth of the Rio de Patias to Cape Pasado, and comprehends the two valleys of Quito and of Hambato and Alausi; to which is added a portion of the eastern plains along the upper courses of the rivers Yapurá, Putumayo, Napo, Tigre, and Pastaza. In the elevated valleys in several places are the ruins of ancient palaces of the Incas, and in many districts there are traces of the great road which in the time of the Incas led from Quito to the southern extremity of the valley of Titicaca (from the equator to 26° S. lat.). Its principal wealth consists in its extensive corn-fields, and its numerous herds of sheep, cattle, asses, and mules: it has also a few mines of silver and gold. It is divided into three provinces, named from three mountains, Imbabura, the northern, Pichincha, the central, and Chimborazo, the southern province. The capital of the republic, the department, and the central province, is Quito. [QUITO.] North of this place lies S. Miguel de Ibarra, or briefly Ibarra, a well-built town, with about 12,000 inhabitants, and manufactures of wool and cotton: it is the capital of the province Imbabura. Not far from it is Otavalo, which likewise has manufactures of wool and cotton, and 20,000 inhabitants. On the coast are the harbours of Esmeraldas,

Atacamea, and Carondelet, but they are not visited by foreign vessels.

South of Quito is Tacunga, with 3000 inhabitants, which, between 1698 and 1797, was four times destroyed by earthquakes. Riobamba was entirely destroyed in 1797. The new town, which was built four or five miles farther south, contains 15,000 inhabitants, and is the capital of the province of Chimborazo. In its neighbourhood, at Tesoan, great quantities of brimstone are made. Hambato, north-east of Mount Chimborazo, with 9000 inhabitants, and Guaranda, south of the same mountain, have some commerce, owing to their situation on the road between Guayaquil and Quito. The *missiones* in the eastern plain have almost disappeared.

2. The department of Guayaquil comprehends the coast between Cape Pasado and a short distance from the boundary-line of Peru, and extends inland to the upper declivity of the Andes. Its commercial wealth consists in its tropical productions, especially in cocoa, of which there are extensive plantations. It is divided into two provinces, Manabi, the northern, and Guayaquil, the southern. The capital is Guayaquil. [GUAYAQUIL.] On the banks of the Rio de Guayaquil are Babayhoyo and Caracol, which are situated at the points where the river ceases to be navigable at different seasons, and consequently on that account are used as commercial depôts. Puerto Vejo, a small place, is the capital of the province of Manabi: its harbour is at Manta. Another harbour is at Punta de S. Elena, where much salt is made. The island of Puna, in the Bay of Guayaquil, has an area of more than 200 square miles. At the arrival of the Spaniards it had a population of 20,000 individuals, who are now reduced to a few fishermen. To this department belong the Galapagos Islands. [GALAPAGOS.]

3. The department of Assuay derives its name from the mountain-ridge which divides the valley of Alausi from that of Cuenca. It comprehends the last-named valley, the mountain-knot of Loxa, and a few miles of sea-coast along the Gulf of Guayaquil, contiguous to the boundary of Peru, with by far the greatest part of the eastern plains. In a few places ruins of ancient temples and palaces occur. Cinchona-bark forms its principal article of exportation. This department contains many herds of sheep and cattle, and the valley of Cuenca produces grain in abundance. A few mines are found, but most of them are, we believe, not worked at present. This department is divided into three provinces, Cuenca, which comprehends its valley and the sea-coast; Loxa, extending over the mountain-region of that name; and S. Jaen de Bracamoros, in which the valley of the Amazon and the eastern plains are included. The capital is Cuenca, 8640 feet above the sea, a large but meanly-built town, with 20,000, or, according to others, 30,000 inhabitants. It has a university; and some institutions for education have been recently established. At Azogues are mines of quicksilver. Loxa, in a valley 6768 feet above the sea, has some fine churches, and 10,000 inhabitants. It trades extensively in cinchona-bark. Zaruma, on the western declivity of the Andes, has a population of 6000, and mines of gold and silver in its neighbourhood. The port of Tumbes, in the Bay of Guayaquil, is the place where Pizarro made his descent on the Peruvian coast: in its neighbourhood are some mines. Jaen de Bracamoros has 4000 inhabitants. Borja is a small place, where the Pongo de Manseriche terminates. The *missiones*, in the eastern plains, which formerly were numerous and extensive, are now reduced to a very low state.

The manufactures in cotton and wool are considerable in Quito as well as in Ibarra and Otavalo. The fabric is coarse, but strong and durable, and was formerly in great request in New Granada, and in several sea-ports; but its use has lately somewhat diminished on the shores of the Pacific. Lace of a good kind is also made in Quito; but there is no other important branch of industry.

All the maritime commerce of Ecuador is concentrated in that of Guayaquil [GUAYAQUIL], from which town there is a road to Quito, running first along the banks of the Rio de Guayaquil to Caracol, and then for some miles through a low and level country. It then begins to ascend the western declivity of the Andes, and between Caluma and Guaranda the ascent is extremely steep. From Guaranda it runs over the plain to Hambato, and thence to Quito. The great road which connects New Granada and Peru runs through the high valleys of Ecuador. It lands

from Almaguer in New Granada over the Páramo de Puruguay (9408 feet above the sea) to Pasto (8578 feet), and hence over the Páramo de Boliche (11,504 feet), and the Alto de Pucara (10,400 feet) to Ibarra (7368 feet) and Quito (9536). In the Alto de Chisincho it attains an elevation of about 10,000 feet. Hence it traverses Hambato (8864 feet), Riobamba Nueva (9472 feet), and Alausi (7984 feet), and attains on the Páramo de Assuay 15,536 feet. In passing this range many lives are annually lost. From Cuenca (8640 feet) it runs over the Alto de Pulla (10,000 feet) to Loxa (6768 feet) and hence to Ayavaca (8992 feet) in Peru. From the latter place it proceeds to Truxillo and Lima. Formerly European commodities were imported into Ecuador by this road from New Granada, but since the opening of the trade nearly the whole country receives them from Guayaquil.

Ecuador was discovered by Francis Pizarro in 1526, and came into the hands of the Spaniards at the downfall of the empire of the Incas. The Spaniards remained in the possession of the country up to the year 1812, when the country declared against them. Quito was then a part of the vice-royalty of New Granada, and it participated fully in the frequent vicissitudes of the war, which ended in 1823 with the complete expulsion of the Spaniards. By the convention of Cucuta in 1821, New Granada and Venezuela united and formed one republic under the name of Colombia, but this union lasted only till 1831, when these countries again separated. Ecuador, or the ancient kingdom of Quito, was then also separated from New Granada, and since that time has existed as an independent state. While it was united to New Granada and Venezuela the whole republic was under a central government. We do not know whether such a government has been preserved in the new republic of Ecuador, or if it at present consists of a number of smaller states united by a federal government. (Condamine, Ulloa, Humboldt, Caldas in Mollien's *Travels*.)

EDDA. The northern mythology, which in regard to wild imagination and sublime conceptions surpasses that of Greece or Rome, is chiefly contained in two collections called 'The Eddas,' which have been handed down from time immemorial by the scalds, or ancient minstrels, of Denmark, Sweden, Norway, and Iceland. The word Edda signifies Mother of Poetry. In the beginning these mythological records were communicated from mouth to mouth, and afterwards written down with the sacred characters of the north, the Runic characters, an alphabet which the Scandinavians are said to have obtained from the seafaring Phœnicians. The Scandinavians initiated in the mysteries of their religion the Saxons, who were forced by Charlemagne to exchange it for Christianity. After the conquest of the Saxons by Charlemagne, the worshippers of the religion of Odin withdrew to Iceland, where the sacred books of the Scandinavians were preserved, from which Samund Sigfusdon, a clergyman, and Are Frode, the historian, collected, between the years 1056 and 1133, the older Edda.

This important work was concealed and forgotten for nearly 400 years. However, in the year 1643 a fine copy of these poems was found by Bishop Svensen, and published in 3 vols. 4to., containing the original text, a Latin translation, and a dictionary of the northern mythology. The contents of the poems are prophecies, elevated conversations, and magic songs.

The new Edda, composed or arranged two hundred years later, is a systematic poetical compendium of the former, and is divided into three books; one dogmatical or doctrinal, the second narrative, and the third critical. The Icelandic text of this second Edda was translated in the year 1640, by Resenius, and hence it is called the Resenian Edda.

Some modern critics have endeavoured to question the authenticity of these books, but their objections have been completely refuted by P. C. Müller, Von der Hagen, and the brothers Grimm.

The distinguishing characteristic of the mythology of the Eddas, as compared with that of Greece and Rome, is its systematic or rather epic unity. The mythology of the Greeks and Romans splits into numerous branches, and loses itself in the ocean of real events. That of the Edda, on the contrary, presents in the very beginning the germs of one all-destroying catastrophe, of a creation which by necessity involves the final destruction of the universe. The cosmology itself is truly original. According to the Edda, there was once no heaven above nor earth below, but

only a bottomless deep, and a world of mist in which flowed the fountain that strives to devour every thing. Twelve rivers issue from this fountain. When they had flowed so far from their source that the liquid which they contained had become hardened, they ceased to flow, and froze into ice; and one layer of ice accumulating over the other, the great deep was thus filled up.

Southward from the World of Mist was the World of Light. From the former proceeded every thing dark and cold; from the latter whatever is warm and light. The one was the principle of wrath and death; the other, the principle of love and life; a warm wind blowing from the latter upon the ice melted it. The melted drops became animated by the power of him who had sent the wind, and from them sprung Ymir the giant, and the holy Ash Ydrasill, or the tree of life, which spreads its roots through all the deep, and its branches over the universe. Under Ymir's left arm grew a little man and woman, and from them proceeded the ice giants, the heroes, and the gods. This cosmogony is the offspring of a northern view of nature. It is natural that ice should appear to the Scandinavians as dead matter, or as the bad principle, and heat and light, on the contrary, as the creative powers, or good principle. The contrast of these two principles under different symbols, of good and bad genii, heroes, and gods, the alternate ascendancy of the one over the other until the fiery snake consumes universal nature with all-destroying flames, forms the cyclus of the great tragedy—among the incidents of which, the death of Baldur, the beau ideal of Scandinavian heroism, the Achilles of the north, forms one of the most heart-touching episodes. The existence of one supreme ruling principle, and the acknowledgment of a spiritual immortal soul in man, are also traceable in different symbols of the Edda. In both Eddas we find also the first rudiments of the great German national epic poem, 'Der Niebelungen Lied.'

Those who wish for further information on this subject may consult *Edda Saemunda hins Froeda*, and Creuzer's *Symbolik*.

EDDOES, the name by which the esculent Caladium is known by the blacks of the Gold Coast. The leaves are boiled and eaten as cabbages with us, but their acidity renders them unsuitable for a European palate.

EDDY is a circular motion of the water, either in rivers or in the sea. It exists more frequently in rivers between the proper current and the counter current. The edges of one current brushing against another give to a small portion of water a circular motion. But an eddy is also produced when the current, running with some violence against a rock or elevated shore, is driven back and meets in the bed of the river or on the opposite shore another obstacle to its course. In this case the eddy generally occupies the greatest part of the bed of the river, and is frequently called a whirlpool. Eddies occur in the sea likewise, where two currents run parallel, but in different directions, as between the Equatorial and North African current. Whirlpools also occur frequently among rocky islands near a coast. (WHIRLPOOL.)

EDDYSTONE or EDDYSTONE LIGHTHOUSE is constructed on the sloping side of a rock which bears from Plymouth south by west, and from the Ram Head south half a point east. It is distant from the anchoring in the Sound four leagues, and from Ram Head about three leagues and a half, which latter is the nearest shore to the lighthouse. The Isle of Maystone bears from the lighthouse about north-east by north, and is also four leagues distant. All the rocks near the house are on the east side, stretching to the north and south, and they are all covered at high water; but on the west side any ship may sail close by the house in twelve or thirteen fathoms water, and there are no hidden rocks. Towards the east by north, about a quarter of a mile from the house, there is a rock which never appears but at low spring tides. (Winstanley's *Lighthouse*, book i., cap. 11; Smeaton's *Narrative*.)

The present edifice is a circular tower of stone sweeping up with a gentle curve from the base, and gradually diminishing to the top, somewhat similar to the swelling of the trunk of a tree. The upper extremity is finished with a kind of cornice, and is surmounted with a lantern, having a gallery round it with an iron balustrade. The tower is furnished with a door and windows, and a staircase and ladders for ascending to the lantern, through the apartments for those who keep watch. Mr. Smeaton undertook the arduous task of constructing the present lighthouse in

the spring of the year 1756, and completed it in considerably less time than was originally proposed, which was four years. In order to form his foundation, Smeaton accurately measured the very irregular surface of the rock, and made a model of it. (Book ii., chap. 11 of his *Narrative*.)

The materials employed in building the tower are moor-stone, a hard species of granite, and Portland stone. The granite rock was partially worked to form the foundations; and as the ground joint would be more subject to the action of the sea than any other, it was found necessary not only that the bed of every stone should have a level bearing, but that every outside piece should be grafted into the rock, so as to be guarded by a border thereof at least three inches in height above it, which would in reality be equivalent to the founding of the building in a socket of three inches deep in the shallowest part. On the 3rd of August, 1756, Smeaton fixed the centre point of the building and traced out part of the plan on the rock; and on the 6th, nearly the whole of the work was set out. (See the plan in the *Narrative*, showing the dovetail recesses.) On the 4th of September, the two new steps at the bottom of the rock and the dovetails were roughed out, and some of the beds brought to a level and finished, after very great labour. The stones for the several courses were rough worked at the quarries according to various draughts made by the engineer.

A part of the upper surface of the rock having been taken carefully off, but without the use of gunpowder, lest it should loosen the rock, six foundation courses dovetailed together were then raised on the lower part of the rock, which brought the whole to a solid level mass. These courses, with eight others raised above them, form the solid bed of the work, and take the form of the swelling trunk of a tree at its base. The courses of masonry are dovetailed together in the most skilful manner, and each layer of masonry is strongly cemented together, and connected by oaken trenails or plugs, and the whole strongly cramped. (See the various plans in the *Narrative*.) The general weight of the stones employed is a ton, and some few are two tons. In the solid work the centre stones were fixed first, and all the courses were fitted on a platform and accurately adjusted before they were removed to the rock.

The first lighthouse built on the Eddystone rock was constructed by Mr. Winstanley, a gentleman of Essex, who was a man of a mechanical turn. His work was begun in 1696, and completed in four years. While some repairs were making under his inspection, the building was blown down in a terrible hurricane during the night of the 26th November, 1703, and he and his workmen perished. Not a vestige, except some iron stanchions and a chain, was left behind. It appears from the drawing to have been insufficient for one of its proposed purposes, durability.

It was not till the spring of the year 1706 that an Act was passed for rebuilding the lighthouse, and Mr. Rudyerd, a silk-mercator, was employed by the lessee of the lighthouse to construct a new building. Mr. Rudyerd's want of personal experience was made up by the employment of two of the shipwrights from the royal arsenal at Woolwich.

Mr. Smeaton was of opinion that Rudyerd directed the performance of his work in a masterly manner, and so as perfectly to answer the end for which it was intended, until it was destroyed by fire in 1755. The worm appears, however, to have affected the timbers.

Winstanley's building was constructed principally of wood, and part of the base of stone; Rudyerd's was built entirely of wood, except five courses of moor-stone on the rock. (See the plates in '*A Narrative of the Building, and a Description of the Eddystone Lighthouse*,' &c., by John Smeaton, Civil Engineer, F.R.S.)

Mr. Foster's lighthouse, built on the Black Rock, at the mouth of the Mersey, and the Bell Rock lighthouse, off the coast of Fife, are similarly constructed.

The Eddystone lighthouse has not only the merit of utility, but also of beauty, strength, and originality, and is itself sufficient to immortalize the name of the architect. The reader will find every thing curious and interesting connected with this undertaking in Smeaton's splendid folio above referred to.

The base of the tower is about 26 feet 9 inches in diameter, taken at the highest part of the rock. The diameter at the top of the solid masonry is about 19 feet 9 inches, and the height of the solid masonry is 13 feet from the

foundation. The masonry may still be considered of solid construction to the top of the stone staircase; the height to the top of which from the centre of the base is 28 feet 4 inches. The height of the tower from the centre is 61 feet 7 inches; the lantern, the base of which is stone, is 24 feet; and the diameter of the tower below the cornice is 15 feet. The whole height is therefore 85 feet 7 inches, according to the scale given by Smeaton to his drawings.

The upper part of the building, constructed of wood, was burnt in 1770, and renewed in 1774.

EDELINCK, GERARD, a distinguished engraver, and likewise eminent as a painter, was born in 1649 at Antwerp, where he acquired the rudiments of his art; but it was in France that his talents were fully developed, and the favours bestowed on him by Louis XIV. induced him to fix his abode in that country. Among his engravings the following are especially worthy of notice:—the Holy Family, after Raphael; Alexander in the Tent of Darius, after Lebrun; the Combat of Cavalry, after Leonardo da Vinci; and, above all, the Crucifixion, after Lebrun. In his larger plates of historical subjects, we too often have reason to lament the choice; many pictures owe all their celebrity to his master-hand. Edelinck was equally happy in his portraits, of which he has left a great number of the most distinguished characters of his age. Several of them are in the collection of eminent men by Perrault. A remarkably pure and brilliant burin, a bold manner, correct drawing, fidelity to nature, and inimitable harmony of execution, place the works of Edelinck in the highest rank among those of his nation. He was engraver to the king, and member of the Royal Academy of Painting, and died at Paris in 1707. Neither his brother John, born 1630, nor his son Nicholas, born at Paris, 1680, equalled him in his art.

EDEN. [CUMBERLAND.]

EDENTATA, Cuvier's sixth order of mammiferous animals, characterized by the absence of teeth in the front of the jaws. Their claws are large, and they are more endowed with strength than agility. Cuvier divides them into three tribes.

1st, the *Tardigrades*. Example, the *Sloths* (*Bradypus*, Linn.) [AI.]

2nd, the *Armadillos* (*Dasypus*, Linn.) [ARMADILLO.] *Chlamyphorus* [CHLAMYPHORUS] comes under this tribe, as well as *Orycteropus* [AARD-VARK], *Myrmecophaga* [ANTEATER], and the *Pangolins* (*Manis*, Linn.).

The third tribe consists of the Monotremes. [ECHIDNA; ORNITHORHYNCHUS; MONOTREMES.]

Some large extinct fossil animals, the *Megatherium*, for instance, belong to this order.

EDESSA. [ORFA.]

EDFU, a small town of Upper Egypt, on the left bank of the Nile, in 25 N. lat., remarkable for its temple, which is one of the finest and best preserved in Egypt, though much encumbered with sand and rubbish, and with the huts of the inhabitants, who have built their village around and on the top of it. The outward access to the temple is between two enormous propylæ, or truncated pyramids, 104 feet long, 37 wide at the base, and 114 feet high. At the summit the horizontal section is 84 feet by 20. On the fronts of these moles immense figures are sculptured in a masterly style. Between the two propylæ is the doorway, after passing which we enter a court, 161 feet long and 140 wide, surrounded with walls; on each side of which there is a row of pillars placed at some distance from the side wall, the space between the pillars and the wall being roofed over with stone, forming a covered portico. From the base of the pillars to the top of the stone covering is about 35½ feet. The court is now filled with rubbish, and encumbered with wretched buildings, forming part of the modern village of Edfu, the remainder being built on the roof of the temple itself. From the entrance of the court there is a gradual ascent by a kind of steps to the pronaos or portico of the temple, which is supported by eighteen pillars, six in a row, the whole height of it being about 56 feet above the lowest level of the court. The intercolumniations of the front pillars are built up to more than half the height. Passing through the pronaos, we come to a doorway leading into a kind of hypostyle hall, 66 feet by 33, supported by twelve pillars, with a flat roof formed by large beams of stone crossing from each pillar to the next in the same row, the whole being covered with thick flat slabs. The pillars have the quadrilateral two-headed capital as at Denderah. From this chamber we pass into another long and narrow

one, from which there are two small entrances to the side galleries, wherein we see flights of steps leading upwards to the roof of the sekos or cell. Proceeding onwards through the middle chamber, we pass into another small one, with an apartment on each side of it, probably for the use of the priests. From this last-mentioned chamber we enter the holy recess itself, an oblong room about 33 feet by 17, in which the figure of the deity was placed. Two galleries run down on each side of it, leading to a doorway at the back of it, by which the priests might walk into a large but perfectly retired space all round the sanctuary, or might ascend on the roof by a flight of steps to enjoy the air and light on the terraced roof, for below they had no light at all, except it might be from small apertures, through which the Fellahs, who now live on the roof with their families and cattle, discharge all their dirt into the temple. The chambers of the Sekos serve them as repositories for grain and other commodities. It will be observed that from the covered gallery or portico on each side of the outer court there is a path continued all round the temple, between the outer and the inner walls. Probably the vulgar were allowed the use of this walk, as a thick wall was between them and the apartments devoted to the priests and the worship of the deity; for none but the priests, and probably the kings, were admitted into the inner apartments, much less into the adytum or sanctuary, which contained the representation of the deity. The temple, as well as every part of the wall, are covered with hieroglyphics and figures. The outer wall, which joins the two propyla and completely incloses both the court and the temple, is 414 feet on each of its longer sides, and 154 on its shorter side at the back of the temple.

The temple of Edfu may be compared with that of Denderah for preservation, and is superior to it in magnificence. The propylæon is the largest and most perfect of any in Egypt; it contains several apartments in the interior, which receive light by square apertures in the sides. The entrance court is the only one to be seen in Egypt in such perfection, though completely encumbered with Arab huts. The pronaos or portico is magnificent, but unfortunately above three-fourths of it are buried in rubbish. Upon the whole, the temple of Edfu, although built much later than many of the others, being generally attributed to the age of the Ptolemies, is perhaps the most complete specimen remaining of an Egyptian temple, which can give a good idea of the respective proportion and distribution of the different parts of their exterior appearance when entire, and the strength of those formidable citadels, which, while they served as a protection to the town, commanded the respect of the inhabitants, and prevented or defeated any attempts to dispute the authority of their priestly rulers. (See *British Museum, Egyptian Antiquities*, vol. I., in the *Library of Entertaining Knowledge*, with a ground-plan of the temple of Edfu; Belsoni; and Wilkinson's *General View of Egypt*.) [EGYPTIAN ARCHITECTURE.]

EDGAR, surnamed the Peaceable, was the second and youngest son of King Edmund I. by his wife Elgiva, or Algiva. He appears to have been born in 943, and consequently was only about three years old at his father's death in 946. His brother Edwy, or Eadwy, may have been a year or perhaps two years older. In these circumstances, Edmund's brother Edred was unanimously chosen to succeed him by the Witenagemote. On the death of Edred, however, in 955, Edwy was placed on the throne; and at the same time his brother Edgar was appointed governor or sub-regulus of Mercia, which was still considered as a distinct though subject kingdom. When, about two years after his accession, the enmity between Edwy and the church interest broke out into an open quarrel, the people of Mercia and Northumbria, instigated to revolt by Archbishop Odo, or at least timing their movement very opportunely for the purposes of the clerical party, placed Edgar at their head and proclaimed him king. It was finally arranged that Edwy should retain the sovereignty of the territory to the south of the Thames, and that all the rest of the kingdom should be made over to Edgar. The death of Edwy, however, about a year after, made Edgar king of all England (A.D. 959).

The celebrated Dunstan, banished by Edwy, had been recalled by Edgar, and made his chief counsellor, as soon as he found himself established as king of the country to the north of the Thames. Being as yet only in his sixteenth year (or perhaps not quite so old) when he became

full king, he was of course entirely in the hands of the monks and clergy, whose instrument he had hitherto been. Dunstan, already bishop both of Worcester and London, was now promoted to the primacy, as well as restored to his abbey of Glastonbury, and became the chief director of affairs both in church and state. The government of the kingdom by Edgar, under the guidance of this ecclesiastic, was unquestionably conducted with remarkable ability and success. Throughout the whole reign England remained undisturbed by war; the northern pirates, who had harassed the country so incessantly for 150 years before, and who, twenty years after the death of Edgar, renewed their attacks, and did not desist until they had effected its conquest, were, during his life, deterred from showing themselves on the English coasts by the powerful naval force that was kept up by this king. The old writers make the fleet of Edgar to have consisted of 3600 ships. 'The number,' says a modern historian, in a somewhat decisive style of narration, 'appears to me enormous: I have therefore retrenched a cipher.' (Lingard, *Hist. Eng.*) In this fleet, which was divided into three squadrons, Edgar is said by Malmsbury to have every Easter circumnavigated the island in person; but this story seems to be merely one of the improbable inventions by which Edgar's monkish admirers have laboured to magnify his name. It may be doubted whether we ought not to regard in the same light what some of the chroniclers tell us about his making annually a progress through the different provinces of his kingdom for the administration of justice. Another work of great public benefit which is attributed to him is the reformation of the coinage. He is also said to have freed Wales from wolves by commuting the money tribute imposed upon the Welsh by his predecessors for a tribute of 300 heads of these animals annually; by which means the wolves were extirpated in four years. But there were wolves in England long after this. Edgar has been chiefly lauded by the monkish annalists for his restoration of the church both to its antient possessions and to a more perfect state of discipline than it had probably ever before known. Under the vigorous administration of Dunstan and his subservient associates Ethelwold and Oswald, the bishops of Winchester and Worcester, the married clergy were at length removed almost to a man from the cathedrals and abbeys; and no fewer than fifty-four monasteries were founded or restored in different parts of the kingdom, and filled with monks as well as richly endowed. They were all subjected to the Benedictine rule.

The laws of Edgar that have been preserved consist partly of some enactments touching the payment of the tithes and other church-dues, and partly of a few civil regulations chiefly relating to the improvement of the police of the kingdom and the better administration of justice. One is directed against the crime of malicious defamation, and enacts that if the falsehood of the evil report can be proved, the defamer should either have his tongue cut out (that was no doubt thought a peculiarly appropriate punishment), or should redeem it with the value of his head, that is to say, should pay the sum at which his life was valued according to the class of society in which he was ranked. Another directs that the Winchester measure should be the standard for the kingdom. These laws, however, were only enforced in the Saxon provinces of Edgar's dominions. To his Danish subjects, who occupied nearly or fully half the kingdom, he appears to have only recommended the adoption of some of the English laws. The majority of these Danes resident in England were still pagans, and were governed by earls of their own nation, though they acknowledged the supremacy of the Saxon king; and it was not till towards the close of the reign of the Confessor that the authority of the English law was fully extended over the part of the country which they occupied. Edgar however had spent his earliest years among the Danes, and it was by their aid chiefly that he had acquired his first throne: these circumstances at once attached them to him, and gave him great influence over them; and this good understanding appears to have formed a chief part of the strength of his government, and to have very essentially contributed to the preservation of the tranquillity which the kingdom enjoyed during his reign.

The monkish chroniclers give the loftiest descriptions of the power and extensive authority of this king, telling us that he was acknowledged as their supreme lord by all the other kings of Britain and the surrounding islands. The

story told in the Saxon chronicle and elsewhere of his having been rowed in his barge on the Dee by the eight subject kings of Scotland, Cumberland, Anglesey with the Isle of Man and the Hebrides, Westmoreland, Galloway, North, South, and Middle Wales, is well known. It is also affirmed that the greater part of Ireland had submitted to his authority. The dominion which he arrogated to himself appears in fact not to have been inferior to what we find claimed for him by his panegyrists. Among the titles assumed by him on his seals and in charters are—'Edgarus Anglorum Basileus, omniumque regum insularum oceani quae Britanniam circumjacent, cunctarumque nationum quae infra eam includuntur, Imperator et Dominus'—'Rex et Primicerius totius Albionis'—'Basileus dilectae insulae Albionis, subditis nobis sceptris Scottorum, Cumbriorumque, atque Brittonum, et omnium circumcirca regionum,' &c. These 'pompous and boastful titles,' observes Mr. Turner, 'sometimes run to the length of fifteen or eighteen lines.' Much difficulty in believing that this assumption of power had any real foundation is occasioned by the absence of any record or notice of the subjugation of the more important of these neighbouring kingdoms by any of the Anglo-Saxon monarchs. What event ever happened for instance that could possibly have induced the king of Scotland to acknowledge himself in this manner as the vassal of the king of England? The pacific character claimed for the reign of Edgar, who is said never to have had occasion to draw the sword against an enemy, makes it still more difficult to understand how he should thus have compelled all his neighbours to do him homage, and take him for their lord and master.

The monkish writers, with whom Edgar is such a favourite, have not altogether concealed the fact that he was no saint in his morals. Even Lingard seems to admit that one story is tolerably well authenticated, which attributes to him the violation of a lady of noble birth, and that too while she was resident in a convent. Another is told of his having, on one occasion, ordered one of his nobles, whose guest he was, to give him his daughter for a bedfellow, and of the young lady's honour having been saved by her mother substituting for her a handsome slave, with whom the king was so well pleased that, after discovering the deception, he took her to court and retained her for some years as his favourite mistress. He was twice married, first to Elfreda the Fair, by whom he had a son, Edward, who succeeded him; and, secondly, to Elfrida, the daughter of Ordgar, Earl of Devonshire, who bore him Edmund, who died in his infancy, and Ethelred, for whom his infamous mother opened a way to the throne by the murder of Edward. The circumstances of the marriage of Edgar and Elfrida—the commission given by the king to Ethelwold to visit the lady and ascertain the truth of the reports of her beauty—the treachery of Ethelwold, who represented her to his royal master as unworthy of her fame, and then married her himself—the discovery by her and Edgar of the deceit that had been practised on both of them—and the subsequent assassination by the king of his unfaithful emissary—are related by Malmsbury on the faith of an antient ballad. There is nothing in the character either of Elfrida or Edgar that need occasion us any difficulty in believing the story.

Edgar, for some reason which does not clearly appear, was not solemnly crowned till the fourteenth year after he succeeded to the throne. The ceremony was performed at Akemancestre, that is, Bath, on the 11th of May, 973. He lived only two years longer, dying in 975, when he was succeeded by his eldest son Edward, afterwards designated the Martyr.

EDGAR ATHELING, that is, Edgar of the blood royal, or Prince Edgar, as we should now say. [ATHELING.] The personage commonly understood in English history by this title is Edgar, the grandson of King Edmund Ironside through his son Edward surnamed the Outlaw. Edward and his brother had been sent from England by Canute in 1017, the year after his accession, to his half-brother Olave, king of Sweden, by whom it was probably intended that they should be made away with; but Olave spared the lives of the children, and had them removed to the court of the king of Hungary. All the English historians make the Hungarian king by whom they were received to be Solomon; but this must be a mistake, for that king did not ascend the throne till 1062, and was only born in 1051. The king of Hungary at the time when the children of Edmund Ironside were sent to that country was Stephen

I., who reigned from 1001 to 1038. The story, as commonly related, goes on to state that one of the brothers, Edmund (or, as some call him, Edwin), married a daughter of the Hungarian king, but died without issue; and that the other, Edward, married Agatha, the daughter of the Emperor Henry II. and the sister of Queen Sophia, the wife of Solomon. Here again there must be some great mistake; for the Emperor Henry II. never had any children. Who Agatha really was, therefore, it is impossible to say. She bore to her husband, besides Edgar, two daughters, Margaret and Christina.

Edgar, as well as his sisters, must have been born in Hungary; but the year of his birth has not, we believe, been recorded. His father, after an exile of forty years, was sent for to England, in 1057, by his uncle King Edward the Confessor, who professed an intention of acknowledging him as next heir to the crown: the Outlaw accordingly came to this country with his wife and children, but he was never admitted to his uncle's presence, and he died shortly after, not without the suspicion of foul play, which one hypothesis attributes to Earl Harold, another to the duke of Normandy. There is nothing like proof, however, of the guilt of either. The event in the mean time was generally considered as placing young Edgar in the position of his father as heir to the crown; and it seems to have been now that the title of the Atheling (which had been borne by his father) was assumed by or conferred upon him. He was at any rate the Confessor's nearest relation; and if Edmund Ironside, from whom he sprung, was illegitimate, as some have supposed, the circumstance of his having worn the crown seems to have been regarded as sufficient to wipe away the stain, and to bring his descendants into the regular line of the succession. All Edmund's brothers and half-brothers, with the exception of the reigning king, had perished, most of them having been cut off by Canute and the other kings of the Danish stock; and the Confessor himself and his grandnephew, young Edgar, were now the only remaining male descendants of Ethelred II.

Edgar was still in England when the Confessor died in January, 1066; but he was yet very young, and appeared to be feeble in mind as well as in body, and therefore was in nowise fitted either to take a part, or to be used as an instrument by others, in the first tumult of the contest in which two such energetic spirits as Harold and the Norman William now proceeded to try their strength. Insignificant as he was, however, from his personal endowments, the Atheling derived an importance from his descent and his position which afterwards occasioned him to be conspicuously brought forward on various occasions, and has made him an historic character. On the destruction of the power of Harold at the battle of Hastings, he was actually proclaimed king by the citizens of London; but on the approach of the Conqueror, he was one of the first to go to him at Berkhamstead and to offer full submission. He then took up his residence at the court of William, who allowed him to retain the earldom of Oxford, which had been bestowed upon him by Harold. When the Conqueror the following year visited his Norman dominions, we find him taking the Atheling in his train. In 1068, however (the Saxon Chronicle says in 1067, but see a note upon the discrepancy of the authorities as to this and other dates in Lord Hailes's Annals, A.D. 1068), Edgar appears to have fallen into the hands of the discontented Northumbrian lords Maerleswegen (or Marleswine), Cospatric, and others, who, deserting the Norman conqueror, carried the heir of the Saxon line and his mother and sisters with them to the court of the Scottish King Malcolm Canmore. This movement was attended with important consequences. Malcolm soon after married Edgar's eldest sister Margaret, and of this marriage came Matilda, whose union (A.D. 1100) with Henry I. of England was the first step towards the reconciliation of the Saxon and Norman races. Meanwhile Edgar and his friends were followed to Scotland by many other Saxon fugitives, who were the means of introducing into that country much of the superior civilization of the southern part of the island. A connection between Scotland and Hungary appears also to have arisen out of this flight of Edgar and the subsequent marriage of his sister with the Scottish king.

It was not intended however by Cospatric and his associates that Scotland should serve them merely as a place of refuge. A powerful confederacy was immediately formed

against the English king, in which they and their protégé Edgar were associated with the men of Northumberland and Sweyn Estridsen the king of Denmark. The united forces of these several powers stormed the castle of York on the 22nd of October, 1069, and put the Norman garrison to the sword; on which, according to some authorities, Edgar Atheling was a second time actually proclaimed king. But the approach of William soon compelled him to fly for his life, and he again took refuge in Scotland. Here he appears to have remained inactive till the year 1073, when he was again induced to engage in a scheme for annoying the English king at the instigation of Philip king of France, who invited him to come to that country, promising to give him some place of strength from which he might attack either England or Normandy. Edgar on this set out with a few ships; but he was wrecked in a storm on the coast of Northumberland, from which he with difficulty made his escape for the third time to Scotland, in a state of almost complete destitution. He was now advised by his brother-in-law Malcolm to make his peace with William; and that king having received his overtures favourably, he proceeded to England, where William gave him an apartment in his palace, and a daily allowance of a pound of silver for his support. In this state of dependence he remained for some years; but at length he seems to have gone over to Normandy, where, after the death of the Conqueror, his son Duke Robert made the Saxon prince a grant of some lands. The grant, however, for some reason which does not appear, was soon resumed, and the Atheling was compelled, for the fourth time, to betake himself to Scotland in 1091. In the end of the same year it is related that a peace was effected by the good offices of Edgar and Duke Robert between Malcolm and William Rufus, when their armies were met and ready to engage, in *Lothene* or *Loidis* (that is, most probably, the part of Scotland now called Lothian, then considered as a part of England). On this occasion Edgar was reconciled to the English king, and he again took up his abode at the court of William. In January, 1092, however, Duke Robert and he suddenly withdrew together to Normandy; and not long after Malcolm and William were again at war. The Scottish king fell in a conflict with an English force commanded by Robert de Moubay near Alnwick on the 13th November, 1093; his eldest son Edward was slain with him; and his Queen, the sister of Edgar Atheling, died three days after, having only survived to learn the loss of her husband and her son. Immediately after this we read of Edgar securing the children of his deceased brother-in-law and sister from the attempts of their uncle, Donald Bane, who had usurped the Scottish throne, and conveying them to a place of safety in England, a circumstance that would apparently imply that he had himself returned to that country from Normandy, and once more secured the protection of the English king. Here he seems to have remained during the remainder of the reign of Rufus. In 1097 he is recorded to have raised, with the approbation and aid of that king, a body of troops, and marched with them into Scotland, where he drove Donald Bane from the throne, and placed on it his nephew Edgar, the son of Malcolm. One account makes him to have immediately after this joined his old friend Robert duke of Normandy in the Holy Land with a force of 20,000 men, collected from all parts of England and Scotland; but this part of his story is neither well supported, nor very probable in itself. It is certain however that on the breaking out of the war between Henry I. and his brother Robert, a few years after the accession of the former to the English throne, Edgar was found on the side of Robert, although the recent marriage of his sister to Henry might be supposed to have attached him to the interests of that prince. He was one of the prisoners taken by Henry at the decisive battle of Tinchebrai on the 27th of September, 1106, in which Robert finally lost his dukedom and his liberty. The victor however treated the Saxon prince with more lenity or contempt than he showed in his treatment of his own brother. Soon after being brought to England, Edgar was restored to liberty; and some accounts state that he subsequently visited Palestine. But the remainder of his history is very obscure. Malmsbury only informs us, without specifying any date of his decease, that he died in England after having lived to a good old age, without ever having been married or having had any issue, leaving behind him the character of a weak but inoffensive and well-intentioned man. He has certainly the distinction of being about the most insipid hero of any-

thing like romance on record, and the narrative of his life may be quoted as a curious instance of the interest that will be sometimes awakened by the position and fortunes of an individual however personally insignificant.

EDGE. [ARRIS.]

EDGEHILL. [CHARLES I. OF ENGLAND.]

EDGEWORTH, RICHARD LOVELL, an ingenious mechanical philosopher, but better known as the father and literary associate of Maria Edgeworth, was born at Bath, in 1744. He was descended from an English family, which had settled in Ireland in the reign of queen Elizabeth, and resided at Edgeworthstown, in the county of Longford, where his boyhood was chiefly spent. A hasty marriage, contracted at the age of nineteen, while he was an under-graduate of Corpus College, Oxford, cut short his studies at that university, and led him to return home; but in 1766, intending to be called to the bar, he came to England, and took a house at Hare Hatch, between Maidenhead and Reading. During his visits to London to keep his terms, he became acquainted with Sir Francis Delaval and other gay and sporting men of the day, concerning whom a number of anecdotes are preserved in Mr. Edgeworth's autobiography. In that society he was distinguished by a high flow of spirits, and an uncommon share of that activity and ingenuity which adapts itself to the lighter pursuits of social amusement as readily as to higher and more serious purposes. At home he was chiefly occupied in prosecuting a variety of ingenious mechanical contrivances, among which we may mention the first erection of a telegraph in England, originating in a bet relative to the speedy transmission of racing news from Newmarket to London. During this residence in Berkshire he became acquainted with the eccentric philanthropist Thomas Day, with whom he lived in the closest friendship. His mechanical pursuits introduced him to Dr. Darwin, and subsequently to Watt and Bolton, Wedgwood, and other eminent scientific men. In 1769, by his father's death, he came into possession of a handsome fortune and gave up the intention of following the law as a profession.

Mr. Edgeworth returned to Ireland in 1782, 'with the firm determination,' he says, 'to dedicate the remainder of his life to the improvement of his estate and the education of his children, and with the sincere hope of contributing to the amelioration of the inhabitants of the country from which he drew his subsistence.' To this resolution, during the remaining thirty-five years of his life, he steadily adhered; devoting his best powers to the useful performance of his duties as a magistrate, a landlord, and a father. He was an active and influential member of the Irish Volunteers, and continued, after their dissolution, and through life, a steady advocate of reform in parliament. He was a member of the last Irish house of commons, and spoke and voted in opposition to the Union. Retaining the ardent spirit of his youth, he engaged in a variety of projects for reclaiming bogs, establishing a system of telegraphic communication, experiments on the construction of carriages, moveable railroads, &c. In the cultivation of his estate and in the management of his tenantry he was skilful, prudent, and humane and in his 'Memoirs' (vol. 2, chap. ii.) may be found an instructive account of the difficulties to be met and the patience requisite in effecting any real improvement in the condition of the Irish peasantry. His judicious and discriminating kindness and his acknowledged impartiality as a magistrate (a rare quality then in Ireland) gained their sincere affection, inasmuch that in the insurrection of 1798, though he was absent and assisting with his corps of yeomanry in the defence of Longford, his house at Edgeworthstown was visited by the rebels, and yet was preserved uninjured and untouched. He died June 13, 1817, after an old age of unusual activity and power of enjoyment.

Mr. Edgeworth married four wives, by all of whom he had children. The number of his children, and their unusual difference in age, a difference amounting, between the eldest and youngest, to more than forty years, gave him unusual opportunities of trying experiments in education, and watching their results. His family were brought up almost entirely at home, and with an unusual degree of parental care. The results of his experience were made public in 1798, in 'Practical Education,' a treatise written principally by Miss Edgeworth, but partly by himself; and based on his theory of education, his

observation, and the experience of his own house. It attracted much attention, and no doubt had considerable effect, in conjunction with the writings of Hannah More and Mrs. Barbauld, in bringing about that improvement in domestic education which has taken place within the last 40 years. Many persons may dissent from some of its views, or some of its principles; but as a repository of valuable suggestions and ingenious expedients, as to children, their habits, tempers, and ways of influencing them, it will always be worthy the attention of parents.

Mr. Edgeworth said he was not a ready writer; and it may have been partly owing to this that he preferred engaging in a sort of literary partnership with his daughter to embarking alone in any work of length. 'Practical Education' and 'Irish Bulls' were avowedly written by them in common; and Miss E. in her father's 'Memoirs' (vol. ii. chap. xvi.) has recorded in warm terms of filial affection her obligations to him in her other works. It was his habit to revise and correct all her productions carefully, and to sanction their issue to the world by his paternal *imprimatur*; a form which the world thought might as well be omitted. But the sterling merits of Mr. Edgeworth's character were amply sufficient to atone for some egotism and vanity.

The following works are published in his name:—'Rational Primer'; 'Poetry Explained'; 'Readings in Poetry'; 'Professional Education'; 'Letter to Lord Charlemont on the Telegraph'; 'Speeches in Parliament'; 'Essay on the Construction of Roads and Carriages.'

He also published papers in the Philosophical Transactions, Nicholson's Journal, and the Transactions of the Royal Irish Academy on various subjects, as the Telegraph, Resistance of the Air, Aerostation, Railroads, the construction of Carriages, and the description of a handsome spire which he had erected *inside* the steeple of the parish church, and then lifted into its place. (*Memoirs of R. E. Edgeworth, 1820.*)

EDICTS, EDICTA, one of the five sources of Roman law enumerated by Gaius (i. § 2). 'The magistrates of the Roman people have authority to make edicts; but the greatest weight is given to the edicts of the two prætors, the Prætor Urbanus and the Prætor Peregrinus. In the provinces the governors (præsides) have the same authority as the prætors (in the city). The authority of the curule ædiles, as to making edicts, is the same as that of the prætors, and in the provinces their powers are possessed by the quæstors.' (On the Edict. *Ædil.* see *Dig.* xxi. tit. 1; *Cod.* iv. tit. 58.)

It was the custom of the prætors on their accession to office to publish edicts, which were rules adapted to regulate the practice of their courts, similar to the Orders promulgated by the English chancellors. This power of legislating having been abused, it was enacted by the Cornelian law b.c. 67, that when a prætor, on his accession to office, had published any edict or general rule, he should be bound to keep to it during the whole year of his office. A prætor was not bound by the edicts of his predecessor: if he confirmed them, the edicts were called *Vetere et Tralatitia*; if he made new edicts, they were called *Nova*. On an occasion mentioned by Cicero (*De Offic.* iii., 20) the prætors and tribunes of the Plebs united in drawing up an edict relative to the coinage. This instance will serve as an example of the extent to which the prætors under the Republic exercised legislative power. Instead of confining themselves to rules for the regulation of the practice of the courts they gradually assumed the power of repealing written law and making new laws, on the ground of correcting the error of the written laws whenever they seemed inapplicable from generality or other defect. (See the various titles of the *Digest.* lib. xxxvii.) From the decisions of the prætors arose a large body of law, which was known by the name of *Jus Honorarium* or *Prætorium* (Papinian. *Dig.* i., tit. 1. 7.), as distinguished from the *Jus Civile*, and may, to a certain extent, be considered as corresponding to the equity of the English Court of Chancery.

Under the early emperors the magistrates published edicts, but Hadrian commissioned Salvius Julianus (A.D. 132) to make a digest of all the best decisions, which were collected in a small volume called the *Edictum Perpetuum*, and ratified by a *Senatus Consultum*. From that time the power of making edicts was taken from the magistrates, and the legislative power was vested in the emperors. (*Cod.* i., tit. 17.) [CONSTITUTIONS, ROMAN.]

EDINBURGH COUNTY, or MID-LOTHIAN, is
P. C., No. 565

bounded on the north by the Frith of Forth; on the south by the counties of Selkirk, Peebles, and Lanark; on the east by Haddington, Berwick, and Roxburgh; and on the west by Linlithgow: comprehending an area of 354 square miles, or 226,560 English statute acres. The surface is in general uneven. The most hilly district is the south-eastern part, which is traversed by the Heriot and Galla Waters. In the high ground which divides this district from that traversed by the rivers falling into the Frith of Forth, is the Sayrs Law, 1739 feet above the sea. The western continuation of this high ground forms the boundary between Edinburgh on the north, and Peebles and Lanark on the south, and perhaps attains a general elevation of 800 or 1000 feet above the sea. It is for the most part rather flat, and covered with bogs and mosses; but in some parts there are hills of considerable elevation, as, near the sources of Muirfoot Water, the Coat Law (1680 feet), and the Blackhope Scares (1850 feet). Between the origin of the North Esk and the Leith Water are several high hills, as the Cairn Hill (1800 feet), and others which belong to the Pentland Hills. Farther west only isolated hills occur, the highest of which, Leven's Seat, at the western extremity of the county, is about 1200 feet above the sea.

Of the country extending between this high ground and the Frith of Forth, only the middle district between the North Esk and Leith Water is very hilly. Here are the Pentland Hills, the highest summits of which are from 1800 to 1900 feet above the sea, but their mean elevation probably does not exceed 1000 or 1200 feet. They terminate to the south of Libberton and to the west of Laswade. The country on both sides of this district is less hilly; the heights neither attain such an elevation, as in the part just described, nor do they terminate with steep declivities, except along the banks of some of the rivers. A line drawn from Dalkeith through Libberton, Collington, and Currie to Rath marks the northern boundary of the more hilly part of the country. North of this line the country presents an undulating surface, on which a few hills rise to a moderate elevation. Such is Arthur's Seat, near Edinburgh, 822 feet above the sea, and farther west the Corstorphine Hills, which extend two miles in length and rise to 470 feet. The principal rivers are the Galla Water, which falls into the Tweed; and the South and North Esk, which unite below Dalkeith; the Water of Leith; and the Almond Water, which separates this county from that of Linlithgow. These rivers fall into the Frith of Forth.

It is said that at Dalkeith, on an average of eight years, the annual fall of rain was 22½ inches. Dr. Brewster states the mean annual temperature at Leith to be 48° 36'. At Edinburgh, which is elevated from 300 to 400 feet above the level of the sea, and situated about two miles from it, the mean annual temperature is 47° 8'. This may be taken as a near approximation to that of the more inland parts of the south of Scotland.

Part of an important mineral district, the great coal-field of Scotland, is within this county. The county also contains considerable beds of limestone and freestone. The former are principally about Dalkeith. The principal freestone quarries are at Craigleith, Hales, and Redkall. Clay soil predominates in the county, and there are few parts remarkable for natural fertility. Two-thirds of the land, however, is now under cultivation, of which from 15,000 to 18,000 acres are employed to raise wheat. There is a considerable number of large estates in the county, but on the whole property is much divided.

The county is in various ways affected by the circumstance of its containing within it the capital of the kingdom. This circumstance evidently modifies the productions and uses of the soil. To this also we owe the excellent state of the public roads in the county, the railways, and the Union canal, though this last has hitherto proved a most unprofitable speculation to the proprietors.

The population of the county has stood as follows:—

| Year. | Persons. | Families. |
|-------|----------|-----------|
| 1755 | 90,412 | |
| 1801 | 122,954 | |
| 1811 | 148,607 | |
| 1821 | 191,514 | |
| 1831 | 219,345 | 47,415 |

Mid-Lothian returns four members to parliament—one for the county of Edinburgh, two for the city, and one for the burghs of Leith, Musselburgh, &c.

EDINBURGH CITY, the chief town of Edinburghshire,
Vol. IX.—2 N

or Mid-Lothian, and the capital of Scotland, is situated in 55° 57' 20" N. lat., and 3° 10' 30" W. long., about 392 miles north from London. It stands upon a group of hills separated by deep depressions, and is at once the site and the scene of views of great beauty and grandeur. On the highest of the hills the Old Town is built; the summit of the hill forms a street upwards of a mile long, ascending in nearly a straight line from the palace of Holyrood on the east, about 120 feet above the level of the sea to the Castle, which is elevated upwards of 380 feet above the same level, and is accessible only on the eastern side, all the others being nearly perpendicular. The view from this height is singularly varied and grand; the spectator is in the midst of an amphitheatre of hills. On the east are the Calton Hill, Salisbury Craigs, and Arthur's Seat, rising 822 feet above the level of the sea; and on the west are the Pentland range, and the woody eminence of Corstorphine. Below, on the north, are the noble mansions of the New Town, the Frith of Forth, with its ports and shipping, and the counties on the opposite coasts to the Highland hills; a landscape forming a beautiful contrast with the rich open country which spreads before us on the south to the hills of Berwickshire and the borders, till at length the eye rests upon the Braid Hills.

Edinburgh is supposed to have derived its name from Edwin, a king of Northumberland in the time of the Heptarchy. Simeon of Durham mentions the town of *Edwinesburgh* as existing in the middle of the eighth century; and in the charter of foundation of the abbey of Holyrood, in the year 1128, King David I. calls it *his burgh of Edwinesburg*, whence we infer it was then a royal burgh. The historians of Edinburgh say that the first parliament held in the city was on the accession of King Alexander II.; but upwards of half a century previous, we find a 'concordia,' or agreement, entered into between the bishop of St. Andrews and the abbot of Dunfermline, *apud Castellum Puellarum* (a name long bestowed on Edinburgh Castle), in presence of the king, Prince Henry his son, and their barons (Connell *On Tithes*, App. No. 1), which we apprehend was no other than an assembly of the great council of the nation. The castle was then perhaps the chief building and place of concourse in the city; and in the reign of King Malcolm IV., Geoffrey de Maleville, of Maleville Castle, in the shire of Edinburgh, was *vicecomes de Castrum Puellarum*, meaning thereby, no doubt, sheriff of the shire, in like manner as Macbeth, the earliest sheriff in the shire of Perth, was styled sheriff of Scone. The abbey of Holyrood, however, was growing into importance. In 1177 a national council was held there on the arrival of the legate Vivian, to determine the dispute between the English and Scottish clergy; and it is not unlikely that its neighbourhood early became a royal residence.

The city appears to have remained open and defenceless till about the middle of the fifteenth century, when, on the representations of the provost and community, King James II. granted the citizens 'full license and leif to fosse, bulwark, wall, tour, turate, and other ways to strength the burgh, in quhat maner of wise or degree that beis sene maist spedeful to thaim.' The same king soon afterwards granted a charter to the city confirming to it the privilege of holding therein the antient and important court of Four Boroughs, 'sicut a temporibus retroactis tenebatur.' His successor, grateful for the interest which the citizens had shown in his behalf when he was at variance with his nobles, erected the city into a sheriffdom within itself, and presented to the incorporated trades a banner or standard, which has since been known by the name of the Blue Blanket, and is still preserved. King James IV. patronized the erection of its first printing-press; and in the succeeding reign it became the undisputed capital of the kingdom; the seat of the royal palace, of the parliament, and of the superior courts of justice.

The accession of King James VI. to the throne of England put a temporary stop to the progress of the town; but at the Union the spirit of improvement revived, and has continued to our own day.

Edinburgh is divided into three principal parts: the Old Town, the South Side, or Southern Districts, and the New Town; each of which has its own peculiar features and character. The Old Town is intersected by the street previously mentioned: on each side descend in regular lines a multitude of narrow wynds, closes, and styles, which on the south lead for the most part into the Cowgate, a confined street running along the southern base of the hill,

and one of the earliest additions to the town after the erection of the city-wall in the middle of the fifteenth century. Over this street the South Bridge, and more lately King George the Fourth's Bridge, are thrown, to connect the Old Town with the South Side or Southern Districts. These districts mostly stand upon a rising ground, which is here closely adjacent to the Old Town ridge, but neither so elevated, so limited in extent, nor so steep in its descent, as that hill. From its western side, however, there runs a hill of a different character, and thence called the High Riggs. It is separated from the Castle-hill by a spacious street called the Grass Market, and on it are built Heriot's Hospital and the neighbouring suburb of Portsburgh. On a line with the South Bridge is the North Bridge, thrown from the summit of the Old Town ridge, at the middle of the High-street, to the rising ground which forms the site of the New Town. This ground partakes much of the character of the Old Town ridge, and terminates like it in a bold rock, namely the Calton Hill; but the aspect of the houses is wholly different: for having been erected according to regular plans conceived in a spirit of improvement, the greatest regularity and beauty characterize its buildings, streets, and squares. From the earth and rubbish thrown from the foundation of the New Town buildings, the Earthen Mound was formed as a communication across the morass which lies between the Old and New Town.

Among the chief buildings of the city is the Castle, which is the most antient part of the city, and must have been of considerable importance in former times. It is now, however, a place of little strength, and derives its interest chiefly from the associations connected with it and its own formidable appearance. At no great distance from the Castle stands the Parliament House, with the courts of justice. In the first of these the parliament of Scotland met between the time of its erection in 1640 and the Union. The hall now forms the Outer House of the Court of Session, and in its immediate neighbourhood are rooms appropriated to the Inner House and to the courts of Justiciary and Exchequer. The valuable library of the faculty of advocates occupied till lately the ground-floor of the Parliament House. A considerable part still remains there; but adjacent buildings have been erected not only for it, but also for the library of the writers to the signet. The courts of the sheriff and justices of the peace are held in the county hall, an elegant building of recent erection, close by the range of building which contains the library of the writers to the signet. The antient Gothic fabric, formerly the cathedral of St. Giles, is also in this neighbourhood; from between the arches which constitute the imperial crown that rests upon its lofty tower, there is an interesting view of the city and surrounding country. On the opposite side of the street is the Royal Exchange, with the common council-room and other offices of the magistracy; and in the centre of the street, a little way down, is a radiated causeway to mark the site of the old market cross, where proclamations used to be made and offenders punished. At the foot of the High Street stands one of the oldest stone houses in Edinburgh, the house of the great Scottish reformer, John Knox; and on the front wall, to the west, is a figure in alto rilievo pointing to a radiated stone, whereon is sculptured the name of the Deity in Greek, Latin, and English. Below this is the Canongate, at the foot of which are the palace and abbey of Holyrood, whose extensive precincts constitute a sanctuary for insolvent debtors. On the summit of the Calton Hill, which rises in the immediate neighbourhood, and commands a delightful prospect of the Forth and surrounding scenery, some columns of the National Monument have been erected, and stand in solitary grandeur. Near them are the observatory and the monuments to Dugald Stewart and Playfair. On the low ground, towards the west, are the bridewell and gaol; and in the same line, at a point nearly equidistant from the palace and castle, stands the Register House, where the public records of the kingdom are preserved, and what is almost peculiar to this part of the empire, the register of all deeds conveying or charging territorial property.

The city churches are properly 13 in number, among which the most deserving of notice are St. Giles's, St. George's, St. Andrew's, St. Stephen's, and St. Mary's: but to these are to be added St. Cuthbert's or West Kirk, the Canongate Church, and various chapels belonging to the establishment. The elegant Gothic edifices, St. Paul's, St. Giles's, and St. George's chapels, belonging to the episcopal communion, are also deserving of attention, and the Roman

Catholic chapel at the head of Leith Walk. The Roman Catholics have another chapel in the town, and at the head of Bruntsfield Links, a convent of nuns, attached to which is an establishment at Milton House, in the Canongate.

Edinburgh has some noble hospitals and charitable institutions. Among these are the Royal Infirmary, erected on a rising ground in the neighbourhood of the college; Heriot's Hospital, already mentioned; Watson's Hospitals, Merchant-Maiden and Trades'-Maiden Hospitals, Orphan Hospital, and Gillespie's Hospital; Institution for the Deaf and Dumb, Asylum for the Blind, Magdalen Asylum, and Lunatic Asylum. Most of the banking-houses of Edinburgh are large edifices: such, in particular, are the Bank of Scotland, the Royal Bank, and the Commercial Bank.

The public amusements of Edinburgh are limited, and do not, generally speaking, succeed. The habits of the people are domestic; and the professional and literary, not less than the religious character which prevails, does not accord with the occupations of the theatre and assembly-rooms. Printing, shawl-making, and coach-building, are carried on with much success; but the manufactures of Edinburgh are of no great importance. The city however is well situated both for water and fuel, which might be made available for manufactures. They have been of essential consequence to the comfort of the inhabitants; and notwithstanding the variable climate, there are few, if any, diseases to which the residents of Edinburgh can be said to be peculiarly liable. The situation of the place is favourable to health and energy, and the mortality, it is believed, is small in proportion to the population. The city returns two members to parliament.

Until a comparatively recent period, Edinburgh was a place of very limited extent. The contiguous country, which has now been made to form a part of the capital, comprehends various places antiently subject to different jurisdictions, and which have as yet continued municipally disunited, except for the purpose of returning members to parliament under the recent Reform Act. Besides various districts subject only to the jurisdiction of the county sheriff, the boundaries fixed by the Reform Act include within their limits—

1. The Royalty of Edinburgh. 2. The Burgh of Regality of Canongate. 3. The Burgh of Barony of Portsburgh, Easter and Wester. 4. Calton.

The existence of Edinburgh as a king's burgh may be traced to the reign of David I., and before the middle of the twelfth century. At a very early period it was one of those burghs royal whose magistrates constituted the Court of Four Burghs; and by a charter dated in 1452 king James II. conferred on it the privilege of being exclusively the seat of that court: the other three burghs were Stirling, Linlithgow, and Lanark. In 1482 the valuable right of sheriffship within the bounds of the burgh was given by James III., and this jurisdiction was confirmed by succeeding monarchs. A general charter of confirmation was granted to Edinburgh by James VI. in 1603; and another charter, known under the name of *Novo Damus*, was the gift of Charles I. in 1636. These charters specify Leith and Newhaven as belonging to the burgh, and detail the markets, tolls, and customs, which constitute 'a part of the common good,' for the protection of which a comprehensive jurisdiction is conferred. Other grants and charters were afterwards obtained at different times from the crown, prior to the Union in 1707; but not any of these created any substantial change in the political or municipal constitution of the burgh. Since the Union, and more particularly within the last fifty years, various acts of parliament have been passed for extending the bounds of the royalty, and for purposes of police. By a charter of George III. in 1794, the provost, who by previous charters was sheriff and coroner, was constituted lord-lieutenant of the county of the city.

Previous to the late Scotch Burgh Reform Act, Edinburgh was governed by a close corporation, the members of which constantly re-elected each other; but by that act (3 and 4 Will. IV., c. 76), the right of election to corporate offices was declared to be in all those persons who are entitled to vote for members of parliament.

The government of the city of Edinburgh is vested in the magistracy and town council. The magistracy consists of a lord provost, a dean of guild, a treasurer, and four bailies, each of whom is *ex officio* a member of the council. The council consists of seventeen merchants, six deacons, and two trades' councillors, in all twenty-five; the six deacons are selected from among fourteen who are elected by

the citizens; the remaining eight, who are called extra deacons, are not called councillors, but have a vote in the council in all cases where the money in question exceeds 1*l.* 13*s.* 4*d.* (20*l.* Scots). For the purposes of the election the city is divided into wards or districts. One-third part of the councillors go out of office every year, but are eligible for re-election. The provost, bailies, treasurer, and other office-bearers, are elected by the councillors. The provost's term of office is three years, and he is eligible for immediate re-election. The other office-bearers go out at the expiration of one year, and cannot be re-elected until each shall have been out of his particular office one year; but this does not prevent their being kept in the council from year to year by their being elected to fill the different offices in succession.

None but burgesses or freemen of the burgh are entitled to carry on trade or manufactures within the bounds. There are eight incorporated crafts within the burgh, all enjoying exclusive privileges and possessed of funds which are appropriated to the support of decayed members or the widows of such as are deceased. These crafts are hammermen, tailors, wrights, bakers, shoemakers, weavers, fleshers, and barbers: the number of burgesses has not been ascertained, but is estimated to amount to about 400. The magistrates grant temporary licenses to trade to persons not freemen, and charge for such licenses from 5*s.* to 10*s.* per annum.

From an early period the property of the burgh has been administered very improvidently. In 1658 the debt of the city was stated to amount to 54,761*l.* sterling, and in 1692 had increased to 64,250*l.* In 1819, when the affairs of Edinburgh were examined by a Committee of the House of Commons, the actual debts of the city were stated to amount to 497,101*l.* including 264,258*l.* incurred on account of the Leith docks; and in 1833 a statement was drawn up under the authority of the magistrates and council which gave the amount of ordinary debts and obligations of the city at 425,194*l.*, in which amount the engagements on account of the Leith docks are not included. The revenue of the city, as stated under the same authority, amounted then to 27,524*l.*, and its annual current expenditure to upwards of 33,000*l.* Under these circumstances, the city was declared insolvent, and an act was passed in August, 1833, conveying its whole properties and revenues to trustees for the general benefit, whereby they were preserved from the legal attacks of individual creditors. Some circumstances connected with the accounts of the city have been published, which have subjected the members of its government to much censure. Among these circumstances, it may be stated that the late Dr. Bell having bequeathed a considerable fund for the purposes of education, a sum of 10,000*l.* 3 per cent. stock was placed in the hands of the magistrates and council in trust to apply the dividends to the support of a school or schools in Edinburgh on the principles of the Madras system. Being pressed by a clamorous creditor for the payment of his claim, this stock was sold, and the greater part of the proceeds appropriated 'to prevent a blow-up in the city's affairs, and to enable them to continue the existing system a little longer.'

The population of the city of Edinburgh and the suburbs, which together constitute the capital, were at each census of the present century as follows:—

| | 1801. | 1811. | 1821. | 1831. |
|---|--------|---------|---------|---------|
| Parishes in the city | 20,658 | 22,578 | 29,850 | 40,315 |
| the suburbs, including Canongate and St. Cuthbert's | 45,896 | 59,306 | 82,385 | 95,379 |
| North and South Leith | 15,273 | 20,263 | 26,000 | 25,955 |
| | 81,814 | 102,147 | 138,235 | 161,649 |

The population of the Shires of Edinburgh at these four periods, including the capital, was 123,954 148,607 191,514 219,945

The further particulars obtained at the census of 1831 exhibit the following results:—

| | Edinburgh city. | Remainder of county. | Total. |
|--|-----------------|----------------------|---------|
| Houses inhabited | 19,179 | 9,565 | 19,744 |
| " building | 95 | 55 | 1,180 |
| " uninhabited | 589 | 87 | 1,149 |
| Families | 36,116 | 19,999 | 47,445 |
| " employed chiefly in agriculture | 563 | 3,976 | 3,639 |
| " " in trade, manufactures, &c. | 17,190 | 3,964 | 21,054 |
| " all not comprised in the two preceding classes | 17,363 | 5,360 | 22,722 |
| Males | 72,999 | 37,504 | 99,808 |
| Females | 69,610 | 39,938 | 119,542 |
| Males 20 years of age and upwards | 66,667 | 13,415 | 80,082 |
| Female servants | 12,429 | 3,045 | 15,474 |

Edinburgh contains the supreme courts of justice for

Scotland, and is the residence of the principal practitioners of the legal profession; it is also the chief school of medicine and other sciences in Scotland. In the strict sense of the word, only a small part of the population, as already observed, can be said to be engaged in manufactures; the number of males 20 years of age stated to be so engaged in 1831 was 792; a great part of these were employed in making shawls, and the rest in weaving hair-cloth and silk, net-weaving, lace-making, and other small wares. The trade of Edinburgh is carried on through its port, Leith, under which head it will be described. [LEITH.] The amount of postage collected in Edinburgh during the last five years was as follows:—

| | | |
|------|-----|---------|
| 1832 | . . | £42,759 |
| 1833 | . . | 41,864 |
| 1834 | . . | 41,680 |
| 1835 | . . | 41,959 |
| 1836 | . . | 43,520 |

The University of Edinburgh consists of the College of King James, founded by James VI. of Scotland, by a charter dated 24th April, 1582. By this charter, which still forms the only constitution of the university, the provost, bailies, and town councillors of Edinburgh, and their successors in office, were invested with the sole power both of electing the professors and of dismissing them. In virtue of this authorization, indeed, the town council, or corporation of the burgh, has ever since assumed nearly the entire direction and control of the university—electing the professors, founding new chairs, managing the funds, and even regulating the class fees and the discipline of the institution. The *Senatus Academicus*, or body of professors, if such a body has any legal existence (for no senate or other academical court or council is constituted by the charter), is understood not to have the right of interfering in any of these matters, although it may sometimes have passed regulations of discipline which the town council has not thought proper to disturb. Indeed the supremacy of the town council, even in regard to making regulations as to the course of study for degrees, when it was a few years ago resisted by the professors, was affirmed in the most ample terms by a judgment of the Court of Session. Some years ago the clergy of the city put forward their claim to a voice in the election of professors, on the ground of a direction in the charter that the right of appointment given to the town council should be exercised *cum avisamento ministrorum*. The claim was keenly agitated in pamphlets and in the church courts, and some steps were taken to enforce it; but on application being made to the Court of Session in the case of a particular election, the court refused to grant an interdict, and the question was dropped. The only interference with their sole right of control that has been submitted to by the town council are the following. In modern times, about eight or nine new professorships have been founded by the crown, of which it has retained the patronage; but against the exercise of this power a protest is regularly taken by the town council that it shall not hurt or prejudice their rights. In the case of a few other chairs there has always been an interference with the nomination of the professor on the part of certain public bodies. For the most part this has been grounded on the contribution by the said bodies of part of the professor's salary; but in one instance at least no such reason for the practice can, we believe, be alleged, in that, namely, of the professorship of Humanity, or Latin, which is besides one of the oldest chairs. The professor of Humanity is thus elected according to the late Report of the Commissioners appointed by the crown for inquiring into the state of the Universities and Colleges of Scotland: 'The Lords of Session name two delegates, the town council name one, the Faculty of Advocates one, and the Society of Writers to the Signet one. They meet together and appoint the professor. They then lay their minute of election before the town council, who issue a commission, in their own name, proceeding on the narrative of the election of the delegates, and binding the professor to obey laws and regulations, the same as if he were appointed solely by themselves,' (p. 117). Many visitations of the university have also taken place under the authority of the crown, of parliament, and even of the general assembly; but what legal force may belong to any regulations that may have been laid down by the visitors does not clearly appear. In this non-recognition of any authority, or at least of any independent and supreme authority, as belonging to either the entire body of the pro-

fessors and students, or even to the *Senatus Academicus*, or council of the professors only, the University of Edinburgh differs from all the other Scottish colleges. 'The *Senatus Academicus*,' says the Report of the Commissioners, 'acknowledge no authority but their own for instituting new faculties, and for fixing the privileges and immunities belonging to them.' But what privileges they can confer, or ever have conferred, is not stated. The *Senatus* does not appear to have ever been recognised by the town council as anything more than a mere meeting of the professors. Until of late years it is not recollected that there ever had been a vote in it (*Report*, p. 115), and it would still probably be impossible to quote any resolution it has passed which has been operative in any quarter except where it was voluntarily acquiesced in.

One of the consequences of this non-incorporation of the university in any form has been, that it is without certain public officers which are found in all the other universities. There is no mention in the charter of a Chancellor; and although in early times the name was occasionally taken by the provost of the city, this must be regarded as having been quite an unauthorized assumption, and the office does not now exist at all, and has not existed for a long period. The case with regard to the office of Rector is nearly the same. 'This important office,' say the Commissioners, 'has been much less efficient in Edinburgh than in the other universities.*** The existence of the office itself has often been, apparently at least, suspended.' They afterwards state that it was held by several persons, though with frequent intervals, during the greater part of a century from the foundation of the university; but from the beginning of the eighteenth century, they conclude, 'till within these few years the office was never heard of in the university, much less known as an office attended with the performance of any duties. It is accordingly explicitly asserted, that no chancellor or vice-chancellor, rector, or dean of faculty, exercises any authority or jurisdiction over the principal, professors, or students in the University of Edinburgh.'—(pp. 114, 115.)

The charter of king James in fact merely gave power to the town council to build houses for professors of certain departments of science and learning, and to engage persons to act as such. Proceeding upon this authority, the provost and magistrates of Edinburgh on the 14th September, 1583, entered into a contract with Mr. Robert Pollock, one of the professors or regents of the university of St. Andrews, to exercise the same office of regent in the new seminary. He was engaged at first only for a year, and at a salary of no more than 40*l.* Scots, that is, between 3*l.* and 4*l.* sterling, in addition to the fees to be paid by the students. In 1584 the king executed a new deed in relation to the university, conferring certain property for its support on the magistrates and council. The following year the council constituted Pollock Principal master of the college. At this time, or soon after, there are said to have been four other regents engaged in teaching. A second charter, ratifying what had been already done, was granted by the king in 1612; and in 1621 an act of the Scottish parliament was passed, confirming certain grants of property which had been made to the town of Edinburgh for the support of the institution. The preamble states, that the college, which is described as 'for profession of Theology, Philosophy, and Humanity,' had greatly flourished during the thirty-five years it had been in existence. It was by this charter that the name of King James's College was conferred upon it.

The system of teaching originally pursued was the same as at the other Scotch universities. The Principal was regarded as Professor of Divinity, and his prelections were confined to that department. But each of the other four regents carried his students, during the four years they remained under his care, over the entire curriculum of literature and philosophy. In 1620 a second Professor of Theology was appointed, and then the Principal ceased to teach that science, though down to the year 1765 he used to deliver one discourse in each session. Since the cessation of this practice, in the time of Dr. Robertson the historian, the office has been a mere sinecure. A commission of visitation, appointed by parliament in 1690, directed that each professor should for the future be confined to one particular department; but this important alteration was not carried into effect till about the year 1708. The old practice was continued in Mareschal College, Aberdeen, down to the year 1753, and in King's College until 1800.

Minute details on the subject of the property belonging

to the university are given in the Report of the Commissioners, pp. 103-113. It is derived from a variety of sources, but is altogether of inconsiderable amount. The management of it is wholly in the hands of the town-council, which is in the habit of supplying the difference betwixt the income and expenditure of the college from the funds of the city. In 1825 the total college revenue amounted only to 888*l.*, while the expenditure was 2223*l.* And in addition to the last-mentioned sum, there were paid to different professors by royal grants the sum of 1435*l.*; by royal grant for the support of the museum 100*l.*; to the Professor of Agriculture 50*l.*, from funds provided by the late Sir William Pulteney, the founder of the chair; and to the professor of Conveyancing 120*l.*, from the Society of Writers to the Signet. From the year 1776, also, to the year 1828 inclusive, it appears that 819*l.* had been granted by the crown for defraying the expenses of the Botanical Garden.

A bequest which is described as of large amount has been left to the administration of the Principal and professors by the will of the late General Reid, dated in 1806, for founding a professorship of music, and making additions to the library, or otherwise promoting the general interest and advantage of the university; but we are not aware that it has yet become available, the income arising from the funds having been left to the testator's daughter during her life. A valuable collection of pictures and marbles was bequeathed for the use of the university by the late Sir James Erskine, of Torry, bart.

The bursaries or exhibitions attached to the university are eighty in number, of which three are of the annual value of 100*l.* each; six of 30*l.*; ten of 20*l.*; five between 20*l.* and 15*l.*; eleven between 15*l.* and 10*l.*; forty-two between 10*l.* and 5*l.*; and three under 5*l.*

The foundation of a university library was laid about the time that the seminary was opened, by the transference to it by the town-council of a library of about 300 volumes,

chiefly theological, which had been bequeathed in 1580 'to Edinburgh and the kirk of God' by one of the citizens, Mr. Clement Little, commissary. The collection was augmented in early times by various donations, among which was one of his whole library, consisting of about 500 volumes, by the poet Drummond of Hawthornden. No catalogue of the university library has ever been printed, although one has been lately completed in manuscript. The entire number of volumes is now not much under 100,000. The annual pecuniary income of the library is stated, in the Report of the Commissioners, at about 1150*l.*, derived chiefly from fees paid on matriculation and graduation. Besides the public library, there is a theological library for the use of the students of theology, founded by Dr. George Campbell, professor of theology, about the end of the seventeenth century. It now consists of above 5000 volumes. An observatory, a museum of natural history, an anatomical museum, and a botanical garden also belong to the university.

The buildings of the university consist of a single quadrangle, which is not yet entirely completed, on a scale reduced from the original design by the late Mr. Robert Adam, although it was begun so long ago as in the year 1789. The funds were at first contributed by subscription, but at length an annual grant of 10,000*l.* was obtained from parliament. The fabric, upon which a very large amount in all has been expended, is one of considerable magnificence. It was originally designed to contain houses for the professors, as well as the library, museums, and class-rooms; but only one official house has been built, which is occupied by the principal librarian.

The progressive increase of the establishment of the university and the particulars of its present state will be most conveniently exhibited in the following table, compiled from the Report of the late commission.

| Office. | Dates of Foundation. | Patrons. | Salaries. | Class Fees. | No. of Students. |
|------------------------------------|----------------------|---|-----------|-------------|------------------|
| | | | £. s. d. | £. s. d. | |

A few observations, however, must be added in explanation of some parts of this statement.

The professorships are considered as divided into the four faculties, or classes, of arts, law, medicine, and theology; 'although,' according to the Report, 'as to some of them

it has not yet been decided to which class they should be assigned.' The professorships of Universal History and of Agriculture are particularly mentioned as in this predicament. None of these faculties, it is added, 'can be traced to any deed, act, regulation, or constitution of a faculty.'

The Principal is considered as *ex-officio* convener of the faculty of theology. The others have each a dean or convener chosen by the faculty.

There is considerable discordance among the statements given in different parts of the Report as to the dates at which the chairs were founded. The four professorships set down as being founded in 1708 were evidently the four regentships, which, along with the principalship, constituted the original establishment of the college, but the holders of which, as already mentioned, were not confined to the teaching each of a particular department till the date here given. The writer of the Report (p. 117) perplexes himself unnecessarily by overlooking this fact. A professorship of Law, it is said in one place (p. 117) was appointed so early as 1588. The present law-school of Edinburgh, however, must be considered as not older than the commencement of the last century, and the medical school as dating from the close of the century preceding. It was not, indeed, till a considerably later period that the latter began to acquire celebrity.

In the few cases in which the right of appointing the professors is shared by the town council with other parties, the mode of the interference of the latter is not uniform. The professors of Scotch Law, of Civil Law, and of Civil History are elected by the council from a list (as it is called) of two names in each case, submitted by the Faculty of Advocates; a form which, in effect, gives the appointment to the latter body. In the appointments to the chairs of Humanity, Agriculture, and Conveyancing, delegates from the different bodies meet and vote. The professor of Botany holds two commissions, one from the crown as *Regius Professor of Botany and Keeper of the Garden*, and another from the town-council, as *Professor of Medicine and Botany*. The class of Clinical Medicine is taught in rotation by certain of the medical professors, according to an arrangement among themselves.

The sums mentioned in the column of salaries include the grants from the crown and the allowances made to some of the professors for house-rent, as well as what are properly called their salaries. The salary and class fees added together give the entire average emoluments of the professorship. The calculations however are, for the most part, made on returns for the five years preceding 1826, and might possibly require to be considerably modified in order to be applicable to the present time. The professors of Divinity and Ecclesiastical History received no fees at the date of the Commissioners' Report; but they are now, we believe, paid two guineas by each student, which would give them about the sums assigned to them in the table. The salary of the professor of Public Law, who teaches no class, is in part made up of a pension of 200*l.* a year from the crown, which the present professor holds so long as he retains the office. The fees at the different classes vary from two to four guineas. The total number of students was, in 1811, 1644; in 1821, 2224; and in 1825, 2236.

For 50 years preceding 1826 the total number of graduates in arts was only 168. During the same period 100 degrees of D.D. were conferred; and 56 of LL.D. The number of medical degrees was 18 in 1776; 32 in 1786; 31 in 1796; 37 in 1806; 76 in 1816; and 118 in 1826. Yet it is stated that the number of medical students was 764 in 1806, and only 896 in 1826.

There is only one regular university session, or term, in the year, beginning on the last Wednesday of October, and ending the last day of April. Some of the classes, however, are not taught for the whole of this time. Of late years a few of the classes, principally of the medical faculty, have also been taught during a summer session, beginning with the 1st of May, and ending with the 31st of July. Each class meets only for an hour at a time; but some of them meet twice in the day; and some of the professors have two or three classes.

No academical dress is worn by the students; no attendance upon divine service is enforced; and scarcely any discipline can be said to be exercised beyond the walls of the class-room. The students are examined in several of the classes; but there is no public examination of any kind in the university.

Schools.—The oldest of the Edinburgh schools is the High School, originally instituted in 1519, and re-erected, upon having fallen into decay, in 1577; it now consists of a rector and four other Greek and Latin masters, a teacher of writing, a teacher of arithmetic and mathematics, and a teacher of

French. The Edinburgh Academy, also principally for instruction in the classics, was founded in 1824, and consists of a rector and four other classical masters, with teachers of English, French, mathematics, and writing. Among the other educational establishments are the Hill-street Institution, opened in 1832, and furnished with teachers of the classics, English, elocution, writing, geography, history, natural history, mathematics, arithmetic, French, German, Italian, and drawing; the Circus Place school, having a rector and five other masters; the Southern Academy, instituted in 1829; the Ladies' Institution for the Southern districts, founded in 1833; the Scottish Institution for the Education of Ladies, founded in 1834; the School of Arts or Mechanics' Institute; Dr. Bell's School, attended by about 400 children; the schools of the Lancasterian School Society, in which there are about 600 boys and girls; and the well-known school, called the Sessional School, so ably conducted by Sheriff Wood.

EDINGTONITE, a rare crystalline mineral, which occurs in the cavities of Thomsonite, near Dumbarton; the crystals are small and distinct, greyish white, translucent, and have a square prism as their primary form. Cleavage parallel to the lateral planes; fracture uneven; hardness 4.0, 4.5; sp. gr. 2.7; lustre vitreous. According to Turner, it contains silica 36.09; alumina 27.69; lime 12.68; water 13.32; and probably 10 to 11 per cent. of some alkali.

EDMUND I., king of the Anglo-Saxons, was the son of King Edward the Elder, by his third wife Edgiva. He appears to have been born in 923, or about two years before his father's death. He succeeded his half-brother Athelstane, 27th October, 941. Immediately after his accession the Danish people of Northumbria rose in revolt under the same Anlaf (as the name is commonly given, but it should probably be Aulaf) or Olave, who had been defeated by Athelstane some years before in the great battle of Brunanburgh, and forced to flee to Ireland. After the war had lasted about a year, an accommodation was brought about by the Archbishops Odo and Wolstan, by which it was arranged that all the territory to the north of Watling-street should be given up to Olave. These terms prove that Edmund had by no means the best of the contest. Fortunately for him, however, the Danish earl died the next year; and Edmund, by a prompt and vigorous use of the opportunity, was successful in recovering all that he had lost. In 945 he also succeeded in reducing the hitherto independent state of Cumbria (including the moities, Cumberland and Westmoreland), which, after cruelly putting out the eyes of the two sons of the king, Dunmail, he made over to Malcolm I. of Scotland, to be held by him as the vassal of the English crown. The reign of Edmund, who was distinguished not only for his personal courage, but by his taste for elegance and splendour, on which account he received the surname of the Magnificent, was terminated 26th May, 946, by a death-blow which he received from an outlaw of the name of Liof, who had the audacity to present himself at the royal table, as the king was celebrating the feast of St. Augustine at Pucklekirk, in Gloucestershire: Edmund, on his refusal to leave the room, rose himself to assist in expelling him, when the ruffian, with a dagger which he had concealed under his clothes, stabbed him to the heart. King Edmund I. left, by his wife Elfiva, two sons, Edwy and Edgar, who eventually both sat on the throne; but as they were mere children at the time of their father's decease, they were set aside for the present, and his immediate successor was his brother Edred.

EDMUND II., king of the Anglo-Saxons, surnamed Ironside, either from his great strength, or the armour which he wore, was the son of king Ethelred II., and was born A.D. 989. According to the account that has commonly been received, his mother was Elfiva, or Ethelgiva, the daughter of earl Thored, or Toreth, who was Ethelred's first wife. Other authorities, however, assert that the mother of Edmund, and also of several of his brothers, was a foreign lady, who was only Ethelred's concubine. On the whole, the point of his legitimacy must be considered doubtful. Among modern historians, Lingard has set him down as the eldest son of Ethelred by his first wife, without intimating that any other account has been given; Turner describes him in one place as illegitimately born, in another, as the son of Ethelred by an earl's daughter whom he had married. (*Hist. Ang. Sax.*, ii, 314 and 323, 3rd edit.)

Edmund appears, in the history of the latter years of his

father's calamitous reign, as the chief champion of the English cause against Canute and his Danes, who had, by this time, nearly overrun the kingdom. On the death of Ethelred in 1016, Edmund was proclaimed king by the burgesses of London, and soon after, at least all the kingdom of Wessex, the hereditary dominion of his family, and which was now considered as comprehending the whole territory to the south of the Thames, appears to have submitted to his authority. He had the year before, by a marriage with Elgiva, the widow of Sigefarth, a thane of Danish descent, who had been put to death by Ethelred, made himself master, in defiance of the despised and dying king, of estates of great extent; and the power he thus acquired is supposed to have materially assisted him in securing the throne.

The short reign of Edmund was nearly all spent in a continuation of the sanguinary struggle in which he had already so greatly distinguished himself. His exploits are dwelt upon by the old national chronicles with fond amplification, but it is not very easy to separate what is of historical value in their narratives from the romantic decorations. Immediately on Edmund's accession, the Danish forces appear to have besieged London. The English king remained in the capital till it was considered secure; after which we find him engaging Canute, first at Pen, in Dorsetshire (or, according to another account, near Gillingham, in Somersetshire); and then at a place called Secorstan, which is supposed to be the spot still marked by a stone at the meeting of the four counties of Oxford, Gloucester, Worcester, and Warwick. In both these fights Edmund appears to have been victorious; that of Secorstan lasted two days. A third engagement took place at Brentford, the issue of which is disputed. Soon after the two armies met again at Ottenford, or Otford, in Kent, when the Danes were defeated with great slaughter. Finally, however, Edmund sustained a decisive discomfiture at the great battle of 'Assandun,' supposed to be Assington, in Essex. After this, according to one account, which, although it has been generally discredited by modern historians, is not without some features of probability, Canute and Edmund agreed to decide their quarrel by single combat, and the encounter accordingly took place on an islet called Alney, or Olney, in the Severn, which some place near Deerhurst, others near Gloucester, between Overbridge and Maysemore. The result was that Canute was obliged to yield and sue for his life. Whether the single combat took place or not, it is certain that an arrangement between the parties was now made, by which Mercia and Northumbria were made over to Canute; while Edmund was allowed to retain possession of the rest of the kingdom, with the nominal sovereignty of the whole. It is also said to have been stipulated that when either should die the other should be his successor. Edmund died a few weeks after this pacification, having worn the crown only about seven months; and although there is considerable variation and obscurity in the accounts of his death, there are strong reasons for believing that he was made away with by the contrivance of Canute. The northern historians state this in distinct terms. Canute immediately mounted the vacant throne A. D. 1016. Edmund Ironside left by his wife, Alghitha, two sons, Edward, called the Outlaw, and another, whom some call Edmund, others Edwin, and of whom it is not known whether he was older or younger than Edward. [See EDGAR ATHELING.]

EDOLIUS. [LANIADÆ.]

EDQM. [IDUMÆA.]

EDRED, king of the Anglo-Saxons, was the youngest of the sons of Edward the Elder, his mother being Edgiva, the second (or, according to some, the third) wife of that king. [EDWARD THE ELDER.] When the throne became vacant, in 946, by the death of his elder brother, Edmund I., Edred was recognized as his successor, Edwy and Edgar, the two sons of Edmund, being considered to be excluded for the present by their extreme youth. Edred was in a bad state of health when he came to the throne, and he does not seem ever to have recovered. Yet he is recorded to have, soon after his accession, repressed in person an insurrection of the turbulent Danish population of Northumberland; and he appears to have reduced that province to greater quiet and subjection than any of his predecessors. In these military operations, as well as in the management of civil affairs, he was mainly directed by the counsels of his chancellor Turketul, who had served in the

same capacity under the two preceding kings, Athelstane and Edmund. Another distinguished character of this reign was the celebrated Dunstan, who owed his first rise at court to the patronage of Turketul, and acquired under Edred that extraordinary power in the state which he preserved during several succeeding reigns. [DUNSTAN.] Edred died, after a reign of between nine and ten years, on the 23rd of November (St. Clement's Day), A. D. 956, and was succeeded by his nephew Edwy, the eldest of the two sons of his predecessor king Edmund.

EDRIOPHTHALMA (Leach), a legion of crustaceous animals with sessile eyes, which are generally compound, but sometimes simple, situated on the sides of the head. The mandibles are often furnished with a palp, and the head is almost always distinct from the body.

Desmarest makes the *Edriophthalma* comprehend the *Amphipoda* of Latreille, which, the former observes, Leach has not admitted, and which includes the two first sections of his legion of *Malacostraca Edriophthalma*, and corresponds to the genus *Gammarus* of Fabricius.

The *Amphipoda* are characterised as having a head distinct from the trunk, and formed of a single piece; mandibles provided with a palp; jaws to the number of three pairs, the external pair of which represent a lip with two palps or two small feet united near its origin; a body laterally compressed, and divided into seven segments; fourteen feet, of which the anterior are often terminated by a claw with a single finger; vesiculous *branchiæ* situated at the internal base of the feet, with the exception of that of the anterior pair; tail composed of from six to seven articulations, and bearing underneath five pairs of false feet, in form of filaments, with two very moveable branches, and thus divided by Desmarest:—

The first section consists of those species whose antennæ are inserted one on each side of the front; whose tail is terminated by styliform filaments; and whose head is large and vertical. Example, *Phronima*, Latr., Leach, Lam., &c. &c. *Cancer*, Herbst, Forak.

The second (not admitted by Leach) comprises those with four antennæ; two flattened leaflets serving for fins, placed at the end of the tail, in place of the styles; and the head large and vertical. Example, *Hyperia*, Latr.

The third includes those which have four antennæ; the tail terminated by styliform filaments; the head moderately large and not vertical, and contains six divisions, some of which are subdivided. *Talitrus*, Latr.; *Astyris*, Leach; *Dexamine*, Leach; *Melita*, Leach; *Gammarus*, Fabr.; *Podocerus*, Leach; *Corophium*, Latr.; *Cerapus*, Say, may be taken as examples of some of the forms of these divisions and subdivisions.

The other orders arranged by Desmarest under the *Edriophthalma* are the *Læmodipoda*, Latr., and the *Isopoda*, Latr.

Mr. Milne Edwards makes the *Edriophthalmians* consist of the same orders, placing them as a legion of the subclass of *maxillated crustaceans*, next to the legion of *Podophthalmians*.

EDRISI, with his complete name Abu-Abdallah Mohammed ben Mohammed ben Abdallah ben Edris, a well known Arabian writer on Geography, who flourished about the middle of the sixth century of the Mohammedan æra. Of the circumstances of his life little is known. He was a descendant of the family of the Edrisides, who for upwards of a century possessed the sovereignty over the Mohammedan provinces of Northern Africa. When, in A. D. 919, the Edriside dynasty in Africa was overthrown by Mahedi Abdallah, the survivors of the family went to Sicily; and there our Edrisi seems to have been born. The geographical treatise, which has made his name celebrated, was written at the command of Roger II. king of Sicily, whom he frequently mentions in the body of the work; he informs us in the preface that he completed it in the year 548 of the Hegira, A. D. 1153-4; and that it was intended to illustrate a silver terrestrial globe, 450 Greek pounds in weight, which King Roger had caused to be made. The time at which he wrote it is further ascertained from an incidental allusion to the fact of the town of Jerusalem being then in the possession of the Christians, which occurs in the work, and to the capture of Tripolis and Bona by Roger, which events happened in the years 540 and 548 of the Hegira (1145-6 and 1153-4 of our æra). The work itself also affords internal evidence of its having been written by a person who had visited Spain and Italy. Gabriel Sienita and Johannes Heoronita, who, in

1619, published a Latin translation of an abridgment of Edrisi's work, were induced by an erroneous reading of the only manuscript which they had, in a passage where Edrisi speaks of the Nile dividing the country adjoining it into two halves (*ardawi* 'our country' instead of *ardihā* 'its country,' the true reading), to suppose him a native of Nubia; and this mistake gave occasion to the designation of *Geographus Nubiensis*, under which Edrisi, of whose real name the translators were ignorant, soon became universally known. His work bears the title *Nuzhat al-mushitāk fi ikhtirāk al-āfāk*, i.e. 'Amusement of the curious in the exploring of countries.' Besides the abridged translation above-mentioned, we now possess the first volume of a French version of what seems to be the complete original work, by M. Amédée Jaubert, made from two Arabic manuscripts, the one found in the royal library at Paris, the other (which is accompanied with maps) recently procured in Egypt by M. Asselin, and now likewise belonging to the Bibliothèque du Roi. Two other manuscripts of the original work of Edrisi are preserved in the Bodleian library at Oxford (Cod. Graves, No. 3837, and Cod. Pocock, 375), an edition and English translation of which, by the Rev. G. C. Renouard, was some years ago announced as preparing for the press under the auspices of the London Oriental Translation Committee. The globe which this treatise was intended to illustrate is entirely lost; but a planisphere, which is inserted in one of the Bodleian manuscripts, may be seen engraved in Vincent's 'Periplus of the Erythrean Sea,' who observes (p. 568) that 'it is evidently founded upon the error of Ptolemy, which carries the coast of Africa round to the east, and forms a southern continent totally excluding the circumnavigation into the Atlantic Ocean.' It appears, from a comparison of this planisphere with the maps of Fra Mauro and the globe of Martin Behem at Nuremberg, that for upwards of three centuries the globe of Edrisi remained the foundation upon which all subsequent representations of the earth's surface were constructed. In his descriptive treatise, Edrisi, like all other Arabian geographers, distributes the portion of the globe known at his time into seven climates, each of which he subdivides into ten regions: in the account which he gives of them he follows the uniform plan of proceeding from west to east; but he does not, like Abulfeda, determine the longitude and latitude of the places which he mentions. The abridgment of the work contains little more than an itinerary of these different regions; but the original performance now translated adds many remarks on their inhabitants, natural productions, &c. Edrisi frequently refers to writers that have preceded him: among others to an Arabic translation of Ptolemy of Claudias, to Abdallah ben Khordadbeh, and Masudi.

The Arabic text of the abridgment of Edrisi's work, which is now extremely scarce, appeared under the following Latin title: *De Geographia universali, Hortulus cultissimus, mire orbis regiones, provincias, insulas, urbes, earumque dimensiones et orizonta, describens*; Romæ, in typographia Medicea, 1592, 4to. The Latin translation of the same by Gabriel Sionita and Johannes Hesronita, bears the title: *Geographia Nubiensis, id est, accuratissima totius orbis in septem climata divisi descriptio*; Paris, 1619, 4to. Of other publications relating to the work of Edrisi, we shall mention only two: *Descripcion de España de Xerif Aladris conocido por el Nubiense*; con traduccion y notas de Don J. A. Conde; Madrid, 1799, 8vo.; and J. M. Hartmann's *Commentatio de Geographia Africæ Edrisiana*; Göttingen, 1791, 4to. The first volume of M. Jaubert's French translation has appeared under the auspices of the French Geographical Society, and forms the fifth volume of the 'Recueil de Voyages et de Mémoires,' published by that society. It has also the following separate title: 'Géographie d'Edrisi, traduite de l'Arabe en Français, d'après deux MSS. de la Bibliothèque du Roi, et accompagnée de notes par M. Amédée Jaubert.' Paris, 1836, 4to.

EDUCATION is the art of preparing youth for the business of after-life. This is not offered as a complete or exact definition; it is only proposed as sufficient to indicate in a general way the subject matter here under discussion.

In every nation, even those called uncivilized, there are, and necessarily must be, certain practices and usages according to which children are instructed in those things which are to form the occupation of their future life; and every civilized nation, and, we may presume, nations also called uncivilized, have some general and collective term by which

they express this process of instruction. In the European languages derived from the Latin, and in others that have a mixture of that language, the general term is Education. It is not important at present to consider the more or less precise notions attached to this or any other equivalent word, but it is enough to observe, that, as the language of every nation possesses such a term, it is a universal truth that all nations or societies of men admit that there is something which is expressed by the comprehensive term Education, or by some equivalent term. But like all other general terms which have been long in use, this term Education comprehends within the general meaning already assigned to it a great number of particulars, which are conceived by various people in such different modes and degrees and in such varying amount as to the number of the particulars, some nations or individuals conceiving a certain set of particulars as essential to the term, others conceiving a different set of particulars as essentials, and others again conceiving the same particulars in such different ways, that two or more persons agreeing in their general description of the term might very probably, in descending into the enumeration of the particulars, find themselves completely at variance with one another. This remark possesses no claim to novelty, but it is not on that account the less important. The discrepancy just stated is apparent not only as to such general terms as education, government, right, duty, and numerous other such words, the analysis of which can only be successfully attempted by those who are accustomed to that kind of inquiry, but it is perceived and occurs even in things obvious to the senses, which consist of a number of parts, such as a machine, or any other compound thing. The general use of a machine, as a mill, for instance, is conceived in the same way by all, by the miller and by persons who know nothing more about the mill than that it is used for grinding corn. As to the particulars, there may be all imaginable discrepancies among the persons who are only acquainted with the general purpose of the mill. But discrepancies as to the mode in which the several parts of a thing and the uses of the several parts are conceived, are generally discrepancies to be referred to the *inaccuracy* of the conceptions; they are, in fact, only errors, not the same but about the same thing. The more completely a large number of persons approach to harmony in their whole views as to this machine, the nearer, as a general rule, do their several views approach to accuracy; it being of the nature of truth to produce a harmony of opinion, the truth being one and invariable; and it being of the nature of error to admit of more varieties than man has yet conceived, inasmuch as men yet unborn will conceive errors never conceived before.

The same holds good as to Education which holds good of the machine. The *general* use, the *general* object of Education is roughly and rightly conceived by all persons to whom the name is familiar; but the great contrariety which exists among mankind as to the particulars which they conceive as entering into and forming a part of this term, and as to their mode of conceiving the same, proves either that all are still wrong as to their particular conceptions of this term, or that hitherto no means have been discovered of producing a general harmony of opinion, or in other words, of approaching to the truth. And here there is no person, or class of persons, who, as in the case of the miller, is or are allowed to be an authority competent to decide between conflicting opinions.

In every society, Education (in what particular manner conceived by any particular society is of no importance to our present inquiry) is, as a *general* rule, and must necessarily be, subjected to the positive law of the society, and to that assemblage of opinions, customs, and habits which is not inappropriately called by some writers the Positive Morality of Society, or the Law of Opinion. This truth, or truism, as some may call it, is the basis of every inquiry into Education. In no country can there exist, as a *general* rule, an Education, whether it be good or bad, not subordinate to the law as above explained: for if such Education did exist, the form of that society or political system could not co-exist with it. One or the other must be changed, so that on the whole there must at last result a harmony, and not a discord. In every country then there does exist Education, either directed by and subordinate to the Positive Law and Positive Morality of that country, or there is an Education not so directed and subordinate, and consequently inconsistent with the continuance of that political system

in which it exists. But such an anomaly, if found anywhere, should not be allowed to exist; because it is inconsistent with the continued existence of the society in which it has established itself; and if such an Education does exist, and can maintain itself in a society, against the will of that society, such a society is not a sovereign and independent society, but is in a state of anarchy. Education then should be in harmony with and subordinate to the political system: it should be part of it; and whether the political system is called by the name good or bad, if that political system is to continue, Education must not be opposed to it, but must be a part of it. From this it follows that the question, What is the best Education? involves the question, What is the best political system? and that question again cannot be answered without considering what are the circumstances of the particular nation or society as to which we inquire what is the best political system. Recollecting however that the question of the best Education and of the best political system cannot be discussed apart, because, as we have shown, Education is a part of the system, still we can consider several important questions quite as fully as if the former question were out of the way.

One is, the political system being given, what ought the Education to be?

And, how far is it the business of the state to direct, control, and encourage that Education?

A man (under which term we include woman) has two distinct relations or classes of relations towards the state: one comprehends his duties as a citizen, wherein he is or ought to be wholly subordinate to the state; the other comprehends all his functions as a producer and enjoyer of wealth, wherein he has or ought to have all freedom that is not inconsistent with the proper discharge of his duties as a citizen. It is barely necessary to state this proposition in order to perceive that his Education as a citizen should be directed by the state. To suppose any other directing power, any power for instance which may educate him in principles opposed to the polity of which he is to form a part, is to suppose an inconsistency which, in discussing any question involving principles, we always intend to avoid.

His Education then as a citizen, it must be admitted, ought to be under the superintendence of the state; but *how* ought the state to exercise this superintendence?

It is not our purpose to attempt to answer this question, which involves the consideration of some of the most difficult questions in legislation. It is our object here to present the questions which it belongs to the civilization of the present and future ages to solve; to show *what* is to be done, not *how* it is to be done.

But we may answer the question so far as this: the state having the superintendence of the citizen's Education, must have the superintendence of those who direct that Education; in other words, must direct those who are to carry its purposes into effect. The body of teachers therefore must be formed by, or, at least, must be under the superintendence of the state. Unless this fundamental truth is admitted and acted on, the state cannot effectually direct or superintend the Education of its citizens.

Every branch of this inquiry into Education runs out into other branches almost innumerable, till we find that the solution of this important question involves the solution of the greater part of those questions which occupy or ought to occupy a legislative body. For this reason, as above stated, we cannot attempt to answer in its full extent, *how* the state must direct the Education of its citizens, because this question involves the consideration of how far the direction and control of the state should be a matter of positive law imperative on all, how far and with respect to what particular matters it should encourage and give facilities only, how far it should act by penalties or punishment, how far it should allow individuals or associations of individuals to teach or direct teaching according to their own will and judgment, or, to express the last question in other words, whether and to what extent the state should allow competition in Education?

To these questions, and more especially to the last, the answer is in general terms, that the *general* interest, considered in all its bearings, must determine what and how much the state must do. This answer may be said to determine nothing. It is true it determines no particular thing, but it determines the principle by which all particular measures must be tested; and it would not be difficult to select instances even from our legislation, where enactments relating

to places of education have been made with a view to particular interests only, without a reference to all the bearings of the question, and which, consequently, if tried by the test above given, would be found to be mischievous. As to the last question the answer more particularly is,—that individual competition must not be destroyed. It is possible to reconcile the two principles of state direction and control and individual competition. The state may allow no person to teach without being examined and registered: such register will show if he has been trained under the superintendence of the state or not. This fact being established, it may be left to individuals or associations of individuals to employ what teachers they please. In all the schools founded by the state, in all schools under the superintendence of the state (to which latter class belong nearly all charitable foundations, and all such foundations which are not under the superintendence of the state ought, consistently with the general principles already laid down, to be brought under that superintendence), it follows as a matter of course that none but teachers trained by the state should be appointed. The selection of the teachers, out of the whole authorized body, for any particular school of the class just described, may be safely left to the local authorities who have the immediate superintendence of these schools.

If the principle that a state ought to exercise the superintendence of the Education of its citizens as citizens be admitted, it may be asked, how far and to what branches of knowledge does this extend? To this we reply that a precise answer can only be given by the legislature of each country, and the question cannot be answered without many years of labour and perhaps without many experiments. But it follows from the principles already laid down that no citizen ought to exercise any function of government, or be intrusted with the exercise of any power delegated by the state, without having received *some* (*what*, we cannot here say) Education under the superintendence and direction of the state.

When the sovereign is one, it is clear how he will and ought to direct the Education of his people. His first object must be to maintain the stability of his own power. It is an absurdity to suppose any Education permitted in any state which shall be *inconsistent* with the existence of that state; and consequently in a monarchy, the first object is and must be the preservation of the monarchy. It is unnecessary to show that the attainment of this object is by no means inconsistent with good Education, and Education which is good when considered with reference to other objects than the conservation of the monarchy.

In a democracy [DEMOCRACY] the business of the state is also plain and easy. It is not plain *how* far and to *what* classes of subjects the superintendence of the state should extend, for that may be as difficult to determine in a democracy as in any other form of government; but it *is* plain to what objects the superintendence of the state in such a community should extend. Its objects should be to maintain in all its purity the principle of individual political equality, that the sovereign power is in all and every person, that the will of the majority is the rule which all must obey, and that the expression of opinion on all subjects, by speaking or writing, should be perfectly free. If any checks are wanting on the last head, they will always be supplied in a democracy by the positive morality of the society in a degree at least as great as is required, and certainly in a greater degree than in any other form of government.

What must the state do in a political system which is neither a monarchy nor a democracy; in a system where there are contending elements, and none has yet obtained the superiority? The answer is, it must do what it can, and that which it does, being the will of the stronger part for the time, must be considered right. But such a political system, though it may continue for a long time, is always moving (at least it is only safe when it is moving) in the direction impressed upon it by one or other of the contending powers which exist in the state. Still, so long as the struggle continues, there can be no Education in the sense which we are considering, no education which has the single, clear, and undivided object proposed to it in a monarchy and in a democracy. Such a political system then would appear to be wanting in one of the chief elements of a political system, which we have explained to be the bringing up of the citizens in such a manner as to secure the stability of that

system under which they live. In such a system as we here imagine, there being no *unity* in the object, there can be no unity of means with reference to any object; and such a system might be more properly called an aggregation of political societies, than one political society; what is implied by the word aggregation being the existence of something just strong enough to keep the whole together. Such a society, in spite of its incongruity, may be kept together by several things: one may be, that the positive morality of the whole society is favourable to order, as characterized by a love of wealth, and impressed with a profound conviction of the necessity of leaving free to every individual the pursuit of wealth and the enjoyment of it when it is acquired. Another may be, that in this same society, though there are contending elements, there may be a slow and steady progress, and a gradual change, tending in one direction only: such a gradual progress in such a system may be regarded as the only security against its destruction.

If the history of the world has ever presented, or if it now presents, such a phenomenon as we have attempted to describe; further, if such a society contains the greatest known number of instances of enormous individual wealth opposed to the greatest amount of abject poverty; the highest intellectual cultivation and the greatest freedom of thought, side by side with the grossest ignorance and the darkest superstition; thousands in the enjoyment of wealth for which they never laboured, and tens of thousands depending for their daily bread upon the labour of their hands and the sensitive vibrations of the scale of commerce; political power in appearance widely diffused, in effect confined to the hands of a few; ignorance of the simplest elements of society in many of the rich and those who have power; ignorance not greater in those who are poor and have none—such a society, if it exists, is a society in which every reflecting man must at moments have misgivings as to its future condition and as to the happiness of those in whom he is most nearly interested. But if such a society contains a class, properly and truly denominated a middle class, a class neither enervated by excessive wealth and indolence nor depressed by poverty; a class that is characterized by industry and activity unexampled; a class that considers labour as the true source of happiness, and free inquiry on all subjects as the best privilege of a free man—such a society may exist and continue to be indefinitely in a state of progressive improvement. Such a society, with its monstrous anomalies and defects, offers to a statesman of enlarged mind and vigorous understanding the strongest motive, while it supplies him with all the means, to give to the political system an impulse that shall carry it beyond the region of unstable equilibrium and place it at once in a state of security.

In such a society the simple enunciation by one possessed of power, that Education is a part of the business of the state, would be considered as the forerunner of some measure which should lay the foundation of that unity without which the temporary prosperity of the nation can never become permanent and its real happiness can never be secured.

The particular questions that the philosophic legislator has then to solve with respect to the education of the citizens, are—1. How are teachers to be taught, and what are they to be taught? 2. How is the body of teachers to be directed, superintended, rewarded, and punished? 3. What schools and what kinds of schools are to be established and encouraged for the Education of the people? 4. What are the teachers to teach in those schools? 5. Where is the immediate government of such schools to be placed? 6. And where the ultimate and supreme direction and control of such schools? The word Schools is here used as comprehending *all* places of Education.

It remains to consider those other relations of a man to the state in which we view him as a producer of wealth for his own enjoyment. Here the general principle is, that the pursuit and enjoyment of wealth must be left as free as the public interest requires; and this amount of freedom will not depend in any great degree on the form of government. To this head, that of the production of wealth, belong all the divisions of labour by which a man, to use a homely but expressive phrase, gets his living, or what in other words are called the professions, trades, and arts of a country. The only way in which the state can with any advantage direct or control the exercise of any profession, trade, or

art, is by requiring the person who undertakes to *exercise* it to have been trained or educated for the purpose. Whether this should be done in all cases, or in some and what cases, and to what extent, and how, are questions for a legislature guided by a philosopher to answer.

In all countries called civilized this has been done to a certain extent. The legislation of our own country offers instances of great errors committed by legislating where no legislation was wanted, or by legislating badly. Perhaps instances may also be noted in all countries where evil has arisen for want of legislation on the subject. We may explain by example.

Perhaps it is unnecessary for a state to require that a shoemaker, or a tailor, or a painter, or a sculptor, should be required to go through a certain course of training before he exercises his art. The best shoemaker and best tailor will be sure to find employment, and individual shoemakers and tailors have as ample means of giving instruction in their craft as can be desired. It may be true or not true, that the best painters and sculptors will meet with most employment: but is it unnecessary or is it necessary for a state to offer facilities and encouragement to those who design to educate themselves as painters and sculptors? Most civilized nations have decided this question by doing so, and there are many reasons in favour of such a policy.

Ought the state to require the professor of law, of medicine, or of religious teaching, to undergo some kind of preliminary Education, and to obtain a certificate thereof? Nearly all civilized countries have required the lawyer and physician to go through some course of Education. There are strong reasons in some countries, our own for instance, both for and against such a requisition; but on the whole, the reasons seem to preponderate in favour of requiring such Education from him who designs to practise law, and still more from him who designs to practise the art of healing. Most civilized countries, perhaps all, except two (so far as we know), require *all* persons who profess the teaching of religion to have received some Education, to be ascertained by some evidence. But in both the nations excepted, any person, however ignorant, may preach on subjects which the mass of the community believe or affect to believe to be of greater importance both for their present and future welfare than any other subjects. Professing to maintain, as we hope they always will do, the principle of religious freedom, these two nations have fallen into the greatest inconsistencies. They have checked the free expression of individual opinion by word of mouth, and fettered it in the written form, in the one country by the severe penalties of positive law and the no less severe penalties of positive morality; and in the other by the penalties of positive morality carried to an excess which is destructive to the interests of the society itself. (See Attorney-General v. Pearson, 3 Merivale, 353.) But both nations allow any person, if he professes to be a teacher of religion, however ignorant he may be, to become the weekly, the daily instructor of thousands, including children, who derive and have derived no instruction of any kind except from this source. Such a teaching or preaching, if it only assumes the name and form of religious teaching, is permitted to inculcate principles which may be subversive of the political system; and it may and often does inculcate principles the tendency of which is to undermine the foundations of all social order; for it should never be forgotten that all religious teaching must include moral teaching, though moral teaching is quite distinct from religious teaching. And though it must be admitted that no teacher of religion recommends a bad thing *as* bad, he may recommend a bad thing as good, solely because he knows no better. We have endeavoured to point out an anomaly which exists in certain political institutions, and which can only be allowed to exist so long as it protects itself under a specious and an honoured but misunderstood name. For though it be admitted that such anomaly exist, it may be said that it cannot be remedied without interfering with the important principle of religious freedom. But what is religious or any other freedom? Is it the individual power of doing or saying what a man likes? Certainly not. It means no more than a freedom not inconsistent with the public welfare. Still it may be urged that this is precisely the kind of freedom with which no state, where the principle of religious freedom is admitted, can safely interfere. But this is only bringing us round again to the question, What is religious freedom? To say that it cannot be interfered with is to

assume an answer to the question. Does what is called religious freedom, as the same is now understood, admitting it to produce much good, produce also any evil? If it does, can the evil be remedied? Is the free practice of any art or profession, medicine or law, for instance, or the art of instructing children in general knowledge, or perfect freedom in teaching and expounding religious doctrines, inconsistent with the condition of *qualification*?* How the *qualification* is to be ascertained, and what it is to be, is the question; and it is a question which may be answered.

In all that we have said on Education as a subject of legislation, it is assumed either that the state can enforce, if necessary, that which it enacts; or that the enactments of the state will be only the expression of the public will; or that they will be founded on reasons so clear and convincing as to receive, when promulgated, the assent and support of a majority large enough to secure their being carried into effect. If some one of these conditions cannot be fulfilled, the legislation is premature, and will probably be injurious.

The extent of that department of Education with which the legislature should not interfere can only be fixed with precision by ascertaining the extent of its proper, that is, its useful interference. We may state, however, in general terms, that the early and domestic Education of the young of both sexes is in nearly all, perhaps all, modern political systems, placed beyond the reach of direct legislative control by the constitution of modern society. But inasmuch as one of the great functions of government is the instruction, direction, and superintendence of the teaching body, even the domestic Education is not beyond its influence, but will be subjected to it in precisely the same degree as the state shall succeed in forming a body of good teachers. For the importance and value of Education (in some sense or other: it matters not here in what sense) are universally admitted. The objects of Education, it is true, are often misunderstood by parents and those who have the charge of youth, and the means are as often ill-calculated for the end proposed. But this is only a consequence of ignorance, not an indication that Education is undervalued. When better objects and better means are proposed, whether by individual example or by associations of individuals called societies, or by the state, such objects and means will be readily embraced by all who can comprehend them. It being assumed that the objects and means thus presented are desirable in themselves, there can be no obstacle to the reception of them, so far as the state allows the reception to be voluntary, except the ignorance and prejudices (which are, in fact, only ignorance under another name) of those to whom they are proposed. But till this obstacle which ignorance presents is overcome, nothing can be effected in the way of improvement; and it being admitted, that as to the department of education under consideration, direct legislation is not the proper means, some other means must be adopted. Individuals and societies often effect their benevolent objects by example and by the authority of their name and character. The state may do the same. The influence of authority and example is in all countries most efficient when the sovereign power calls them in to its aid. Individuals may do much; societies have done more; but Society (the whole, in its collective power) is the body from which all improvements must come that are calculated to operate on the mass. From these considerations we conclude that if any state seriously and anxiously apply itself to the business of forming a body of teachers, it is impossible to foresee how far the beneficial influence of such a body, well organized, may extend. It may penetrate into the house of the wealthy, where the child who is born to the possession of wealth is not thereby secured in the enjoyment of it, or against any one calamity of human life. His wealth may be wasted by improvidence; his health may be enfeebled by indolence and debauchery; his understanding may be cramped and corrupted by vicious Education and bad example; and he may become an object of detestation and contempt, though born to the command of wealth sufficient to purchase all that society has to offer. This influence may also reach, and perhaps

sooner and more effectually reach, the hovels and the garrets of the poor, where thousands of children are now brought up under such circumstances, that to be unhealthy, vicious, criminal, and unhappy, are the only results which, as a general rule, can follow from the given conditions of their existence. When the unhappy wretch, who cannot be other than what he is, has at last transgressed the limits of the positive morality of society, and got within the verge of the penalties of the law, his crimes are blazoned forth by thousands, the respectable part of society are shocked at the disclosures, and are only relieved from their pain when the criminal is hid in a prison, or his life is taken by the executioner. But the example is soon forgotten, and misery and vice fester in the very heart of society unheeded, till some new warning again startles it from its lethargy.

It may appear almost superfluous to state that the true interest of the sovereign power, considered in all its bearings, must coincide with the interest of the governed; the difference in forms of government or in the distribution of the sovereign power being mainly to be considered a difference in the instruments or means by which an end is to be obtained. Nor is this difference an unimportant one. Where the sovereign power is in all those who as individuals are subject to it, the coincidence of power and of interest is complete; and the nearer any form of government approaches to this distribution of power, the more obvious and the stronger is the principle laid down. The principle may express a common-place truth; but the consequences that flow from it are numerous and important. When it is clear that the state will promote the general good by its regulations, its business is to make regulations. If regulations will not promote the general good, that is a reason for not making them. Now to protect a man in the enjoyment of his property, and to preserve him from the aggressions of others, is a main part of the business of governing. For this purpose restraints and punishments are necessary; immediately, to protect the injured, and give compensation, when it can be given; remotely, to prevent others from being injured, and, so far as it can be done, to reform the offender. But the punishment of any offender, in its extremest shape, can do little more than prevent the same person from offending again. Those who are deterred from crime by his example can at any rate only be those to whom the example is known, and they are a small portion even of the actual society. Generally, then, those who do not offend against the laws, do not offend, either because they have been sufficiently educated to avoid such offence, or because the opportunity and temptation have not been presented to them, or because they know that punishment may follow the crime. But a large class of offenders have not been sufficiently educated to enable them to avoid the commission of crime; a very large number are brought up amidst the opportunities, the temptations, and the example of crime, to oppose all which the single fact of knowing that the crime *may* be punished (and even that amount of knowledge is not always possessed by the criminal) is all the means of resistance that such persons are armed with. In societies which boast of their wealth, their civilization, and their high intellectual cultivation, such is the feeble barrier opposed by those who have the government of a people between thousands of their fellow-citizens and the commission of crimes the penalties of which are always severe and often cruel.

If the general considerations which we have urged are of any weight, there is no branch of legislation which comprehends so many important questions as are comprehended in the word Education, even when taken in its ordinary acceptance; but when viewed in all its bearings, it is of all questions most peculiarly that which it concerns the present age and the present state of society to determine. That Education was an integral, an essential part of legislation, was clearly seen by the Greeks, to whom belongs the merit of having approached, and often having solved, nearly all the important questions that affect the constitution of society. It was their good fortune to contemplate many truths from a nearer point of view and in a clearer light than we can do now. The relations of modern society are so numerous and complicated, that the mind is bewildered amidst the multiplicity and variety of facts, the claims of opposing interests, and the number and magnitude of the objects which are presented for its consideration. It is only by keeping ourselves as free as possible from mere partial influences, and steadily looking to the general welfare at the end to be attained by and the true test of all politics

* In discussing a subject of this kind in a limited space, it is not possible to anticipate objections that may be fairly urged, or to state and answer them. For example, it may be said, if a man ought not to preach without some evidence of qualification, why should a man print a book on religious subjects without some evidence of qualification? The answer is not difficult; but we have not space to answer either this or numerous other objections that may be made.

institutions, that we can hope to discover and apply the principles which shall secure, so far as such a thing can be secured, the universal happiness of a nation.

That the legislator should especially occupy himself with the education of youth, no one can dispute; for when this is not done in states, it is a cause of damage to the polity (form of government). For a state must be administered with reference to its polity; and that which is the peculiar characteristic of each polity is that which preserves and originally constitutes it; as, for instance, the democratic principle in a democracy, and the oligarchal in an oligarchy; and that which is the best principle always constitutes the best polity. Further, in every occupation and art a person must receive previous instruction and discipline, in order to the exercising of the occupation or art; consequently also to the enabling him to the exercise of virtue. Now, since the end of every state is one, it is evident that the education must be *one*, and of necessity the same for all, and that the superintendence of the education must be with the public and not with individuals, as it now is, when each individual superintends his own children singly, and teaches them what he chooses. But when things are matter of public concern, the discipline pertaining to them must also be matter of public concern; and we must not consider any citizen as belonging to himself, but all as belonging to the state; for each is a part of the state, and the superintendence of each part has naturally a reference to the superintendence of the whole. In the matter of education, as well as in other matters, the Lacedæmonians deserve praise; for they take the greatest pains about the education of their children, and that, too, as a public concern. That then a state ought to legislate on education and make it a public concern, is clear; but what education is, and how education must be conducted, is a subject for consideration. (Aristotle, *Politik*, book viii.)

EDWARD I., surnamed the Elder, king of the West Saxons, and with some pretensions to be regarded as king of all England, was the eldest son of Alfred the Great, by his queen Alswitha, the daughter of Earl Æthelred. On the death of his father, 26th October, 901, Edward was recognized by the Witenagemote as his successor; but the throne was contested by his cousin Ethelwald, who was the son of one of the three elder brothers and predecessors of Alfred, but whether of Ethelbald, Ethelbert, or Ethelred, is uncertain. The cause of Ethelwald received from the first the support of the Danes of the north, and by their assistance in 904 he compelled the submission of the people of Essex, and in the following year that of the East Anglians. The contest however was at length terminated, in 906 or 907, by the death of Ethelwald, in a battle fought between his forces and those of Edward. The people of East Anglia returned on this under submission to the king of Wessex, and the Northumbrian Danes concluded a peace with him: but three or four years afterwards we find the Danes breaking this pacification; nor do they appear to have been quieted, or the people of Essex finally brought back to their obedience, till the year 920 or 921. Mercia in the mean time had continued to be governed as a separate state, though subject to the supremacy of Wessex, first by the ealdorman Etheled or Ethelred, to whom it had been entrusted by Alfred, and, after his death in 912, by his widow Ethelfleda, the sister of Edward. The Lady Ethelfleda survived till 920, conducting the affairs of her government with distinguished ability, and all along acting in concert with her brother in his efforts against the Danes and his other enemies. On her death, Edward took the government of Mercia into his own hands. After this, if we may believe the old historians, not only did all the Danes, including even those of Northumbria, make full submission to Edward, but their example was followed by the Welsh and the people of Strathclyde, and the king of the Scots and all his subjects also chose the English monarch as their lord. The military successes however, which must have been achieved to compel the submission of all these neighbouring powers, if such submission actually took place, are not recorded.

Some of the laws of Edward the Elder are preserved; but they do not demand any particular notice. He died in 925, and was succeeded by his eldest son Athelstane, born to him by a shepherd's daughter named Egwina, who is stated by some of the old writers to have been his wife, by others only his mistress. He had also another son and a daughter by Egwina. By another lady, to whom he is

allowed to have been married, but whose name is unknown he had two sons and six daughters; and by another wife, Edgiva, he had two sons, Edmund and Edred, both of whom were afterwards kings of England, and two daughters.

EDWARD II., king of the Anglo-Saxons, surnamed the Martyr, was the eldest son of Edgar the Peaceable, by his first wife, Elfreda. On the death of Edgar, in 975, the accession of Edward was opposed by a faction headed by his father's widow, Elfrida, who on the pretence that the elder brother was excluded by the circumstance of having been born before his father had been crowned, maintained that the right to the vacant throne lay with her own son Ethelred. To create for herself the appearance of a national party she and her associates proclaimed themselves the patrons of the cause of the married clergy in opposition to Dunstan and the monks; but after a short period of confusion, the latter prevailed in the Witenagemote, and Edward was formally accepted as king by that assembly. Elfrida however seems still to have continued her intrigues; and her unscrupulous ambition at last led her to the perpetration of a deed, which has covered her name with infamy. This was the murder of her step-son by a hired assassin, as he stopped one day while hunting at her residence, Corfe Castle, in Dorsetshire; he was stabbed in the back as he sat on his horse at the gate of the castle drinking a cup of mead. The 18th of March, 978, is the date assigned to the murder of King Edward, who was only in his seventeenth year when he was thus cut off. He was never married, and leaving no children, was succeeded by his half-brother, Ethelred, the only individual then remaining whose birth gave him any pretensions to the throne.

It was in the reign of Edward that the national council was held at Calne which is so famous for the catastrophe of the floor giving way, with the exception of the part on which Dunstan and his friends stood. [DUNSTAN.]

EDWARD III., king of the Anglo-Saxons, surnamed the Confessor, was the eldest of the two sons of Ethelred II. by his second wife Emma, the daughter of Richard I., duke of Normandy. He was born at Islip, in Oxfordshire, probably in the year 1004. In the close of 1013, when the successes of Sweyn, the Dane, drove Ethelred from his throne, and compelled him to retire to the Isle of Wight, he sent over his wife, with Edward and his younger brother Alfred, to Normandy, to the care of their uncle Duke Richard II. Hither Ethelred himself, being assured of a favourable reception, followed his family, about the middle of January, 1014. When, on the death of Sweyn, within three weeks after, Ethelred was recalled by the Witenagemote, he sent back his son Edward along with the plenipotentiaries, whom he despatched previously to setting out himself to complete the arrangements for his restoration. On the death of Ethelred in 1016, Emma and her two sons returned to Normandy. When Canute the Dane obtained the throne in the latter part of the same year by the death of Edmund Ironside, it is affirmed that Duke Richard either fitted out a naval force or threatened to do so, with a view of supporting the claims of his nephew Edward; but this intention, if it ever was entertained, was effectually diverted before it led to any thing by the proposals which now proceeded from Canute for the hand of the widowed Emma. Canute and Emma were married in July, 1017. From this time till the death of Canute in 1035, Edward appears to have remained quiet in Normandy. He is said to have spent his time chiefly in the performance of the offices of religion and in hunting, which continued to be his favourite occupations to the end of his days. On Canute's death, and the disputes for the succession between his sons Harold and Hardicanute, Edward was induced to make a momentary demonstration in assertion of his pretensions: he crossed the channel with a fleet of forty ships, and landed at Southampton; but finding that instead of being supported, he would be vigorously opposed by his mother, who was exerting all her efforts for her son Hardicanute, he gave up the attempt, and returned to Normandy after merely plundering a few villages. In 1037 his younger brother Alfred was tempted by an invitation purporting to come from Emma to proceed to England at the head of another expedition, which terminated in his destruction, brought about apparently by treachery, though there does not seem to be any sufficient ground for the horrid suspicion, which some writers have been disposed to entertain, that the contriver of the plot

was his own mother. When Hardicanute became undisputed king of all England by the death of Harold in 1040, he sent for his half-brother Edward, who immediately came to England, where he was allowed a handsome establishment, and appears to have been considered as the heir to the crown in default of issue of the reigning king. Hardicanute died on the 4th of June, 1042, and Edward was immediately recognized as king by the assembled body of the clerical and lay nobility; the former, it is said, having been chiefly swayed by Livingus, bishop of Worcester, the latter by the powerful Earl Godwin.

A menace of opposition to this settlement of the English crown by Magnus, king of Norway, was defeated, after it had put Edward to the expense of fitting out a fleet to maintain his rights, first by the occupation which Magnus found at home in defending himself against another claimant to the Danish throne, Sweyn, the nephew of Canute, and soon after, more effectually, by the death of Magnus. In 1044, Edward, probably in compliance with a promise which he had made to Godwin, married Editha, the only daughter of that earl, having previously informed her, however, that although he would make her his queen, she should not share his bed. This unnatural proceeding, by which Edward gained from his church the honour of canonization and the title of Confessor, and by which, to pass over his treatment of his wife and his violation of his marriage vows, he involved his country in the calamities of a disputed succession, and eventually of a foreign conquest, has been usually attributed to religious motives. The Confessor seems to have been without human affections of any kind. His first act after coming to the throne was to proceed to the residence of his mother at Winchester, and to seize by force not only all her treasures, but even the cattle and corn upon her lands. One account further states that he endeavoured to destroy her by an accusation from which she freed herself by the ordeal; and though this part of the story has been generally rejected by modern writers, its falsehood is by no means clearly established. The circumstance of Emma (who lived for ten years after this) having, as it would appear, retained her dower, which has been urged in disproof of any criminal charge having been brought against her, is rather a confirmation of the truth of the old account, inasmuch as it is not likely her son would have allowed her to remain thus undisturbed after his first treatment of her, unless her triumphant escape from the ordeal had enabled her for the rest of her life to defy his power.

The public events that form the history of the reign of the Confessor resolve themselves for the most part into a contest between two great parties or interests which divided the court and the country. The connexion between England and Normandy had commenced forty years before the accession of this king by the marriage of Ethelred; but it became very intimate after the accession of Edward, who had spent in Normandy all his life since his childhood, whose tastes and habits had been formed in that country, and all whose oldest personal friends were necessarily Normans. In fact Edward himself, when he came to the throne, was much more a Norman than an Englishman; and he not unnaturally surrounded himself with persons belonging to the nation whose language and manners and mode of life were those with which he had been so long familiar, rather than with his less polished fellow-countrymen. Many Normans came over to England as soon as he became king, and some of the highest preferments in the kingdom were bestowed upon these foreigners. But while the inclinations of Edward were probably from the first with the Normans, he was to a great extent in the hands of the opposite, or English party, from his connexion with Earl Godwin, its head. Besides the influence which he derived from having his daughter on the throne, this powerful nobleman held in his own hands, and in those of his sons, the government of more than the half of all England. The eldest of these sons, Sweyn, very early in the reign of Edward, had been obliged to fly from the vengeance of the law for the daring crime of violating the person of an abbess; but after some time Edward consented, or found himself obliged, to pardon him, and to restore him to all his estates and honours. It was not till the year 1051 that the strength of the English and Norman parties was tried in any direct encounter; but that year, on occasion of a broil which arose out of the visit to England of Edward's brother-in-law, Eustace, count of Boulogne, their long-accumulated enmity broke forth into

a violent collision. The first effect was the banishment of all the Godwin family, and the degradation and imprisonment of the queen. At this crisis William, the young duke of Normandy, afterwards king of England, came over with a powerful fleet, and prepared to render Edward what assistance he might have needed. The following summer however witnessed the complete overthrow of all that had been thus accomplished. Godwin and his son Harold forced their way back to the country at the head of armaments which they had prepared, the former in Flanders, the latter in Ireland; a negotiation was entered into with the king, and the issue was, that the earl and his party were restored to greater power than ever; the queen was re-established in her possessions and her place, and the Normans were all expelled from the kingdom.

Earl Godwin only survived this counter-revolution a few months: he died suddenly as he sat at the royal table, on the 15th April, 1053. His son Harold, however, inherited his possessions and his power, and the ascendancy of the family under its new head continued as great as ever during the remainder of the Confessor's reign. In 1055 a dispute arose between Harold and the rival family of Leofric, earl of Leicester, which disturbed the kingdom for nearly two years. Leofric died in 1057; but the feud was continued by his son Alfgar, who called in to his assistance Griffith or Griffin, king of the Welsh. This drew down the vengeance of Harold upon that prince and his subjects; and the issue was, that, after some fighting, Griffin consented to swear fealty to Edward. This event is assigned by the Saxon Chronicle to the year 1056. The war with the Welsh was renewed in 1063; Harold had again the command, and prosecuted hostilities with so much success, that king Griffin's head was cut off by his own subjects, and sent by them to the English king in token of their submission. In 1065 the public tranquillity was for a short time disturbed by an insurrection of the Northumbrians; but this was quelled without bloodshed. Edward died on the 5th of January, 1066, and was buried the following day in the new Abbey of Westminster, which had just been finished and consecrated with great pomp about a week before. On the same day Earl Harold was solemnly crowned king of England. [EDGAR ATHELING; HAROLD II.]

England undoubtedly made a considerable advance in civilization during the reign of the Confessor. For this it was indebted partly to the intercourse which Edward's accession opened with Normandy and France, but perhaps in a still greater degree to the freedom which the kingdom enjoyed from those foreign invasions and internal wars which had distracted it, with the exception of some short intervals of tranquillity, for the greater part of a century preceding. The only events, as we have seen, which disturbed the public peace during the reign of Edward, were one or two border wars and local insurrections, none of which occasioned any general disquiet, or lasted for any considerable time. This period accordingly was long traditionally remembered as the happiest that England had known. It formed in the national imagination the bright spot between the time of the Danish rule on the one hand, and that of the Norman on the other; the age of English freedom and independence which succeeded the deliverance of the country from the one foreign conquest, and preceded its subjection to the other. For many generations after the establishment of the Norman power in the island, the constant demand of the great body of the people to their rulers was for the restoration of the laws and customs of the Confessor. But we have no reason to suppose that this king was the author of any entirely new code of laws, or even that he made any material additions to the laws that had been in force before his time. On coming to the throne he was required by the Witenagemote to promise to observe the laws of King Canute, which seem to have been then universally held to be the fairest and the best the nation had known. Edward took an oath in conformity with this demand at his coronation. No laws attributed to Edward remain in Saxon; but there has been preserved, both in Latin and in Romance, or Romanic French, a body of laws and constitutions which the Conqueror is said to have granted at an assembly of the most distinguished of his English subjects, held about four years after his seizure of the crown, and they are described in the title as the same which his predecessor and cousin, King Edward, had before observed. The French text, preserved in Ingulphus, has generally been held to be the original; but Sir Francis

Palgrave has stated reasons which throw considerable doubt upon this supposition. Both versions are given in the most correct form, and accompanied with a learned and valuable commentary, in the *Proofs and Illustrations* appended to Sir Francis Palgrave's *Rise and Progress of the English Commonwealth*, pp. lxxviii.—cxl.

Edward the Confessor has the credit of being the first of our kings who touched for the king's evil. He was canonized by Pope Alexander III. about a century after his death, and the title of the Confessor was first bestowed upon him in the bull of canonization. It may also be mentioned, that the use of the Great Seal was first introduced in this reign.

EDWARD I., king of England, surnamed Long-shanks, from the excessive length of his legs, was the eldest son of King Henry III. by his wife Eleanor, second daughter of Raymond, count of Provence. He was born at Westminster, June 16, 1239. In 1252 he was invested by his father with the duchy of Guienno; but a claim being set up to this territory by Alphonso X., king of Castile, who pretended that it had been made over to his ancestor Alphonso VIII. by his father-in-law, Henry II., it was arranged the following year that the dispute should be settled by the marriage of Prince Edward with Eleanor, the sister of Alphonso, who thereupon resigned whatever right he had to the duchy to his brother-in-law. After this, by letters patent, dated February 14, 1254, we find the lordship of Ireland, and by others dated February 18, in the same year, all the provinces which had been seized from his father, John, by the king of France, granted by Henry III. to his son Prince Edward. (Rymer, I.)

Edward early manifested a character very unlike that of his weak and imprudent father. While yet only entering upon manhood, we find him taking part in important affairs of state. Thus the agreement which Henry made in 1256 with Pope Alexander IV. in relation to the kingdom of Sicily, which the pope granted to Henry's second son Edmund, was ratified by Prince Edward in a letter to his Holiness, still preserved. In 1258 he signed, along with his father, the agreement called the Provisions or Statutes of Oxford, by which it was arranged that the government of the country should be put into the hands of twenty-four commissioners, appointed by the barons; and two years after, when Henry violently broke through this engagement, Edward came over from Guienne, where he was resident, and publicly expressed his disapprobation of the king's conduct. For the next two or three years Edward may be regarded as placed in opposition to his father's government. In 1262, however, Henry, in a visit which he paid him in Guienne, succeeded in gaining him over to his side, and from this time the prince became the king's most efficient supporter. In the summer of 1263, the quarrel between Henry and his barons came to a contest of arms, which lasted, with some brief intermissions, for four years. During this period the military operations on the king's side were principally conducted by Prince Edward. In the beginning he was unfortunate, having been driven first from Bristol and then from Windsor, and having been finally defeated and taken prisoner with his father at the battle of Lewes, fought May 14, 1264. After being detained however about a twelvemonth, he made his escape out of the hands of the earl of Leicester; and on the 4th August, 1265, his forces having encountered those of that nobleman at Evesham, the result was that Leicester was defeated and lost his life, and the king was restored to liberty. From this time Edward and his father carried everything before them till the war was concluded, in July, 1267, by the surrender of the last of the insurgents, who had taken up their position in the Isle of Ely.

Soon after this, at a parliament held at Northampton, Prince Edward, together with several noblemen and a great number of knights, pledged themselves to proceed to join the crusaders in the Holy Land. The Prince accordingly, having first, in a visit to Paris, in August, 1269, made his arrangements with St. Louis, set sail from England to join that king in May, the year following. St. Louis died on his way to Palestine; and Edward, having spent the winter in Sicily waiting for him, did not arrive at the scene of action till the end of May, 1271. Here he performed several valorous exploits, which however were attended with no important result. His most memorable adventure was an encounter with a Saracen, who attempted to assassinate him, and whom he slew on the spot, but not before he had received a wound in the arm from a poisoned

dagger, from the effects of which he is said to have been delivered by the princess, his wife, who sucked the poison from the wound. At last, having concluded a ten years' truce with the Saracens, he left Palestine in August, 1272, and set out on his return to England. He was at Messina, on his way home, in January, 1273, when he heard of the death of his father on the 16th of November preceding. He proceeded on his journey, and landed with his queen in England 25th July, 1274. They were both solemnly crowned at Westminster on the 19th of August following. The reign of Edward I., however, appears to have been reckoned not from the day of his coronation, according to the practice observed in the cases of all the preceding kings since the Conquest, but, according to the modern practice, from the day on which the throne became vacant, or at least from the 20th of November, the day of his father's funeral, immediately after which the clerical and lay nobility who were present in Westminster Abbey on the occasion had sworn fealty to the new king at the high altar of that church.

The first military operations of Edward's reign were directed against the Welsh, whose prince Llewellyn, on being summoned to do homage, had contemptuously refused. Llewellyn was forced to sue for peace in November, 1277, after a single campaign; but in 1281 he again rose in arms, and the insurrection was not put down till Llewellyn himself was slain at Llanfair, 11th December, 1282, and his surviving brother Prince David was taken prisoner soon after. The following year the last-mentioned prince was barbarously put to death by drawing, hanging, and quartering, and Wales was finally united to England.

The conquest of Wales was followed by the attempt to conquer Scotland. By the death of Alexander III., in 1285, the crown of that country had fallen to his granddaughter Margaret, called the Maiden of Norway, a child only three years old. By the treaty of Brigham, concluded in July, 1290, it was agreed that Margaret should be married to Edward, the eldest surviving son of the English king; but the young queen died in one of the Orkney Islands on her voyage from Norway in September of the same year. Edward made the first open declaration of his designs against the independence of Scotland at a conference held at Norham on the Tweed with the clergy and nobility of that kingdom on the 10th of May, 1291. Ten different competitors for the crown had advanced their claims; but they were all induced to acknowledge Edward for their lord paramount and to consent to receive judgment from him on the matter in dispute. His decision was finally pronounced in favour of John Balliol, at Berwick, on the 17th of November, 1292; on the next day Balliol swore fealty to him in the castle of Norham. [BALLIOL.] He was crowned at Scone under a commission from his liege lord on the 30th of the same month; and on the 26th of December he did homage to Edward for his crown at New-castle. The subject king, however, was soon made to feel all the humiliation of his position; and the discontent of his countrymen equalling his own, by the summer of 1294 all Scotland was in open insurrection against the authority of Edward. Meanwhile, Edward had become involved in a war with the French king Philip IV. The first act of the assembled estates of Scotland was to enter into a treaty of alliance with that sovereign. But although he was farther embarrassed at this inconvenient moment by a revolt of the Welsh, Edward's wonderful energy in a few months recovered for him all that he had lost. In the spring of 1296 he laid a great part of Scotland waste with fire and sword, compelled Balliol to resign the kingdom into his hands, and then made a triumphant progress through the country as far as Elgin in Murray, exacting oaths of fealty from all classes wherever he appeared. It was on his return from this progress that Edward, as he passed the cathedral of Scone in the beginning of August, carried away with him the famous stone, now in Westminster Abbey, on which the Scottish kings had been accustomed to be crowned. He now placed the government of Scotland in the hands of officers appointed by himself, and bearing the titles of his ministers. But by the month of May in the following year Scotland was again in flames. The leader of the insurrection now was the celebrated William Wallace. He and his countrymen had been excited to make this new attempt to effect their deliverance from a foreign domination, partly by the severities of their English governors, partly by the circumstances in which Ed-

ward was at this time involved. The expenses of his Scottish and French wars had pressed heavily upon the resources of the kingdom; and when he asked for more money, both clergy and laity refused him any farther grant without a redress of grievances and a confirmation of the several great national charters. After standing out for some time, he was obliged to comply with these terms: Magna Charta and the Charter of Forests were both confirmed, with some additional articles, in a parliament held at Westminster in October of this year.

Meanwhile, although he had got disencumbered for the present of the war on the Continent, by the conclusion of a truce with King Philip, the rebellion in Scotland had already gained such a height as to have almost wholly cleared that country of the English authorities. The forces of the government had been completely put to the rout by Wallace at the battle of Stirling, fought on the 11th September, and in a few weeks more not a Scottish fortress remained in Edward's hands. Wallace was now appointed Governor of Scotland, in the name of King John (Balliol). In this state of things Edward, about the middle of March 1298, returned to England from Flanders where he had spent the winter. He immediately prepared to march for Scotland. The great battle of Falkirk followed on the 22nd of July, in which Wallace sustained a complete defeat. But although one consequence of this event was the resignation by Wallace of his office of governor, it was not followed by the general submission of the country. The next five years were spent in a succession of indecisive attempts on the part of the English king to regain possession of Scotland; the military operations being frequently suspended by long truces. At length, having satisfied his barons by repeated renewals of the charters, and having finally relieved himself from all interference on the part of the king of France by a definitive treaty of peace concluded with him at Amiens on the 20th May, 1303, Edward once more set out for Scotland at the head of a force too numerous and too well appointed to be resisted by any strength that exhausted country could now command. The result was again its temporary conquest, and merciless devastation from the Tweed to the Murray Frith. The Castle of Stirling was the last fortress that held out; it did not surrender till the 20th of July in the following year. Edward meanwhile had wintered in Dunfermline; he only returned to England in time to keep his Christmas in Lincoln. Wallace fell into his hands in a few months afterwards, and was hanged, drawn, and quartered as a traitor, at Smithfield in London, on the 23rd August, 1305. But another champion of the Scottish independence was not long in appearing. Robert Bruce, Earl of Carrick, whose grandfather had been the chief competitor for the crown with Balliol, had resided for some years at the English court; but he now, in the beginning of February, 1306, suddenly made his escape to Scotland; and in a few weeks the banner of revolt against the English domination was again unfurled in that country, and the insurgent people gathered around this new leader. Bruce was solemnly crowned at Scone on the 27th March. On receiving this news Edward immediately prepared for a new expedition to Scotland; and sent the Earl of Pembroke forward to encounter Bruce, intending to follow himself as soon as he had completed the necessary arrangements. The army of Bruce was dispersed at Perth on the 19th June by Pembroke, who had thrown himself into that town; and the king of the Scots became for a time a houseless fugitive. But the great enemy of that unfortunate people had now reached the last stage of his destructive career. Edward got no farther than a few miles beyond Carlisle in his last journey to the north. After spending the winter months at Lanercost, where he was detained by a severe illness, he appears to have arrived in that city in the beginning of March, 1307; here he was again taken ill, but his eagerness to advance continued unabated: having somewhat recovered he again set out, although he was still so weak and suffered so much pain that he could accomplish no more than six miles in four days. On the 6th of July he reached the village of Burgh-upon-Sands, 'and next day expired,' to copy the words of Lord Hailes, 'in sight of that country which he had devoted to destruction.' On his death-bed he is said to have enjoined his son and successor to prosecute the design which it was not given to himself to finish: according to Froissart, he made him swear that after the breath had departed from the royal body he would cause it to be boiled in a cauldron till the flesh fell off, and that he

would preserve the bones to carry with him against the Scots as often as they should rebel. This oath, however, if it was taken, was not kept. The corpse of King Edward was interred in Westminster Abbey on the 28th of October.

Edward I. was twice married. By his first wife Eleanor, daughter of Ferdinand III., king of Castile and Leon, he had four sons: John and Henry, who both died in infancy while their father was in the Holy Land; Alphonso, born at Maine in Gascony, 23rd November, 1273, who died at Windsor, 4th August, 1285; and Edward, who succeeded him. He had also by Eleanor nine daughters: Eleanor, born in 1266, married to Henry earl of Bar; Joanna of Acre, born in that town in 1272, married first to Gilbert de Clare, earl of Gloucester and Hereford, and secondly to Sir Ralph Monthermer; Margaret, born 1275, married to John duke of Brabant; Berengera, born in 1276; Alice; Mary, born 22nd April, 1279, who at ten years of age took the veil in the monastery of Ambresbury; Elizabeth, born in 1284, married first, to John earl of Holland and Zealand, secondly, to Humphrey Bohun earl of Hertford and Essex; Beatrice; and Blanch. Queen Eleanor died 28th November, 1291, at Grantham, or, according to another account, at Hardeby, in Lincolnshire: her body was brought to Westminster Abbey to be interred, and crosses were afterwards erected on the several spots where it rested on the way, namely, at Lincoln, Grantham, Stamford, Goddington, Northampton (near which town one exists), Stoney Stratford, Dunstable, St. Albans, Waltham, (where the cross, a very beautiful one, still stands, and has been lately restored,) and Charing, then a village near London, but now the centre of the metropolis, under the name of Charing Cross. Edward's second wife was Margaret, eldest daughter of Philip III., and sister of Philip IV., kings of France. He was married to her on the 10th of September, 1299, she being then in her eighteenth year. By Queen Margaret he had two sons: Thomas, born at Brotherton in Yorkshire, 1st June, 1300, afterwards created earl of Norfolk and earl marshal; and Edmund, born 5th August, 1301, afterwards created earl of Kent; and one daughter, Eleanor, born at Winchester, 6th May, 1306, who died in her childhood. Queen Margaret died in 1317.

The rapid narrative that has been given of the acts of his reign sufficiently indicates the main constituents of the character of this king. He had his full share of the ability and the daring of the vigorous line from which he was sprung; a line that (including himself) had now given nine kings to England, and only two of them not men of extraordinary force of character. With all his ambition and stern determination, however, Edward neither loved bloodshed for itself, nor was he a professed or systematic despiser of the rules of right and justice. It is probable that in his persevering contest with the Scots he believed that he was only enforcing the just claims of his crown; and his conduct, therefore, ferocious and vindictive as in many respects it was, may be vindicated from the charge of want of principle, if tried by the current opinions and sentiments of his age. Putting aside considerations of morality, we perceive in him an ample endowment of many of the qualities that most conduce to eminence—activity, decision, foresight, inflexibility, perseverance, military skill, personal courage and power of endurance; and, united with boldness in conceiving and executing his designs, great patience and sagacity in preparing and managing his instruments, and bending circumstances to his will. Engaged as he was during the greater part of his reign in war, he was not advantageously placed for the full application of his talents to the business of civil government; but his reign is notwithstanding one of the most remarkable in our history, for the progress which was made in it towards the settlement of the laws and the constitution. On this account Edward I. has often been styled (though, as is obvious to any one who knows what Justinian's legislation was, not with any propriety) the English Justinian; and Sir Matthew Hale (*Hist. of the Common Law of England*, chap. 7) has remarked that more was done in the first thirteen years of his reign to settle and establish the distributive justice of the kingdom than in all the next four centuries. Blackstone has enumerated under fifteen heads the principal alterations and improvements which the law underwent in the reign of Edward I.: we can only here notice the confirmation and final establishment of the two great charters; the definition and limitation of the bounds of ecclesiastical jurisdiction; the ascertainment and distribution of the

powers and functions both of the supreme and the inferior courts; the abolition of the practice of issuing royal mandates in private causes; the establishment of a repository for the public records of the kingdom, 'few of which,' as Blackstone remarks, 'are antienter than the reign of his father, and those were by him collected;' the improvement of the law and process for the recovery of debts by the Statutes Merchant and Elegit [ELEGIT]; and the check imposed on the encroachments of the church by the passing of several statutes of mortmain. The object of the statute De Donis was to render lands which were the subject of this particular form of grant inalienable, and so far to put restraints upon the disposal of landed property, which however were soon evaded. [CONDITION; ESTATE.] 'Upon the whole, we may observe,' concludes Blackstone after Hale, 'that the very scheme and model of the administration of common justice between party and party was entirely settled by this king.' The forms of writs by which actions are commenced, it is added, were perfected in this reign. While the English laws were fully extended to Ireland and Wales, it was under Edward I., also, that the foundations of the constitution of the kingdom may be considered to have been laid by the new form and the new powers which were then assumed by the parliament. The earliest writs that have been preserved for summoning knights, citizens, and burgesses to parliament, are, as is well known, those that were issued by Simon de Montfort, earl of Leicester, the leader of the barons, in 1264, in the name of king Henry III., who was then a prisoner in his hands. Whether this representation of the commons was then first introduced or not, it was in the course of the succeeding reign that it first became regular and influential. The division of the legislature into two houses, in other words the institution of our present House of Commons, appears to be clearly traceable to the time of Edward I. It was in his time also that the practice began fairly to take root of the king refraining from arbitrary exactions and coming to parliament for supplies, and that the earliest effective examples were afforded of the grant of supplies by that assembly being made dependent upon the redress of grievances. Edward I., with all his military habits and genius, had at length the good sense to perceive that the time was come for abandoning the attempt to govern by the prerogative alone, which had been clung to by all his predecessors from the conquest: in his disputes with the barons he never allowed matters to come to a contest of force, as his father and grandfather had done; and in the latter part of his reign, although more than once compelled to stop short in his most favourite designs by the refusal of the national representatives to furnish him with the necessary means, he seems to have kept to the system of never resorting to any other weapons than policy and management to overcome the opposition with which he was thus thwarted. It was in the last year but one of this reign that the royal assent was given to the famous enactment commonly called the 'Statute de Tallagio non Concedendo,' by which the right of taxation was first distinctly affirmed to reside in the parliament: 'no tallage or aid,' the first chapter runs (in the old English translation), 'shall be levied by us or our heirs in our realm, without the good will and assent of Archbishops, Bishops, Earls, Barons, Knights, Burgesses, and other Freemen of the land.' The same principle had been conceded ten years before (by the 25th Edward I., c. 6), but not in such explicit terms.

The trade and foreign commerce of England appear to have advanced considerably during the reign of Edward I.; but rather owing to the natural progress of the civilization of this country and of Europe, than from any enlightened attention which the king showed to these interests. He seems to have been principally solicitous to turn the increasing intercourse of the country with foreign parts to his own particular profit by the increase of the customs. A few of his laws, however, were beneficial to the trading community, and were made with this express object, especially the act for the better recovery of debts, commonly called the Statute of Merchants, passed at Acton-Burnell in 1283; and the extension of the same by a subsequent act; and the Elegit above mentioned. On the other hand, he lowered, though slightly, the real value of the coin, thereby setting the first example of a most pernicious process, which was afterwards carried much farther. He also cruelly pillaged and oppressed the Jews; and finally, in 1290, expelled the entire body of that people from England, and seized all their houses and tenements. Before this (in 1275) a law

had been passed prohibiting the Jews from taking interest for money on pain of death.

The most distinguished names in literature and science that belong to the reign of Edward I. are Duns Scotus, his disciple William Occam, and the illustrious Roger Bacon. Among the historical writers or chroniclers who flourished at this time, may be mentioned Thomas Wikes, Nicolas Trivet, Walter de Hemmingford, and, according to one account, Matthew of Westminster, though he is placed by some considerably later. The law writers of this reign are the author of the work entitled *Fleta*, Britton (if that be not a corruption of Bracton), Hengham, and Gilbert de Thornton, chief justice of the King's Bench, the author of an abridgment of Bracton, which has not been printed.

EDWARD II., the eldest surviving son of Edward I., was born at Caernarvon 25th April, 1284, and became the heir apparent to the crown by the death of his elder brother, Alphonso, a few months after. In 1289 he was affianced to the young queen of Scotland, who died the following year. On the 1st of August, 1297, his father, before setting out for Flanders, assembled a great council at London, and made the nobility swear fealty to the prince, whom he then appointed regent of the kingdom during his absence. The parliament in which the first statute *De Tallagio non concedendo* received the royal assent was held at Westminster by prince Edward a few months after his father's departure. In the summer of 1300 we find him accompanying his father in a military expedition to Scotland, and he is particularly mentioned as leading one of the divisions of the army, called the Shining Battalion, in an encounter with the Scottish forces on the banks of the river Irvine. As he grew towards manhood, however, he appears to have begun to form those vicious associations which were the chief source of the calamities of his life. It is recorded by Stow and Fabyan that in October of this same year the notorious Piers Gaveston was banished by the king from about the person of prince Edward, who, through his persuasion, had been guilty of several outrages against the bishop of Lichfield, and the prince himself was ordered to prison for stealing the bishop's deer. Gaveston was the son of a knight of Gascony, and is admitted to have been distinguished by his wit and accomplishments as well as by his personal advantages, but he is affirmed to have, as the prince's minion, carried himself to men of all ranks with unbearable insolence. In 1301 Edward was created Prince of Wales and Earl of Chester. He was again in Scotland with his father in the expedition in the summer of 1303: while the king proceeded along the east coast, the prince marched westward, and the latter afterwards wintered in Perth, while his father remained in Dunfermline. When Edward was preparing for his last Scottish expedition after the insurrection under Robert Bruce, he knighted his eldest son at Westminster on the morrow of Whitsuntide, 1306; after which the prince bestowed the same honour on three hundred gentlemen, his intended companions in arms. He was at the same time invested by his father with the duchy of Guienne. The royal banquet that was given on this occasion is celebrated for what is called the Vow of the Swans, an oath taken by the king to God and to two swans, which were brought in and set upon the table, that he would take vengeance on Robert Bruce and punish the treachery of the Scots. The prince also vowed that he would not remain two nights in the same place until he reached Scotland. He set out accordingly before his father, and as soon as he had crossed the borders he began to signalize his march by such unsparing devastation that even the old king is said to have reproved him for his cruelty. While king Edward was at Lanercost in February, 1307, he found it necessary, with the consent of the parliament there assembled, to issue an order banishing Gaveston for ever from the kingdom, as a corrupter of the prince. It is doubtful, notwithstanding the story told by Froissart [EDWARD I.] if the prince of Wales was with his father when he died on the 7th of July following; but he was at any rate at no great distance, and he was immediately recognized as king. His reign appears to have been reckoned from the day following.

The new king obeyed his father's injunctions to prosecute the war with Scotland, by proceeding on his march into that country as far as Cumnock, in Ayrshire. But here he turned round without having done anything, and made his way back to England. Meanwhile his whole mind seems to have been occupied only with one object—

the advancement of the favourite. A few dates will best show the violence of his infatuation. His first recorded act of government was to confer upon Gaveston, now recalled to England, the earldom of Cornwall, a dignity which had hitherto been held only by princes of the blood, and had a few years before reverted to the crown by the death, without issue, of Edmund Plantagenet, the late king's cousin: the grant, bestowing all the lands of the earldom as well as the dignity, is dated at Dumfries, the 6th of August, 1307. About the same time Walter de Langton, bishop of Lichfield, who was lord high treasurer, was imprisoned in Wallingford castle, as having been the principal promoter of Gaveston's banishment. In October the new earl of Cornwall married the king's niece, Margaret de Clare, the daughter of his sister, Joanna, countess of Gloucester. He was also made guardian during his minority to her brother, the young earl. The grant of several other lordships followed immediately, and it is even said that the reckless prodigality of the weak king went the length of making over all the treasure his father had collected for the Scottish war, amounting to nearly a hundred thousand pounds, to the object of his insane attachment. Finally, he left him guardian of the realm while he set out for Boulogne in January, 1308, to marry Isabella, the daughter of the French king, Philip V., to whom he had been affianced ever since the treaty concluded between Philip and his father in 1299. The marriage took place on the 25th of January, and on the 25th of February the king and queen were crowned at Westminster.

The history of the kingdom for the next five years is merely that of a long struggle between the king and his disgusted nobility about this Gaveston. The banishment of the favourite being insisted upon by a formidable league of the barons, Edward was obliged to give in; but instead of being ignominiously sent out of the country, Gaveston was merely appointed to the government of Ireland. In June his royal master accompanied him as far as Bristol on his way to that country. Even from this honourable exile, however, he returned in October following. The barons immediately again remonstrated, and in March, 1310, the king found himself compelled to sign a commission by which he resigned the government of the kingdom for the ensuing year into the hands of a committee appointed by the parliament. A sentence of banishment was soon after passed upon Gaveston, and he retired to France; but by the close of the year 1311 we find him again in England. The earl of Lancaster, the king's cousin, now placed himself at the head of the malecontents: finding petitions and remonstrances unattended to, he and his associates at length openly rose in arms: Gaveston was besieged in Scarborough castle, and having been forced to surrender, his career was ended by his summary execution at Warwick on the 19th of June, 1312. Having thus attained their main object, the insurgent barons made their submission to the king, and a peace was finally concluded between the parties in December.

In the course of the last two or three years Robert Bruce, left unmolested in Scotland, had not only nearly recovered every place of strength in that country, but had been accustomed to make an annual plundering inroad across the borders. It was now determined to take advantage of the cessation of domestic dissensions to effect the reconquest of the northern kingdom; and in June, 1314, Edward set out for that purpose at the head of the most numerous army that had ever been raised in England. The issue of this expedition was the signal defeat sustained at the battle of Bannockburn, fought the 24th of June, at which the magnificent host of the English king was completely scattered, he himself narrowly escaping captivity. After this the few remaining fortresses in Scotland that were still held by English garrisons speedily fell into the hands of Bruce; the predatory and devastating incursions of the Scots into England were renewed with more audacity than ever; and Bruce and his brother Edward even made a descent upon Ireland, and for some time contested the dominion of that island with its English masters. At length, in September, 1319, a truce for two years with the Scots was arranged with difficulty. Nor was it long observed by the party most interested in breaking it. The Scots easily found pretences on which to renew their attacks, and Edward's efforts to check them proved as impotent as before.

Meanwhile, a new favourite began to engross him, Hugh le Despencer, the son of a nobleman of the same name. P. C., No. 567.

Upon him Edward now bestowed another daughter of his sister, the countess of Gloucester, in marriage, and many large possessions. Another armed insurrection of the barons was the consequence; and in July, 1321, the Despensers, father and son, were both banished by act of parliament. Before the end of the same year, however, they were recalled by the king; and now for a short time the fortune of the contest changed. The earl of Lancaster was taken and beheaded at Pontefract, 23rd March, 1322; and the sentence against the Despensers was soon after formally revoked by parliament. About twenty of the leaders of the insurrection in all were put to death; but the estates of many more were forfeited; and most of the immense amount of plunder thus obtained by the crown was at once bestowed upon the younger Spencer. Edward imagining that he had now an opportunity of which he might take advantage, set out once more for the conquest of Scotland in August, 1322; but after advancing as far as Culross, in Fife, he returned without having accomplished anything more than the destruction of a few religious houses; and on the 30th of March, 1323, he concluded another truce with the Scots, to last for thirteen years.

New storms, however, were already rising against the unhappy king. Charles IV., called the Fair, the youngest brother of Edward's queen, had recently succeeded to the French throne, and had begun his reign by quarrelling on some pretence with his brother-in-law, and seizing Guienne and Edward's other territories in France. After some other attempts at negotiation, it was resolved that queen Isabella should herself go over to France to endeavour to bring about an arrangement. The queen had been already excited against the Despensers; she had long probably despised a husband who was the object of such general contempt, and who besides openly preferred his male favourites to her society. At the French court she found collected many English nobles and other persons of distinction, whom their dissatisfaction with the state of affairs, or the enmity of the Despensers, had driven from their country. All these circumstances considered, it is easy to understand how she might naturally become the centre and head of a combination formed by the discontented exiles among whom she was thrown, and their connexions still in England, for the professed object of compelling her husband to change his system of government and of removing the pernicious power that stood between the nation and the throne. Among the foremost figures of the association with which she thus became surrounded was the young Roger de Mortimer, a powerful baron, who had made his escape from England after having been condemned, for taking part in the former confederacy against the Despensers, to imprisonment for life. There is no doubt that the connexion between Queen Isabella and Mortimer became eventually a criminal one. The plot against the king was begun by the conspirators contriving to get the heir-apparent, Prince Edward, into their power. It was arranged that King Charles should restore Guienne upon receiving from the prince the homage which his father had refused to render. On this Prince Edward, now in his thirteenth year, was sent over to France to his mother. The first use Isabella made of this important acquisition was to affianc the boy to Philippa, the daughter of the earl of Hainault, who in return agreed to assist her and the confederates with troops and money. Thus supported, she set sail from Dart with a force of 3000 men, under the command of the earl's brother, and landed at Orwell in Suffolk, the 22nd of September, 1326. She was immediately joined by all the most distinguished persons in the kingdom, including even the earl of Kent, the king's own brother. Edward, deserted by all except the two Despensers and a few of their creatures, left London, and took refuge at first in Bristol; he then embarked for Ireland, or, as another account says, with the design of making for the small isle of Lundy, at the mouth of the Bristol Channel; but being driven back by contrary winds, he landed again in Wales, and shut himself up in Neath Abbey, in Glamorganshire. Meanwhile, the queen's forces attacked the castle of Bristol, where the elder Despencer, styled earl of Winchester, had been left governor by the king. When the siege had lasted only a few days, the garrison rose in mutiny and delivered up the old man. He was ninety years of age; but his grey hairs did not save him; he was immediately executed with every circumstance of barbarous insult the ingenuity of his captors could devise. The next day (26th

October) the prelates and barons in the queen's camp declared Prince Edward guardian of the kingdom. The king was discovered in his place of concealment about three weeks after, and was conducted in custody first to the castle of Monmouth, and then to that of Kenilworth. The younger Despencer was also taken; he was hanged and quartered at Hereford on the 24th of November. The parliament assembled on the 1st of January, 1327; and after going through some forms of negotiation with the imprisoned king, it was resolved, on the 25th of that month, that the crown should be taken from him and conferred upon his son Prince Edward. A deputation announced this resolution to the deposed monarch. He remained for some months longer at Kenilworth: he was then transferred successively to Corfe, Bristol, and Berkeley Castles. At length, when it was found that mere insult would not kill him, he was, on the night of the 20th of September, murdered in the last-mentioned place by his keepers Sir Thomas Gournay and Sir John Maltravers, who with detestable brutality thrust a red-hot iron into his bowels through a pipe, thus contriving to destroy him without leaving any external marks of their atrocious operation.

Edward II. left by his Queen, Isabella of France, two sons, Edward, who succeeded him, and John, born at Eltham 15th August, 1316, created earl of Cornwall, in 1327, who died at Perth in October, 1336; and two daughters, Joanna, married 12th July, 1328, to Prince David, eldest son of Robert Bruce, afterwards King David II. of Scotland, and Eleanor, who became the wife of Reginald Count of Guelders.

Some attempts have been made in modern times to dispute the justice of the character which has been generally given of this king, and to throw the blame of the civil distractions which rendered his reign so unhappy and so ignominious a one, rather upon his turbulent nobility than himself. Hume, whose good nature and indolent generosity of feeling inclined him in this as well as in other cases to side with the unsuccessful party, while his quiet temper made him also constitutionally averse to that revolt against established authority and those other irregular proceedings with which the barons are chargeable in their contest with Edward II., has written the history of the reign with a studied endeavour to put the former in the wrong throughout, and to represent Edward as the victim, not of his own weaknesses and vices, but rather of the barbarism of the age. The facts, however, on which the common verdict rests cannot be thus explained away. It may be admitted that among the motives which excited and sustained the several confederacies against the king, and in the conduct of some of those who took the lead in them, there was violence and want of principle enough; it is of the nature of things that the baser passions should mix themselves up and even act an important part in all such conflicts, however righteous in their origin and general object; but nothing that can be alleged on this head can affect the question of Edward's unfitness to wear the crown. That question must be considered as settled, if not by the course of outrage against all decency manifested by his conduct in the matter of Gaveston, certainly by his relapse into the same fatal fatuity a few years after, when he fell into the hands of his second favourite Despencer. Hume has spoken of the acts of maladministration objected to the king and his minions as 'of a nature more proper to excite heart-burnings in a ball or assembly than commotions in a great kingdom.' The admitted fact of the universal indignation which the acts in question did excite is a sufficient answer to this statement of the case.

To the reign of Edward II. belongs the memorable event of the suppression in England, as in the other countries of Europe, of the great order of the Knights-Templars. Their property was seized all over England in 1308; but the suppression of the order in this country was not accompanied by any of that cruel treatment of the persons of the members which they experienced in France. In 1324 the lands which had belonged to the Templars were bestowed upon the order of St. John of Jerusalem.

The most important legal innovation of this reign was that made by the statute of sheriffs (9 Edward II., st. 2), by which the right of appointing those officers was taken from the people and committed to the chancellor, the treasurer, and the judges. Several of the royal prerogatives, relating principally to tenures, were also defined by the statute entitled '*Prærogativa Regis*' (17 Edward II., st. 1).

The statutes down to the end of the reign of Edward II. are commonly distinguished as the '*Vetera Statuta*.' Pleading now began to assume a scientific form. The series of year-books, or reports by authority of adjudged cases, is nearly perfect from the commencement of this reign. The only law treatise belonging, or supposed to belong, to the reign of Edward II. is Horne's *Miroir des Justices*.

The circumstances of the reign were as little favourable to literature as to commerce and the arts. Warton observes that though much poetry now began to be written, he has found only one English poet of the period whose name has descended to posterity; Adam Davy or Davie, the author of various poems of a religious cast, which have never been printed. Among these, however, is not to be reckoned the long work entitled '*The Life of Alexander*,' which is erroneously attributed to him by Warton, but which has since been conclusively shown not to be his. It is printed for the first time in Weber's *Metrical Romances*. There is still extant a curious Latin poem on the battle of Bannockburn, written in rhyming hexameters by Robert Baston, a Carmelite friar, whom Edward carried along with him to celebrate his anticipated victory, but who, being taken prisoner, was compelled by the Scotch to sing the defeat of his countrymen in this jingling effusion. Bale speaks of this Baston as a writer of tragedies and comedies, some of which appear to have been English; but none of them are now known to exist.

EDWARD III., king of England, the eldest son of Edward II. and Isabella of France, was born at Windsor (whence he took his surname), 13th November, 1312. In the first negotiations with the court of France after the breaking out of the quarrel about Guienne in 1324, a proposal seems to have been made by the French king, Charles IV., for a marriage between a daughter of his uncle, the count de Valois, and the young prince of Wales, as Edward was styled; but it was coolly received by the king of England, and ended in nothing. In September of the year following Prince Edward proceeded to Paris, where his mother now was, and did homage to his uncle, king Charles, for the duchy of Guienne and the earldom of Ponthieu, which his father had previously resigned to him. He was induced by his mother to remain with her at the French court, notwithstanding the most pressing letters from his father (Rymer, iv.), begging and commanding him to return. Meanwhile Isabella, having previously solicited from the pope a dispensation (which however she did not obtain) to permit her to marry her son without his father's knowledge, had arranged a compact with William earl of Hainault, by which the prince was affianced to Philippa, the second of the earl's four daughters. Edward was soon after carried by his mother to Valenciennes, the residence of the earl of Hainault, where he met Philippa, and, it is said, fell ardently in love with her. He landed with his mother in England in September, 1326; was declared guardian or regent of the kingdom about a month after; and was proclaimed king on the deposition of his father, 25th January, 1327. [EDWARD II.] He was crowned at Westminster the following day.

The government of the kingdom during the king's minority was placed by the parliament in the hands of a regency, consisting of twelve noblemen and bishops, with Henry earl of Lancaster (the brother of Thomas, executed in the preceding reign) at their head. The queen however and Mortimer (now created earl of March) from the first assumed the chief management of affairs, and soon monopolized all power. They must be considered as having been the real authors of the murder of the deposed king. Their authority seemed for the moment to be rather strengthened than otherwise by the failure of a confederacy formed among the nobility to effect their overthrow in the winter of 1328-9. In March, 1329, signal proof was given of their determination and daring in the maintenance of their position, by the fate of the king's uncle, the earl of Kent, who having become involved in what was construed to be a plot against the government, was put to death on that charge.

Meanwhile the king, young as he was, and although thus excluded from the government, had not passed his time in inactivity. He was married to Philippa of Hainault, 24th January, 1328. A few months after his accession he had marched at the head of a numerous army against the Scotch, who had again invaded and ravaged the northern counties; but they eluded all his attempts to come up with them, and after a campaign of three weeks this expedition

ended in nothing. Soon after this a treaty of peace was concluded between the two kingdoms, on the basis of the recognition of the complete independence of Scotland. This important treaty was signed at Edinburgh, the 17th of March, 1328, and confirmed in a parliament held at Northampton on the 4th of May following. One of the articles was, that a marriage should take place between prince David, the only son of the king of Scotland, and the sister of the king of England, the princess Joanna; and, although the bride was only in her seventh, and the bridegroom in his fifth year, the marriage was celebrated accordingly at Berwick on the 12th of July. The illustrious Bruce just lived to see this truly epic consummation of his heroic labours. He was able to receive the youthful pair on their arrival at Edinburgh after the nuptials; but he was now worn out by a disease which had for some time preyed upon him, and he returned immediately to his country-seat at Cardross, where he expired on the 7th of June, 1329.

The settlement of the dispute between the two countries which thus seemed to be effected, proved of very short duration. In a few months a concurrence of important events altogether changed both the domestic condition and the external relations of England. In the close of the year 1330, Edward at length determined to make a bold effort to throw off the government of Mortimer. The necessary arrangements having been made, the earl and the queen-mother were seized in the castle of Nottingham on the 19th of October; the execution of Mortimer followed at London on the 29th of November; many of his adherents were also put to death; Isabella was placed in confinement in her house at Risings (where she was detained for the remaining twenty-seven years of her life); and the king took the government into his own hands. In the course of the following year Edward seems to have formed the design of resuming the grand project of his father and his grandfather—the conquest of Scotland. For this design he found an instrument in Edward Balliol, the son of the late king John, who, in April, 1332, landed with a small force at Kinghorn, in Fife, and succeeded so far, in the disorganized state of the Scottish kingdom under the incompetent regency of the earl of Mar, and by the suddenness and unexpectedness of his attack, as to get himself crowned at Scone on the 24th of September. Edward, on this, immediately came to York; and on the 23rd of November Balliol met him at Roxburgh, and there made a solemn surrender to him of the liberties of Scotland, and acknowledged him as his liege lord. The violation of his late solemn engagements committed by Edward in this affair was rendered still more dishonourable by the caution and elaborate duplicity with which he had masked his design. Only a few weeks after doing his homage, Balliol found himself obliged to fly from his kingdom; he took refuge in England; various military operations followed; but at last Edward advanced into Scotland at the head of a numerous army: on the 19th of July, 1333, a great defeat was sustained by the Scotch at the battle of Halidon Hill, near Berwick; the regent Douglas himself was mortally wounded and taken prisoner; and every thing was once more subjected to Edward Balliol. King David and his queen were conveyed in safety to France. On the 12th of June, 1334, at Newcastle, Balliol, by a solemn instrument, made an absolute surrender to Edward of the greater part of Scotland to the south of the Forth. But within three or four months the puppet king was again compelled to take flight to England. Two invasions of Scotland by Edward followed; the first in November of this year; the second in July, 1335; in the course of which he wasted the country with fire and sword almost to its extreme northern confines, but did not succeed in bringing about an engagement with the native forces, which, notwithstanding, still kept the field. In the summer of 1336 he took his devastating course for the third time through the northern counties, with as little permanent effect. On now retiring to England he left the command to his brother John, styled earl of Cornwall, who soon after died at Perth.

From this time, however, the efforts of the English king were, in great part, drawn off from Scotland by a new object. This was the claim which he had first advanced some years before to the crown of France, but which he only now proceeded seriously to prosecute, determined probably by the more open manner in which the French king had lately begun to exert himself in favour of the Scots, whom, after repeated endeavours to serve them by mediation

and intercession, he had at length ventured to assist by supplies of money and warlike stores. Charles IV. of France had died in February, 1328, leaving a daughter who was acknowledged on all hands to have no claim to the crown, which it was agreed did not descend to females. In these circumstances Philip of Valois mounted the throne, taking the title of Philip VI. He was without dispute the next in the line of the succession if both females and the descendants of females were to be excluded. Edward's claim rested on the position that although his mother, Isabella, as a female, was herself excluded, he, as her son, was not. If this position had been assented to he would undoubtedly have had a better claim than Philip, who was only descended from the younger brother of Isabella's father. But the principle assumed was, we believe, altogether new and unheard of—and would besides, if it had been admitted, have excluded both Philip and Edward, seeing that the true heir in that case would have been the son of Joanna Countess d'Evreux, who was the daughter of Louis X., Isabella's brother. It would also have followed that the two last kings, Philip V. and Charles IV., must have been usurpers as well as Philip VI.; the son of Joanna, the daughter of their predecessor and elder brother, would, upon the scheme of succession alleged by the king of England, have come in before both. Undeterred by these considerations, however, or even by the circumstance that he had himself in the first instance acknowledged Philip's title, and even done homage to him for the Duchy of Guienne, Edward, having first entered into an alliance with the earl of Brabant, and taken other measures with the view of supporting his pretensions, made an open declaration of them, and prepared to vindicate them by the sword. The earliest formal announcement of his determination to enforce his claim appears to have been made in a commission which he gave to the earl of Brabant and others to demand the crown of France and to take possession of it in his name, dated 7th October, 1337.

We cannot here pursue in detail the progress of the long war that followed. Edward embarked for the continent on the 16th July, 1338, and arrived at Antwerp on the 22nd. Of his allies the chief were the emperor and the free towns of Flanders, under nominal subjection to their earl, but at this time actually governed by the celebrated James Van Artevelde. The emperor made him his vicar, and at Artevelde's suggestion he assumed the title of king of France. The first important action that took place was the sea-fight off Sluys, on the 22nd June, 1340, in which the English were completely victorious. It was followed by long truces, which protracted the contest without any decisive events. Meanwhile, in Scotland, the war proceeded, also with occasional intermissions, but on the whole to the advantage of the national cause. Balliol left the country about the close of 1338; and in May, 1341, King David and his consort Joanna returned from France. In 1342 the Scots even made several inroads into the northern counties of England. A suspension of hostilities however took place soon after this, which lasted till the close of 1344.

In 1345 Edward lost the services of his efficient ally Van Artevelde, who was murdered in an insurrection of the populace of Ghent, excited by an attempt, which he appears to have made somewhat too precipitately, to induce the free towns to cast off their sovereignty, the earl of Flanders, and to place themselves under the dominion of the son of the king of England, Edward, prince of Wales. Edward, afterwards so distinguished under the name of the Black Prince (given to him from the colour of his armour), was born at Woodstock, 15th June, 1330, and was consequently only yet in his sixteenth year. His father nevertheless took him along with him to win his spurs, when in July 1346, he set out on another expedition to France with the greatest army he had yet raised. After reducing Caen and Lower Normandy, he proceeded along the left bank of the Seine till he reached the suburbs of the capital, and burnt the villages of St. Germain and St. Cloud. The memorable battle of Crecy followed on the 26th of August, in which the main division of the English army was commanded by the prince. Between thirty and forty thousand of the French are said to have been slain in this terrible defeat. Among those who fell was John of Luxemburg, king of Bohemia; he fell by the hand of Prince Edward, who thence assumed his armorial ensign of three ostrich feathers and the motto *Ich Dien* (I serve), and transmitted the badge to all succeeding princes of Wales.

The defeat of the French at Crecy was followed on the

17th October, in the same year, by the equally signal defeat of the Scots at the battle of Nevil's Cross, near Durham, in which the greater part of the nobility of Scotland were either taken prisoners or slain, and the king himself, after being wounded, fell into the hands of the enemy. Froissart says that Queen Philippa led the English army into the field on this occasion; but no native contemporary or very ancient writer mentions this remarkable circumstance.

Three days after the battle of Crecy, Edward sat down before the town of Calais. It did not however open its gates to him till after a glorious defence of nearly eleven months. On its surrender the English king was prevented, by the intercession of Queen Philippa, from making his name infamous for ever by taking the lives of the six burghesses whom he commanded to be given up to his mercy as the price for which he consented to spare their fellow-citizens. The reduction of Calais was followed by a truce with France, which lasted till 1355. When the war was renewed, Philip VI. had been dead for five years, and the throne was occupied by his son John. On the 19th of September, 1356, the Black Prince gained the battle of Poitiers, at which the French king was taken prisoner. The kings both of France and Scotland were now in Edward's hands; but neither country was yet subjugated. At last, after many negotiations, David II. was released, in November, 1357, for a ransom of 100,000*l.*, to be discharged in ten yearly payments. King John was released on his parole in 1360, when a treaty of peace was concluded between the two countries at Bretigny, confirming to the English the possession of all their recent conquests. But after remaining in France for about four years, John returned to captivity on finding that he could not comply with the conditions on which he had received his liberty, and died in London, 8th April, 1364. He was succeeded by his son, Charles V., who had acted as lieutenant of the kingdom during his absence.

It would appear that during the Scottish king's long detention in England he had been prevailed upon to come into the views of Edward, at least to the extent of consenting to sacrifice the independence of his country after his own death; and it is probable that it was only upon a secret compact to this effect that he obtained his liberty. Joanna, the consort of David, died childless in 1362; and in a parliament held at Scone the following year the king astounded the estates by proposing that they should choose Lionel, duke of Cambridge, the third son of the king of England, to fill the throne in the event of his death without issue. At this time the next heir to the throne in the regular line of the succession was the Stewart of Scotland, the son of David's elder sister Marjory; and a wish to exclude his nephew, against whom he entertained strong feelings of dislike, is supposed to have had a considerable share in influencing the conduct of the king. The proposal was rejected by the parliament unanimously and with indignation. A few months after this the death of Edward Balliol without issue removed all chance of any competitor arising to contest David's own rights; and he became of course a personage of more importance than ever to the purposes of the ambitious and wily king of England. David now repaired to London; and here it was agreed in a secret conference held between the two kings on the 23rd of November, that in default of the king of Scots and his issue male, the king of England for the time being should succeed to the crown of Scotland. In the mean time, the king of Scots was to sound the inclinations of his people and to inform the English king and his council of the result. (See the articles of the agreement, twenty-eight in number, in the sixth volume of Rymer's *Fœdera*.) From this time David acted with little disguise in the interests of the English king, and even spent as much of his time as he could in England. One effect of this policy was, that actual hostilities between the two countries ceased; but no public misery could exceed that of Scotland, distracted as it was by internal convulsions, exhausted by the sufferings and exertions of many preceding years, and vexed by the exactions necessary to defray the ransom of the king, his claim to which Edward artfully took advantage of as a pretext for many insults and injuries, and a cover for all sorts of intrigues. In 1365, however, it was agreed that the truce (for the cessation from hostilities was as yet nothing more) should be prolonged till 1371.

In 1361 the prince of Wales had married Joanna, styled the Fair, the daughter of his great uncle the earl of Kent, who had been put to death in the beginning of the present

reign. This lady had been first married to William de Montacute, earl of Salisbury, from whom she had been divorced; and she had now been about three months the widow of Sir Thomas Holland, who assumed in her right the title of earl of Kent, and was summoned to parliament as such. Soon after his marriage the prince of Wales was raised by his father to the new dignity of prince of Aquitaine and Gascony (the two provinces or districts of Guienne); and in 1363 he took up his residence, and established a splendid court in that quality, at Bordeaux. Edward's administration of his continental principality was very able and successful, till he unfortunately became involved in the contest carried on by Pedro surnamed the Cruel with his illegitimate brother Henry of Trastamare for the crown of Castile. Pedro having been driven from his throne by Henry, applied to the Black Prince for aid to expel the usurper. At this call Edward, forgetting everything except the martial feelings of the age and what he conceived to be the rights of legitimacy, marched into Spain, and defeated Henry at the battle of Najera, fought on the 3rd of April, 1367. He did not, however, attain even his immediate object by this success. Pedro had reigned little more than a year when he was again driven from his throne by Henry, by whom he was soon after murdered. Henry kept possession of the throne which he had thus obtained till his death, ten years after. Prince Edward, meanwhile, owing to Pedro's misfortunes, having been disappointed of the money which that king had engaged to supply, found himself obliged to lay additional taxes upon his subjects of Guienne, to obtain the means of paying his troops. These imposts several of the Gascon lords refused to submit to, and appealed to the king of France as the lord paramount. Charles on this summoned Edward to appear before the parliament of Paris as his vassal; and on the refusal of the prince, immediately confiscated all the lands held by him and his father in France. A new war forthwith broke out between the two countries. For a time the wonted valour of Prince Edward again shone forth; but among the other fruits of his Spanish expedition was an illness caught by his exposure in that climate, which gradually undermined his constitution, and at length compelled him, in January, 1371, to return to England. He had just before this lost his eldest son, Edward, a child of six years old. King Edward's consort, Queen Philippa, had died on the 15th of August, 1369.

On his departure from Guienne, Prince Edward left the government of the principality in the hands of his brother John of Gaunt, duke of Lancaster. The duke shortly after married a daughter of Pedro the Cruel, in whose right he assumed the title of king of Castile, and before the end of the year followed his brother to England. Affairs on the continent now went rapidly from bad to worse. The great French General Duguesclin drove the English everywhere before him. In the summer of 1372 two expeditions were fitted out from England, the first commanded by the earl of Pembroke, the second by King Edward in person, accompanied by the Black Prince; but both completely failed. The forces of the earl of Pembroke were defeated while attempting to land at Rochelle by the fleet of Henry King of Castile; and those conducted by the king and his son, which were embarked in 400 ships, after being at sea for six weeks, were prevented from landing by contrary winds, and obliged to put back to England. At last, in 1374, when he had lost everything that had been secured to him by the treaty of Bretigny, Edward was glad to conclude a truce for three years.

Thus ended the French wars of this king, which had cost England so much blood and treasure. Those which he waged against Scotland equally failed of their object. David II. had died in February, 1371, and the Stewart of Scotland immediately ascended the throne without opposition under the title of Robert II. No serious attempt was ever made by Edward to disturb this settlement, though he at one time seemed inclined to threaten another Scottish war, and he never would give Robert the title of king, he contented himself with styling him 'the most noble and potent prince, our dear cousin of Scotland.'

The latter years of Edward's long reign presented in all respects a melancholy contrast to his brilliant commencement. The harmony which had hitherto prevailed between the king and his parliament gave way under the public misfortunes, and the opposition to the king's government was headed by his eldest son. The Black Prince, however,

died in his 46th year, on the 8th of June 1376. He was in the popular estimation the first hero of the age, and to this reputation his military skill, his valour, and other brilliant and noble qualities, may be admitted to have entitled him; but, with all his merits, he was not superior to his age, nor without his share of some of the worst of its faults. He left by his wife Joanna one son, Richard, a child in his tenth year; and he appears also to have had a daughter, who became the wife of Waleran de Luxemburg, count de Ligny; his illegitimate sons were Sir John Sounder and Sir Roger de Clarendon. King Edward, in the weakness of old age, had now for some time given up the entire management of affairs to his second son the unpopular Duke of Lancaster, and fears were entertained that he intended the duke to inherit the crown; but these apprehensions were removed by his creating Richard of Bordeaux prince of Wales, duke of Cornwall, and earl of Chester, and declaring him in parliament his heir and successor. Since the death of his queen also he had attached himself with doting fondness to Alice Perers, one of the Ladies of her Bedchamber, and had excited great public disgust by the excesses to which this folly carried him. The last fortnight of his life he spent at his manor of Shene, now Richmond, attended only by this lady. But even she deserted him on the morning of his death; and no one save a single priest was by his bed-side, or even in the house, when he breathed his last. This event happened on the 21st of June, 1377, in the 65th year of his age and the 51st of his reign.

Edward III. had by his queen, Philippa of Hainault, seven sons: 1. Edward prince of Wales; 2. William of Hatfield, born 1336, who died young; 3. Lionel, duke of Clarence, born at Antwerp 29th November, 1338; 4. John, duke of Lancaster, called of Gaunt, or Ghent, where he was born in 1340; 5. Edmund, duke of York, born at Langley, near St. Alban's, in 1341; 6. William, born at Windsor, who died young; 7. Thomas, duke of Gloucester, born at Woodstock, 7th January, 1355; and five daughters: 1. Isabella, married to Ingelram de Courcy, earl of Soissons and Bedford; 2. Joanna, born in August, 1334, who was contracted, in 1345, to Pedro the Cruel, afterwards king of Castile, but died of the plague at Bordeaux, in 1349, before being married; 3. Blanche, called De la Tour, from having been born in the Tower of London, who died in infancy; 4. Mary, married to John de Montford, duke of Bretagne; and 5. Margaret, married to John de Hastings, earl of Pembroke.

It has been observed, in regard to Edward III., by Sir James Mackintosh, that 'though his victories left few lasting acquisitions, yet they surrounded the name of his country with a lustre which produced strength and safety; which perhaps also gave a loftier tone to the feelings of England, and a more vigorous activity to her faculties.' 'During a reign of fifty years,' it is added, 'Edward III. issued writs of summons, which are extant to this day, to assemble seventy parliaments or great councils: he thus engaged the pride and passions of the parliament and the people so deeply in support of his projects of aggrandisement, that they became his zealous and enthusiastic followers. His ambition was caught by the nation, and men of the humblest station became proud of his brilliant victories. To form and keep up this state of public temper was the mainspring of his domestic administration, and satisfactorily explains the internal tranquillity of England during the forty years of his effective reign. It was the natural consequence of so long and watchful a pursuit of popularity that most grievances were redressed as soon as felt, that parliamentary authority was yearly strengthened by exercise, and that the minds of the turbulent barons were exclusively turned towards a share in their sovereign's glory. Quiet at home was partly the fruit of fame abroad.'

The two great charters were repeatedly confirmed in this reign, and a greater number of important new laws were passed than in all the preceding reigns since the Conquest. Among them may be particularly noticed the celebrated statute (25 Ed. III., st. 5, c. 2) defining and limiting the offence of high treason; the numerous provisions made to regulate the royal prerogative of purveyance, and diminish the grievances occasioned by it; the law (1 Ed. III., c. 12) permitting tenants in chief to alienate their lands on payment of a reasonable fine; the several prohibitions against the payment of Peter's Pence: and the first statute (the 27th Ed. III., st. 1, c. 1) giving a writ of *præmunire* against such as should presume to cite any of the king's subjects to

the court of Rome. In this reign also began the legislation respecting the poor, by the enactment of the statute of Labourers (23 Ed. III., c. 1), which was followed by several other acts of the same kind, setting a price upon labour as well as upon provisions. Trial by Jury also now began to acquire a decided ascendancy over the old modes of trial and various regulations were made for improving the procedure of the courts and the administration of justice. Justices (at first called keepers) of the peace were established by the statute 34 Ed. III., c. 1. In 1362 was passed the important act (36 Ed. III., st. 5, c. 15) declaring that henceforth 'all pleas should be pleaded, showed, defended, amended, debated, and judged in the English tongue,' and no longer in the French, which is described as 'much unknown in the realm.' They were ordered still however to be entered and enrolled in Latin. The acts of parliament continued to be written sometimes in Latin, but most generally in French, long after this time. The science of legal pleading is considered by Coke to have been brought to perfection in this reign. The only law treatises which belong to this reign are those entitled the *Old Tenures*, the *Old Natura Brevium*, the *Novæ Narrationes*, and the book on the Diversity of Courts. They are all in Norman French.

The commerce and manufactures of the country made some advances with the general progress of the age in the course of this reign; but they certainly were not considerable for so long a space of time. The woollen manufacture was introduced from the Netherlands, and firmly rooted in England before the close of the reign. Some augmentation also seems to have taken place in the shipping and exports of the country. On the other hand, the king's incessant wars operated in various ways to the discouragement of commerce. Sometimes foreign merchants were afraid to send their vessels to sea lest they should be captured by some of the belligerents. On one occasion at least (in 1338), Edward made a general seizure of the property belonging to foreign merchants within his dominions, to supply his necessities. At other times he resorted to the ruinous expedient of debasing the coin. Many acts were passed by the parliament on the subject of trade, but they involved for the most part the falsest principles; some prohibiting the exportation of money, of wool, and of other articles; others imposing penalties for forestalling; others attempting to regulate wages, prices, and expenditure. Of course such laws could not be executed; they only tormented the people, and aggravated the mischiefs they were intended to cure; but in consequence of being thus inefficient, they were constantly renewed. The most memorable invention of this age is that of gunpowder, or rather its application in war. It appears to be certain that cannons were used at the battle of Crecy in 1346; but there is reason to believe that they were in use about twenty years earlier. They were certainly familiarly known before the close of the reign.

Among the more elegant arts, architecture was that which was carried to the greatest height. Edward III. nearly rebuilt the Castle of Windsor, which however has undergone great improvements and alterations since his time: the beautiful chapel of St. George, at Windsor, was also built, or at least finished, by this king. But splendour and luxury generally made undoubtedly great advances among the wealthier classes, although it may be questioned if wealth was more generally diffused throughout the community, or if the poverty and wretchedness of the great body of the people were not rather increased than diminished. The increase of licentiousness of manners among the higher ranks appears to have kept pace with that of magnificence in their mode of living. This was the age of tournaments, and of the most complete ascendancy of the system of chivalry; but all this, at least in its direct and immediate effects, was more favourable to the improvement of the outside polish and formal courtesies of life within a narrow circle, than to the diffusion of any humanizing influences throughout the mass of society. The Order of the Garter was instituted by Edward III., it is generally supposed in the year 1349.

In literature, this was the age of Chaucer, the Morning Star of our poetry, and of his friend Gower, and also of Wicliffe, who first translated the Scriptures into English, and who has been called the Morning Star of the Reformation. The principal chroniclers of the time of Edward III. are Thomas Stubbs, William Thorn, Ralph

Higden, Adam Merimuth, Henry de Knighton, and Robert de Avesbury.

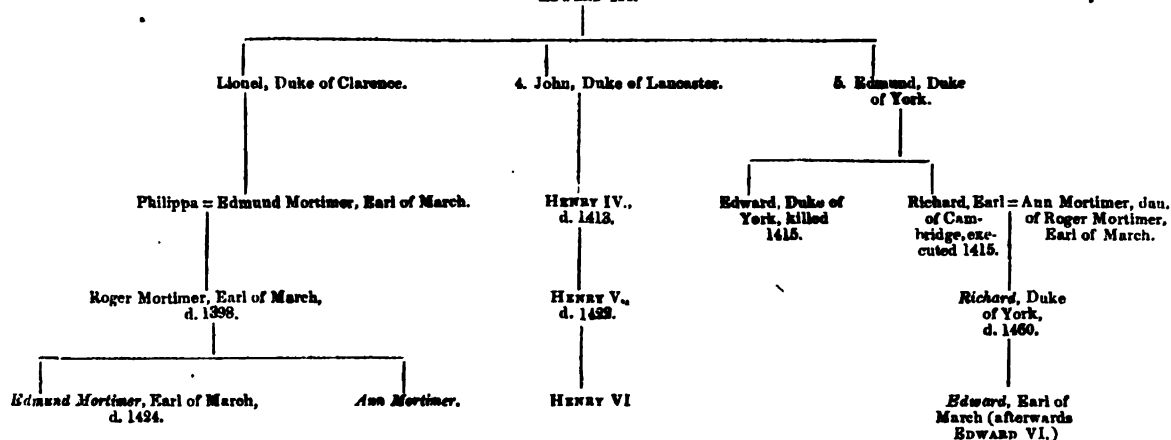

The convulsion in the church excited by Wicliffe began in the last years of Edward III., but the history of it more properly belongs to the next reign, that of his grandson Richard II.

EDWARD IV., king of England. During the reign of Richard II. the heir presumptive to the crown was Roger Mortimer, earl of March, the son of Philippa Plantagenet, who was the only child of Lionel duke of Clarence, the second of the sons of Edward III. that left any descendants. Roger earl of March died in Ireland, where he was lord-lieutenant, or governor, in 1398. His son Edmund Mortimer, earl of March, was a child of only ten years of age at the deposition of Richard II. in 1399; but in his person resided the right to the crown by lineal descent so long as he lived. Although however his name was mentioned on several occasions in connexion with his dangerous pretensions, and he more than once ran the risk of being made a tool of in the hands of persons more ambitious than himself, he never made any attempt against the house of Lancaster. We may here remark, that much confusion has been introduced into the common accounts of Edmund Mortimer by his being confounded with his uncle Sir Edmund Mortimer. It was the latter personage, for instance, who, having married the daughter of Owen Glendower, engaged with the Percies in their insurrection in 1403, and performed the rest of the part assigned to the Lord Mortimer in Shakespeare's play of the First Part of Henry the Fourth. It is to him also we suppose that we are to attribute the pun put by the common histories into the mouth of his nephew the earl of March at the coronation of Henry IV., when, on that king claiming the crown as the heir male of Henry III., he said that he was indeed *Hæres Malus*. 'But Edmund had his jest and Henry his crown,' observes Bishop Kennet in telling this story (*Complete History of England*, i. 274). The young earl of March, with the other children of his father, was detained in a sort of imprisonment at Windsor during all the reign of Henry IV., but on the accession of Henry V. he was set at liberty. In 1415 he became involved in the conspiracy planned against Henry V. by Richard earl of Cambridge; but it is most probable that he was not answerable for the use which was made, or rather intended to be made, on this occasion, of his name. Indeed

the common account makes him to have been the person who gave Henry information of the conspiracy, after he had been applied to by the earl of Cambridge, who had married his sister, to join it. After the accession of Henry VI. he was sent as lord lieutenant to Ireland; and he died there in the castle of Trim in 1424. He left no issue, nor did his brother Roger, nor his sister Eleanor; but his sister Ann, married to the earl of Cambridge, had a son named Richard, who consequently became his uncle's representative, and (at least after the death of his mother) the individual on whom had devolved the claim by lineal descent to the crown. This Richard was also the representative of Edward III.'s fifth son, Edmund duke of York, his father the earl of Cambridge having been the second son of that prince, whose eldest son and heir, Edward duke of York, had fallen at the battle of Agincourt, leaving no issue, only a few months after his brother had been executed for the conspiracy mentioned above. At the time of his uncle's death, Richard, in consequence of his father's forfeiture, had no title; but he seems to have immediately assumed that of Earl of March, at least he is so called by some of the chroniclers, and the same title was also afterwards borne by his son, although the right of either to it may be questioned, inasmuch as it appears to have been only descendible to heirs male. Richard however is best known by his title of duke of York, which he took in 1425, on being restored in blood and allowed to inherit the honours both of his father and uncle. But it is important to recollect that the claim of the house of York to the crown in opposition to the house of Lancaster was not derived from Edward III.'s fifth son Edmund duke of York, who was younger than John of Gaunt, the founder of the house of Lancaster, but from Lionel duke of Clarence, who was that king's third son, John of Gaunt being his fourth.

As a clear notion of the above genealogical statement is important to the understanding of a considerable portion of English history, it may be proper once for all to exhibit it in the form most convenient for its ready apprehension and for future reference to it. The line of the eldest son of Edward III. having failed in Richard II., and his second son having died without issue, the contest for the crown in the fifteenth century lay among the descendants of his third, fourth, and fifth sons, whose connexion with him and among themselves stood thus:—

EDWARD III.

The persons whose names are printed in Italics are those in whom successively the hereditary right vested. We cannot discover however how long Ann Mortimer survived her brother, or even that she survived him at all, although it seems to be usually assumed that she did.

Richard, duke of York, first makes his appearance in public affairs in the end of the year 1435, when he was appointed by Henry VI. to the regency of France on the death of the duke of Bedford. By the time he entered upon his office, however, Paris had been evacuated, and their French dominion was fast passing out of the hands of the English. He was recalled in 1437, but was reappointed on the death of his successor, the earl of Warwick, in July, 1440. On the 29th of April, 1441 (or, according to another account, in September, 1442), his son Edward, earl of March, afterwards Edward IV., was born at Rouen. The duke of York remained in France till after the conclusion of the king's marriage with Margaret of Anjou, in 1446; and his government was then prolonged for another term of five years; but in 1447 he was recalled, through the influence of the queen and the favourite, the marquess of

Suffolk, and Edmund Beaufort, earl (afterwards duke) of Somerset, the chief of the younger branch of the Lancaster family, appointed his successor. It is understood that before this the unpopular government of the queen and the favourite had turned men's minds to the claims of the duke of York; and it is said that he himself, though he moved warily in the matter, was not idle by his emissaries in encouraging the disposition that began to grow up in his favour. The progress of events in course of time enabled him to take a bolder part in the promotion of the design he had already in all probability formed, of securing the crown for himself and his family. In 1449 he gained additional popularity by the able and conciliatory manner in which he suppressed an insurrection in Ireland. In the rising of the people of Kent the next year, their leader, Jack Cade, assumed the name of Mortimer as a sort of title. When he rode

in triumph through the streets of the metropolis, he called out, as he struck London Stone with his sword, 'Now is Mortimer lord of the city!' When the duke returned from Ireland, in August, 1451, some steps seem to have been taken by the court to oppose his landing; but he made his way to London, and immediately entered there into consultations with his friends. It was determined to demand the dismissal and punishment of the duke of Somerset, now the king's chief minister; but although this attempt was supported by an armed demonstration, it ended after a few months in the duke of York dismissing his followers, returning to his allegiance, and agreeing to retire to his estate. The king had now been married for several years without having any children, and it appears to have been generally expected that the duke, by merely waiting for his death, would obtain the crown without any risk or trouble. On the birth of the prince of Wales, however, in October, 1453, it became necessary to adopt another course. The spirit that showed itself in the parliament the following year forced the court to admit the duke of York and his chief friends and confederates, the two Nevilles (father and son), earls of Salisbury and Warwick, into the council, where their first act was to arrest the duke of Somerset and send him to the Tower. A few weeks after this (on the 3rd April, 1454), the duke of York was appointed by the parliament protector and defender of the kingdom during the illness of the king, who had fallen into a state of mental as well as bodily imbecility. In the following spring however Henry partially recovered, and resuming the management of affairs, released Somerset. This brought matters to a crisis. The duke of York now withdrew from court, and both parties collected their forces to decide their quarrel by the sword. The two armies met at St. Alban's on the 23rd of May, 1455, when the king was defeated, he himself being wounded and taken prisoner, and the duke of Somerset and others of the royal leaders slain. Henry, detained in the hands of the victor, was obliged to call a parliament, which met at Westminster on the 9th of July; and here the helpless king declared the duke and his friends to be innocent of the slaughter at St. Alban's, and greeted them as his 'free and faithful liegemen.' The parliament met again, after prorogation, on the 12th November, when the duke was a second time appointed protector. He was removed however by the king on the 23rd February, 1456; on which he again retired from court with his friends. The next two years passed without any further encounter, each party hesitating to attack the other. At last, in the spring of 1458, York and his friends were invited by the queen to London, to be reconciled to the Lancastrian party; an agreement to live for the future in peace was made with much solemnity; and the duke of York and the earls of Salisbury and Warwick were again admitted into the council. All this however seems to have been merely a stratagem of the queen's to get them into her power: their danger soon became apparent; and before the end of the year they all again withdrew from court. The resort to the final arbitrament could not now be much longer deferred. Both parties again collected their armed strength. Their first meeting took place at Blore-heath, near Drayton, in Shropshire, on the 23rd September, 1459, when the royal forces under Lord Audley were defeated by the earl of Salisbury, Audley himself being slain. On the 12th of October however the king's army met that of York and Warwick near Ludlow: ample offers of pardon were made to all who would come over to the royal side; and the consequence was, that so many of the insurgents deserted, that, almost without striking a blow, the rest threw down their arms, and their leaders were obliged to save themselves by flight. The duke of York and his adherents were attainted and their estates confiscated, at a parliament which met at Coventry a few weeks after. By June, 1460, however, the dispersed insurgents were again in arms. York landed from Ireland and Warwick from France nearly at the same time; the latter, whose numbers had now increased to 40,000 men, entered London on the 2nd of July; and on the 9th the royal forces, advancing from Coventry, were met near Northampton, by York's son Edward, the young earl of March, and signally defeated, the king being taken prisoner, and the queen and her son obliged to fly for their lives. This is the first appearance of Edward on the scene. Up to this time also the duke of York had never disputed Henry's title to the crown; he professed to have taken

arms only to compel the king to dismiss his evil counsellors and to govern according to the laws. Even now Henry's name was still made use of by the victorious party. He was made to call a parliament, which met at Westminster on the 2nd October, and immediately annulled every thing that had been done by the late parliament of Coventry. But at this point the duke at last threw off all disguise. On the 16th he delivered to the parliament by his counsel a written claim to the crown. The question was formally discussed, and it was at length determined that Henry should be allowed to remain king during his life, but that the duke of York should be immediately declared his successor. Richard was accordingly, on the 1st of November, solemnly proclaimed heir apparent and protector of the realm; being in the latter capacity invested with rights and powers which already threw into his hands all of royalty except the name. But his dignity and authority were soon brought to an end. The queen found means to assemble an army in the north; on hearing which news the duke, on the 2nd of December, marched from London to give her battle. They met on Wakefield Green on the 31st, and the issue of their encounter was the complete defeat of York. He himself and one of his younger sons were slain, and the earl of Salisbury was taken prisoner, and executed the next day at Pomfret, with twelve of his associates. Edward, now duke of York, was at Gloucester when he heard of this disaster. A formidable royal force, commanded by the earls of Pembroke and Ormond, hung on his rear; this he attacked on the 2nd February, 1461, at Mortimer's Cross, near Hereford, and completely routed. He then set out for London, upon which the queen also was now directing her march. The next engagement that took place was at Bernard's Heath, near St. Alban's, where the queen was met on the 17th by the earl of Warwick: the earl, who had the king with him in the field, was defeated, and his majesty regained his liberty. The approach of the duke of York however deterred Margaret from continuing her advances upon the capital; she retired to the north, while he entered London on the 28th, amid the congratulations of the citizens. On the 2nd of March he laid his claim to the crown, founded on King Henry's alleged breach of the late agreement, before an assembly of lay and clerical lords; on the same afternoon an assembly of the people was held in St. John's Fields, at which his nomination as king was received with unanimous acclamations of assent; and two days after he was solemnly proclaimed by the name of Edward the Fourth. The 4th of March was considered as the day of his accession.

The first three years of the reign of Edward IV. were occupied by a prolongation of the contest that raged when he mounted the throne. The Lancastrians sustained a severe defeat from the king in person at Towton in Yorkshire, on the 29th of March, 1461; but Queen Margaret was unwearied in her applications for assistance to France and Scotland, and she was at last enabled to take the field with a new army. That too however was routed and dispersed at Hexham by the forces of Edward under the command of Lord Montagu, on the 17th of May, 1464. This victory, and the capture of Henry, which took place a few days after, put an end to the war. An event however occurred about the same time out of which new troubles soon arose. This was the marriage of the king with Elizabeth Woodville, the young and beautiful widow of Sir Thomas Gray, and the daughter of Sir Richard Woodville (afterwards created Earl Rivers) by Jacquetta of Luxemburg, whose first husband had been the late duke of Bedford. The connexions of the lady, both by her birth and by her first marriage, were all of the Lancastrian party; but Edward's passion was too violent to allow him to be stopped by this consideration; he was privately married to her at Grafton, near Stoney Stratford, on 1st May, 1464: she was publicly acknowledged as his wife in September; and she was crowned at Westminster on Ascension Day in the following year. The first effect of this marriage was to put an end to a negotiation, in which some progress had been made, with the French King Louis XI. for Edward's marriage with his sister-in-law the Princess Bonne of Savoy, any alliance which it was hoped might have proved a bond of amity betwixt the two kingdoms. It at the same time alienated from the king the most powerful of his supporters, the earl of Warwick, by whom the French negotiation had been conducted, and whose disapprobation of the king's conduct in a political point of view was consequently sharp

ened by the sense of personal ill usage. Above all, the honours and bounties lavished by Edward upon the obscure family of his queen disgusted the old nobility, and raised even a national feeling against him. It was some time before matters came to extremities; but at last, Warwick and Queen Margaret having entered into close alliance, England was once more, in 1469, deluged with the blood of a civil war. Nearly the whole of that and the following year was a season of confusion, of which it is scarcely possible to derive any consistent or intelligible account from the imperfect documents of the time that remain, and the ill-informed chroniclers who have attempted to describe the course of occurrences. At last, in the beginning of October, 1470, Edward found himself obliged to embark and fly to Holland. King Henry was now released from the Tower, in which he had been confined for the preceding six years, and the royal authority was again exercised in his name. This revolution earned for Warwick his well-known title of the King-maker. Henry's restoration however was a very short one. On the 14th March, 1471, Edward landed, with a force which he had raised in the Low Countries, at the mouth of the Humber, made his way to London, was received with acclamations by the citizens, again obtained possession of the imbecile Henry, and sent him up in his old prison. He then, on the 14th April, went out to meet Warwick, who was advancing from St. Alban's: the two armies encountered at Barnet; and the result was that the forces of the earl were completely defeated, and both he and his brother Lord Montagu were left dead on the field. The war was finished by the second defeat of the Lancastrians on the 14th May, at the great battle of Tewkesbury, where both Queen Margaret and her son Prince Edward fell into the hands of their enemies. Margaret was sent to the Tower, and was detained there till she was set at liberty in conformity with one of the articles of the treaty of Pecquigny, concluded with France in 1475, the French king paying for her a ransom of 50,000 crowns. Her unfortunate son was brought before Edward on the day after the battle, and brutally put to death in his presence by the hands of the dukes of Clarence and Gloucester (the king's brothers), assisted by two other noblemen. King Henry terminated his days in the Tower about three weeks after; and it has generally been believed that he was also violently taken off, and that his murderer was the duke of Gloucester. Many executions of the members of the Lancastrian party followed, and confiscations of their property in all parts of the kingdom.

The remainder of the reign of Edward IV. was marked by few memorable events. One that may deserve to be noticed is the fate of the king's next brother, George duke of Clarence, who was attainted of treason by a parliament which met in January, 1478, and immediately after privately put to death, being drowned, it was generally believed, in a butt of malmsey. He had at one time taken part with Warwick against his brother, and had sealed his alliance with the earl by marrying his daughter; nor, although he afterwards saw it prudent to break this connexion, had he and Edward ever probably been cordially reconciled. It seems to have been chiefly his nearness to the throne that at last fixed his brother in the determination of getting rid of him. Edward was at war both with Scotland and with France during the greater part of his reign; but the military operations that took place were unimportant, and are not worth relating: they were never carried on with any vigour, and were frequently suspended by long truces, which however, in their turn, were generally broken by the one nation or the other before the proper term. In June, 1475, Edward having previously sent a herald to King Louis to summon him to surrender the whole kingdom of France, embarked with a large force, and landed at Calais; but the expedition ended within three months in the treaty of Pecquigny, or Amiens, already mentioned. By one of the articles it was agreed that the dauphin, Charles, should marry Elizabeth, the king of England's eldest daughter; and Louis also engaged to pay Edward an annuity of 50,000 crowns a year as long as they both lived. It appears that Edward's ministers as well as their royal master consented to receive pensions from the French king: large amounts of money were distributed among them from time to time; and in their case at least this foreign pay was a mere bribe to engage them in the interests of the power from which they received it. Edward however is asserted to have himself shared in their gains;

indeed his own acknowledged annuity, though it might bear the appearance of a compensation for advantages which he had given up, was itself in reality nothing else than a bribe; it was a supply obtained independently of parliament and the country. He was driven indeed to many other shifts and illegal methods, as well as this, to raise money for his wasteful debaucheries and extravagant expenditure on the mistresses, favourites, and others that ministered to his personal pleasures. Louis however appears never to have had any intention of fulfilling his engagement as to the marriage; for some years he evaded Edward's importunities as well as he could; till at length, in 1482, he contracted the dauphin in another quarter. Edward, incensed in the highest degree, was preparing to avenge this affront by a new descent upon France, in which the parliament had eagerly promised to assist him with their lives and fortunes, when he was suddenly cut off by a fever, on the 9th of April, 1483, after a reign of twenty-two years.

Edward IV. had by his wife Elizabeth three sons; Edward, who succeeded him; Richard, duke of York, born in 1474; and George, duke of Bedford, who died in infancy; and seven daughters; Elizabeth, born 11th February, 1466, contracted to the dauphin, and afterwards married to Henry VII.; Cecilia, contracted to Prince James (afterwards James IV.) of Scotland, and afterwards married first to John Viscount Wells, secondly to Mr. Kyme, of Lincolnshire; Anne, contracted to Philip, son of the archduke Maximilian of Austria and his wife the duchess of Burgundy, and afterwards married to Thomas Howard, duke of Norfolk; Bridget, born at Eltham, 10th November, 1480, who became a nun at Dartford; Mary, contracted to John I., king of Denmark, Norway, and Sweden, but who died at Greenwich, in 1482, before the marriage was solemnized; Margaret, born 19th April, 1472, who died 11th December following; and Catherine, contracted to John, elder son of Ferdinand and Isabella of Spain, and afterwards married to William Courtenay, earl of Devonshire. By one of his many mistresses, Elizabeth Lucy, he had two natural children; Arthur, surnamed Plantagenet, created Viscount Lisle by Henry VIII.; and Elizabeth, who became the wife of Thomas lord Lumley.

Edward IV. has the reputation of having been zealous and impartial in the administration of justice; but with the exception of some statutes abridging the antient jurisdiction of sheriffs, and transferring part of the powers of those officers to the quarter-sessions, no important innovations were made in the law during this reign. It is from this period however that the rise of what is called indirect pleading is dated. In this reign also the practice of suffering common recoveries by a tenant in tail, as a means of barring his estate tail, and also all the estates in remainder and reversion, was fully established by judicial decision (in the 12th year of this king) after it had been interrupted for some time by the statute of Westminster 2, 13 Ed. I., c. 32. The reduction of the law and its practice to a scientific form is considered to have made great progress in the latter part of the reign of Henry VI., and in that of Edward IV. To the latter belong the treatise 'De Laudibus Legum Angliæ' of Sir John Fortescue, the celebrated treatise on Tenures of Sir Thomas Littleton, and the work called Statham's Abridgment of the Law. The Year Books also began now to be much more copious than in former reigns.

Many laws relating to trade and commerce passed in the reign of Edward IV. attest the growing consequence of those interests, but are not in other respects important, and do not show that more enlightened views began to be entertained than had heretofore prevailed. The manufacture of articles of silk, though only by the hand, was now introduced into this country; and we find the parliament endeavouring to protect it by the usual method of prohibiting the importation of similar articles made abroad. This reign is illustrious as being that in which the art of printing was introduced into England. [CAXTON.]

The testimony of historians concurs with the probabilities of the case in assuring us that the country must have been subjected to much devastation and many miseries during the bloody and destructive wars of York and Lancaster; but this contest was undoubtedly useful in shaking the iron-bound system of feudalism, and clearing away much that obstructed the establishment of a better order of things. The country seems to have very soon recovered from the

immediate destruction of capital and property occasioned by these wars.

EDWARD V., the eldest son of Edward IV., was born 4th of November, 1470, in the Sanctuary of Westminster Abbey, where his mother had taken shelter when her husband was obliged to fly to the Continent on the return of Queen Margaret and the earl of Warwick. He was consequently only in his thirteenth year when his father died. His reign is reckoned from the 9th of April, 1483, the day of his father's decease; but during the few weeks it lasted he never was a king in more than name. The public transactions of his reign all belong properly to the history of his uncle, Richard III. Edward was at Ludlow in Shropshire at the time of his father's death, and possession of his person was obtained at Northampton by Richard (then duke of Gloucester) as he was on his way to London in charge of his maternal uncle Anthony earl Rivers. He appears not to have been brought to London till the beginning of May. In the course of that month, and probably between the 24th and 27th, Richard was declared at a great council protector of the king and the kingdom. On the 16th of June he contrived to obtain Edward's younger brother, the duke of York, out of the hands of the queen his mother, who had taken refuge in Westminster Abbey with him and his sister. The two boys were forthwith removed to the Tower, then considered one of the royal palaces, there to remain, as was pretended, till the coronation of the young king, which was appointed to take place on the 22nd. Before that day arrived however Richard had completed his measures for placing the crown on his own head. The 26th of June is reckoned the commencement of his reign, and the close of that of his nephew. After this Edward and his brother were seen no more. They were however universally believed to have been made away with by Richard. The account which has been generally received is that given by Sir Thomas More, whose testimony may be regarded as that of a contemporary, for he was born some years before the death of Edward IV. His statement is in substance that Richard, while on his way to pay a visit to the town of Gloucester after his coronation, sent one John Green, 'whom he specially trusted,' to Sir Robert Brackenbury, the constable of the Tower, with a letter desiring Sir Robert to put the children to death; that Brackenbury declared he would not commit so dangerous a deed; that Sir James Tyrrel was then despatched with a commission to receive the keys of the Tower for one night; and that under his directions the children were about midnight stifled in bed with their feather-beds and pillows, by Miles Forest, 'one of the four that kept them, a fellow fleshed in murder beforetime,' and John Dighton, Tyrrel's own horse-keeper, 'a big, broad, square, and strong knave.' The relation is given in the fullest and most particular form, not in the Latin translation of More's History, or in the re-translation of that into English, published (with a strange ignorance that the work already existed in English) in Bishop Kennet's Collection of Histories (3 vols., folio, 1706); but in the English work, which we believe is the original. It is printed in full from More's works in Holinshed, who describes it as written about the year 1513. More does not give the story as merely 'one of the various tales he had heard concerning the death of the two princes' (Henry's *Hist. of Great Britain*; and Walpole's *Historic Doubts on the Life and Reign of Richard III.*); he introduces it by saying, 'I shall rehearse you the dolorous end of those babes, not after every way that I have heard, but after that way that I have so heard by such men and by such means, as methinketh it were hard but it should be true;' and he closes the narrative by repeating that it is what he had 'learned of them that much knew, and little cause had to lie.' It is perfectly evident that he had not himself a doubt of its truth. 'Very true it is,' he says moreover, 'and well known, that at such time as Sir James Tyrrel was in the Tower, for treason committed against the most famous prince, king Henry VII., both Dighton and he were examined, and confessed the murder in manner above written.' The common story seems to be supported by the honours and rewards which were immediately bestowed by Richard upon Tyrrel, Brackenbury, Green, and Dighton. (See these stated in Strype's *Notes on Sir George Buck's Life and Reign of Richard III.*, book 3rd.) Symnel, or Sulford, who in the reign of Henry VII. assumed the character of Edward Plantagenet, son of George duke of Clarence, seems to have originally intended to pass himself as Edward V. Perkin Warbeck,

who appeared some years after, called himself Edward's brother, Richard duke of York.

Buck and others, who have endeavoured to disprove King Richard's guilt, have rested much of their argument on the fact that the remains of Edward and his brother never could be found in the Tower, although much search had been made for them; but on the 17th of July, 1674, in making some alterations, the labourers found covered with a heap of stones at the foot of an old pair of stairs a quantity of partially consumed bones, which, on examination appeared to be those of two boys of the ages of the two princes. They were removed by order of Charles II. to Henry VII.'s chapel in Westminster Abbey, where the inscription placed over them recites that they appeared by undoubted indications to be those of Edward V. and his brother. (*Ossa desideratorum diu et multum quæsitæ, &c., scalarum in rudibus (scalæ istæ ad sacellum Turris Albæ nuper ducebant) alte defossa, indicibus certissimis sunt reperta, &c.*) This discovery is sufficiently in conformity with More's account, who tells us that Tyrrel caused the murderers to bury the bodies 'at the stair foot, meetly deep in the ground under a great heap of stones.' It is true he mentions a report that Richard 'allowed not the burying in so vile a corner, saying that he would have them buried in a better place, because they were a king's sons; whereupon they say that a priest of Sir Robert Brackenbury's took up the bodies again, and secretly interred them in such place as, by the occasion of his death which only knew it, could never since come to light.' This however is evidently a story both improbable in itself, and one which, although it might naturally enough arise and get into circulation, could never have rested on any trustworthy authority. More gives it as a mere rumour, and we may fairly infer, from the words ('as I have heard') with which it is introduced, that he did not himself believe it. He carefully adds, in his notice of the examination of Tyrrel and Dighton, 'but whether the bodies were removed they could nothing tell. Tyrrel was executed for his treason; but Dighton still lived when More wrote. He says of him, 'Dighton indeed yet walketh on alive, in good possibility to be hanged ere he die.' According to Grafton, 'Dighton lived at Calais long after, no less disdained and hated than pointed at.' The reader may also compare upon this subject the account of the examinations of Tyrrel and Dighton given by Bacon in his History of King Henry VII. (Montagu's edition of Bacon's Works, iii., 287, 288.) It agrees very closely with the story told by More. Bacon says that Dighton, who was set at liberty after the examinations, 'was the principal means of divulging this tradition;' and from the use of that expression it has been inferred that Bacon regarded the whole as an idle tale. But he has in several places in this work distinctly expressed his belief of the guilt both of Richard and Tyrrel; especially in his notice (p. 385) of the execution of Tyrrel, 'against whom,' he says, 'the blood of the innocent princes, Edward V. and his brother, did still cry from under the altar.' Tyrrel's examination, we may observe, appears to have taken place in 1493; but he was not executed till 1503. He was committed to the Tower in the first of these years on the appearance of Perkin Warbeck, expressly that he might be examined touching the murder; and it was on quite another charge that he was executed ten years after. More's account therefore of the circumstances of his confession is slightly inaccurate. He does not however expressly say, as Sir James Mackintosh makes him do (*Hist. Eng.*, ii., 59), that Tyrrel 'confessed his guilt when he was executed twenty years after for concealing the murder of the earl of Suffolk.' Bacon himself, who relates, in their proper places, both his first imprisonment and his execution, says inaccurately that he was beheaded 'soon after' the examinations. [RICHARD III.]

EDWARD VI., the only son of Henry VIII. who survived him, was born at Hampton Court 12th October, 1537. His mother, Queen Jane Seymour, died on the twelfth day after giving him birth. The child had three stepmothers in succession after this; but he was probably not much an object of attention with any of them. Sir John Hayward, who has written the history of his life and reign with great fulness, says that he 'was brought up among nurses until he arrived to the age of six years.' He was then committed to the care of Dr. (afterwards Sir Anthony) Cooke, and Mr. (afterwards Sir John) Cheke, the former of whom appears to have undertaken his instruction in philosophy

and divinity, the latter in Greek and Latin. The prince made great proficiency under these able masters. Henry VIII. died at his palace at Westminster early in the morning of Friday the 28th of January, 1547; but it is remarkable that no announcement of his decease appears to have been made till Monday the 31st, although the parliament met and transacted business on the intervening Saturday. Edward, who was at Hatfield when the event happened, was brought thence in the first instance to the residence of his sister Elizabeth at Enfield, and from that place, on the 31st, to the Tower at London, where he was proclaimed the same day. The council now opened the will of the late king (executed on the 30th of December preceding), by which it was found that he had (according to the powers granted him by the acts 28 Hen. VIII. ch. 7, and 35 Hen. VIII. ch. 1) appointed sixteen persons under the name of executors, to exercise the powers of the government during the minority of his son. One of these, the king's maternal uncle, Edward Seymour, earl of Hertford, was immediately elected by the rest their president, and either received from them in this character, or assumed of his own authority, the titles of governor of his majesty, lord protector of all his realms, and lieutenant-general of all his armies. He was also created duke of Somerset, and soon after took to himself the office of lord high treasurer, and was further honoured by being made earl marshal for life. About the same time his brother, Sir Thomas Seymour, was created Baron Seymour of Sudley, and appointed lord high admiral. The elevation of Somerset had been opposed by the lord chancellor Wriothesley (now earl of Southampton); but the protector in a few weeks got rid of his further interference by taking advantage of an informality into which the earl had fallen in the execution of his office of chancellor, and frightening him into a resignation both of the seals and of his seat in the executive council.

The period of the administration of the protector Somerset forms the first of the two parts into which the reign of Edward VI. divides itself. The character of the protector has been the subject of much controversy; but opinions have differed rather as to the general estimate that is to be formed of him, or the balance of his merits and defects, than as to the particular qualities, good and bad, by which he was distinguished. It may be said to be admitted on all hands that he was a brave and able soldier, but certainly with no pretensions in that capacity to a humanity beyond his age; that as a statesman he was averse to measures of severity, and fond of popular applause, but unstable, easily influenced by appeals either to his vanity or his fears, and without any fertility of resources, or political genius of a high order. It must be admitted also that he was both ambitious and rapacious in no ordinary degree. Add to all this, that with one of the two great parties that divided the country he had the merit, with the other the demerit, of being a patron of the new opinions in religion—and it becomes easy to understand the opposite feelings with which he was regarded in his own time, and the contradictory representations that have been given of him by party writers since.

One of the first acts of his administration was an expedition into Scotland, undertaken with the object of compelling the government of that country to fulfil the treaty entered into with Henry VIII. in 1543 for the marriage of the young Queen Mary to Edward. The Scottish forces were signally defeated by the English protector at the battle of Pinkie, fought 10th September, 1547; but the state of politics, as bearing upon his personal interests in England, compelled Somerset to hasten back to the south without securing any of the advantages of his victory. He returned to Scotland in the summer of the following year; but he wholly failed in attaining any of the objects of the war. The young queen was conveyed to France; and the ascendancy of the French or Catholic party in the Scottish government was confirmed, and continued unbroken during all the rest of the reign of Edward.

Meanwhile great changes were effected in the domestic state of England. The renunciation of the supremacy of the pope, the dissolution of the religious houses, and the qualified allowance of the reading of the Scriptures in English, were the principal alterations in religion that had been made up to the death of the late king. Only a few months before the close of the reign of Henry, Protestants as well as Catholics had been burned in Smithfield. Under Somerset and the new king measures were immediately taken

to establish Protestantism as the religion of the state. Even before the meeting of parliament, the practice of reading the service in English was adopted in the royal chapel, and a visitation, appointed by the council, removed the images from the churches throughout the kingdom. Bishops Gardiner of Winchester and Bonner of London, who resisted these measures, were committed to the Fleet. The parliament met in November, when bills were passed allowing the cup to the laity, giving the nomination of bishops to the king, and enacting that all processes in the ecclesiastical courts should run in the king's name. The statute of the Six Articles, commonly called the Bloody Statute, passed in 1539, was repealed, along with various other acts of the preceding reign for the regulation of religion. By the parliament of 1548 the use of the Book of Common Prayer was established, and all laws prohibiting spiritual persons to marry were declared void. At the same time an act was passed (2 and 3 Ed. VI. c. 19) abolishing the old laws against eating flesh on certain days, but still enforcing the observance of the former practice by new penalties, 'the king's majesty,' says the preamble, 'considering that due and godly abstinence is a mean to virtue, and to subdue men's bodies to their soul and spirit, and considering also specially that fishers, and men using the trade of living by fishing in the sea, may thereby the rather be set on work, and that by eating of fish much flesh shall be saved and increased.'

But Somerset's path was now crossed by a new opponent, in the person of his own brother, Lord Seymour. That nobleman, equally ambitious with the protector, but of a much more violent and unscrupulous temper, is supposed to have, very soon after the king's accession, formed the design of disputing the supreme power with his brother. It is said to have been a notice of his intrigues that suddenly recalled Somerset from Scotland after the battle of Pinkie. The crime of Seymour does not appear to have gone farther than caballing against his brother; but Somerset contrived to represent it as amounting to high treason. On this charge he was consigned to the Tower; a bill attainting him was brought into the House of Lords, and read a first time on the 25th of February, 1549; it was passed unanimously on the 27th. The accused was not heard in his own defence, nor were any witnesses examined against him; the House proceeded simply on the assurance of his brother, and of other members of the council, that he was guilty. The bill was afterwards passed, with little hesitation, by the House of Commons; it received the royal assent on the 14th of March; and on the 20th Lord Seymour was beheaded on Tower-hill, with his last breath solemnly protesting his innocence.

During the summer of this year the kingdom was disturbed by formidable insurrections of the populace in Somerset, Lincoln, Kent, Essex, Suffolk, Devon, Cornwall, and especially in Norfolk, where a tanner of the name of Kett opposed the government at the head of a body of 20,000 followers. The dearth of provisions, the lowliness of wages, the enclosure of common fields, and in some places the abolition of the old religion, with its monasteries where the poor used to be fed, and its numerous ceremonies and holidays that used to gladden labour with so much relaxation and amusement, were the principal topics of the popular clamour. It is worth noticing that the agency of the press was on this occasion employed, probably for the first time, as an instrument of government. Holinshed records that 'while these wicked commotions and tumults, through the rage of the undisciplined commons, were thus raised in sundry parts of the realm, sundry wholesome and godly exhortations were published, to advertise them of their duty and to lay before them their heinous offences.' Among them was a tract by Sir John Cheke, entitled 'The Hurt of Sedition, how grievous it is to a Commonwealth,' which is a very able and vigorous piece of writing. It was found necessary however to call another force into operation: the insurgents were not put down without much fighting and bloodshed; and many of the rebels were executed after the suppression of the commotions. The institution of lords lieutenants of counties arose out of these disturbances.

A few months after these events brought Somerset's domination to a close. His new enemy, John Dudley, formerly Viscount Lisle, and now Earl of Warwick, the son of that Dudley whose name is infamous in history for his oppressions in the reign of the seventh Henry, had probably been watching his opportunity, and carefully maturing his

designs against the protector, for a long time. It is supposed to have been through his dark and interested counsel that Somerset was chiefly impelled to take the course which he did against his brother; Warwick's object was to destroy both, and he probably counted that by the admiral's death, and the part which the protector was made to take in it, he both removed one formidable rival, and struck a fatal blow at the character and reputation of another. He himself meanwhile had been industriously accumulating popularity and power. He had greatly distinguished himself at the battle of Pinkey, and in other passages of the Scotch war; and it had been chiefly by him that the late insurrection in Norfolk had been so effectually quelled. The energy which he showed on this occasion was contrasted by the enemies of the protector with what they represented as the feebleness of the latter, who had, they contended, encouraged the insurrection by the hesitation and reluctance which he manifested, on the first threatenings of it, to take the necessary measures for putting it down. The protector had at this time incurred considerable odium by his lavish expenditure (out of the spoils, as it was said, of the church) on his new palace of Somerset House, and certain violations both of public and of private rights of which he was accused of having been guilty in procuring the space and the materials for that magnificent structure. A cry was also raised against him on account of a proposition he had made in the council for a peace with France on the condition of resigning Boulogne for a sum of money. In the beginning of October he learned that measures were about to be immediately taken against him. In fact Warwick and his associates in the council had collected their armed retainers, and were now ready to employ force if other means should fail. They had retired from Hampton Court, where the king resided, and fixed themselves in London, where they had contrived to obtain possession of the Tower. Somerset, on the first notice of their proceedings, carried off the king to Windsor Castle, and shut himself up there as if with the intention of holding out; but he soon found himself nearly deserted by all; and after a few days the king himself was obliged to sanction the vote for his deposition passed by the majority of the council. On the 14th he was brought to London in custody, and sent to the Tower. From this moment Warwick, though without his title of protector, enjoyed his power. Somerset, reduced to insignificance by this usage, but especially by an abject submission which he made in the first moments of danger, was some time after this released from confinement, and was even allowed again to take his seat at the council-table; but he either engaged in designs to regain his lost place, or Warwick, now duke of Northumberland, and possessed almost of undivided power in the state, felt that he should not be quite secure so long as his old rival lived. An apparent reconciliation had been effected between the two, and ratified by the marriage of Warwick's eldest son to Somerset's daughter; but this connexion was no shelter to the overthrown protector: on the 1st of December, 1551, he was brought to trial before the high steward and a committee of the House of Lords, on charges both of high treason and of felony; he was convicted of the latter crime; and was executed on Tower Hill, the 22nd January, 1552. He met his death with great manliness, and the popular sympathy was deeply excited in his favour, both by the feeling that, with some faults, he had fallen the victim of a much worse man than himself, and by the apprehension that in his destruction the great stay which had hitherto supported the Reformation in England was thrown down.

Warwick however (although at his death, a few years after this, he declared that he had always been a Catholic) did not feel himself strong enough to take any measures openly in favour of the ancient faith, opposed as he knew he would be in that course by the great mass of the nation. It is probable that he cared little which religion prevailed so that he remained at the head of affairs. The government accordingly continued to be conducted in all respects nearly as it had heretofore been. In March, 1550, a peace had been concluded with France, one of the articles stipulating for the surrender of Boulogne, the support of which very proposition had been made the principal charge against Somerset a few months before. In the following July another treaty between the two countries was signed at Angers, by which it was agreed that the king of England should receive in marriage Elizabeth, the daughter of the king of France. Meanwhile at home the

matter of religion continued to be treated by the new government much as it had been by the old. No Roman Catholics were put to death during this reign, though many were fined, imprisoned, and otherwise not capitally punished; but on the 2nd of May, 1550, an unfortunate fanatic, Joan Becher, commonly called Joan of Kent, was burnt for certain opinions considered to be neither Catholic nor Protestant, in conformity with a warrant extorted by Cranmer from the king about a year before; and on the 2nd of May, 1551, an eminent surgeon, named Von Panis, of Dutch extraction, but resident in London, paid the same penalty for his adherence to a similar heresy. Bishop Bonner was deprived of his see in September, 1549; Gardiner, in January, 1551; and Day of Chichester, and Heath of Worcester, in October of the same year. The forty-two articles of belief, afterwards reduced to thirty-three, were promulgated in the early part of this year.

In April, 1552, Edward was attacked by small-pox; and, although he recovered from that disease, the debility in which it left him produced other complaints, which ere long began to assume an alarming appearance. By the beginning of the following year he was very ill. Northumberland now lost no time in arranging his plans for bringing the crown into his own family. In May his son Lord Guilford Dudley married the Lady Jane Grey, the eldest daughter of the duchess of Suffolk, who was herself the eldest daughter, by her second marriage with Charles Brandon, duke of Suffolk, of Mary Tudor, the ex-queen of France, and the daughter of Henry VII., upon whose descendants Henry VIII. had by his will settled the crown on failure of the lines of his son Edward and of his daughters Mary and Elizabeth. This settlement, it is to be remembered, had been made by Henry under the express authority of an act of parliament, which empowered him to dispose of the kingdom to whomsoever he chose, on failure of his three children. Northumberland now applied himself to induce Edward to make a new settlement excluding Mary and Elizabeth, who had both been declared illegitimate by parliament, and to nominate Lady Jane Grey (in whose favour her mother the duchess of Suffolk, still alive, agreed to renounce her claim) as his immediate successor. The interest of the Protestant religion, which it was argued would be more secure with a sovereign on the throne whose attachment to the principles of the Reformation was undoubted, and upon whose birth there was no stain, than if the succession were left to be disputed between the king's two sisters, one of whom was a bigoted Catholic, and the legitimacy of either of whom almost implied the illegitimacy of the other, is believed to have been the chief consideration that was urged upon the dying prince. Edward at all events was brought over to his minister's views. On the 11th of June, Montague, the chief justice of the Common Pleas, and two of his brethren, were sent for to Greenwich, and desired to draw up a settlement of the crown upon the Lady Jane. After some hesitation they agreed, on the 14th, to comply with the king's commands, on his assurance that a parliament should be immediately called to ratify what was done. When the settlement was drawn up, an engagement to maintain it was subscribed by fifteen lords of the council and nine of the judges. Edward sunk rapidly after this, and lived only till the evening of the 6th of July, when he expired at Greenwich. His death, however, was concealed for two days, and it was not till the 9th that Lady Jane Grey was proclaimed.

Edward VI. is stated by the famous Jerome Cardan, who was brought to see him in his last illness, to have spoken both French and Latin with perfect readiness and propriety, and to have been also master of Greek, Italian, and Spanish. In his conversation with Cardan, which the latter has preserved, he showed an intelligence and dexterity which appear to have rather puzzled the philosopher. Walpole has set him down among his royal authors on the strength of his 'Diary,' printed by Barnet in his History of the Reformation, and the original of which is still preserved among the Cottonian manuscripts; a lost comedy which is attributed to him, called 'The Whore of Babylon;' some Latin epistles and orations, of which specimens are given by Strype; a translation into French of several passages of scripture, preserved in the library of Trinity College, Cambridge; a tract in French against popery, entitled 'L'Encontre des abus du monde;' and a few other productions of a similar kind which have not been printed.

The act of the 1st Edward VI. gave to the king all the colleges, free-chapels, chauntries, hospitals, &c., which were not in the possession of his father by the act passed in the 37th year of Henry's reign. This act was much abused; for though one professed object of it was the encouragement of learning, many places of learning were actually suppressed under it. The king, however, afterwards founded a considerable number of grammar-schools, which still exist and are popularly known as King Edward's Schools. [BIRMINGHAM, &c.] (Strype's *Ecclesiastical Memorials*, vols. ii. iii.; *Journal of Education*, No. 19.)

In 1556, in the reign of Queen Mary, a boy of the name of William Fetherstone, or Constable, a miller's son, was hanged at Tyburn for giving himself out to be Edward VI.

EDWARD THE BLACK PRINCE. [EDWARD III.]

EDWARDS, JONATHAN, was born at East Windsor, in the province of Connecticut, on the 5th of October, 1703. He was the only son, among eleven children, of Timothy Edwards, who was minister of East Windsor, or (as it was then) the eastern parish of Windsor, during a period of sixty-three years, and who, being a learned, exemplary, and devout man, was much beloved and respected by his flock. Until the age of thirteen, Jonathan was educated at home. He began to learn Latin when six years old, under the care of his father and elder sisters, all of whom the father had made proficient in that language. He seems to have begun writing letters and essays at a very early age; and such of his early compositions as are preserved show a remarkable inquisitiveness concerning both mental and natural phenomena, and a by no means contemptible skill in explaining them. President Dwight, his biographer, has given a fragment written by him in the bantering style, when he could not have been more than twelve years old, against some one who had contended for the materiality of the soul, which shows considerable wit, reach of thought, and power of expression. There is also preserved an entertaining and instructive account of the habits of spiders, as observed by himself, which was written before he was thirteen. He was also led very early to religious meditation, and imbued with a deep sense of religion. He says of himself, in an account of his religious progress, written later in life for the benefit of his children:—'I had a variety of concerns and exercises about my soul from my childhood; but had two more remarkable seasons of awakening before I met with that change by which I was brought to those new dispositions, and that new sense of things, that I have since had. The first time was when I was a boy, some years before I went to college, at a time of remarkable awakening in my father's congregation. I was then very much affected for many months, and concerned about the things of religion, and my soul's salvation; and was abundant in religious duties. I used to pray five times a-day in secret, and to spend much time in religious conversation with other boys. . . . I, with some of my school-fellows, joined together, and built a booth in a swamp, in a very retired spot, for a place of prayer. And besides I had particular secret places of my own in the woods, where I used to retire by myself, and was from time to time much affected.'

He went to Yale College, in Newhaven, at the age of thirteen. In the second year of his residence at the college, when only fourteen, he read through Locke's 'Essay on the Human Understanding;' and President Dwight has published some of his notes on the topics treated of in the essay, which show that he could then understand and appreciate it. The same biographer has published notes on the natural sciences and on theology, which were collected by Edwards during his stay at college. It was in the fourth and last year of his collegiate life that his second 'awakening' took place, an awakening which was speedily followed by a second relapse. 'But in process of time,' he observes in continuation of what has been already quoted, 'my convictions and affections wore off; and I entirely lost all those affections and delights, and left off secret prayer, at least as to any constant performance of it; and returned like a dog to his vomit, and went on in the ways of sin. Indeed I was at times very uneasy, especially towards the latter part of my time at college; when it pleased God to seize me with a pleurisy, in which he brought me nigh to the grave, and shook me over the pit of hell. And yet it was not long after my recovery before I fell again into my old ways of sin. His final and entire conversion took place shortly after his taking his B.A. degree, in September, 1720. The chief

symptom of his 'conversion' is thus described by him:—'From my childhood up, my mind had been full of objections against the doctrine of God's sovereignty in choosing whom he would to eternal life, and rejecting whom he pleased; leaving them eternally to perish, and be everlastingly tormented in hell. It used to appear like a horrible doctrine to me; but I remember the time very well when I seemed to be convinced, and fully satisfied, as to this sovereignty of God, and his justice in thus eternally disposing of men according to his sovereign pleasure. . . . And there has been a wonderful alteration in my mind with respect to the doctrine of God's sovereignty, from that day to this; so that I scarce ever have found so much as the rising of an objection against it in the most absolute sense, in God showing mercy to whom he will show mercy, and hardening whom he will. God's absolute sovereignty and justice, with respect to salvation and damnation, is what my mind seems to rest assured of, as much as of anything that I see with my eyes; at least it is so at times.'

Edwards stayed at college two years after taking his B.A. degree, preparing for the ministry. In August, 1722, he went to New York, having been invited by the English Presbyterians in that town to come among them as their minister. His diary records constant religious meditations during his eight months' stay at New York; and on the 12th of January, 1723, he relates that he solemnly dedicated himself to God. 'I made a solemn dedication of myself to God, and wrote it down, giving up myself, and all that I had, to God; to be for the future in no respect my own; to act as one that had no right to himself in any respect.' He left New York in April, 1723, and returned home. In September of the same year he took his M.A. degree, and shortly after he was chosen tutor of Yale College. Two years after he accepted an invitation from Northampton, in Massachusetts, to assist his maternal grandfather, the Rev. Solomon Stoddard, in the ministry; and, having resigned his tutorship, he was ordained colleague to his grandfather at Northampton in February, 1727, in the twenty-fourth year of his age. Shortly after, he married.

Between the time of his going to New York and his settlement at Northampton, Edwards wrote out seventy resolutions, which he kept before him as his guides through the remainder of his life. They are published in President Dwight's Life. They mostly refer to the governing of his morals and the performance of religious exercises.

He remained at Northampton, first as assistant to his grandfather, and, after his grandfather's death, as sole minister, for twenty-three years. He was, all this while, indefatigable in the discharge of his duties as minister, and diligent in self-improvement. He was an effective preacher, and acquired much fame on the occasion of a very general revival in the years 1740 and 1741: ministers and congregations from all parts of New England applied to Edwards for assistance, and solicited him to come among them and preach. It was at the time of this revival, and in order to moderate men's zeal, that he wrote his treatise on 'Religious Affections.' A revival had previously taken place in his own parish of Northampton, in 1734; an account of which was at the time published by himself under the title, 'A faithful narrative of the surprising work of God, in the conversion of many hundred souls in Northampton.'

On the 22nd of June, 1750, Edwards was dismissed ignominiously from his charge at Northampton. He had offended a large and influential part of his congregation, no less than six years previously, by taking some very active and, as they appeared, arbitrary measures in consequence of a reported circulation of obscene books among the younger members of his flock. He was openly resisted in his attempts to make a public example of the offenders; and from that time his influence over his flock was greatly weakened. But the cause of the final rupture between himself and his flock, and of his dismissal, was a different one. It was a refusal to admit 'unconverted' persons, or (in other words) persons who either could or would not say that they had really embraced Christianity, to a participation in the sacrament. The custom of admitting such persons had been introduced by his predecessor, and not without opposition; and now, after the custom had been established some time, a fiercer opposition was raised by an attempt to get rid of it. On Edwards's first announcement of his disapprobation of the custom, and of his determination to end it, his dismissal was immediately clamoured

for. This was in the spring of 1744; and the six intervening years having been spent in continual disputes, and fruitless attempts to effect a reconciliation, he was dismissed in 1750. A council had been appointed, consisting of ten neighbouring ministers, to adjudicate between Edwards and his flock; and this council determined by a majority of one, 'that it is expedient that the pastoral relation between Mr. Edwards and his church be immediately dissolved, if the people still persist in desiring it.' On its being put to the people, more than two hundred voted for his dismissal, and only twenty against it.

In August, 1751, Edwards went as missionary to the Indians at Stockbridge, a town in the western part of Massachusetts Bay, having been applied to for the purpose by the Boston Commissioners for Indian Affairs, and having also received an invitation from the inhabitants of Stockbridge. Here he had much leisure; and it was during his stay at Stockbridge that he wrote his *Inquiry into the Freedom of the Will*, and his *Treatise on Original Sin*. The first of these works, and that on which his fame chiefly rests, was written in nine months, and was published in 1754. In 1757 he was chosen, without any solicitation on his part, and much to his surprise, president of Princeton College, New Jersey. Having after some deliberation accepted the appointment, he went to Princeton in January, 1758, and was installed president. He died of the small-pox on the 22nd of the following March.

It may be inferred, from the account which we have given of his life, that the character of Jonathan Edwards was eminently estimable. He was an industrious, meek, conscientious, kind, and just man. In religion he was a Calvinist; and his principal work, that on the Will, was written in defence of the Calvinistic views on that subject and against those entertained by Arminians.

Edwards's chief works are, 1. 'A Treatise concerning Religious Affections;' 2. 'An Inquiry into the modern prevailing notions respecting that Freedom of the Will which is supposed to be essential to Moral Agency, Virtue and Vice, Reward and Punishment, Praise and Blame;' 3. 'The Great Christian Doctrine of Original Sin defended; containing a Reply to the Objections of Dr. John Taylor;' 4. 'The History of Redemption;' 5. 'A Dissertation concerning the end for which God created the World;' and 6. 'A Dissertation concerning the true nature of Christian Virtue.' The three last works were published after his death.

The best and most complete edition of Edwards's works is that edited by President Dwight, in 10 volumes. There is also an edition in 8 volumes, published in London, 1817. The 'Inquiry into the Freedom of the Will' has lately been published separately, with an Introductory Essay by Mr. Taylor, the author of 'The Natural History of Enthusiasm.'

EDWARDS, BRYAN, the historian of the British West India colonies, was born at Westbury, in Wiltshire, May 21, 1743. Family distresses caused him, towards the end of 1759, to go to Jamaica, where he was most kindly received by his mother's brother, Zachary Bayly, a rich, generous, and enlightened planter, who, seeing the young man's fondness for books, and thinking well of his talents, engaged a tutor to reside with him. His early instruction had been confined to reading, writing, and the French and English languages; and his studies in Jamaica, by his own account, were slight and desultory: still we may fairly ascribe to them no small share in preserving him from that intellectual listlessness into which Europeans sent out in early life to tropical climates are apt to fall. At this period the autobiography prefixed to the second and later editions of his 'History of the West Indies' ends; and the accounts given of his remaining life are extremely scanty. It appears, however, that in due time he succeeded to his uncle's estate, became a wealthy merchant, and an active member of the House of Assembly. In 1784 he published a pamphlet in opposition to the government policy of limiting the trade between the West Indies and the United States to English bottoms, in which he maintains that 'even the welfare of the planter concurs with the honour of government and the interests of humanity, in wishing for the total abolition of the slave-trade;' an opinion which he recanted after the subject of the slave-trade had been brought before parliament. In 1791 he went to St. Domingo, on the breaking out of the insurrection of the negroes, and acquired the materials for his 'Historical

Survey' of that island, published in 1797. Afterwards he removed to England, where, in 1796, we find him M.P. for Grampound, which he represented until his death, July 15, 1800.

His principal work, the 'History, Civil and Ecclesiastical, of the British Colonies in the West Indies,' was published in 1793. It treats of the history, constitution, and political relations towards Britain, of these colonies; the manners and dispositions of the inhabitants, especially the negroes; the mode of agriculture, and produce. It is a valuable contribution to our literature. The style is somewhat ambitious, but lively and attractive; the matter varied and interesting. The author enters largely into the question of the slave-trade, the cruelty of which he does not attempt to deny, though he is warm in defence of the planters against the charges of cruelty brought against them in England; but his arguments are evidently tinctured by the feeling that, lamentable as it may be, slaves must be had. Mr. Edwards has the merit of having carried a law to prevent cruelties to which slaves in Jamaica were at least legally exposed, whatever the practice might be.

The edition of 1819 contains also the history of St. Domingo, proceedings of the governor, &c., in regard to the Maroon negroes (1796), a continuation of the history down to that time, and one or two other pieces by other hands.

EDWIN, king of Northumbria, was the son of Ella, who appears to have reigned in that kingdom from about A.D. 559 to 589. On the death of Ella, the throne was seized by Edilfrid, or Ethilfrith, the husband of his daughter Acca, and Edwin, an infant, of only three years old, was conveyed to the court of Cadvan, the king of North Wales. Edilfrid on this made war upon Cadvan, and defeated him near Chester, on which occasion it is said that 1200 monks of the monastery of Bangor, who had assembled on a neighbouring hill to offer up their prayers for the success of Cadvan, were put to death by the pagan victor. After this Edwin wandered about for some years till he was, at last, received and protected by Redwald, king of the East Angles. It appears to have been while resident here that he married Cwenburgha, the daughter of Ceorl, king of Mercia. Edilfrid, however, who had made himself by his military success very formidable to all the neighbouring princes, still pursued him, and partly by threats, partly by promises, had nearly induced Redwald to give him up, when (by a miraculous interposition, as Bede would have us believe) more generous counsels prevailed, and the East Anglian king determined to brave the hostility of Edilfrid. Redwald is the fifth in the list of the Bretwaldas, or supreme kings of Britain, as given by Bede; and as he succeeded Ethelbert of Kent, who died in A.D. 616, he probably now held that dignity. The consequence of his refusal to deliver up Edwin was a war with Edilfrid; they met on the right bank of the Idel in Nottinghamshire in A.D. 617, and in a great battle which was there fought Edilfrid was defeated and slain. His children, of whom the names of six are recorded, fled, and Edwin ascended the throne of Northumbria. His valour and abilities eventually acquired for him great power. On the death of his friend Redwald, A.D. 624, he was acknowledged as his successor in the dignity of Bretwald; and two years after he made war upon the powerful state of Wessex, whose king Cuicelm is accused of having attempted to take him off by assassination, and reduced it for the moment to subjection, though it does not appear that he retained his conquest. Bede affirms that his sovereignty extended over all the English, excepting only the people of Kent, and that he also subjected to his dominions all the Britons, and the Islands of Man and Anglesey. It is probable that he was accounted the leading power among the sovereigns of Britain in his time. Bede says that he was addressed by Pope Boniface as 'Rex Anglorum.' The event for which his reign in Northumbria is chiefly memorable is the introduction of Christianity into that kingdom. The legend is related at great length by Bede in the second book of his History. Of the dreams or visions, the prophecies, and the supernatural visitations, which constitute the greater part of it, it is impossible to make anything in the absence of all other testimony except that of the credulous historian; but the result appears to have been brought about by the exertions of Edwin's second wife, Edilberga, the daughter of Augustine's patron, Ethelbert king of Kent, and of Paulinus, a Roman missionary whom she had been allowed to bring with her from her father's court. Edwin had long stood out against the per-

suasions of his queen and Paulinus; but his escape from the attempt against his life by the king of Wessex, and the birth of a daughter, happening simultaneously, powerfully affected him, and Edilberga and her chaplain, taking advantage of the moment of emotion, prevailed with him to call a meeting of his witan to discuss the question of the two religions. When the nobility of Northumbria assembled, Coiffi, the high priest, was himself the first to profess his disbelief in the deities he had been accustomed to serve. This ended the dispute; the chief temple of the idols, which stood at a place still called Godmundham (that is, the hamlet of the enclosure of the God), was profaned and set fire to by the hand of Coiffi; the king and all the chief men of the country offered themselves to be baptized, and the commonalty soon followed their example. Paulinus was made bishop of Northumbria, his residence being established at York, in conformity with the design of Gregory the Great, when the original mission to England was arranged. The archiepiscopal dignity was soon after conferred upon Paulinus by Pope Honorius. Edwin however did not long survive these events. The Mercians, under their King Penda, revolted against the supremacy claimed by Northumbria; and a war which arose in consequence was ended on the 12th of October, 633, by a battle fought at Heathfield, or Hatfield, in Yorkshire, in which Edwin was defeated by Penda and his ally Ceadwalla, king of North Wales, and lost at once his kingdom and his life. His eldest son was slain at the same time; another, whom he also had by his first wife, was afterwards put to death by Penda; and Edilberga, with her children and Paulinus, was compelled to fly to the court of her brother in Kent. One of Edwin's daughters, Eanfled, afterwards married Oswio, a son of Edilfrid, who mounted the throne of Northumbria in 642 and reigned till 670. He defeated Penda, and regained the title of Bretwalda, which Edwin had first brought into his house.

EDWY, called the Fair, king of the Anglo-Saxons, was the eldest of the two sons of Edmund I., but, being only in his seventh or eighth year at his father's death in 946, he and his brother Edgar were set aside for the present in favour of their uncle Edred. On Edred's death in 955, Edwy became king, and his brother appears to have been at the same time appointed subregulus of Mercia. About two years after, the Mercians and Northumbrians rose in revolt, with Edgar as their leader, and a war ensued, which terminated in an agreement between the two brothers that Edwy should retain the country to the south of the Thames, and that Edgar should be acknowledged king of all England to the north of that river. In this revolt Edgar, a mere boy, seems to have been an instrument in the hands of the clerical party, whom Edwy had made his enemies almost from the moment of his accession. In whatever it was that the quarrel began, it soon led to the dismissal of Dunstan and his friends, who had acquired so great an ascendancy in the government in the reign of the preceding king. The writers upon whom we are dependent for the history of this period were all monks, and their testimony is to be cautiously received; but still it is probable enough that they had too much ground for their accounts, which all concur in representing Edwy as a prince of the most dissolute manners, and the kingdom as given up to oppression and anarchy under his rule. The tragical story of Elgiva, as commonly told, is familiar to most readers. Edwy is said to have married this lady, though they were related within the prohibited degrees, and to have incurred the enmity of the ecclesiastics by that violation of canonical law more than by any other part of his conduct. On the day of his coronation, Dunstan tore him rudely from the arms of Elgiva, to whose apartment he had retired from the drunken revelry of the feast; Dunstan's friend, archbishop Odo, subsequently broke into one of the royal houses with a party of soldiers, and, carrying off the lady, had her conveyed to Ireland, after having disfigured her by searing her face with a red-hot iron; and when some time after she ventured to return to England, some of the archbishop's retainers seized her again, and put her to death by the barbarous process of cutting the sinews of her legs with their swords. This story has lately been the subject of some controversy, and the defence of Dunstan and Odo has been undertaken by Dr. Lingard, who does not however deny the main facts of the conduct imputed to them. 'Ham-stringing,' he says, 'was a cruel but not unusual mode of punishment in that age.' He has however made it probable that the lady,

whose name seems to have been Ethelgiva, was not the wife but the mistress of Edwy; and, that being the case, he contends that Odo was justified, first, in sending her to Ireland, by a law of king Edward the Elder, which declared that 'if a known whore-queen be found in any place, men shall drive her out of the realm;' and then in having her put to death on her return, inasmuch as 'he believes, that, according to the stern maxims of Saxon jurisprudence, a person returning without permission from banishment might be executed without the formality of a trial.' For the full discussion the reader is referred to Lingard's *Antiquities of the Anglo-Saxon Church*; Lingard's *History of England*; Lingard's *Vindication of his History*, 8vo., 1827; *Letter to Francis Jeffrey, Esq.*, by John Allen, Esq., 8vo., 1827; and the articles on Dr. Lingard's two works in the *Edinburgh Review*, vol. xxv., pp. 346-354, and vol. xlii., pp. 1-31; both in that letter acknowledged to be by Mr. Allen.

Edwy died in 958, within a year after the pacification with his brother. It is difficult to say whether the expressions of the chroniclers imply that he was murdered, or only that he died of a broken heart. Edgar now became sole king.

EECKHOUT, GERBRANT VANDER, born at Amsterdam in 1621, was a disciple of Rembrandt, whose manner of designing, colouring, and pencilling, he imitated with such felicity, that it is difficult to distinguish some of his paintings from those of his master; and he rather excelled him in the extremities of his figures. His principal employment was for portraits, in which he was admirable, and he especially surpassed all his contemporaries in the power of portraying the mind in the countenance. His masterpiece was the portrait of his own father, which astonished even Rembrandt.

But though his excellence in portraits brought him continual employment in that branch, he greatly preferred painting historical subjects, in which he was equally successful. His composition is rich and judicious; and his distribution of light and shade excellent. His back-grounds are in general clearer and brighter than those of Rembrandt; and he was by far the best disciple of that master on the other hand, it must be allowed that he shared in his defects, being incorrect in his drawing, deficient in elegance and grace, and negligent of costume. He died in 1674.

EECKHOUT, ANTHONY VANDER, was born at Brussels in 1656. It is not known under whom he studied; but he went to Italy with his brother-in-law, Lewis Deyster, a very eminent artist, and painted in conjunction with him during his residence abroad; Deyster painting the figures, and Eeckhout the fruit and flowers: yet there was such a harmony in their style of colouring and touch, that their works appear to be all by one hand. Though he was received with great marks of distinction on his return to Brussels, and appointed to an honourable office, he was resolved to leave his friends and country, and the brilliant prospects which he had before him, in order to return to Italy, intending to spend there the remainder of his days. The vessel however chanced to touch at Lisbon, and he was induced to stop in that city. His pictures sold at excessively high prices; and he had made so many sketches of fine fruit and flowers in Italy, that he had sufficient for all his future compositions, in which he arranged them with infinite variety and great taste. He had not been above two years in Lisbon, when a young lady of quality and large fortune married him. Unhappily his success and his wealth excited the envy of some miscreants, who shot him as he was taking an airing in his carriage. The assassins were never discovered.

EELCOO. A town and commune in East Flanders, situated on the high road between Bruges and Ghent, about nine miles north-west from Ghent. Eelcoo is a place of considerable trade, and contains manufactures of woollen and cotton stuffs, of soap, tobacco, and hats, breweries, distilleries, tanneries, oil-mills, and salt refineries. The weekly market for grain is the largest and best frequented in the province. The town contains 980 houses, mostly well built; there are several public squares, and the streets are well paved. It has two churches, a town-hall, an ancient convent, and eight schools. The population is 8350.

EEL. [MURENIDÆ.]

EFFENDI is a Turkish word, which signifies 'Master, Monsieur,' and is subjoined as a title of respect to the names

of persons, especially to those of learned men and ecclesiastics, e.g. *Omar Effendi*, *Ahmed Effendi*, in the same manner in which *Agha* is placed after the names of military and court officers. The word *Effendi* occurs also as part of some titles of particular officers, as *Reis Effendi*, the title of the principal secretary of state, and prime minister of the Ottoman empire, which is properly an abbreviation of *Reis-al-Kottâb*, i.e., 'the head or chief of secretaries or writers.'

EFFERVESCENCE is the rapid disengagement of a gas taking place in a liquid in consequence of chemical action and decomposition; it is most commonly applied to the effect produced by adding an acid to a carbonate, by which numerous bubbles of carbonic acid gas rise to the surface of the liquid, and forming a frothy head burst with a hissing noise. Fermentation is accompanied with a slower kind of effervescence; and when metals are dissolved in acids, gaseous matter is frequently formed and expelled with considerable force. Its nature depends upon that of the acid and metal employed: thus when diluted sulphuric acid is poured upon iron, the effervescence is owing to the escape of hydrogen gas from the decomposition of water; when, on the other hand, dilute nitric acid is poured upon copper, nitric oxide gas is liberated.

EFFLORESCENCE is the property by which certain salts containing water of crystallization lose it, and become opaque by exposure to the air; in some cases, salts which do not contain much water preserve their form, whilst others which contain a large quantity are not only rendered opaque, but lose their crystalline figure, and become powdery by efflorescence: such are sulphate and carbonate of soda.

The efflorescence of some salts may be prevented by varnishing or oiling them. It has also been observed by Professor Faraday that the property of efflorescence appears in some cases to depend upon the superficial fracture of the crystal: thus he found that crystals of carbonate, phosphate, and sulphate of soda, having no parts of their surfaces broken, and carefully preserved from external violence, remained perfect; but upon breaking or scratching their surfaces efflorescence began at that part, and eventually extended all over the crystal.

EGBERT, styled the Great, king of the West Saxons, was, according to the Saxon Chronicle, the son of Alchmond, whose descent is traced up through Esa, or Eata, and Eoppa, to Inigisil, or Ingild, the brother of the great Ina, and the undoubted descendant of Cerdic. The Chronicle states Alchmond to have reigned in Kent; but this point, as well as the whole of the genealogy of Egbert, must be considered as doubtful. All that can be certainly affirmed is, that he was of the blood of Cerdic, and that he eventually came to be regarded as the representative, if not the only remaining male descendant, of that founder of the royal house of Wessex. When Beorhtic, or Brihtric, became king in 786, Egbert, then very young, or his friends for him, had claimed the throne. Brihtric is said to have soon after made an attempt on his life, upon which he took refuge at the court of Offa, the powerful king of Mercia. After a short time however he lost Offa's protection, on Brihtric marrying Eadburga, the daughter of that king. Egbert then fled to France, where he was received by the Emperor Charlemagne, and at his court he abode till the death of Brihtric in 800. He was then recalled, and by the unanimous vote of the witan appointed to the vacant throne. William of Malmesbury, who wrote in the twelfth century, is the only authority for this history of Egbert's early life. He says, that besides other accomplishments he learned the art of war under Charlemagne, in whose armies he served for three years.

At the date of Egbert's accession the Saxon states in England were reduced to three independent sovereignties; Northumbria, comprehending what had occasionally been the separate kingdoms of Deira and Bernicia; Mercia, which had reduced to subjection Kent, Essex, and East Anglia; and Wessex, with which Sussex had become incorporated. Of these three powers, Northumbria was torn by internal dissensions, and probably was indebted for the preservation of its independence chiefly to the rivalry between the other two. The conquests and the able rule of Offa however had raised Mercia to a decided pre-eminence over Wessex; and at this time the Mercian throne was occupied by Cenwulf, who was well qualified to wield the sceptre

of Offa, and who had even extended the territory which he had inherited from that king. The two states were at war when Egbert became king; but a peace was soon concluded between them; and so long as Cenwulf lived Egbert made no attempt at conquest over any part of Saxon England. For the first nine years of his reign indeed he seems not to have drawn his sword. He then (A.D. 809) engaged in war against the alien tribes that still remained unsubdued in the west; and between that year and 814 he is recorded to have subjugated, or at least overrun and reduced to temporary submission, all Cornwall (including Devon) and South Wales. But soon after the death of Cenwulf in 819 we find him entering upon a new career. In 823 a dispute about the succession to the Mercian crown raised the East Angles in revolt; Egbert's aid, upon being applied for, was readily given to the insurgents; and a great battle took place at 'Ellerdune,' supposed to be Wilton, which ended in the complete defeat of the Mercians. Essex and Kent were immediately seized by Egbert, or voluntarily submitted to him. The East Angles in the mean time he professed to leave independent; and Mercia itself he did not think yet sufficiently weakened to be attacked with effect. A continuance of the dispute about the succession, however, and another revolt of the East Angles (which he probably fomented), soon produced the state of things he waited for. In 827 he marched against Mercia; Wiglaf, the king, fled, on his approach, to the monastery of Croyland; but soon after made his submission, and was permitted to retain his kingdom as the vassal or tributary of Egbert. East Anglia Egbert appears to have now taken under his own immediate government. He is affirmed by Bede to have subjected to his rule all England to the south of the Humber. Without loss of time also he led his army against the Northumbrians; their king Eanred offered no resistance, but, meeting Egbert at a place called Dore, to the north of the Humber, acknowledged him as Bretwalda. He is the eighth Saxon king who is stated to have acquired this dignity; the last was the Northumbrian king Oswio. [EDWIN.]

In the last year of the reign of Egbert several of those descents of the Danes or northern pirates were made upon the English coasts, which produced so much public confusion and calamity when renewed in the times of his son and his grandsons. In 832 they ravaged the Isle of Sheppey; and next year, appearing with a fleet of five-and-thirty sail in the river Dart, they landed and defeated a force that Egbert sent against them. When they returned however in 835, and landed in Cornwall, they and a number of the people of that district whom they had induced to join them, sustained a decisive overthrow from the king of Wessex in person. Egbert died the next year, after a reign of thirty-seven years and seven months; leaving his dominions between his son Ethelwulf and Athelstane, whom some of the chroniclers make the son, others the brother, of Ethelwulf. [ETHELWULF.]

Egbert is commonly said to have been the first Anglo-Saxon king who called himself king of the Angles or of England; but only one charter is known to exist in which he is styled Rex Anglorum. In general both he and his successors down to Alfred inclusive call themselves only kings of the West Saxons. And although Egbert asserted a supremacy over the other states, which remained ever after with his kingdom of Wessex, it is to be recollected that he did not incorporate either Mercia or Northumbria with his own dominions. It does not appear that he even assumed to himself the appointment of the kings of those states. The reigning families seem to have continued in possession, with merely an acknowledgment of his supremacy as Bretwalda. (See Turner's *A. Saxons*, l. 422.)

EGEON (zoology), Risso's name for a genus of macrurous decapoda, whose characters are generally like those of *Crangon* (shrimp), but with the following differences. The fourth or last visible joint of the external *jaw-feet* is nearly twice as large as the preceding. The *feet* of the second pair are extremely short, slender, and didactylous; those of the third long, very slender, and terminated by a single nail; those of the fourth and fifth pairs larger, and ending by a compressed nail. The *carapace* elongated, cylindrical, spinous, and terminated anteriorly by a small *rostrum*.

The extreme brevity, observes Desmarest, of the second pair of feet, and the roughness of the carapace, are the most remarkable of these differences; but they do not, in his opinion, present characters sufficient for the establishment

of a genus. Example, *Egeon loricatus*, Risso (crust.); *Pontophilus spinosus*, Leach. (See *Trans. Soc. Linn.*, t. xi., p. 346, and *Malac. Brit.*, tab. 37 A.)

Description.—Carapace supporting three longitudinal denticulated carinae above; rostrum very short; total length about an inch and a half. Locality, coasts of England, those of Nice, and the Adriatic Sea.

The term *Egeon* is used by Denys de Montfort for one of the *Nummulites*—*Nummulina*, D'Orbigny.

Egeon loricatus. a, left foot of the first pair magnified

EGER, a river of Bohemia, which, soon after it quits the Fichtelberg, in Bavaria, where it has its source, enters the west of Bohemia at Hohenberg, and flows eastwards until it reaches Theresienstadt, where it joins the Elbe: from the point of their confluence the Elbe becomes navigable. The length of the Eger, from Hohenberg to Theresienstadt, is about 80 miles; it has a fall of 158 ft. between the frontier and the Elbe; its banks are high, and its bed is hard and stony. The circle of Eger, in the greater circle of Ellbogen, in Bohemia, is the most western point of that kingdom; it contains an area of about 105 square miles, and about 24,000 inhabitants.

EGER (in Bohemian CHEB or CHEBBE) is situated on a rocky eminence on the right bank of the river of the same name, in 50° 5' N. lat. and 12° 24' E. long. In former days it was strongly fortified; but most of its defences have been levelled, and the ditches have been filled up. It has about 800 houses and 9500 inhabitants. There are several handsome buildings in the town, among which are the deanery church, six other churches, the spacious town-hall, a Dominican and a Franciscan monastery, and the barracks, formerly a Jesuits' college. Eger has likewise a high school or gymnasium, a military seminary for boys, a head national school (*haupt-schule*), two hospitals, an infirmary, and an orphan asylum. There is an apartment in the burgomaster's residence, in the market-place, in which the celebrated Austrian commander, Wallenstein, was assassinated in the year 1634; and in the town-hall are some paintings which depict the violent deaths of that leader and his adherents. The ruins of the 'Steinhaus' (house of stone), the former residence of the margraves of Vohburg, to whom Eger once belonged, are remarkable for an ancient square tower of black rusticated freestone. There are several manufactures, principally of woollens and kerseymeres, cottons, leather, soap, meal, alum, and fire-engines; and the town has a transit trade with the neighbouring German states. About 3 miles to the north of Eger are some saline hot-wells, opened in 1793, and called 'The Emperor Francis's Baths'; they are much frequented in the summer season, and rendered attractive by the beauty of the surrounding scenery. About 15,000 dozen bottles of the waters are annually exported.

EGE'RIA (zoology), a genus of brachyurous decapod crustaceans established by Leach, and thus characterized.

External antennae short, inserted on the sides of the rostrum, having their second joint much shorter than the first. External jaw-feet having their third articulation straight

on the internal border, and terminated by a point. Claws delicate, linear, double the length of the body in the males, nearly equalling it in the females, much shorter in both sexes than the rest of the feet, which are very slender, those of the fifth pair being five times the length of the body. Carapace triangular, tuberculated, and spinous, terminated by a rather short rostrum, which is bifid, with diverging points. Eyes much larger than their peduncle. Orbits having a double fissure on their superior border.

Desmarest observes that this genus, somewhat hastily established by Leach, if the number of articulations of the abdomen in the species which compose it were seven, would be nearly approximated to *Maia*, *Pisa*, *Mithrax*, and *Micippa*, in the form of the body; but the difference lies in the delicacy and disproportioned length of the feet. If the number of articulations composing it be six, as there is room for believing, although neither Latreille nor Leach say so positively, it would bear great relationship to the long-legged genera, *Macropodia*, *Leptopodia*, and *Doclea*, for example. But it has not the long, slender, divided rostrum, as well as the long claws larger than the feet, which characterize the first; nor does it present the very long, very slender, and entire rostrum, as well as the very elongated and linear claws, of the second; and finally, it has not the globular body and the very short and delicate claws of the last. It is removed from *Inachus* by the claws, which are proportionally shorter and less thick than those of the last named crustaceans, by the other feet, which are relatively longer than theirs, by the antennae, of which the two first joints of the base, and not the third, are longer than the others, and by the double fissure of the bottom of the orbits above.

Example, *Egeria Indica*.

Description. In size, general form of the body, and length of the feet, bearing a great resemblance to *Inachus Scorpio*; but besides the generic differences pointed out, it is still further removed from it in having a larger rostrum which is deeper incised in the middle, and in having the points with which the elevated and distinct regions of the carapace above are beset, disposed in the following order: 3, 2, 1 and 1. A rather long, sharp, post-ocular point is directed forwards. The arms are rather short and slender. Locality, the Indian Seas.

Egeria Indica.

Egeria is also used by De Roissy for a genus of conchifers which M. Sander Rang considers identical with *Galathea*, Brug., and *Potamophilus*, Sow.

EGERTON, FRANCIS. [BRIDGWATER, DUKE OF.]

EGG PLANT, the *Solanum Melongena* of botanists, is a native of the north of Africa, and was introduced to this country in the year 1597.

It grows to the height of two, or two and a half feet, has leaves of an ovate form, which, as well as the stem, are prickly and downy; its flowers are generally of a violet colour, and its fruit is a large ovate or globose berry

resembling a hen's egg, or sometimes larger; whence the name of egg-plant, which has been given to it.

There are many varieties of this plant, of which two only are commonly cultivated in gardens, namely the small white and the large purple. They are raised from seed, which should be sown early in spring, in light soil on a hot-bed, and treated in every respect like a tender annual. After the plants are strong enough they must be taken up and potted, and regularly shifted when necessary into pots of a larger size. They may either be allowed to fruit in flower-pots in an airy green-house or vinery; or they may be planted out in June in a warm border on the south side of a wall, where they will have the benefit of the reflected rays of the sun. Of the two varieties above mentioned, which by some botanists are regarded as distinct species, that with white fruit is small, and rather an object of curiosity than of use; the other, with purple fruit, which sometimes attains a pound weight, is a favourite article of food in hot countries; under the name of Brinjal and Begom it is well known in India, and by that of Aubergine in France. The fruit is brought to table boiled or fried, or in stews; and if well cooked is delicate and agreeable; but it is necessary in the first instance to deprive it of a bitter nauseous viscid juice, or it is unfit for food; and as the cooks of this country do not generally understand the art of doing this, the egg-plant is here very seldom seen on the table.

It is said by those who have visited China that the Chinese, on days of festivity, cook this fruit while hanging on the plant, and in that way introduce it to table.

EGHAM. [SURREY.]

EGINHARDT, a native of Austrasia or East France, was instructed by Alcuinus, and by him introduced to Charlemagne, who made him his secretary, and afterwards superintendent of his buildings. His wife Emma, or Imma, is said by some to have been a daughter of that prince, and a curious story is related of their amours previous to the marriage, but the whole seems an invention. Eginhardt himself does not reckon Emma in his enumeration of the children of Charles. After the death of that monarch, Eginhardt continued to serve his successor, Louis le Débonnaire, who entrusted him with the education of his son Lotharius. But after a time Eginhardt resigned his office, left the court, and withdrew to the monastery of Fontenelle, of which he became abbot: his wife also retired into a nunnery. After remaining seven years at Fontenelle, he left it, about A.D. 823, and went to another monastery, but in 827, having received from Rome the relics of the martyrs Marcellinus and Petrus, he placed them in his residence at Mulinheim, which he converted into an abbey, which took afterwards the name of Seligenstadt, where he fixed his residence. (*De Translatione SS. martyrum Marcellini et Petri*, in the *Acta Sanctorum* of Bollandus. The account is written by Eginhardt.) Eginhardt seems to have still repaired to court from time to time, when his advice was needed, and he appears by his own letters to have endeavoured to thwart the conspiracy of Louis's sons against that unfortunate monarch. He spent his latter years in retirement and study: he was still living in 848, but the time of his death is not ascertained. His wife had died before him, a loss by which he was greatly grieved, although they had lived separately for many years. Eginhardt wrote, 1. 'Vita et Conversatio gloriosissimi Imperatoris Karoli Regis magni,' divided into two parts, one relating to the public and the other to the private life of his hero. It has gone through many editions, and has been also translated into various languages. The style is remarkably good for the times. 2. 'Annales Regum Francorum, Pipini, Karolomagni, et Ludovici Pii, ab anno 741 ad annum 829.' 3. 'Epistolæ,' which are found in Duchesne's 'Historiæ Francorum Scriptores,' vol. ii. These letters, of which only sixty-two have been preserved, show Eginhardt's character to great advantage, and afford considerable information on the manners of that period. 4. 'Breviarium Chronologicum ab orbe condito ad ann. D. 829,' which is an abridgment of Bede's Chronicle. There is a notice of Eginhardt by Duchesne, prefixed to his life of Charlemagne, in the collection already mentioned.

EGLANTINE, the old English name of the Sweet Briar Rose; aiglantier and eglantier in French. Milton misapplies the word to the Honeysuckle in the following lines:—

Through the Sweet Briar, or the Vine,
Or the twisted Eglantine.

EGMONT, Count of Lamoral, Prince of Gavre, a de-
P. C., No. 569.

scendant of those dukes of Guelders who had signalized themselves against the house of Austria, was born in 1522 in Amsterdam. The fame of his ancestors is celebrated in the annals of his country, one of whom enjoyed, during the reign of Maximilian, the supreme magistracy of Holland.

Egmont's marriage with Sabina, duchess of Bavaria, reflected additional lustre upon his noble birth, and increased his influence by powerful alliances. In the year 1546 Charles V. conferred upon him the order of the Golden Fleece. Under this emperor he learned the art of war, and, being appointed by Philip II. commander of the cavalry, he gathered his first laurels in the fields of St. Quentin and Gravelingen (1557, 1558).

The Flemish people, chiefly occupied with commerce, and indebted for the preservation of their prosperity to these victories, were justly proud of their countryman, whose fame was spread through all Europe. The circumstance of Egmont being the father of a numerous family served also to increase their affection, and they saw with delight the prospect of this illustrious family being perpetuated among them.

Egmont's demeanour was courteous and noble; his open countenance was an index of the singleness of his mind; his religion was one of mercy and philanthropy; far from being a bigotted Romanist, or a reckless reformer, he elevated himself above the contending parties, and laboured to bring about a peaceful reconciliation. It was only towards the close of his life, when all attempts to disarm the fury of the Spaniards against his Protestant countrymen had failed, that he showed himself willing to defend them against their oppressors. His motives however were not any predilection for the Protestant doctrine, but pure love of justice, peace, and humanity.

A man possessed of such qualities, and enjoying so much popular influence, naturally awoke suspicion and jealousy in the heart of the Spanish despots whenever the interests of the Flemish came into collision with those of the crown. Philip however, in order to conceal his dark designs against the supposed protectors of the religion of his rebellious subjects, on visiting Brabant gave to Egmont the government of Artois and Flanders, and exempted his estates from taxation. But upon his return to Madrid the tyrant changed his plans, and sent his favorite, Alva, to Flanders, with instructions to get rid of Egmont and his friend Count Horn.

In order to secure them both Alva invited them to dinner, under the pretence of wishing to consult them on public affairs. When they had entered his private room, they were seized, and thrown into prison in Ghent, where they remained during nine months. At the expiration of this time they were carried to Brussels under an escort of ten companies of Spanish soldiers. Here Alva, invested with the power of captain-general and supreme judge, compelled the criminal court to pronounce Egmont guilty of high treason and rebellion, and to sentence him to be beheaded. This sentence was pronounced on the 4th June, 1568, without any substantial evidence, and was supported only by the depositions of his accusers. His estates were also confiscated. During his imprisonment the emperor of Germany, the knights of the Golden Fleece, the electors, the duchess of Parma, and his wife, used every possible exertion to save his life; but Philip was immovable. The sentence was executed on the 5th of June, 1568, and both Egmont and Horn fell by the sword of the executioner on a scaffold erected in one of the principal squares of Brussels. Egmont died with courage, after having written a dignified letter to the king and a tender one to his wife.

He was but 46 years of age. The people, who assembled in crowds to witness this mournful spectacle, were loud in their lamentations; they rushed towards the scaffold and dipped their handkerchiefs in the blood of the martyrs of Flemish independence. His friend, Count Horn, was executed immediately after him. Egmont's wife died the 19th of June, 1598. It is said that the bishop of Ypres, a most pious and upright prelate, who had been deputed by Alva to prepare the two prisoners for their execution, after hearing the confession of Egmont, was so persuaded of his innocence that he went to Alva and begged him on his knees to suspend the execution. But Alva, besides his natural ferocity, bore a mortal enmity to Egmont on account of his military reputation, and rejected the bishop's intercession with insolent contempt. When Philip II. heard that these two noble lords had been executed he exclaimed, 'I have caused these two heads to fall because the heads of such salmons are worth more than many thousand frogs.'

The death of Egmont has supplied to Goethe an admirable subject for one of the best of his historical tragedies, for which Beethoven composed one of his finest overtures and some beautiful melodies to the songs interspersed through the play.

The latest life of Egmont is that by Clouet, *Éloge historique du Comte d'Egmont*, Bruxelles, 1825.

EGREMONT. [CUMBERLAND.]

EGRIPOS. [EUBŒA.]

EGYPT AND EGYPTIANS. Egypt, Mizr or Mizraim in Hebrew, Masr in Arabic, and Chamr or Chemt in Coptic, is generally reckoned within the limits of Africa, though several geographers have considered it as physically belonging to Asia. It is bounded on the north by the Mediterranean, on the east by the little river of El Arish on the borders of Palestine and the Syrian or Arabian desert, which extends from the Mediterranean to the Gulf of Suez, and from thence southwards by the west coast of the Red Sea, and on the west by the Libyan desert. To the south its boundary from the oldest time has been fixed at the rapids or cataracts of Assouan, the ancient Syene, which are formed by a number of granite rocks that lie across the bed of the river. The fall of the water, however, is only a few feet, and boats can easily pass down the rapids. But the political limits of Egypt have extended both in ancient and modern times further south along the valley of the Nile into the country known by the general name of Nubia. The length of Egypt from the cataracts of Syene $24^{\circ} 8' N.$ lat. to the most northern point of the Delta on the Mediterranean $31^{\circ} 25'$, measures on the map about 500 English miles. But the length of the cultivated parts of Egypt, or valley of the Nile, is considerably greater, owing to the numerous bends of the river, which give it a course of about 500 miles from Assouan to a few miles north of Kahirah or Cairo, where the valley terminates: this estimate is exclusive of the length of the Delta, which is nearly 100 miles more. The breadth of Egypt is difficult to determine. As to its physical boundaries it may be considered to extend from the shores of the Red Sea to the range of hills which bounds the valley of the Nile to the west; it may even be extended over the western desert as far as the Oases which are dependencies of Egypt; or it may be restricted to the breadth of the cultivated land in the valley of the Nile and Delta, which are the only parts, excepting the Oases, where there is a settled population. We may therefore consider Egypt under each of these four great divisions: 1. The valley of the Nile; 2. The Delta; 3. The western desert and the Oases therein inclosed; 4. the Eastern country towards the Red Sea.

1. *Valley of the Nile.* The Nile coming from Nubia runs through a deep and narrow valley, sunk between two ridges of rocky hills which rise in some places above 1000 feet above the level of the river. The breadth of the valley varies considerably, but it is seldom more than ten miles, and in many places, especially in Upper Egypt, it is not two, including the breadth of the river, which varies from 2000 to 4000 feet. In its course within Egypt the Nile contains numerous islands. From Assouan to Selseleh, a distance of about 40 miles, the river runs nearly in the middle of the valley, leaving little cultivable land on each side. As we advance farther north the western ridge recedes from the river, so as to leave a space of several miles between the left bank and the foot of the hills, while the east chain keeps closer to the corresponding or right bank of the Nile. North of Keneh the river forms a great bend to the west and north-west as far as Minyeh, near which it reaches its westernmost point, which is about 120 miles to the west of the longitude of Keneh; it then inclines again to the north-east as far as Benisouef and a few miles beyond it, after which it assumes a course nearly due north as far as the apex of the Delta. From Farshout, half way between Keneh and Girgeh, a canal runs parallel to and west of the course of the Nile, under the different names of Moya Souhadj, Bahr Joussouf, &c., for about 250 miles to Benisouef, where an opening in the western ridge allows a branch of it to pass into the district of Faioum, which it irrigates and fertilizes. Its surplus waters then flow into the Birket-el-Keroun, the ancient Mœris lake. [BIRKET-EL-KEROUN and FAIOM.] Another branch of the Bahr Joussouf continues to follow the course of the Nile northwards as far as the Delta. The Bahr Joussouf, from Ashmounein to Benisouef, runs at the distance of three to six miles from the river; the western ridge being here from eight to ten miles

from the Nile, and near Benisouef fifteen miles distant from it. The banks of the Bahr Joussouf, like those of the Nile, are raised higher than the rest of the valley. Consequently between the canal and the Nile there is a kind of depression. On the other or west side of the canal there is a strip of cultivated land as far as the inundation or artificial irrigation extends, beyond which and to the foot of the ridge there is a strip of sand, light and drifting in the neighbourhood of the cultivated ground, upon which it seems to encroach in many places, and coarser and mixed with pebbles near the base of the hills. Consequently the cultivable land along the banks of the Nile, both to the east and to the west of the river, by no means occupies the whole breadth of the valley. The Bahr Joussouf appears to be the same as the Oxyrhynchus canal of ancient times, which Strabo, while sailing along it, mistook for the Nile itself, on account of its magnitude. North of Benisouef, the western range, the height of which becomes less and less as it advances northwards, again approaches the river near Sakkarah, and forms in the neighbourhood of Jizeh a kind of natural terrace, on which the great pyramids stand. The ridge then continues to skirt the western or Rosetta branch of the river as far as the neighbourhood of the Canal Bahireh, which once communicated with the lake Mareotis. The ridge here inclines to the west, and may be considered as joining the hills which skirt the valley of the Natron lakes. [BAHR BELA-MA.] The general character of the western ridge which borders the valley of the Nile is a limestone formation which contains numerous fossil shells. The great pyramid is built of this kind of stone. In the neighbourhood of Esneh, in Upper Egypt, a sandstone formation commences, alternating with limestone, but the mountains contain also slate and quartz of various colours. The great slabs used in the construction of the temples of Egypt, with the exception of those of the Delta, were of sandstone, as well as many of the sculptures or statues. In the neighbourhood of Selseleh are extensive quarries of sandstone.

The mountain range on the eastern side differs in some respects in its geological character from the western ridge, and it generally rises more abruptly, and often close to the edge of the river. From Mount Mokattam, near Cairo, the limestone extends southwards, though with many interruptions, as far as on the western side of the Nile. But the serpentine and granite appear to commence earlier, and to characterize the eastern more strongly than the western side. Near Assouan the granite alternates with the decomposed sandstone, exhibiting an irregular and broken appearance, which has sometimes been compared to a ruin. On the east side of the Nile, near Syene, scattered about the foot of the mountains, and occasionally close to the river, are those extensive granite quarries which furnished the ancient Egyptians with materials for their colossal statues and obelisks.

The eastern range leaves the banks of the Nile at a higher or more southern point than the west ridge. From Mount Mokattam, near Cairo, it turns off abruptly to the east, and under the name of Jebel Attaka runs to the Red Sea, near Suez. North of it the sands of the desert of Suez spread close to the eastern skirts of the Delta.

2. *The Delta.* The Nile issuing from the valley a few miles north of Cairo, enters the wide low plain which, from its triangular form and its resemblance to the letter Δ , received from the Greeks the name of the Delta. The river divides into two branches, that of Rosetta or old Canopic, and that of Damiat or Phatnitic. The figure of the Delta is now determined by these two branches, although the cultivated plain known by that name extends considerably beyond to the east and west, as far as the sandy desert on each side. In ancient times the triangle of the Delta was much more obtuse at its apex, as its right side was formed by the Pelusiatic branch, which, detaching itself from the Nile higher up than the Damiat branch, flowed to Pelusium, at the eastern extremity of Lake Menzaleh. This branch is now in great measure choked up, though it still serves partly for the purpose of irrigation. West of the Pelusiatic branch the Moes canal corresponds with the Tanitic or Saitic branch of the antients, and the Menzaleh canal with the Mendesian branch; they both enter Lake Menzaleh, a vast salt marsh, forty miles long, which communicates with the sea by several outlets. (Andreossi's *Memoir on Lake Menzaleh*, with *Map* of the same in the great French work on Egypt.) Between the Damiat and the Rosetta branch are numerous canals, large and small,

intersecting the country in every direction. Along the sea-coast is another salt lake or marsh, called Bourlos, communicating with the sea by an outlet, which is probably the same as the Sebennytic mouth of the ancient geographers. Proceeding westward we meet with the Rosetta or Bolbitine mouth, which with that of Damiat are now the only two entrances from the sea into the Nile, and they are accessible only to small vessels. The Nile at Rosetta is 1800 feet wide, and at Damiat only 800 feet. West of Rosetta, a salt marsh, called Lake Etko, has been formed, which communicates on one side with the Nile, and on the other with the sea or Aboukir Bay, by an outlet which corresponds to the old Canopic mouth. West of Lake Etko is the lake of Aboukir, which likewise communicates with the sea, and is divided from Lake Mareotis to the south-west of it by an isthmus, along which passes the canal of Alexandria, which has been restored by Mehemet Ali. [ALEXANDRIA; BIRKET EL MARIOUT.] The greatest breadth of the Delta, or cultivated plain of Lower Egypt, is about eighty miles from east to west; its length from the bifurcation of the river to the sea is about ninety. The interior of the country, which is covered with fields, orchards, and plantations, exhibits different aspects according to the various seasons. The rise of the Nile occasioned by the periodical rains of Central Africa, begins in June about the summer solstice, and it continues to increase till September, overflowing the lowlands along its course. The Delta then looks like an immense marsh, interspersed with numerous islands, with villages, towns, and plantations of trees just above the water. Should the Nile rise a few feet above its customary elevation, the inundation sweeps away the mud-built cottages of the Arabs, drowns their cattle, and involves the whole population in ruin. Again, should it fall short of the ordinary height, bad crops and dearth are the consequences. The inundations having remained stationary for a few days, begin to subside, and about the end of November most of the fields are left dry, and covered with a fresh layer of rich brown slime: this is the time when the lands are put under culture. During our winter months, which are the spring of Egypt, the Delta, as well as the valley of the Nile, looks like a delightful garden, smiling with verdure, and enamelled with the blossoms of trees and plants. Later in the year the soil becomes parched and dusty; and in May the suffocating Khamseen begins to blow frequently from the south, sweeping along the fine sand, and causing various diseases, until the rising of the beneficent river comes again to refresh the land. Showers are very rare in Egypt, except on the sea-coast: it rains three or four times in the year at Cairo, and once or twice in Upper Egypt, but perhaps not every year. The nights however are cool, and the dews heavy. Strong winds blow from the north during the summer, at the period of the inundation, and are very useful in propelling vessels up the Nile against the current.

It is generally presumed that the Delta has been formed or at least considerably enlarged by the alluvial soil of the Nile. This was already the belief in the time of Herodotus. The advance of the coast since then does not appear to have been very great, if we may judge from the position of the old towns mentioned by the Greek geographers: on the side of Thamiatis, the old Damiatta, the sea has not retired above two miles. The time in which the Delta may be supposed to have been a gulf of the sea must be placed long previous to the historical period. At present it seems ascertained that the coast of the Delta does not advance, and the currents which sweep along the north coast of Africa must prevent any permanent accession of alluvial soil to the Egyptian shore. The gradual elevation of the soil of the Delta and valley of the Nile has also been much exaggerated. It does not appear to have risen above seven or eight feet since the time of the Ptolemies, and the bed of the river has also risen in proportion. The height of the inundation requisite for the irrigation of the land, making allowance for the difference of measures, appears to be nearly the same as in the time of Herodotus. (Wilkinson, ch. vi., pp. 313. 40.) The vertical increase of the cultivated soil must not be confounded with the accumulation of sand in some particular places, as round the great sphinx, &c., which has been in many instances the work of the wind.

3. *The Western or Libyan Desert.*—The nominal limits of Egypt along the sea-coast west of Alexandria are the mountains at Akabah el Soloum, the Catabathmus Magnus of the antients, about 25° E. long., where the

nominal limits of the pachalik of Tripoli begin, but this extensive tract of country is occupied by independent tribes of nomadic Arabs. In-land to the south is the oasis of Siwah or of Ammon, described by Hornemann, which is now considered as within the political limits of Egypt, and pays tribute to it. [SIWAH.] Farther to the south-east, and nearer to the valley of the Nile, is a succession of oases, beginning with the Little Oasis, now called Wah el Bahryeh or Wah el Behnesa, having been colonized by people from Behnesa or Oxyrhynchus. The chief town or village is El Kasr, about 28° 16' N. lat. and 28° 55' E. long. It is three caravan days' journey south-west of Faioum across the desert. This Wah is fertilized by irrigation from plentiful and never-failing springs; it produces wheat, rice, barley, clover, liquorice, and a variety of fruit trees. It pays a tribute of 20,000 reals, about 643½ sterling, and has an armed force of several hundred men for maintaining the peace. A short day's journey to the south of it is the small Wah of El Hayz, and three days further south is that of Farafreh, with about seventy inhabitants, the rest having been kidnapped some years since by a party of roving blacks from the west. About five or six days west of the road to Farafreh, some say three days due west of the oasis of Dakhleh, is another oasis, called Wady Zerzoora, abounding in springs and palma. It was discovered about ten years since by an Arab in search of a stray camel, and from the footsteps of men and sheep he met with is believed to be inhabited. Gerbabo, another Wah, lies six days still farther to the west, and twelve days from Augila; the inhabitants are said to be black, probably Tibboos, and are far removed beyond the dominion of Egypt. Four days south of Farafreh is the Wah el Gharbee, or Wah el Dakhleh, which, although mentioned by Arab writers, was unknown to Europeans till discovered by Sir A. Edmonstone in 1819. It has however a temple of Roman date, with the names of Nere and Titus upon it. The condition and population of this oasis is superior to those of the others already mentioned: it contains eleven villages or towns, and a population of 6000 male inhabitants. It abounds with fruit, particularly olives and apricots; but dates, as in all the oases, form the principal produce of the district. The principal village, El Kasr Dakhel or Dakhleh, is in about 26° 35' N. lat. and 28° 55' E. long., nearly three degrees west of Thebes. There is a warm spring, of the temperature of 103° Fahr., which supplies several baths attached to the mosque. The people are hospitable, and neither so ignorant nor so bigoted as those of the Little Oasis. Three days to the eastward of Dakhleh, in the direction of Esneh, is the Great Oasis, or Wah el Khargeh. It extends in length from 24° 30' to near 26° N. lat., and has many villages and springs, as well as ruins of the ancient Egyptian time, of the Roman period, and of the Christian and the Saracenic æras. Several roads lead from the Great Oasis to the Nile, to Eneh, Siout, Farshoot, and Thebes. The road to Dar-fur passes through it. This oasis, as well as that of Dakhleh, are nearly on the same level as the valley of the Nile, while the Little Oasis is about 200 feet higher than the Nile in the latitude of Benisouef. (Wilkinson's *Thebes*, ch. vi.) The Great Oasis has been described by Browne, who visited it on his way to Dar-fur.

4. *The Eastern Country.*—The large tract between the valley of the Nile and the Red Sea has a different character from the western or Libyan desert. Its general character is that of a mountainous region, which, although generally rocky and barren, is intersected by numerous wadys or ravines, fertilized by springs and clothed with vegetation. Several Arab tribes divide among themselves the whole tract, which cannot therefore be called properly a desert. These tribes are:—the Maazy, east of Benisouef; the Atooni and the Beni ouassel, south of the Maazy; and the Ababde, further south, towards Nubia. In ancient times the roads leading from the valley of the Nile to the shores of the Red Sea passed by regular stations, and villages and towns with a resident population. Mines of various metals and quarries of porphyry and other valuable stones are scattered among the mountains, and were once regularly worked. At present, the only fixed habitations are at the port of Cosseir, and at the Coptic monasteries of St. Anthony and St. Paul. The road to the latter leads from the east bank of the Nile, opposite Benisouef, along an undulating plain or broad valley, called Wady Arabah, which extends nearly due east to the Red Sea, between two ridges of mountains, both called Jebel Kelalla; the south range is also called

Kolzim, and projects into the sea at Zaffarana Point, south of the bay of that name, about $28^{\circ} 55'$ N. lat. The distance from the Nile to the Red Sea is here about 90 miles. The convent of St. Anthony is about 17 miles from the shore of the Mersa, or bay of Zaffarana, which terminates the wady Arabah. The patron and founder of the order is St. Anthony of Thebes, who lived in the time of Constantine. The monks have two very fine gardens, which, as well as the convent, are surrounded by high walls to protect them from the Arabs. From St. Anthony to Deir Bolos, or St. Paul, is a distance of about 14 miles by the road. The Kolzim ridge lies between the two. Deir Bolos is only 9 miles from the sea to the south-east of Deir Antonios, and at Wady Girfi between it and the sea are the remains of houses and catacombs which appear to belong to the Greek period. (Wilkinson's *Notes on a part of the East Desert of Upper Egypt, with maps*; in the 2nd vol. of *The Journal of the Royal Geographical Society of London*.) The Convent of Deir Bolos appears to be wealthier and finer than that of Deir Anthony, but the monks are fewer in number: both live chiefly on vegetables and fish. From Deir Bolos Mr. Wilkinson proceeded southwards, between the Kolzim range and the sea, to Jebel Tenesep, about 15 miles south-east of Deir Bolos, where the mountains diverge into the interior to the south and south-west towards the Nile, and are succeeded near the sea by a range of primitive mountains which run down the whole way to Cosseir, at a distance of from about 20 to 30 miles from the coast, the intervening space being occupied in some places by low lime-stone and sand-stone hills. Jebel Gharib, about $28^{\circ} 15'$ N. lat., in the primitive range, is described as resembling in its lofty peaks the Aiguilles of Chamouny; its height is estimated at nearly 6000 feet above the sea. About 20 miles farther south, in a range of low hills, are copper mines, which appear to have been once extensively worked. At Jebel Dokhan, lat. $27^{\circ} 26'$ and about 25 miles from the sea, are the ruins of a town, and vast quarries of porphyry with antient roads crossing the mountains in all directions, and two wells cut through a solid porphyry rock. A small temple of red granite, with an inscription of the time of Hadrian, and dedicated to Serapia, has been left unfinished; all the materials are on the spot, but not a column was ever put up, and nothing was completed. A road led from Dokhan to Coptos, now Koft, on the Nile, about 100 miles to the south-west, and another road to the port of Myos Hormos, once a great mart on the Red Sea, but which was already deserted in the time of Pliny. There are some fine valleys in these mountains, but the sea coast is marshy and unwholesome. At Fateereh, about 40 miles south-east of Dokhan, in the old road to Cosseir, are ruins of a Roman station, with a temple of the time of Trajan, and quarries of granite. From Fateereh to Cosseir is three days' distance, according to the Arabs. South of Cosseir the mountains continue to run parallel to the coast as far as Jebel Zabarah or the mountain of emerald, which is about eight hours from the coast, and farther south-east to the ruins of Berenice, which are described by Belzoni. [BERENICE]. The coast of the Red Sea was surveyed in 1830-3 by Commander Moresby and Lieutenant Carless, E.I.C. service.

Antient History.—Egypt was one of the countries earliest civilized, and brought under a fixed, social, and political system. The first king mentioned as having reigned over that country is Menes or Men, who is supposed to have lived above 2000 years B.C., about the time fixed by biblical chronologists for the foundation of the kingdom of Assyria by Nimrod, and corresponding also with the sara of the Chinese emperor Yao, with whom the historical period of China begins. All inquiries concerning the history of nations previous to this epoch are mere speculations unsupported by evidence. The records of the Egyptian priests, as handed down to us by Herodotus, Manetho, Eratosthenes, and others, place the sara of Menes several thousand years farther back, reckoning a great number of kings and dynasties after him, with remarks on the gigantic stature of some of the kings and of their wonderful exploits, and other characteristics of mystical and confused tradition. (See Eusebius, *Chronicon Canonum libri duo*, edited by A. Mai and Zohrab, Milan, 1818.) It has been conjectured that several of Manetho's dynasties were not successive, but contemporaneous, reigning over various parts of the country. From the time of Menes, however, something like a chronological series has been made out by Champollion, Wilkinson, and other Egyptian archaeologists, partly from

the list of Manetho and partly from the Phonetic inscriptions on the monuments of the country. (Wilkinson's *Chronology of the Kings of Egypt*, at the end of his *Topography of Thebes*.) The immediate successors of Menes are unknown till we come to Suphis and his brother or brothers, to whom the great pyramid is attributed by some, and who are supposed to be the same as the Cheops and Cephren of Herodotus, although that historian has placed them much later, after Sesostriis and Mæris. Abraham visited Egypt about 1920 B.C., and we have the testimony of the Scripture as to the high and flourishing state of that country at that early period. The Scripture calls the kings of Egypt indiscriminately Pharaohs, which is now ascertained to be not the proper name of the individual monarchs, but a prefix like that of Cæsar and Augustus given to the Roman emperors. The word Phra in the Egyptian language meant the sun. Little or nothing is known of several successive dynasties except the names of some of the kings, until we come to Osirtesen I. of the sixteenth dynasty, who began to reign about 1740 B.C. Very few monuments remain of a date prior to his reign. The obelisk of Heliopolis bears the name of Osirtesen. The sixteenth dynasty, which reigned from 1812 to 1650 B.C., was from Lower Egypt, where the kings of this dynasty resided. Memphis however is said to have been built long before this, by King Menes, who diverted the course of the Nile in that neighbourhood, which before ran close to the western ridge, and made it run into a new channel in the middle of the valley. Under the sixteenth dynasty, about 1706 B.C., Joseph, and afterwards Jacob and his family, came to Egypt, where their descendants settled and multiplied in Lower Egypt. Egypt was then the granary of the neighbouring nations, and apparently the centre of a great caravan trade carried on by the Arabs or Ishmaelites, who brought to it the spices and other valuable products of the east. (*Genesis* xxxvii. 25.) Joseph died very old, under the seventeenth dynasty, which was also from Lower Egypt, and which reigned from 1651 to 1575 B.C. About this last period 'there arose a new king who knew not Joseph.' (*Exodus* i. 8.) This was the head of the eighteenth dynasty, from Diospolis, or Thebes, which dynasty reigned 340 years, according to Eusebius and other chroniclers, and which contains the names of the most illustrious sovereigns of antient Egypt. It appears probable that this dynasty was the continuation of the line of the old Diospolitan kings, who are mentioned as having reigned before Osirtesen I., which line may have been dispossessed by some revolution of the throne, or at least of the greater part of the country, which was occupied by a new race from Lower Egypt during the 16th and 17th dynasties. The irruption of the Hyksos, or shepherds, is supposed by some to have occurred during this period. Manetho's seventeenth dynasty consists of shepherd kings, who are said to have reigned at Memphis. These shepherds, who are represented as people with red hair and blue eyes, came from the north-east, perhaps from the mountains of Assyria; they conquered or overran the whole country, committing the greatest ravages, and at last settled in Lower Egypt, where they had kings of their own race. They were finally expelled by Tutthmosis or Thothmes I. of the 18th dynasty, after remaining in the country for more than 100 years. Some have conjectured that the hard task-masters of the Israelites were these same shepherd kings, but all this is involved in great doubt. One thing seems ascertained, namely, that the shepherds destroyed most of the monuments of Egypt raised by the former dynasties; and a remarkable fact is quoted in corroboration of this, that at Karnak and other of the oldest monuments of Thebes, raised under the 18th dynasty, sculptures and painted stones of good workmanship are found used as mere materials in the body of the walls. (Champollion, *Lettres au Duc de Blacas*.) The Exodus of the Israelites, 1491 B.C., falls, according to Wilkinson, under the reign of Thothmes III., 439 years after the visit of Abraham to Egypt. The Scripture says that Pharaoh perished in the pursuit of the Israelites, and it is remarkable that Amunoph II., the son and successor of Thothmes III., is represented in a drawing at Thebes as having come to the throne very young and under the tutelage of his mother. (Wilkinson's *Chronology*.) Under Amunoph III., who reigned about 1430 B.C., the emigration of Danaus to Argos is conjectured to have taken place. Osirei I., according to the Phonetic hieroglyphics, appears to have reigned about 1385, and his reign would fall nearly about

the time of the Mæris of Herodotus, who lived about 900 years before that historian's visit to Egypt. The name of Mæris however is not found in the Phonetic inscriptions. Remeses II., or the Great, son of Osirei I., ascended the throne about 1350 B.C. and reigned about 40 years. This is supposed to be the Sesostri or Sesoosis of the Greek historians. Manetho places Sesostri much earlier, in the 12th dynasty, but it is thought probable by some that his Sesostri was a mythical personage, one of the early reported Egyptian conquerors, and that the name of Sesostri was afterwards given as a title of honour to other illustrious monarchs. At all events we now know from the monuments of Thebes that Remeses II. was one of the most warlike monarchs of ancient Egypt; that his wars extended far, and against many nations. Some of these are represented as of much lighter complexion than the Egyptians, with flowing beards, and dresses evidently Asiatic. It is probable that his campaigns extended to Asia, perhaps against the kings of Assyria. That the old kings of Egypt extended their dominions to the east and north-east, as was done by their Greek and Mohammedan successors, is not only very likely, but it is attested as a fact by the Scripture, 2 *Kings* xxiv. 7, where, at a later period, when the power of Egypt had begun to decline, we are told that the king of that country 'came not again any more out of his land; for the king of Babylon (Nebuchadnezzar) had taken from the river of Egypt unto the river Euphrates all that pertained to the king of Egypt,' which seems to prove that the dominion of Egypt had extended at one time as far as the Euphrates. It has also been remarked that the figures of the prisoners made by Tirhakah, who fought against Sennacherib, previous to Nebuchadnezzar's time (2 *Kings* xix. 9), are represented in the Egyptian monuments as similar to those captured by the earlier kings of the 18th dynasty.

Remeses II. was succeeded by his son Amenophis, according to Manetho (Phtahmen Thmeiofsep, according to the Phonetic signs), who seems to be the same as the Phoron (Pharaoh?) of Herodotus and the Sesoosis II. of Diodorus, who, according to both the latter historians, was struck blind, but recovered his sight. With him ended the 18th dynasty. The 19th dynasty, also of Diospolitans, began about 1270 B.C., and reigned till 1170. During this period the war of Troy took place, in the reign of a Remeses, supposed to be the fifth of that name, according to Pliny. Herodotus and Diodorus give King Proteus as contemporary with the war of Troy. Of the 20th and 21st dynasties nothing is known beyond the mere names of some of the kings, according to the Phonetic signs. The Pharaoh whose daughter Solomon married, 1013 B.C., must have been one of the 21st dynasty. It is curious that, from the Exodus till Solomon's time, a period of nearly five centuries, no mention is made in the Scriptures of Egypt, which proves that the storm of war, if such there was, passed off either to the eastward of Palestine, or that the Egyptian conquerors followed the maritime road by Gaza and the Phœnician coast, leaving the high land of Judæa to their right. (Wilkinson, *Materia Hieroglyphica*, Part ii.) The 22d dynasty, beginning with Sesonchis, according to Manetho, and Sheshonk, according to the Phonetic signs, who began to reign about 978 B.C., and who is the Shishak of the Scripture, at whose court Jeroboam took refuge and married his daughter, and who, after Solomon's death, plundered the temple of Jerusalem in the 5th year of Rehoboam (2 *Chronicles*, xii.). Shishak is represented as coming to the attack 'with 1200 chariots and 60,000 horsemen, and an immense multitude of Libyans (probably Libyans), of Sukkiims, and Ethiopians.' Of Osorkon I., the successor of Sheshonk, we have a date at Thebes commemorating the 11th year of his reign. Zerah, the Ethiopian king or chief, who attacked Asa, king of Judah (2 *Chron.* xiv.), was Osorkon's contemporary.

The 23rd dynasty, called Diospolitans, like the preceding, began about 908 B.C. with Osorkon II. Homer is believed to have flourished about his time, and he speaks of Egypt under its Greek name. The 24th dynasty, which is called Saite, from Sais, a district of Lower Egypt, begins with the Bocchoris of Manetho, the Bakhor or Pehor of the Phonetic signs, about 812 B.C. Diodorus places a long period between his reign and that of Sabacos, the Ethiopian, who however follows Bocchoris next but one in the Phonetic chronology and in that of Manetho. Sabacos (Sabakoph, Phonetic) begins the 25th dynasty of Ethiopians, who, about this time, invaded Egypt, or at least Upper Egypt. Tehrak or Tirhakah, one of his successors, attacked Sennacherib,

710 B.C. Sethos, a priest of Hephæsus, the great temple of Memphis, became king, and ruled at Memphis, contemporary with Tirhakah. After Sethos' death a great confusion or anarchy took place. At last twelve chiefs or monarchs assembled at Memphis, and took the direction of affairs, which they retained for 15 years. After this Psamatik I., or Psammitichus, the son of Nechao or Necos, who had been put to death by Sabacos, became, by the aid of Greek mercenaries, king of all Egypt, about 650 B.C. His son Necos II., the Pharaoh Nechoh of the Scripture (2 *Kings* xxiii.) marched against the king of Assyria to the river Euphrates: he defeated and slew Josiah, king of Judah, 610 B.C. He also began the canal that joined the east branch of the Nile with the Red Sea. His successor, Psamatik II., was followed by Psamatik III., supposed by some to be the Apries of Manetho, and the Pharaoh of Hophra of the Scripture, who defeated the Phœnicians, took Sidon, and invaded Cyprus, which was finally subjected by Amasis, who succeeded him on the throne. The reign of Amasis lasted forty-four years, according to a date on the monuments: his successor, Psammenitus, reigned only six months, when Egypt was invaded by Cambyses, 525 B.C., who overran and ravaged the country, and lost the greater part of his army in the neighbouring deserts.

The 27th dynasty includes the Persian Kings from Cambyses to Darius Nothus, during which time Egypt was a province, though a very unruly one, of the Persian monarchy. It was during this period that Herodotus visited Egypt. Though he saw that country in a state of humiliation and depression, yet he was powerfully struck by its buildings, and its highly advanced social state, as well as by the peculiarities of its manners and institutions. Egypt appears to have made upon Herodotus an impression something like that produced by England upon French or other continental travellers in the last century, as being a country unlike any other. But Herodotus derived his information concerning Egyptian history chiefly from the priests of Memphis, and consequently his account is very meagre in all that relates to Thebes and Heliopolis, the two other great centres of Egyptian hierarchy.

After several revolts the Egyptians succeeded in placing Amyrtæus, or Aomahorte, a Saite, on the throne, about 414 B.C. This king alone constitutes the 28th dynasty. He was succeeded by the 29th dynasty, of Mendesians, who defended Egypt against the repeated attacks of the Persians, with the assistance of Greek auxiliaries under Agesilaus and others. At last Neotanebos, being defeated by Ochus, fled into Ethiopia, 340 B.C., and Egypt fell again under the yoke of the Persians. The Persians were succeeded by the Macedonians, who, after the death of Alexander, founded the dynasty of the Ptolemies, or Lagidæ, who ruled over Egypt for nearly 300 years, and restored that country to a considerable degree of prosperity. [PROLEXMY.] At the death of Cleopatra, 30 B.C., Egypt was reduced to a Roman province by Augustus.

Having now closed this brief summary of the history of ancient Egypt, imperfect and conjectural in part as it unavoidably is, we shall, in a few words, advert to the social condition of the country under its native kings. That condition is now tolerably well known by the attentive examination of its remaining monuments and their sculptures and paintings. The researches of the French in the expedition to Egypt, and of Belzoni, Champollion, Rosellini, and others, have put us in possession of a series of sketches evidently drawn from the life, and descriptive of the arts, industry, and habits of the ancient Egyptians. To these works and the plates which accompany them we must refer the reader. There is no doubt that this singular nation had attained a high degree of refinement and luxury at a time when the whole western world was still involved in barbarism; when the history of Europe, including Greece, had not yet begun; and long before Carthage, Athens, and Rome were thought of. This high state of material civilization was attained under a system of institutions and policy which resembles in some respects those of the Hindoos. It was a monarchy based upon an all-powerful hierarchy. The inhabitants were divided into a kind of hereditary castes, the first of which consisted of the priests, who filled the chief offices of the state. They were the depositaries and the expounders of the law and the religion of the country. They monopolized the principal branches of learning: they were judges, physicians, architects. Their sacred books, like their temples, were not open to the vulgar.

They had a language or at least a writing peculiar to themselves. The king himself, if not of their caste, was adopted into it, was initiated into its mysteries, and became bound by its regulations. The priests were exempt from all duties, and a large portion of land was set apart for their maintenance; and we read in *Genesis*, that when Pharaoh in a season of famine bought, by the advice of Joseph, all the land of the Egyptians on condition of feeding them out of his stores, 'only the land of the priests bought he not, for the priests had a portion (of corn) assigned them of Pharaoh, and did eat their portion which Pharaoh gave them, wherefore they sold not their lands.' (xlvii. 32.) And again when Joseph, after the scarcity was over, made it a law of the land that the king should have for ever after a fifth part of the produce of the soil, restoring the rest to the owners, he excepted only 'the land of the priests,' which became not Pharaoh's.' (ib. 26.) The testimony of the Scripture is here perfectly in accordance with that of Herodotus and other historians. The priests were subject to certain strict regulations: they abstained from certain meats, and at times from wine, made their regular ablutions, had but one wife, while polygamy was allowed to the other castes, and they wore a peculiar dress according to their rank.

The soldiers formed the second caste, for Egypt had a standing army from a very remote period, divided into regiments or battalions, each having its standard with a peculiar emblem raised on a pike and carried by an officer. Their arms were the bow, sword, battle-axe, shield, knife or dagger, spear, club, and sling. Their besieging engines were the battering-ram, the testudo, and the scaling ladder. They had a military music, consisting of a kind of drum, cymbals, pipe, trumpet, and other instruments. The military caste was held in high repute and enjoyed great privileges. Each soldier was allowed a certain measure of land, exempt from every charge, which he either cultivated himself when not on active service, or let to husbandmen or farmers. Those who did the duty of royal guards had besides an ample allowance of rations. They were inured to the fatigues of war by gymnastic exercises, such as wrestling, cudgelling, racing, sporting, and other games, of which the representations still exist on their monuments.

The husbandmen formed another class, which was next in rank, as agriculture was highly esteemed among the Egyptians. They made use of the plough and other implements. They had various breeds of large cattle, sheep, goats, pigs, and a quantity of poultry reared chiefly by artificial means, the eggs being hatched in ovens, as it is the practice of the country in this day. The peasants appear to have been divided into hundreds, each with a peculiar banner, which they followed when presenting themselves before the magistrate for the census, which was taken at stated periods, when they were obliged to give an account of their conduct; and if found delinquent, were punished with the stick.

The next class was that of the artificers and tradesmen, who lived in the towns. The progress made by the Egyptians in the mechanical arts is evident from their monuments, paintings, and sculptures; in which the various handicrafts are represented. The mines of gold, copper, iron, and lead, which are in the mountains between the Nile and the Red Sea, were worked at a very remote date under the early Pharaohs. There is a passage in the work of Agatharchides on the Red Sea which describes their manner of working the gold mines and smelting the metal, and the sufferings of the people who were compelled to do that labour. (*British Museum, Egyptian Antiquities*, vol. ii. ch. 9.) The Egyptians were acquainted also with the art of gilding. The art of fabricating glass was early known among them. Beads of glass, generally coloured blue, are found on many mummies, as well as other ornaments of a coarse kind of the same material. A kind of antique porcelain, sometimes covered with enamel and varnish is found in great quantities in Egypt. Their pottery was often of the most elegant forms. The taste displayed by the Egyptians in several of their articles of furniture is not surpassed by our most refined manufactures of modern times. In the great French work and in the recent one of Rosellini we have specimens of many articles of furniture, especially chairs and couches, which are singularly beautiful in their forms. Linen cloth, plain or embroidered, white or dyed, was an article of Egyptian manufacture highly in repute among foreign nations. (*Ezekiel* xxvii. 7.) The art of making leather was also known to them.

The last class or caste included pastors or herdsmen,

poulterers, fishermen, and servants. The herdsmen and shepherds appear to have been held in peculiar contempt among them. Besides servants, they had a number of slaves, both black and white. Fish was an article of common food, except to the priests. Wine of native growth was used by the rich, and a kind of beer was the drink of the poor. An account of the different grains, plants, and trees, the produce of ancient Egypt, and also of its native animals, is given in Wilkinson's *Topography of Thebes*, ch. v., on the manners and customs of the ancient Egyptians. The above-mentioned five castes as specified by Diodorus i. 74, were subdivided into ranks according to the various callings and trades, and this has occasioned some variety in their enumeration. Herodotus reckons seven castes, Plato six, others have not reckoned the despised shepherds as a caste, and others have counted the military as one caste with the husbandmen, as being drafted from the body of the latter. Like the Hindoo, every Egyptian was required to follow his father's profession and to remain in his caste.

That such institutions were incompatible with our modern notions of independence and freedom is evident enough; but freedom is a word differently understood in different ages and countries, and the Egyptians, trained up as they were from infancy to reverence laws which they deemed immutable, might have enjoyed as great a degree of happiness as most nations in the old world. But the degradation of the lowest caste, and the waste of human strength and human life in the working of their mines and the building of their pyramids and other colossal structures, and the frequency and nature of the summary punishments inflicted, as mentioned by Diodorus and confirmed by their monuments, seem to imply that the mass of the people, and the lower classes especially, found their superiors of the sacerdotal caste to be hard task-masters.

The progress of the Egyptians in the exact sciences has been taken for granted without sufficient evidence. Of their astronomy we know but little, but it appears to have been confounded with mythology and astrology, and made subservient to religious polity. [DENDERAH, ZODIAC OF.] Their year was of 365 days: for their method of correcting it see *SOTHIAIC PERIOD*. Diodorus says that they foretold comets; but he also says that they foretold future events, leaving us in doubt whether they were successful in either or both cases. We cannot here enter into the vast and intricate ground of Egyptian mythology, and must refer the reader to the special works on that subject by Champollion, Wilkinson, and others. Their mythology appears to have been originally symbolical, but afterwards degenerated, at least for the vulgar, into gross idolatry. That they had some practical knowledge of geometry, which indeed must have been requisite for the construction of their buildings, &c. is generally admitted. Yet they appear not to have known until a comparatively later period that the level of the Red Sea was much higher than that of the Mediterranean or of the Nile. Their boats were rude and clumsy, and chiefly constructed for river navigation. They were for a long time averse to maritime expeditions from superstitious prejudice, probably instilled by their priests in order to keep them secluded from the rest of the world, and the Phœnicians were then the sea-carriers of Egypt. It was chiefly after the restoration effected by Psameticus I., and their consequent intercourse with the Greeks, that their rigidity in this and other respects relaxed: they had their ships of war both on the Mediterranean and Red Sea, and under Apries Egypt had sufficient naval power and skill to cope with the fleets of Tyre. His predecessor Necos II. is said by Herodotus to have dispatched some Phœnician vessels by the Red Sea to circumnavigate Libya (Africa), and to return to Egypt by the Pillars of Hercules, which they effected. The truth, or at least the extent of this expedition has been much questioned. [AFRICA.] There is a curious story in Plato's 'Critias,' of Sonchis, an Egyptian priest, having told Solon of the Atlantic isles, which he said were larger than Asia and Africa united, which seems to imply something like a knowledge of the existence of the Western Continent.

The money of the Egyptians was in rings of silver and gold, similar to those still used in Sennar, and its value was ascertained by weight, and its purity by fire. Gold was brought to Egypt from different tributary countries of Ethiopia and Asia, besides what they drew from their own mines. The revenue of Egypt, derived from the taxes alone, amounted, even during the negligent administration of Ptolemy Auletes, to 12,500 talents, between three-

and four millions sterling. Diodorus reckoned its population at seven millions, and Josephus at seven millions and a half, exclusive of that of Alexandria, which exceeded 300,000. For further particulars on the commerce, resources and policy of antient Egypt, see Heeren's *Researches*. Champollion le Jeune in his 'Egypte sous les Pharaons,' has endeavoured to retrace the national names and localities of the antient Egyptian towns, many of which had disappeared long before Strabo's time, or their names had been disfigured by the Greek writers. Egypt was, according to Champollion, divided already under the Pharaohs into 36 nomes or governments, 10 in the Thebais or Upper Egypt, 16 in Middle Egypt, and 10 in Lower Egypt, commonly called the Delta. Each nome was subdivided into districts or toparchies. This was exclusive of the Oases, the dependencies on the side of Nubia, &c.

With regard to the principal existing monuments of antient Egypt we refer the reader to the respective heads, such as DENDERAH, EDFO, PYRAMIDS, THEBES, &c., and for the general character of Egyptian architecture to the following article.

Modern History. Passing over the ages during which Egypt was a province of the Roman Empire (see Hamilton's *Egyptiaca*, on the State of Egypt under the Romans, and *map of Egypt* with the names of the Roman period, by Raoul Rochette), we begin the modern history of Egypt at the Mohammedan conquest. Under the Caliphate of Omar, successor of Abu Bekr, Amer Ebn el As invaded Egypt, A.D. 638, and took Pelusium and Babylon of Egypt, a strong Roman station, which sustained seven months' siege. John Mecaukes, governor of Memphis for the Byzantine emperor, treacherously surrendered his trust, and the Copts agreed to pay tribute or a capitation tax to the Caliph, with the exception of old men, women, and monks. The hatred, not only political but religious, which the Copts bore to the Greeks, facilitated the success of the Moslems. The first mosque on Egyptian ground rose with the new town of Fostat on the site of Roman Babylon. Alexandria made a long and obstinate defence; it fell at last, and was plundered. The Saracen General asked the Caliph what was to be done with the library, and Omar ordered it to be burnt. But the libraries of the Ptolemies had perished before—the Bruchion was destroyed during the siege of Julius Cæsar, and that of the Serapion was dispersed by Theophilus the Patriarch, A.D. 390; the library destroyed by Omar's order was therefore a more recent collection. [ALEXANDRIAN LIBRARY.] The whole of Egypt as far as Syene was soon reduced to a province of the Caliphate, the capital of which was Fostat. In A.D. 868, Ahmed ebn e' Tooloon, governor of Egypt for the Abbaside Caliphs, usurped the sovereignty of the country and founded the dynasty of the Tooloonides, which lasted till 906, when the Caliphs retook Egypt. But in 912 Abayd Allah el Mahdee after usurping the government of Eastern Africa, invaded Egypt, which he retained till 934, when he was defeated by the forces of the Caliph. In 936 El Akhshad Mohammed ebn Tughg, a Turkish chief in the service of the Caliph, usurped the government of Egypt, and began a new dynasty which lasted till 970, when the Fatmieh or Fatemides, the successors of Mahdee, who had continued to rule in Africa, took possession of Egypt. El Moez, who styled himself Caliph, built Misr el Kahirah, where he fixed his residence, leaving Yousef Ebn Zeiri his viceroy in Africa. From that time till 1171, the Fatemite Caliphs reigned over Egypt, independent of and rivals to the Abbaside Caliphs of Bagdad. This was the period of the wars of the early Crusades, in which the Fatemides acted a conspicuous part. Egypt retained much of its importance and splendour under their dynasty. (See *Etat Arabe de l'Egypte*, by Sylvester de Sacy, joined to his translation of Abdallatif.) The Kurd Salah e' deen Yoosuf Ebn Eyoob succeeded to the Fatemides in 1171, and founded the dynasty of the Eyoobites, which lasted till 1250, when El Moez, a Turkoman memlook or slave, after murdering Touran Shah, usurped the throne, and founded the dynasty of the Baharite Sultans, who took possession of Syria also. Baybars, a memlook also, assassinated his master in 1261 or 62, made himself Sultan of Egypt, retook Syria from the Tatars, took Damascus, and put an end to the Caliphate of Asia, and extended his conquests as far as and over part of Armenia. His descendants reigned till 1382, maintained possession of Syria as far as the Euphrates, and encouraged agriculture and the arts. Their dynasty is known by the name of Baharite Memlook Me-

leks or Sultans. They did not assume the title of Caliphs, but allowed the descendants of the Abbasides to retain that name, and to live in Egypt under their subjection, as a sort of state prisoners.

In 1382 Dowlet el Memeleek el Borgée, a Circassian slave, took possession of the throne and founded the dynasty of the Borgée, or Circassian Memlooks, which lasted till 1517, when Selim I., the Ottoman sultan, advanced into Egypt, defeated the Memlooks at the battle of Heliopolis, and caused Toman Bey, the last of their kings, to be hanged at Cairo. Selim abolished the dynasty, but not the aristocracy of the Memlooks; he even made conditions with the Memlooks by a regular treaty, in which he acknowledged Egypt as a republic, governed by twenty-four beys tributary to him and his successors, who appointed a pacha, or governor, to reside at Cairo. This pacha, however, was to make no alterations in the system of government without the consent of the beys, who might even suspend him from his functions if he acted arbitrarily, until the pleasure of the Porte should be known. The beys were to elect from among themselves a sheik of Belad to be their head, who was looked upon by the Porte as the chief of the republic. In time of war the republic was to send 12,000 men to join the Ottoman armies. In other respects the republic, that is to say, the Memlook aristocracy, was to enjoy absolute power over the inhabitants of Egypt, levy taxes, keep a military force, raise money, and exercise all the rights of sovereignty. This treaty was signed in the year 887 of the Hegira, A.D. 1517. (Savary, *Lettres sur l'Egypte*, vol. ii.) Under this form of government Egypt remained nominally subject to the Porte, against whose authority the Memlooks often openly revolted, till the French invasion of 1798, when Bonaparte, under the pretence of delivering Egypt from the yoke of the Memlooks, took possession of the country. The English sent an expedition in 1801 to aid the Porte, which drove away the French, and restored the pacha appointed by the sultan. The Memlooks and the pacha, however, could not agree; scenes of bloodshed and treachery took place, and at last the present pacha, Mehemet, or rather Mohammed Ali, contrived to collect most of the beys with their principal officers within the citadel of Cairo, under pretence of an entertainment, where he had them all massacred in March, 1811. A few escaped into Upper Egypt, from whence they were driven into Nubia, and being also driven from thence in 1821, the few who survived took refuge in Dar-fur. [DONGOLA.] Thus ended the Memlook power, which had ruled over Egypt for more than four centuries. Savary gives an account of the institutions of that singular body, which were still in full force in his time. Their destruction, although perfidiously contrived, has been undoubtedly a benefit to Egypt, for their government was as tyrannical and oppressive as their moral character was depraved. It was a government of slaves who had become masters, for the body of Memlooks was perpetually recruited from young slaves brought chiefly from Georgia and Circassia. Every bey was a tyrant in his own district. There was not even union among them, as they were frequently at war with each other. Personal bravery or animal courage was their only virtue, if it deserves that name. Egypt suffered more under the Memlooks than during any other period of its history.

Present State of Egypt.—This country is commonly divided by geographers into three regions, namely, Bahari, or Maritime, or Lower Egypt; Vostani, or Middle Egypt; and Said, or Upper Egypt. But the administrative division of the country is by provinces, or prefectships, of which there are fifteen in Lower Egypt, and ten in Middle and Upper Egypt together. The provinces are—1. Masr, or Cairo, with the town of that name, the capital of the whole country, and the town of Boolak, the port of Cairo on the Nile, Old Cairo, or Fostat, and Suez, on the Red Sea; 2. Kelioub, north of Cairo, with the towns of Kelioub, Matarieh, near the ruins of Heliopolis; Artrib, Choubra, where the pacha has a fine country residence, and Abouzabel, where is the new College of medicine and surgery, with 300 pupils, and a large hospital attached to it; 3. Belbeys, east of Kelioub, on the borders of the Desert; 4. Chibeh, north of Belbeys, with the towns or villages of Chibeh, and Tell Bastah, and Heydeh; 5. Mit Ghamer, north of Kelioub and near the Damietta branch of the Nile; 6. Mansourah, north of Mit Ghamer, likewise on the east bank of the Damietta branch, with the town of Mansourah, and the village of Tmay el Emdid, which has a monolith of granite; 7. Damietta, with the towns of Damietta and

Menzaleh, and the forts of El Arish and Tynoh, on the borders of the Syrian Desert; 8. Mehallet el Kebir, with the town of that name, within the actual Delta, on the left bank of the Damietta branch, and the small towns of Semennout and Abousir; 9. Tantah, south of Mehallet, with the town of Tantah, situated near the middle of the Delta, one of the principal towns of Lower Egypt, remarkable for its fine mosque, and the fair which takes place three times a-year, and is much frequented by pilgrims who come to visit the tomb of Seyd Ahmed el Bedaouy, a celebrated Mohammedan saint; 10. Melig, south of Tantah with the towns of Melig and Chibn el Koum; 11. Menouf, south of Melig, and within the angle formed by the bifurcation of the Nile; 12. Negileh, with the town of that name, on the left or west bank of the Rosetta branch, and the towns of Terraneh and Wardan; 13. Fouah, north-west of Mehallet, with the town of Rashid, or Rosetta, and the towns of Fouah and Deirout; 14. Damanhour, on the left bank of the Rosetta branch, north of Negileh, with the towns of Damanhour and Rahmanyeh; 15. Alexandria, with the city of that name.

On entering the valley of the Nile from the Delta side we find, 1. Jizeh, on the left or west bank of the river, opposite Cairo, a small town, head of the prefectship of that name, near the great pyramids, and not far from the ruins of Memphis, upon which are built three modern villages, Bedreshin, Mit Rahyneh, and Memf; 2. Benisouef, south of Jizeh, on the same side of the Nile, a considerable and industrious town, in one of the most fertile districts of the valley of the Nile, with the towns of Abou Girgeh and Sammallout further south; 3. On the opposite or east bank of the Nile is Atfyh, a town and prefectship; 4. West of Benisouef is the district of Faïoum, with the town of Medinet el Faïoum; 5. South of Benisouef, but extending on both banks of the Nile, is the district of Minyeh, with the towns of Minyeh, Melaoui, and Eshmounein on the left, and those of Sheyk Abadeh and El Bershel on the right bank; 6. Manfalout, south of Minyeh, with the town of that name on the left bank, and several villages on both banks of the Nile; 7. Siout, with the town of that name, the capital of Upper Egypt, and the residence of a governor. It is situated on the left bank, is a great slave-market, and the entrepôt of the caravan trade with Darf-fur and Sennaar, with a spacious bazaar, and 12,000 inhabitants—Richardson says 20,000; 8. Girgeh, south of Siout, with the towns of Girgeh, 7000 inhabitants, on the left, and Ekhmyim, 10,000, on the right bank of the Nile; 9. Kenéh, with the town of that name, on the right bank, which has 5000 inhabitants, and carries on a considerable intercourse with Cosseir and the opposite coast of Arabia, and is known for its manufactory of porous earthen vessels used for keeping water cool. Kous, near the ruins of Coptos, Denderah, on the left bank, and the ruins of Thebes and of Abydos are in the prefectship of Kenéh; 10. Esneh, the most southern province of Egypt, with the town of that name, on the left bank, with about 4000 inhabitants, manufactories of cottons and shawls, and pottery; it is a great market for camels, and the emporium of the Abyssinian trade. The other towns are Edfu, Assouan or Syene, Koum Ombou, with a fine temple, and Selseleh, with its quarries.

For the principal towns of Egypt see the respective heads ALEXANDRIA, CAIRO, DAMIETTA, ROSETTA, &c. The population of the smaller towns is very difficult to be ascertained, as there is no census or register kept.

The whole of the cultivable land of Egypt, in the valley of the Nile and the Delta, is reckoned at 17,000 square miles. The resident population has been generally stated at two millions and a half, but a recent traveller thinks it does not exceed two millions at the utmost, of whom 1,750,000 are Mohammedan Egyptians, including the fellahs or peasants and the townspeople; 150,000 are Copts or Christian Egyptians; 10,000 are Osmanlees or Turks and Albanians, as yet the ruling race; 5000 Syrians, 5000 Greeks, 5000 Jews, and 2000 Armenians, and about 70,000 are black slaves, Nubians, Moghrebins, &c. (Lane's *Modern Egyptians*.) In this calculation the nomadic Arabs of the neighbouring deserts, whose number cannot be ascertained, are not included. The language of the natives is Arabic; but Turkish is still the language of the government. For the Copts and Coptic language see those articles. The great bulk of the Mohammedan natives is of Arab stock, but many Copts or aborigines have at different times embraced Mohammedanism, and numerous intermarriages have taken place between the Arab settlers and

the Copts, Nubians, &c. The fellahs of Egypt have lost much of their original Arabian character; they are become proverbially tame and servile, and are despised by the neighbouring Beduins, who never give them their daughters in marriage. The townspeople may be considered as having attained as high a degree of civilization as any in the East, and 'Cairo,' says Mr. Lane, 'must be regarded as the first Arab city of our age. There is no other place in which we can obtain so complete a knowledge of the most civilized class of the Arabs.' The men are generally well proportioned and muscular, their height about five feet eight or five feet nine; the women beautifully formed, and not too fat. Their complexion in Cairo and the northern provinces is clear, though yellowish, and their skin soft; the lower classes are darker and coarser. The people of middle Egypt are of a more tawny colour, and those of the southern provinces are of a deep bronze complexion. Their countenance in general is of a fine oval form; the nose is straight though rather thick, the lips rather full, the eyes black and brilliant, the beard commonly black and curly, but scanty. For the dress and habits of the various orders, see Lane's *Modern Egyptians*, vol. i.

The climate of Egypt, during the greater part of the year, is salubrious. The khamseen, or hot south wind, which blows in April and May, is oppressive and unhealthy. The exhalations from the soil after the inundation render the latter part of the autumn less healthy than the summer and winter, and cause ophthalmia and dysentery, and other diseases. The summer heat is seldom very oppressive, being accompanied by a refreshing northerly breeze, and the air being extremely dry. This dryness however causes an excessive quantity of dust, which is very annoying. The thermometer in Lower Egypt in the depth of winter is from 50° to 60° in the afternoon and in the shade; in the hottest season it is from 90° to 100°, and about ten degrees higher in the southern parts of Upper Egypt. The climate of Upper Egypt, though hotter, is more healthy than that of the lower country. The plague seldom ascends far above Cairo. Ophthalmia is also more common in Lower Egypt; it generally arises from checked perspiration, but is aggravated by the dust and other causes, and by the neglect and filth of the natives, so that great numbers of Egyptians are blind in one or both eyes. The houses of the wealthier classes in the principal towns are substantially built, roomy, and commodious, but the dwellings of the lower orders, especially of the peasants, are of a very mean description, being mostly built of unbaked brick, cemented with mud. Many of them are mere hovels. Most of the villages of Egypt are situated upon eminences of rubbish, the materials of former buildings, and thus rise a few feet above the reach of the inundation: they are surrounded by palm-trees.

The agricultural produce of Egypt consists of the following winter plants, which are sown after the inundation and reaped in about three or four months after: wheat, barley, beans, peas, lentils, vetches, lupins, clover, flax, coleseed, lettuce, hemp, cummin, coriander, poppy, tobacco, water-melons, and cucumbers; and of the following summer plants, which are raised by artificial irrigation by means of water-wheels and other machinery: doorah, Indian corn, onions, millet, hennah, sugar-cane, cotton, coffee, indigo, madder. Rice is sown in the spring and gathered in October, chiefly near Lake Menzaleh. Of the fruit trees, which grow mostly in gardens near the principal towns, the mulberry and Seville orange ripens in January, apricots in May, peaches and plums in June, apples, pears, and caroobs at the end of June, grapes at the beginning of July, figs in July, prickly pears end of July, pomegranates and lemons in August, dates in August, citrus medica in September, oranges in October, sweet lemons and banana in November. The poor fellah or farmer who cultivates the soil derives but little benefit from the prodigality of nature; he is compelled to pay a heavy land-tax, another tax to government for the use of the water-wheels, besides additional taxes and exactions of the local sheikh, the Copt scribe, and the Turkish officers, and then he is obliged to sell a portion or the whole of the produce of his land to the government at a fixed price, and to carry it to the granary at his own expense. The fellah, to supply the bare necessities of life, is often obliged to steal and convey secretly to his hut as much as he can of the produce of his own labour. He may either himself supply the seed for his land, or obtain it as a loan from the government; but in the latter case he receives hardly three-

fourths of what he pays for, the remainder being stolen by the subordinate officers. The pacha has dispossessed all the private proprietors throughout his dominions, giving to each, as a partial compensation, a pension for life, so that the farmers are now his own tenants and entirely at his mercy. (Lane, vol. i., c. 4, and Wilkinson's *Thebes*, pp. 268 and foll.)

The government of Mohammed Ali, too extravagantly praised by some, is certainly much more rational, orderly, and humane, than that of the memlooks or that of the old pachas in the other dominions of the Porte. He administers impartial justice to all his subjects, without regard to race or religion; has established regular judicial courts and a good police; has done away with tortures and other barbarous punishments; has encouraged instruction to a certain extent; has removed most of the ignorant prejudices which existed among his subjects against the arts and learning of Europe; and has introduced European manufactures and machinery; he keeps a printing-office and a journal; has formed schools and colleges for the arts and sciences and for military and naval tactics. All this is much more than it may seem at first sight to a person unacquainted with the state of Egypt and other Turkish provinces forty years ago. But the pacha's ambition and the difficulties of his situation have obliged him to resort to two violent expedients, an enormous taxation and an oppressive conscription. The pretended legislative assembly sitting at Cairo is a mere fiction of enthusiastic panegyrists. The government of Egypt is still absolute in the strictest sense of the word, though the present pacha has chosen to govern according to forms and regulations which he has himself established. He has formed a council consisting of his chief officers and of the provincial and local governors and sheikhs, whom he occasionally consults. Many of the subordinate agents of the government in the provinces still exercise occasional acts of capricious tyranny, which seldom reach their master's ears, but whenever they do he is not slow in punishing the offenders and redressing the grievances of the oppressed. Of what Mohammed Ali has really done a good sketch may be found in Planat, *Histoire de la Régénération de l'Égypte*, 8vo., Paris, 1830, and in a notice of the same work in No. xiv. of the *Foreign Quarterly Review*, April, 1831. The reforms effected by Mohammed Ali are far more complete and effective than those of Sultan Mahmood in Turkey, and are directed by a keener sagacity and with a steadier purpose. Mengin, 'Histoire de l'Égypte sous le gouvernement de Mohammed Ali,' 2 vols. 8vo. with an atlas, Paris, 1823, gives a full account of the career of this extraordinary man. At the end of the atlas there is a 'Tableau du Commerce de l'Égypte avec l'Europe.' For the various arts and manufactures of Egypt see Lane's vol. ii. 1.

The present dominions of the ruler of Egypt extend on one side to Sennaar and Kordofan, and on the other over all Syria to Adana, a part of Cilicia at the foot of Mount Taurus. He is likewise possessed of the fine island of Candia. In Arabia he is protector of Mecca and Medina, and lord of the Hedjaz. He is possessed of at least as extensive a tract of country as any of his predecessors of the Fatimite, Ptolemaic, or Pharaoh dynasties. Whether this empire will survive his death is a very doubtful question. His power is founded on a strong military force, which consists of between fifty and sixty thousand regular troops, the officers of which are mostly proud Osmanlees, aliens to Egypt, and the soldiers are the sons of the poor, oppressed, despised fellows. No Arab officer, says Planat, is raised above the rank of lieutenant. The Osmanlees fill likewise the principal offices of the government. But the native Egyptians are said to be quick at learning, hardy, frugal and persevering; they make excellent soldiers; they divest themselves of old prejudices more easily than the Turks, and in their intercourse with Europeans they exhibit none of the jealousy and pride of the latter. Whatever therefore may be the consequences of Mohammed Ali's reforms, with regard to the stability of his dynasty, there is some reason to hope that the impulse which he has given to the native population will not be lost, and that the seeds of improvement scattered about Egypt will spread in course of time to other parts of the Arab world, of which Egypt forms the central and so important a part.

EGYPTIAN ARCHITECTURE. This was not included under the head of CIVIL ARCHITECTURE, for the reason that it is purely monumental or historical, and not at all the object of study to the architect except as belonging to the archaeology of his art, and as matter of curiosity; so

totally distinct is it in its taste from what is termed classical antiquity. Indeed, until of comparatively very late years, hardly any thing was known of the Egyptian style, or the edifices executed in it, with the exception of the pyramids; for previously to the French expedition to Egypt, at the close of the last century, no satisfactory delineations had been taken of the temples and their details; but merely such views as were calculated to convey some general idea of their enormous masses and colossal grandeur. Hence it has been—we may say even still continues to be—regarded as wonderful both for the gigantic vastness of its structures, and the prodigious solidity of the materials and mode of construction employed, but at the same time as utterly devoid of beauty in its forms and proportions,—uncouthly sublime. Yet as the first impression of strangeness wears off—when the eye, so long habituated to Grecian and modern architecture, becomes more accustomed to it, and the first prejudices against it are overcome, it will be found to possess much elegance in some of its forms, together with powerful and legitimate architectural effect.

In character, the Egyptian is the very reverse of the Gothic style; for although both are distinguished by grandeur and solemnity, the one aims at ponderous massiveness, and affects low proportions, and great extent of unbroken horizontal lines; while the other affects exactly the contrary—slenderness and loftiness, forms aspiring upwards, and extreme diversity of outlines. Notwithstanding, too, that Egyptian architecture has much in common with that of Greece, it exhibits, together with what stamps the affinity between them, many striking points of difference. While they agree in having columns supporting a horizontal epistylum, or entablature, and in the general proportions resulting from such a disposition, they disagree in almost all their other subordinate particulars. It will, therefore, not only be interesting in itself, but facilitate explanation, to compare the Egyptian style with the Greek, as described in the articles CIVIL ARCHITECTURE and COLUMN. Although, in the massiveness of its proportions, in simplicity and breadth of effect, its character partakes more of that of the earlier Doric—the latter being, in fact, the first remove from it,—there is one remarkably striking difference between them; for Egyptian columns are as frequently cylindrical as not; whereas those of the earlier Doric taper very suddenly, owing to the difference between their upper and lower diameter, and the shortness of their shafts. In Egyptian buildings, on the contrary, the profile of the columns is vertical, or nearly so, while that of the walls is sloped; thus producing the same degree of contrast between the two which is observable in the Greek Doric, although the mode adopted in the one case is just the reverse of that pursued in the other. It may further be remarked that in both styles the general outline was nearly the same, it being sloped in each; in the Egyptian, by the walls; in the Doric, by the external peristyle of columns enclosing them; whereby, in the latter case, as well as in the former, the base is wider than a horizontal line on the level with the upper part of the columns. Or if we take the ground-line formed by the lowest of the steps on which the columns are placed, we find that it accords very nearly with that of the cornice, or uppermost line of the building, similarly as in Egyptian edifices. This will be tolerably well understood from the view, in the next page, of the front of the temple at Denderah, which exhibits the sloping or tapering profile we have been describing, and to which we shall have occasion again to refer in explanation of various other particulars. From what has been stated as to Egyptian columns being cylindrical, it is not to be understood that they were either invariably or perfectly so, but that such was their general form; because there is occasionally a slight difference between the upper and lower diameter; or else the shaft is cinched at intervals by bands consisting of three or more rings encircling it, and thereby increasing the diameter in those parts. In addition to this species of ornament, the shaft was variously decorated in other respects, the spaces between the bands being sometimes sculptured with hieroglyphics; at others, reeded, that is, its surface was divided into a series of upright mouldings, or staves, so as to have the appearance of a bundle of smaller pillars bound together, of which mode, as well as that of encircling the shaft with ring mouldings, frequent examples occur in Gothic buildings. The kind of striating, or striping, just described, is the reverse of that practised in the Doric and other Grecian orders, since in the latter it was produced by concave channels, or flutings, but in this by convex surfaces. The diver-

Front of the Temple at Denderah.

sity observable in Egyptian columns is so great that it is impossible to specify here all their varieties, which can be learned only by studying them in engravings; equally impossible is it, too, to reduce them to any kind of system, there being neither any peculiar form of capital, or other distinct characteristic, nor any thing in regard to proportions whereby they can be classified; for we find columns similar in proportions differing materially in all the rest, or else *vice-versa*.

Egyptian columns have rarely any distinct base, seldom more than a circular plinth; but they have frequently an ornamental footing, which differs, however, from a base, in being contracted instead of expanded below. It may be described as shaped like the calyx of a flower, the resemblance to which is increased by its being sculptured into some forms of foliage, so that the shaft appears to be set in and rise out of a plant. Of this description are the bases of the columns of the temple at Latopolis or Esné. By some this has been insisted upon as a defect and as indicative of weakness; consequently, contrary to that law of architecture which prescribes that there should be apparent as well as real strength, more especially where the expression of solidity is naturally looked for. Still it may not unreasonably be urged that, as in all such cases, the judgment comes to the aid of and corrects the eye, what is known to be strong cannot fairly be said to appear weak; and the solidity of columns which have stood the test of some thousands of years cannot possibly be called in question. Were we unacquainted with its properties, even the form of the arch might be thought ill calculated for sustaining pressure; by others pendants likewise from vaulted roofs might be deemed blemishes rather than ornaments, as carrying with them a decided appearance of insecurity. The particular kind of Egyptian base here alluded to is certainly not in accordance with Grecian principles, yet it does not therefore exactly follow that it is faulty in itself. On the contrary, it may be argued that the excess of strength which they gave their structure, and the prodigious solidity and durability of the materials employed, allowed the architects of Egypt to contract the diameter of their columns below, without rendering them at all weak. Perhaps, too, one motive for doing so was thereby to produce a still more effective contrast between the columns and the general outline of the building, which, as already explained, sloped upwards.

The most usual form adopted for capitals was bell-shaped, that is, resembling a bell reversed, or rather the bell and petals of a flower, with a rim bending downwards, which was sometimes quite circular, thereby giving the whole somewhat the appearance of a mushroom; at others, jagged, the circumference being divided into a number of convex curves, forming so many distinct petals. The six specimens given in the article COLUMN, vol. vii., page 383, exhibit two of the latter, and three of the first-mentioned variety of the bell-shaped capital.

From these it will be seen what variety prevailed in the decorative details, some being cut into distinct leaves, either convex or concave, others embellished with sculpture representing branches and flowers. It will also be per-

ceived that in their general mass the capitals of this class far from having anything in common with that of the (Grecian) Doric, bear some general similarity to that of the Corinthian order; at the same time both the foliage itself and its arrangement are altogether of a different character. even were the resemblance more perfect in these respects there would still exist an exceedingly wide distinction between them and every variety of either Grecian or Roman capitals, namely, in the abacus being a mere square plinth considerably smaller than the capital itself. Consequently it bears no similitude whatever to that of the Doric, which overhangs the echinus, and extends beyond the architrave which rests upon it; while it is equally remote from that of the Corinthian, since, besides being enriched with mouldings, the latter has its sides curved so that the angles extend those of the volutes. The Egyptian abacus, on the contrary, is anything but ornamental in itself, and would be a defect, were it not that in the buildings themselves it

Column from Denderah.

hardly be seen, owing to its smallness, and the projection of the rim of the capital; consequently, unless it happens to be very deep, it serves chiefly to detach the capital from the architrave, and prevent that heaviness of appearance which would otherwise be occasioned. The first figure among the specimens above referred to shows an example of what may be termed the double capital, peculiar to Egyptian architecture, for above the usual shaped capital is a square member, sculptured on each of its sides with an Isis' head, and on this again is placed a small temple, so that instead of a double this may be termed a triple capital. The columns of the temple at Tentyra or Denderah offer another instance of the double capital in some respects similar to, in others greatly differing from the preceding.

Here the lower capital consists of four Isis' faces, disposed so as to form a square, larger than the shaft, the folds of the head-dress hanging down and projecting beyond it: above each face is a kind of fluted abacus; and above is a square temple. The shaft also varies considerably from those shown in the preceding examples; for instead of being striated vertically and banded horizontally, this is covered with hieroglyphics disposed in series of rings. Another remarkable circumstance is the great height of the whole capital, it being not less than two-fifths of the shaft.

There is another species of capital of very frequent occurrence, which is totally distinct from either of the above two classes; and although its form may, at first sight, be considered uncouth, it is well calculated for effect; neither is it devoid of simplicity. After sweeping out from the shaft, instead of continuing to expand as it proceeds upwards, it slopes back so as to diminish until it is contracted again to the diameter of the shaft itself. The decoration consists in its

being subdivided into eight lesser shafts, inscribed with hieroglyphics, as are likewise the faces of the abacus, which member here becomes very pronounced, and occasions a picturesque play of light and shade. Capitals of this kind, as well as other varieties, occur at Luxor. In their proportions Egyptian columns vary no less than in other particulars, their height amounting in some instances to no more than three diameters, in others extending to eight or upwards. Yet such difference is not attended by any regularly corresponding one, either as regards the column itself, or the parts connected with it. Further, it is by no means unusual to meet with square pillars or *tetrapleurons*, with either a statue, or a caryatid figure standing before, but distinct from it.

The Egyptian entablature is so far from displaying any thing like the same variety as the columns, that it is nearly uniformly the same in buildings which differ very much from each other in regard to their columns. Unlike that of the Greeks, it consists of only two divisions, the epistylum or architrave, and the cornice; the height of both being generally one-third of that of the columns. More frequently than not the epistylum was enriched with sculpture in hieroglyphics; which circumstance alone constitutes a great difference between the practice of the Egyptians and that of the Greeks. Another singularity is, that the epistylum was included within the convex moulding or *torus* carried up at the angles of the building, and then returned horizontally along the front, owing to which the architrave itself (epistylum) appears to be returned downwards, like

that of a door or window. This will be at once understood by referring to the view of Denderah on the opposite page, by which it will also be seen that the cornice consists of little more than a deep cove, enriched with sculpture; a form peculiarly adapted for effect in a climate like that of Egypt, as it not only casts a bold shadow but receives a strong reflected light.

With the cornice the building terminated, for the roof being a flat terrace, there was no indication of roof; consequently Egyptian architecture is entirely destitute of what are such expressive and highly ornamental features in that of Greece, namely, the pediment, antifixæ, and ridge tiles. By way of indemnity for its deficiency in this respect, and the sameness arising from it, greater latitude was allowed to it in others. Not only was there far greater diversity in the forms and ornaments of columns, which do not appear to have been subject to any regulations beyond those prescribed either by symbolic allusions or by national taste; but columns of very different character appear in the same edifice, and even capitals of different design in the same range of columns; wherein again a kindred spirit may be observed between Egyptian and Gothic architecture, notwithstanding that in treatment they are so dissimilar from each other. Another thing peculiar to Egyptian buildings is the frequent use in the external porticoes of temples of intercolumnar walls, or screens, that is, walls built between the columns and carried up half their height; thereby giving to the open part of the intercolumns above them somewhat the appearance of windows. For an example, we again refer to the view of Denderah, in which instance these walls are brought forward so as to enclose the shafts of the columns between them, and fling a shadow upon them. Like every other part of the front in the same edifice, these walls are decorated with sculpture and hieroglyphics; for the Egyptians were exceeding lavish of that species of embellishment, not confining it to particular situations, as did the Greeks, namely to the pediment, frieze, and inner frieze behind the columns, along the walls of the cella, but extending it over the entire surface, in compartments forming tier above tier. These architectural sculptures were generally in very low relief, and some of them also occasionally in intaglio, or hollowed into the surface instead of projecting from it. There are even instances of a combination of both modes, the figures being outlined by a groove or incision, so as to give them greater apparent relief; a mode that has been denominated by some *intaglio-rilevato*. In addition to this species of enrichment may be added that of colours and gilding, especially in the interior and upon beams and ceilings. In this respect, however, the Greeks displayed a similar taste; for it has been recently established beyond all doubt that their temples were decorated with colours and gilding, externally as well as internally, even those of the Doric order, where what have hitherto been considered mere plain mouldings and surfaces, because they were unsculptured, were, in fact, highly ornamented, and frequently with embellishments remarkable for their delicacy.

Having thus given some notion of the elementary parts and features of Egyptian temples, we proceed to describe their general plan and distribution, selecting by way of explanatory illustration the ground plan of the temple at Edfu, or Apollinopolis Magna, one of the largest in Egypt.

This, it will instantly be seen, was far more varied and complex than the plan adhered to by the Greeks, which, as has been shown in the article *CIVIL ARCHITECTURE*, consisted merely of a cella, either surrounded entirely with columns, or with columns only in front, or at both ends. Here, on the contrary, the temple is placed within an enclosure, forming a court in front of it, surrounded on three of its sides by colonnades; and the entrance to this court was through a colossal doorway, or propylæum, placed between two enormous pyramidal towers, or moles, covered with colossal figures in sculpture. These vast masses of structure, which rose considerably higher than the temple itself, had the usual cornice, and likewise the torus moulding running up their angles. Other conspicuous objects frequently accompanying such propylæa, were lofty obelisks, as was the case at Luxor, where there still exists one in front of each mole. These moles may almost be said to be solid, for although they contained chambers and staircases, such spaces amounted to no more than voids left in the mass. Within the court the colonnades were pycnostyle, which seems to have been the usual mode of intercolumniation adopted by the Egyptians, the columns being seldom more

than a diameter and a half from each other, except in the centre of a portico, where there was generally a doorway between the columns, the lower part of the other intercolumns being walled up, as described above, and as shown in the view of Denderah. Such is the case in that of Edfu, which also agrees with the one just mentioned in the number of its columns in front. Owing to their being

Plan of the Temple of Edfu.

The figures in the plan are feet and decimal parts of a foot.

enclosed at their extremities, both these examples answer to a Greek hexastyle in antis [CIVIL ARCHITECTURE], or an octastyle; because although there are but six columns, there are seven intercolumns. They agree, too, in having other rows of columns within, parallel to those in front; but in this respect that at Denderah is richer than the other, for while it has three inner ranges of columns, that at Edfu has only a couple. Even this, however, exceeds what we meet with in Grecian buildings, where there is only—neither is that very general—a single row of columns in antis behind those in front, forming the pronaos or vestibule to the cella—for being inclosed not only at its sides, but in front, by the intercolumnar walls, it answers more to the character of a *pronaos* than a portico. The plan of such structures as the propylæa at Athens and Eleusis corresponds more with that of an Egyptian portico than does any thing else in Grecian architecture; they being, like the latter halls, open in front and enclosed at their sides or ends, and having files of columns within. Beyond this portico, or first hall, is one of smaller extent, passages being cut off at its ends by exceedingly thick partition walls. This has three rows of four columns each, so disposed as to occupy the whole area, leaving merely narrow aisles in every direction between them—a mode peculiar to Egyptian architecture, occasioned by the necessity for employing such thickly-set columns to prop the massive beams and slabs of stone composing the ceiling; and hence such apartments have obtained the name

of *hypostyle* halls. It is hardly necessary to observe that they are altogether different from what has oddly enough acquired the title of an 'Egyptian hall' in this country, (for instance, the large room in the Mansion House, London; the entrance hall at Holkham, &c.), which, besides being utterly unlike Egyptian architecture as to style, has merely a peristyle of columns, or else only colonnades along its sides. To this hypostyle succeed two chambers, the farther one having smaller lateral rooms attached to it, which, it is conjectured, were appropriated to the use of the priests; and facing its entrance was that leading into the *sekos* or shrine containing the figure of the deity. While all the preceding vestibules and chambers are placed transversely to the longitudinal direction of the building, the last and innermost apartment is parallel to that direction, and in continuation of the line of approach; the reason for which is obvious enough, it being almost indispensably requisite that the statue of the divinity should be at one end, and directly facing the entrance. In all probability likewise the object aimed at in disposing the rest as we perceive it to be, was twofold; first, for the sake of having a greater number of apartments to be crossed before the sanctuary was reached and thus rendering it more difficult of access and more mysterious; and secondly, for the sake of contrast; the other divisions of the plan being intended to be merely passed through, but this, on the contrary, being the termination of the whole. If we keep this in view, and the peculiar nature of the worship to which these temples were dedicated, the arrangement must be allowed to be judicious and appropriate, notwithstanding that under different circumstances it might be objected to as constituting a very strong anti-climax, since every portion of it successively diminishes, the last of the sacred chambers being, as the plan shows, hardly equal to the space forming the great doorway between the two moles. Yet what is thus an anti-climax, if we have regard to dimensions alone, became a perfect climax that must have made a powerful impression on those who were allowed to penetrate into the *adytum*—the most sacred part of the fane—the presence chamber, as it were, of the presiding divinity, where the sanctity of the whole precinct was concentrated in a focus, and to which the magnificence and colossal grandeur of all the rest served merely as preparation and prelude.

Such was the general disposition and distribution of an Egyptian temple, which, besides other very obvious distinctions, differs from those of Greece in the columns being situated chiefly within the building, for even the colonnades may be considered in some degree to be so, with respect to the entire plan. The portico, again, was neither *prostyle*, or advanced before the body of the temple itself, nor *peristyle*, that is, continued around it, but enclosed by the lateral walls, as is the case with a Greek temple in antis. Except in the particular instances already alluded to, columns are of very rare occurrence within Grecian edifices, except they were of large dimensions and *hypæthral* (like the Parthenon), that is, open to the sky, having no roof except over the aisles between the walls and the colonnades along them. A court-like area of this latter description was altogether different in character from the hypostyle halls within Egyptian temples, which, owing to the multiplied files of columns and the narrowness of the intercolumns, presented the appearance of a grove of pillars; and had it not been for the great diameter of the columns themselves, their being set so close together would have been no small inconvenience. But the columns themselves were generally of such prodigious bulk, that the space of a diameter and a half between them would generally be equal to about eight or ten feet, and in some instances to much more. In the vast hypostyle hall at Karnak, which is about 338 feet by 170 in extent, and has 134 columns disposed in nine parallel rows one way, and sixteen the other, the smaller pillars are nearly nine feet in diameter, and the larger almost eleven! In comparison with such enormous dimensions both in this and every other respect—for the whole structure extended several thousand feet—the most astonishing works of Roman and of modern architecture shrink into insignificance—even the Colosseum and St. Peter's, and the largest Gothic cathedrals, cease to appear astonishing in point of magnitude.

Some particulars remain yet to be noticed in respect to the temple at Edfu. Instead of being level, the court has a slight ascent towards the front of the temple; not however in one continued slope, but in a succession of low and very wide steps, each being the width of a column and

intercolumn, as indicated by the plan; and the columns around the court are not so lofty as those of the portico, whereby the temple itself acquired greater dignity. Of these latter the capitals are bell-shaped, but not uniform as to design; while those of the pillars in the hypostyle hall have quadrilateral capitals with the four Isis' faces similar to those at Denderah. This hall, again, is not so lofty as the outer one or portico, but the height is proportioned to its other dimensions.

As in Grecian, so in Egyptian architecture, doorways are conspicuous and important features, more particularly in the latter, where they occur as distinct parts of the design in the form of propylæa; sometimes standing quite insulated after the manner of arches or gateways; yet more usually placed between and connecting two pyramidal moles that rise to a great elevation above the propylon itself; consequently such entrance is both lower and narrower than the parts attached to it; which is altogether contrary to what is observable in Grecian composition, where the centre is, if not uniformly more elevated than the rest, at least not depressed; whereas there is here something analogous to what we observe in the façade of a Gothic cathedral, where the portail and body of the church are similarly flanked by towers. In its general form the propylon or gateway resembled the temple itself, yet with this difference, that the proportions of the one are lofty and narrow; of the other, wide and low, and its opening filled with columns supporting the lintel or epistylum. Their similarity in all other respects is obvious enough, owing to the epistylum of the portico being returned and carried downwards just as the lintel of the door is in order to form its jambs. The outer angles are similarly inclined in both cases, and ornamented with the same torus moulding on their edge. It should be understood, however, that the jambs of the doorway were, for the most part, not vertical next the opening, but sloped like the external angles, so that the aperture was narrower at top than at bottom, which form seems to have been copied by the Greeks in that of their doors and windows. The lintel and cornice above it were also proportionably much deeper than the epistylum and corresponding member, over columns, in order to produce sufficient mass; otherwise the effect would have been both unarchitectural and disagreeable, too much like that of the mere framing of a door, standing, although not quite insulated, yet distinct from the rest of the composition. Some idea may be given of the imposing magnitude of such doorways or propylæa, by stating that the one at Edfu measures 74 feet to its summit, and 51 to that of the aperture, which gives a depth of 23 feet, or nearly one-third of the whole height, for the lintel and cornice.

The magnificence of these propylæa was greatly enhanced by colossal statues or obelisks—in some instances both—placed on either side of the entrance. Besides which there were sometimes two or even more propylæa and courts preceding the temple, which were in their turn preceded by avenues of gigantic sphinxes or crio-sphinxes (that is, sphinxes with rams' heads). There are, likewise, instances of avenues of columns crossing the courts in a line from the entrance. The remains at Luxor furnish an example of the kind, where, after the first court (which has a double peristyle), there is a second with a double range of columns extending down it, that are $11\frac{1}{2}$ feet in diameter and 56 high, and beyond this was a third court, flanked by colonnades, consisting of double rows of pillars.

Having thus far given a sketch of the leading characteristics of the Egyptian style, in respect to the principal forms and details, together with their disposition and the arrangement of the buildings themselves, we shall touch very briefly upon the subject of the pyramids, because, interesting as they are in themselves, they are structures of so very peculiar and distinct a nature, as to have but little connection with the architecture of the country in general, being, when considered with reference to it, little more than uniform and simple, although enormous masses. They are, in fact, greatly more important in an historical and archaeological point of view than in one purely architectural. Their shape is so familiar to every one that it requires no description, but may be defined as square in plan and triangular in section, its four sides being as many triangles united so as to terminate in a point; and as the height is much less than the width of the base, each side constitutes nearly an equilateral triangle. Hence, to say nothing of the amazing difference in regard to bulk and dimensions, an Egyptian pyra-

mid is altogether dissimilar in character from a Gothic spire, notwithstanding that Murphy and some other writers have considered it the prototype of the latter. The magnitude of these singular erections, to which there is nothing corresponding in the architecture of any other country (except in Mexico), will be rendered more striking by observing that the base of the great pyramid is of the same dimensions as the area of Lincoln's Inn Fields, namely, about 700 feet square and 450 in height, while the corresponding admeasurements of the second and third pyramids are 650 feet and 280, and 400 and 160. Owing to these proportions, which in the latter case are much lower than those above stated, the extraordinary height is combined with imperishable stability and solidity, the whole being nearly one entire mass of the hardest materials, for the inner galleries and chambers form but mere veins and cavities compared with the entire mass.

In the Great Pyramid three chambers, hitherto undiscovered, have been lately (1836-7) explored and opened by Colonel Vyse. The largest, measuring 38 feet 1 inch by 17 feet 1 inch, has been denominated by him the 'Wellington Chamber'; the second (38 feet 9 inches by 16 feet 8 inches) named 'Nelson's'; and the third (37 feet 4 inches by 16 feet 4 inches) has been named after Lady Arbuthnot, who was present at the time of the discovery. These chambers vary as to height, and the blocks of granite which form the ceiling of the one below serve as the pavement to the next above it. According to the colonel, were chiefly intended as voids in that portion of the pyramid above what is termed the King's Chamber,—the only one that appears to have had any destination—and thereby to lessen the superincumbent mass.

Notwithstanding Egyptian architecture is so dissimilar in its character, in the taste and feeling manifested by it, from every modern style founded upon that of the Greeks and Romans, as to offer little that can be directly applied to any modification of the forms we are accustomed to; it is highly worthy of study by professional men, were it only on account of the beautiful and picturesque arrangements, the skilful contrasts, and varied harmony in the distribution of plan, which it exhibits. For our buildings in general it would be utterly inappropriate, but it might be adopted both with propriety and economy in such as require the expression of massive strength: namely, prisons, manufactories, propylæa entrances to railroads, and works of that description; for which purposes it has been recommended by Dr. Macculloch. Neither need it be an objection that it is quite as remarkable for the high finish and multiplicity of ornament, as for its other qualities; because, apart from all that is merely decorative, it is well calculated to produce effect by its forms and masses alone. It must also be admitted that, although its chief monuments are of colossal bulk and extent, such magnitude is not absolutely essential to the style itself, since there are many moderate-sized edifices still remaining; among others, the temple of Dandour, which does not exceed 22 feet by 44, a scale not very extravagant even for a mere ornamental building in a garden.

We cannot here, as in the article on CIVIL ARCHITECTURE, refer to actual examples at home: still there are two buildings in the metropolis which, as far as single features and details go, may be cited as specimens of Egyptian architecture, viz.: the 'Egyptian Hall,' Piccadilly, and a smaller structure in Welbeck-street. The latter was, as originally erected, the most correct in point of character, but has since been almost spoiled by very barbarous alterations. The other conforms to the style only in certain peculiarities and separate parts, such as the columns, the general outline as indicated by the inclined torus-moulding at the extremities of the front, the cornice, &c., for the composition of the design itself is quite at variance with the principles of genuine Egyptian architecture, the front being divided into two floors with wide windows to both; whereas windows, wherever they do occur in Egyptian buildings, which is but rarely, are exceedingly small and narrow apertures; consequently the Piccadilly example must be looked at with some degree of mistrust. It must also be confessed that any imitation of the style is better adapted for situations where no other buildings would interfere with it, than for street architecture, where a building of such design will look small unless actually much larger than any of those around it.

Hitherto the taste of the Egyptians has been called in question, as being confined to a feeling for grandeur and magnificence, yet evincing very little refinement or percep-

tion of beauty. When examined with unprejudiced eyes, however, many of these forms, especially those of the bell-shaped and lotus-leaved capitals, will be found to possess much of the last-mentioned quality; while recent discoveries in the palaces, tombs, and temples of Upper Egypt, communicated to the world in the splendid publications of Rossellini and others, show not only the great variety and taste manifested in decoration and embellishment of every kind, but prove that many ornamental forms we have been accustomed to consider as essentially Greek, and have imitated as such, are really Egyptian. This is rendered strikingly evident by the delineations given in Rossellini of the various pieces of furniture, musical instruments, vessels of gold and silver, and other articles, from the royal tombs and palaces; and in regard to which luxury and refinement appear to have attained the highest pitch. Not only their archetypes, but even the express forms, till now attributed to the Greeks exclusively, are thus shown not to have been of their invention, but borrowed by them from the Egyptians, in like manner as they have since been copied by ourselves, while ignorant of their real origin. In consequence of this highly curious and important discovery, it is exceedingly probable that the subject of Egyptian architecture will engage attention in a much greater degree than it has ever before done.

EGYPTIAN BEAN, a name sometimes given to the bean-like fruits of *Nelumbium speciosum*, from the notion that they were the beans which the disciples of Pythagoras were forbidden to eat.

EHRENBREITSTEIN, a township on the right bank of the Rhine, in the circle of Coblenz, and in the Prussian province of the Lower Rhine. It contains one town and eight villages, with about 6400 inhabitants; an increase of 568 since the year 1817. The town is called Thal Ehrenbreitstein (Vale Ehrenbreitstein), and is situated at the foot of a precipitous height 772 ft. in elevation, opposite to Coblenz, in 50° 23' N. lat. and 7° 36' E. long. It occurs in records of the year 1210 under the name of Mulne or Mullenheim; but in 1533 the name appears to have been changed into Mühlheim and Müllenthal, probably from the number of mills in the valleys of two rivulets close to it. It contains 2 Roman Catholic churches, a synagogue, 11 public buildings, 9 mills, about 270 dwelling-houses, and 2400 inhabitants. The electoral palace is in a state of great decay. The town has a tobacco manufactory; the acidulous spring in the town is of some repute; and it has a brisk trade in wine, corn, iron, clay for tobacco-pipes, &c. Above the town stands the fortress, which has been entirely reconstructed since the year 1817, with the addition of three forts on adjacent heights, which command the mouth of the Moselle and the access to it from the Lower Rhine. These are, Fort Alexander, on a height in front of Coblenz; Fort Francis, on St. Peter's Hill, on the left bank of the Moselle; and the Pfaffendorf redoubt, opposite the flying bridge across the Rhine. The road up to it from the town is about 1200 paces long; it is fortified, and rests almost entirely upon arches built over the chasms in the rock of which the height consists. The 'Cavalier,' or highest point of this formidable stronghold, is not accessible to strangers, as it affords a full view of the detail and interior of the defences; but the prospects from other points are extensive and beautiful. According to Professor Klein, the Romans had a watch-tower on this height in the times of the Emperor Julian; subsequently the Franks built a burg or castle on the site; and in 1153 it was restored, enlarged, and fortified by the then archbishop of Treves. In 1632 it fell into the hands of the French, whom the Imperialists drove out by famine in 1637. In 1795, 1796, and 1797 it was blockaded by Generals Marceau, Jourdan, and Goullus successively; and in 1799 it surrendered to the French, who the next year razed all its fortifications.

EHRETIA/CEÆ, a small natural order of exogenous plants consisting of shrubs or trees inhabiting the warmer countries of the world, and having rough leaves, monopetalous regular flowers, a definite number of stamens, a superior ovary, a two-lobed style whose divisions are capitate, and a nucamentaceous undivided fruit. The flowers are more or less gyrate, and the order itself, which contains no species of economical value, is so near Boraginaceæ as to render it doubtful whether it ought to be separated. The common heliotrope is the most generally known representation of Ehretiaceæ, forming however the type of a sectional division, characterized by the fruit being dry, not succulent.

Beurreria superlenta.

1, An ovary with the style and double stigma; 2, a ripe fruit with the calyx at the base; 3, a section of the same showing the seeds.

EICHHORN, JOHANN GOTTFRIED, an eminent professor of oriental and biblical literature in the university of Göttingen, and one of the most learned and distinguished scholars of Germany, was born in 1752, at Dorrenzimmern, in the principality of Hohenlohe Oeringen, and at first was rector of the school at Ohrdruf, in the principality of Gotha. Having applied with great success to the study of the oriental languages, he obtained, in 1775, a professor's chair in the university of Jena, where he continued thirteen years, giving instruction in Hebrew, Arabic, &c., and was made, in 1783, a court councillor by the duke of Saxe Weimar. In 1788 he was appointed to the professorship previously held by Michaelis in the university of Göttingen, of which institution he continued a very distinguished ornament during the remainder of his life, as professor of oriental and biblical literature.

His reputation was equally high as a proficient in oriental, classical, and scriptural antiquities; in philosophical criticism; in the history of nations, and of ancient and modern literature and science; and in universal bibliography. He was made, in 1811, a doctor of divinity; in 1813 the directorship of the Royal Scientific Society of Göttingen was conferred on him, and the office of pro-rector of that university; in 1819 he was appointed privy councillor of justice for the kingdom of Hanover (Geheimer Justizrath). He died in 1827, on the 25th of June, at the age of 75. These few incidents, which appear to be all which are published, verify the trite observation that the secluded lives of students furnish but scanty materials for biographical memoirs. In completing the present notice it is therefore only necessary to enumerate the principal works of Eichhorn, and to give a brief and general account of his doctrines as a divine and critic.

The following statements are made, partly from an examination of the works enumerated, and partly on the authority of several German bibliographical publications, and the last edition of the *Conversations Lexicon* (3rd vol., 1833). While at Jena, Eichhorn first displayed his knowledge of Oriental literature in a history of East Indian commerce prior to the time of Mohammed (*Geschichte des Ostind. handels vor Mohammed*), Gotha, 1775. This was followed by a survey of the most ancient monuments of the

Arabs (*Monumenta antiquissimæ Historiæ Arabum*, post Schultensium collecta atque edita, cum animadversionibus), Gotha, 1775: and a treatise on the ancient numismatical history of Arabia, Gotha, 1775. He next published a large collection of learned and valuable treatises, entitled a *Repertorium* of biblical and oriental literature (*Repertorium für biblische und morgenländische Litteratur*), 18 vols. Leipzig, 1777-86. After removing to Göttingen he devoted his attention almost exclusively to the archæology of biblical literature, and the results of his studies appeared in a general repository of biblical literature (*Allgemeine Bibliothek der biblischen Litteratur*) 10 vols. 1788-1801; and in a disquisition on primitive history (*Urgeschichte*) 2 vols., Altdorf and Nurnberg, 1790-93, with an introduction and notes by the learned Gabler. This work contains a searching and bold criticism of the Mosaic Pentateuch. The two next are among the most important of the author's productions, namely, the introduction to the Old Testament (*Einleitung in das Alte Test.*) of which a 4th and improved edition, in 5 vols., appeared at Gotha in 1824: and the introduction to the New Testament (*Einleitung in das Neue Test.*) new edition in 2 vols. 1827. These were accompanied with an introduction to the apocryphal writings of the Old Testament (*Einleitung in die apokryphischen Schriften des Alten Test.*) Leipzig, 1795, Götting. 1798; and a revised and uniform edition of the three, with the title of *Critical Writings* (*Kritische Schriften*) was published at Leipzig in 7 vols. 1804-14.

The other works of Eichhorn on biblical criticism and philology are a commentary on Revelations (*Commentarius in Apocalypsin Joannis*) 2 vols., Gotting. 1791. A revised and enlarged edition of Professor Simon's Hebrew and Chaldaic Lexicon, Halle, 1793. A critical translation and exposition of the writings of the Hebrew prophets (*Die Hebraischen Propheten*), 3 vols. Götting. 1816-20. Commentaries on the prophetic poetry of the Hebrews (*Commentationes de Prophetica Poesi Hebræorum*), 4to., Götting. 1823. Preface to the '*Nova Bibliotheca Hebraica*' by Koecherus; and numerous critical treatises in a learned periodical work entitled *Mines of the East* (*Fundgruben des Orients*); and in the *Commentaries of the 'Göttingen Royal Society of Sciences'* (*Commentarii Societ. Reg. Scientiarum Göttingensis*).

In 1796 he published the plan of a comprehensive history of arts and sciences from their revival in Europe to the end of the 18th century, and wrote, as a part of the work, a general history of civilization and literature in modern Europe (*Allgemeine Geschichte der Cultur und Litteratur des neuern Europa*), 2 vols., Götting., 1796-99. The History of modern Poetry and Eloquence, by Bouterwek, and the History of Military Science, by Hoyer, constituted other parts of the undertaking, which was left unfinished. The first three parts and the fifth part, of a similarly extensive and uncompleted work were written by Eichhorn, namely the History of Literature, ancient and modern, from its commencement to the present time (*Geschichte der Litteratur von ihrem Ursprunge bis auf die neuesten Zeiten*), 6 vols., Götting., 1805-11. He also wrote Literary History (*Literargeschichte*), 2 vols., Götting., 2nd edition, 1813-14. A History of all parts of the world during the last three centuries (*Geschichte der drey letzten Jahrhunderte, &c.*), 6 vols., Götting., 3rd edition, 1818. An Historical Survey of the French Revolution (*Uebersicht der franz. Revolution*), 2 vols., Götting., 1797. And a Universal History (*Weltgeschichte*) on the plan of Gatterer's universal statistics (*Weltstatistik*) 4 vols., Götting. 3rd edition, 1818-20. The two following laborious and judicious compilations have obtained a high repute in the schools of Germany, namely, a History of ancient Rome, composed entirely of connected passages from the ancient Roman writers (*Antiqua Historia ex ipsis veterum script. Roman. narrationibus contexta*), 2 vols., Götting., 1811; and a History of ancient Greece, constructed on the same plan, from the ancient Greek historians (*Antiqua Historia, &c.*), 4 vols., Leipzig, 1812. His last historical work was a curious research on the early history of the illustrious house of the Guelphs, in which the ancestors of the present royal family of England are traced up to the middle of the 5th century. (*Urgeschichte des erlauchten Hauses der Welfen*, von 449-1055), 4to., Hanover, 1817. From the year 1813 to his death in 1827, Professor Eichhorn was the editor of the *Göttingen Literary Gazette* (*Göttingische gelehrte Anzeigen*). His critical writings display extensive and exact learning, which in his biblical treatises

he employs for the development of doctrines often the reverse of those which are generally regarded as orthodox. As a divine, his character, with reference to one of his principal works, is thus described in Orme's *Bibliotheca Biblica* (p. 166): 'Professor Eichhorn is the Goddess of Modern Germany, and has performed for the Old Testament what Michaelis, whom he succeeded, did for the New. Possessing the erudition, the diligence, and all the bold free-thinking of his celebrated predecessor, he introduces the Old Testament by demolishing its authority, by denying its inspiration, and by calling in question the antiquity of its chief historical documents.' It is added, that many of the author's opinions can meet with few supporters in England, except among those who arrogate the title of rational divines; and that the work is noticed only on account of its celebrity in Germany; a statement strangely inconsistent with the fact of its being in the hands of every learned student of divinity in Europe and America. Eichhorn applies to the Hebrew Scriptures the principles on which Heyne explained the mythology of the Greeks, and his name is conspicuous in the theological school commenced by Michaelis and Semler, and extended by Rosenmüller, Kuhnol, Döderlein, Rohr, Teller, Schmidt, Henke, Ammon, Steinbart, Wegscheider, &c., as an ultra rationalist, and a promoter of the system of logical religion and morality, founded on the Kantian transcendental theory of ideology, so generally prevalent in the universities of Germany, and which in truth is a system of mere moral philosophy and philosophical theism, exhibited under the ostensible profession of Christianity; since all traditional doctrines and statements are made to give way to the operation of 'abstract, universal, and eternal principles of reason.' By his superior knowledge of Oriental antiquities, and by his bold mode of thinking, Eichhorn established a new system of scriptural explication, in which he displays a degree of learned and philosophical scepticism much beyond that of his predecessor Michaelis. He denies all supernatural revelation to the Hebrew prophets, believing them to have been clever and experienced persons, who, from their peculiar abilities, were likely to foresee political and other events. He examines, questions, and rejects the authenticity of several books of the Old Testament, and of some of the epistles in the New, and asserts generally that miraculous appearances, visions, voices, &c., are explainable by the laws of nature and the principles of human physiology and psychology, and that supernatural communications are chiefly referable to the mysterious traditions and superstitious notions common to all people in a state of ignorance and barbarism. His theory of the origin of the canonical gospels which regards them as compilations from anterior documents has been adopted by many subsequent critics (See Dr. Schleiermacher's work on the Gospels.) Many of the sceptical positions of Eichhorn have been attacked in Germany by the anti-rationalist class of divines. On this point see '*The Present State of Protestantism in Germany*,' by the Rev. Hugh Rose, 2nd edition, 1829, and the controversial publications which it elicited.

EICHSTÄTT, a bailiwick in the circle of the Regen, and in the west part of Bavaria. It gives the title of Prince to the duke of Leuchtenberg, and forms a portion of his mediatised possessions in the Bavarian dominions. The country, which is mountainous and well wooded, is traversed by the Altmühl: it produces grain, flax and hemp, hops, timber, iron, potters' clay, slate, &c.

EICHSTATT or EICHSTÄDT, is a handsome town situated in a narrow but productive valley on the left bank of the Altmühl, across which four bridges have been built. It is the residence of the duke of Leuchtenberg, as well as of a bishop. It lies in 48° 53' N. lat., and 11° 10' E. long. The town is walled round, has four suburbs, about 900 houses, and a population of about 7800, distributed in three parishes. It has an ecclesiastical seminary, a Latin or grammar-school, a capuchin monastery, a nunnery, an hospital, an orphan asylum, and other charitable institutions, a cathedral church and chapter, and four other churches. Among the buildings of note are the ducal palace, with the celebrated Brazilian cabinet, a library and museum of antiquities, the fine arts, &c.; the cathedral church; and the burg or stronghold of St. Willibald, which overlooks the town from the summit of the mount of that name, and has a well 1200 feet deep. This burg is said to be on the site of Auretum, a Roman castle, and was the abode of the

first bishop, Willibald, who was the builder of the cathedral church and the adjacent dwellings for his clergy, in the middle of the eighth century. For this purpose he cleared an area covered with oaks, whence the town derives its name of Eichstädt, or town of oaks. In the romantic grounds called Aumühlwald, near this place, is a tablet of cast-iron, set in a block of marble, 198 feet square, and laid into a mass of rock: it was erected by the citizens in memory of Eugene Beauharnois, step-son of Napoleon, and viceroy of Italy. This prince was afterwards duke of Leuchtenberg, and prince of Eichstädt. The town manufactures woollens, earthenware, beer, iron ware, &c., and has quarries in the neighbourhood.

EIDER. [DENMARK.]

EIDER-DUCK. [FULIGULINÆ.]

EIGHTH (in music), the octave or eighth note of the diatonic scale. It is a perfect concord [CONCORD], and in harmony is accompanied by the 5th and 3rd; but being almost identical with the base note, it may form a part of any chord, or be omitted at discretion.

EIKON BASILIKE. [CHARLES I. OF ENGLAND.]

EILENBURG, a town in the county or administrative circle of Merseburg, and in the minor circle of Delitsch, which, before its transfer to the Prussian crown, formed part of the circle of Leipzig in Saxony. It is situated on an island of the Mulde, in 51° 28' N. lat., and 12° 37' E. long. The town is surrounded by walls and ditches, and has two gates and a bridge over each arm of the river, four suburbs, an old castle, two churches, an hospital, and infirmary, a civic school, about 640 houses, and 6300 inhabitants. The manufactures consist of cottons, bleached wax, starch, vinegar, brandy, woollen-yarn, crucibles, &c.

EIMBECK or **EINBECK**, the chief town of the former principality of Grubenhagen, which is now incorporated with the principality of Göttingen, a portion of the Landrostei or bailiwick of Hildesheim in Hanover. It is encircled by two arms of the Ilm, and lies in 51° 48' N. lat., and 9° 51' E. long. The walls which enclose it have five gates; the streets are crooked and ill-paved; and the houses, about 780 in number, are old and originally built in the middle ages. The number of inhabitants was 4995 in 1812, and is at present about 5150. It has three churches (one of which, St. Alexander's, contains the sarcophagi of the princes of Grubenhagen, and has a chapter attached to it), an orphan asylum, where woollen yarns are spun, two hospitals, a refuge for the indigent, a gymnasium or high school, and six elementary schools. The church of the Blessed Virgin has likewise a chapter attached to it. Eimbeck, besides a considerable traffic in agricultural products, possesses manufactories of woollens, cottons, tobacco, linens, leather, beer, &c., and there are large bleaching grounds outside the walls.

EIRE'NE. (Zoology.) [MEDUSA.]

EISENACH, a principality in the centre of Germany, forming the western portion of the grand duchy of Saxe-Weimar-Eisenach, from which it is disjoined by the intervention of part of the Prussian province of Erfurt, and the Saxe-Coburg-Gotha territory. It is bounded on the north by Prussian Saxony, on the north-east by the principality of Gotha, on the south-east by Saxe-Meiningen, on the south and south-west by Bavaria, and on the north-west by the electorate of Hesse-Cassel. The detached district of Ostheim, also part of Eisenach, lies to the south within the Bavarian confines, and there are likewise other small and detached portions of the Eisenach territory within the boundaries of Gotha and Saxe-Meiningen. The principality is of greater extent than it formerly was, since it now comprehends the bailiwicks of Lichtenberg, Kaltennordheim, Geiss, Dermbach, Vach, Frauensee, Völkershausen, and some minor tracts, which have been acquired by cession or exchange from the territories of Fulda, Henneberg, and Hesse-Cassel. Its area is about 440 square miles, rather less than a third part of the grand duchy of Saxe-Weimar-Eisenach; and it has a population of about 78,500 souls; in 1818, the numbers were 65,349, and in 1835, 77,729. The greater part of this principality belongs to Thuringia, and a considerable portion of it is traversed by the Thuringian Forest mountains (*Thüringer-Wald-Gebirge*); between which and the Rhön mountains the principality comprehends a tract about forty-two miles in length, and from nine to fourteen in width. The country presents a succession of hills and mountain-heights, uninterrupted by any extensive levels, and the soil is con-

sequently not very favourable to cultivation. It is watered by the Werra, with its tributaries, the Nesse and Hörsel, Ulster, Fulda, Sulz, Suhl, and Vach. The climate is pure and healthy, though, from the proximity of the Thuringian heights, it is variable and not so mild in Franconia and on the Rhine. The products consist of grain, which is not adequate to the consumption, timber, potashes, and tar, rape-seed, flax, hemp, hops, fruit, &c. Horned cattle and sheep are reared in great numbers, as well as swine. Mining has been much neglected; copper, iron, vitriol, alum, and coals, in small quantities, are obtained; and there are quarries of stone and marble, as well as salt-springs near Kreutzburg, from which about 500 tons of salt are annually extracted. Potters' clay and fullers' earth are found. There is more mechanical industry in Eisenach than in Saxe-Weimar: its principal manufactures are linens, woollens, cottons, iron and copper ware, yarn, potashes, leather, earthenware, and articles of wood. Eisenach is divided into eleven bailiwicks, and contains eight municipal towns, twelve market-towns, or villages with markets, and 130 villages and hamlets. The chief towns are Eisenach, Ruhla (3000 inhabitants, of whom 1800 are subjects of Saxe-Gotha), Dermbach (800), Geisa (1700), Berka (1000), Gerstungen (1300), Kaltennordheim (1200), Kreutzburg (1700), Lengsfeld (2100), Ostheim (2600), Vacha (1600), and Völkershausen (1000). The principality fell to the grand-dukes of Saxe-Weimar upon the decease of the last duke of Saxe-Eisenach, who left no issue, in the year 1741.

EISENACH, the chief town and seat of government of the principality of Eisenach, is situated at the confluence of the Hörsel and Nessel, which unite immediately north of the town, and then flow through it in one channel: the village of Fischbach touches it on the east; and the celebrated Wartburg, a mountain fastness, commands it on the south. Eisenach lies in 50° 58' N. lat. and 10° 18' E. long. It is surrounded by walls, has five gates, is well built, and has broad, clean, well-paved streets. It contains about 1450 houses, and has about 9300 inhabitants; an increase of about 1042 since the year 1818, when the number was 8258 independently of the military. The grand-ducal palace, or house of princes (Fürstenhaus), a structure of the last century, is a large and handsome edifice. Among other public buildings there are five churches; a gymnasium, founded in 1233, with an extensive library; a handsome civic school which ornaments the spacious market-place, and was erected in 1825; a seminary for the education of schoolmasters; and an academy for young men designed for the profession of superintendents of woods and forests, an important branch of study in those countries where wood supplies the place of coals. Eisenach has also an agricultural institute for the instruction of youth intended for husbandry, a school of design, a free-school, as well as six elementary schools, a house of correction and orphan asylum, two hospitals, an infirmary, a school of industry for indigent girls, a bible society, and several philanthropic associations. The chief manufactures are woollens, cottons, linens, soap, white-lead, meerschaum heads of pipes, leather, and carpets. The original name of the town was Ysenaha or Ysenacha: it was the abode of Hilten, who preceded Luther as a reformer of the church, and of Amsdorf (a first bishop of Naumburg, and afterwards Luther's bosom friend and fellow-labourer), who died here in 1565. A steep ascent through a fine park leads to the well-known stronghold called the Wartburg, which is about a mile and a quarter from Eisenach, and at an elevation of 1318 feet above the level of the sea. The original burg was built by Lewis the Jumper in 1140, and was the residence of the landgraves of Thuringia until the year 1406: a large portion of it was rebuilt in the beginning of the present century. On this spot, in the early part of the thirteenth century, the minnesänger, or minstrels of Germany, used to contend; and it is still better known as the place of refuge or 'Patmos,' as Luther styled it, to which that great reformer was conveyed in 1521, on his way back from attending the Diet of Worms: here he found an asylum for the ten succeeding months, which he devoted principally to his translation of the Scriptures. The little chapel in which he frequently preached, with its altar-piece, a fine carving in wood representing the Entombment of Christ, and the cell which Luther inhabited, have been carefully preserved in the same state as when he used them. In the ancient portion of the Wartburg

also the Baronal Hall (*Rittersaal*), in which the minstrels held their poetic contests; and the Armoury, built in 1810, which contains reliques of the paraphernalia of Pope Julius II., the Princess Cunigunda, and other personages. This hold is still protected by external works, and is now made use of as a prison. In the grounds between the Wartburg and the town is the remarkable rock in which the hand of nature has sculptured the representation of a monk and nun.

EISENBURG, or in Hungarian *Vas Vármegeye*, and Slavonian *Zelezne Mesto*, a large county in the western part of Hungary, bounded on the north-west by the Austrian province 'below the Ens' (or Lower Austria), on the south-west and west by Styria, and on the east by the counties of Oedenburg, Vezprim, and Szalad. It contains an area of about 2037 square miles, which is divided into 6 circles, and has 1 royal free town (Güns or Koeszoeg), 1 episcopal town (Stein), 41 market towns, 612 villages, 57 prædia or privileged settlements, and about 304,000 inhabitants. The southern and western parts of Eisenburg are very mountainous; for here the Alpine chains which traverse Styria and the duchy of Austria terminate. The northern districts are hilly; but extensive and highly productive plains lie on both sides of the Kemeses, an elevated plateau on the right bank of the Raab. This river is the principal stream in the county, and flows through its southern parts, whence it takes a direction to the north-eastern: the three lesser rivers, the Pinka, Sorok, and Güns, which water the centre and western districts, fall into the Raab on its left bank. Eisenburg, though it has many forests, is on the whole a fertile and productive land: and it has been estimated that of the 1,039,000 acres available for useful purposes, 530,700 are already under the plough; 48,000 have been converted into vineyards; and 358,300 are occupied by woods and forests. Wheat, oats, barley and maize, peas and beans, and flax, are grown in abundance; the Yánosháza tobacco is in repute; and much wine is made. There are many rich pasture lands, and the extensive forests, particularly the Farkas, afford plenty of timber and fuel. Large herds of horned cattle are kept, along the banks of the Raab especially; more pains are now bestowed on the breeding of sheep; poultry is extensively fed for the Vienna market; and there is much game. Near Bernstein, a mining district in the north-west of Eisenburg, large quantities of sulphur are dug: quicksilver, also vitriol, ironstone, and copper, are obtained here on a small scale. Coals are dug at Mariadorf. Marble and alum, are likewise among the products of this county. The majority of the inhabitants are Roman Catholics, of whom there are about 170,000, and of Protestants about 60,000. They are as much distinguished by their mechanical as their agricultural industry, and have a good trade with various parts of Austria.

The most remarkable spot in Eisenburg is Stein-anger (Szombathely), the Sabaria of the Romans, an episcopal town, lying between the Perenth and Güns, in 47° 13' N. lat., and 16° 37' E. long., with about 3800 inhabitants. This town, where the states of the county hold their meetings, as well as its environs, abounds in remains of Roman art, in columns, sepulchral tablets, votive stones, inscriptions, &c. The cathedral is a handsome modern edifice: the town has three other churches, an episcopal residence, seminary, and chapter-house, three monasteries, a Roman Catholic gymnasium, college of philosophy, county-hall, and other handsome buildings. At Tatzmannsdorf (Tarcza), a beautifully situated village in the north-western part of the county, there are excellent and much-frequented chalybeate springs. The dignity of Obergespan (or Headman of the county) is hereditary in the Bathányi family.

EISENSTADT (in Hungarian *Kis-Martony*), a royal free town in the Hungarian county of Oedenburg, finely situated in a noble expanse of country bounded by the Leitha mountain range, in 47° 33' N. lat., and 16° 24' E. long. It lies about 26 miles south-east of Vienna, and contains about 5400 inhabitants. The town itself is walled round, has two gates, and three main streets, a church, and a Franciscan monastery, in which is the sepulchral vault of the Esterházy family, a monastery, and hospital of the Brothers of Charity, a town-hall, and the offices for the administration of the Esterházy domains. The 'Schlossgrund,' or palace-domain, is an extensive suburb, containing about 2600 of the population, and comprising the 'Judenstadt' or Jew's Town, where 500 of that community P. C. No. 571.

reside here are Mount Calvary, laid out in conformity with the supposed disposition of the site in Palestine, and enriched in the eyes of the Roman Catholics by a miraculous effigy of the Virgin; and the palace called *Kis-Martony*, a splendid quadrangular structure, erected in 1805 by Prince Esterházy, to whose family the whole suburb belongs. The park is large, rises in terraces towards the Leitha hills, and is embellished with temples, a canal and cascades, an avenue of rose-trees, 262 paces in length, an orangery of 400 trees, nine large conservatories, containing nearly 70,000 plants, water-works impelled by steam, &c. Eisenstadt possesses a head-school, a Protestant public school, a town-hospital, and an institute for forest economy. Much wine is brought here for sale.

EISLEBEN, formerly the capital of the earldom of Mannsfeld, the chief town of the Mannsfeld circle of the Lake, in the administrative circle or county of Merseburg, in Prussian Saxony. It is situated on an eminence on the banks of the Böse, in 51° 33' N. lat., and 11° 32' E. long., and in the vicinity of two lakes. The town has two subdivisions; the Old Town, which is surrounded by walls and ditches, and has seven gates, and the New Town; besides these it has five suburbs. Eisleben contains altogether four churches, a Protestant gymnasium, several elementary schools, two hospitals, and has about 7500 inhabitants: between the years 1817 and 1831 the number increased from 6330 to 7230. The chief manufactures are potashes and tobacco; and there are copper and silver mines in the neighbourhood, with two smelting works. The town has a brisk inland trade. Luther was born here on the 10th of November, 1483, and died here on the 13th of February, 1546; but neither his parents nor himself had a permanent residence in Eisleben. The object of greatest attraction in it was the house in which he was born. After escaping several extensive conflagrations, it was at last destroyed by fire in June, 1689; and nothing was saved but a wooden table on which Luther's portrait was carved, an old engraving which also represented him, and a window, on the glass of which he and Melancthon were portrayed in the old style. On the site of this house a more solid building of stone was soon afterwards erected, and on the 31st of October, 1693, it was solemnly consecrated to the purposes of a poor-house and free-school. This is the structure which is at present shown to visitors as Luther's house. A stone bust of the reformer stands over the entrance, with the well-known saying inscribed beneath it:

Gottes Wort ist Luthers Lehr,
Dram vergeht als nimmermehr.

The word of God is Luther's say,
And it shall never pass away.

The old portraits of Luther and Melancthon on glass have been introduced into one of the windows. Over the door of one of the rooms is the portrait of Luther in wood, and beneath it is the distich,

Hostis eram Papæ Sociorum pestis et hujus;
Vox mea cum scriptis nil nisi Christus erat.

Anno post R. S. 1594, mense Majo renovata.

This inscription refers to the verse, 'Pestis eram vivens; moriens ero mors tua, Papa' which Luther is said to have written at Altenburg in the year 1530, and was fond of quoting. Several articles are exhibited, such as what is called Luther's table, which in fact never were his. At St. Andrew's, the principal church in the town, the little pulpit in which Luther preached is still preserved. Sermons to his memory are regularly delivered from this pulpit on the days of his birth and decease, and on the first day of public catechizing. There are busts of Luther and Melancthon in the same church. On the day of the jubilee of the Reformation in 1817, several additions were made to Luther's house, at the expense of the present king of Prussia, who bestowed a sufficient endowment to preserve it against future decay, and perpetuate its benevolent object.

EISTEDDFOD, from *eistedd* to sit; a meeting or assembly. This term was more especially used as the name for the session of the bards and minstrels which was held in Wales for many centuries. [BARD.]

EJECTMENT is the name of an action at law of a nature partly real and partly personal, and therefore called a mixed action, by which a party entitled to the immediate possession of lands or other corporeal hereditaments may recover that possession from the party wrongfully withholding it.

Since the disuse of real actions, and under the provisions of the 3rd and 4th Will. IV., c. 27, for the abolition of real

and some mixed actions, it has become the only legal mode of trying the title to lands and tenements.

The remedy by ejectment is founded almost entirely upon a succession of legal fictions, and it is therefore necessary to give a short account of its history and the proceedings under it.

Originally this action was brought by any person having a lease for years of lands, &c., to repair an injury done him by dispossession; but gradually it became the means of indirectly bringing in question the title to the lands, which was thus collaterally tried with the supposed trespass. For this purpose it was necessary that the claimant should enter upon the lands in order to empower him to constitute a lessee for years who would be capable of receiving the injury of dispossession. A lease for a term of years is therefore stated in the declaration (for there is no other process in this action) to have been made by the party claiming title to the plaintiff, who is generally a fictitious person. It is also stated that the lessee, in consequence of the demise to him, entered into the premises, and that the defendant, who is also a fictitious person, and called the *casual ejector*, entered thereupon and ousted the plaintiff, for which ouster the plaintiff brings his action.

Under the declaration is a notice in terms professing to be written by the casual ejector to the tenant in possession of the premises, advising him to appear in court at a certain time and defend his title; otherwise he, the casual ejector, will suffer judgment to be had against him, by which means the actual tenant would inevitably be turned out of possession.

The declaration, as well as the notice, is then served upon the tenant in possession of the premises, who has thus an opportunity of defending his title. If he omits to do so within a limited time, he is supposed to have no right; and upon judgment being obtained against the casual ejector, the real occupier is turned out of possession by the sheriff.

If the tenant apply to be made a defendant, he is allowed upon condition that he enters into a rule of court to confess at the trial of the cause four of five requisites for the maintenance of the plaintiff's action—the lease of the lessor, the entry of the plaintiff, the ouster by the tenant himself, and the possession by the tenant. These requisites (except in certain cases, as of vacant possession, &c.) are wholly fictitious; and if the plaintiff should put the defendant to the proof of them, he would of course be nonsuited at the trial; but the stipulated confession of lease, entry, and ouster being made, the case then rests upon the merits of the title only. The cause goes to trial under the name of the fictitious lessee on the demise of the lessor, who is the person claiming title against the defendant.

The lessor is bound to make out on the trial his title to the premises; and if he do so in a satisfactory manner, judgment is given for the nominal plaintiff, and a writ of possession goes to the sheriff to deliver up the possession to him, under which process it is in fact delivered to his lessor, the real claimant. If it appears that the person claiming title to the lands has no right of entry, that is, no right to the immediate possession, he cannot maintain this action.

A mortgagee may maintain an action of ejectment against the mortgagor to gain possession of the mortgaged premises without giving any notice, unless the mortgagor is protected by the covenant for quiet enjoyment until default. He may also eject the lessee, to whom the mortgagor has made a lease subsequent to the mortgage, without giving him notice to quit. Where the right of the tenant to retain the possession has ceased by effluxion of time, by a legal notice to quit, or by the commission of an act of forfeiture, a landlord may bring an ejectment against his tenant; and various other persons who have a right of entry in law upon the premises may take advantage of the same remedy.

The time within which an action of ejectment may now be brought is regulated by the 3 and 4 Wm. IV. cap. 27, which enacts that no person shall bring an action to recover any land or rent (the meaning of which terms is explained by the first section of the act) but within twenty years next after his right to bring such action, or that of the person through whom he claims, shall have first accrued. The third section fixes the time at which the right shall be deemed to have first accrued. (*Runninton On Ejectment*; *Adams On Ejectment*; *Blackstone's Com.*)

EKATARINBURG or **YEKATARINBURG** (Catherine's borough), the chief town of a circle in the government of Perm (Permia), in the western part of Asiatic Russia, was founded by Peter the Great, in the year 1723, who gave it the name which it bears in honour of his consort. It is situated on both sides of the Icteth or Isset, the western quarter of the town being built along the slope of a gentle acclivity of the Ural mountains. It is at an elevation of about 860 feet above the level of the sea: in 56° 50' N. lat., and 60° 41' E. long. It is fortified and regularly constructed: the streets are long and straight, but they are unpaved, and have planks laid on each side of them by way of a foot-pavement. The greater part of the houses are of wood, but there are many handsome stone buildings: the chief of them form three sides of a square, the fourth side of which is the right bank of the Icteth: this range of buildings is composed of the Mining Department (for Ekatarinburg is the seat of administration for the Ural mines), a museum of mineralogy, a public library, an excellent chemical laboratory, an imperial mint, works for cleansing and amalgamating metals, as well as for cutting and polishing precious stones, a school for educating miners, a hospital, storehouses, a guardhouse, &c. A handsome bridge unites both quarters of the town, and on the acclivity on the left bank of the river is a long range of wooden tenements where the work-people reside, with the stone residences of the public offices between them and the bridge. The merchants and dealers' houses in the town are also of stone, and would be an ornament to any city in Europe. Besides five churches, there are a Greek monastery, a public school for 300 pupils, a German school, a large bazaar, a magazine for grain, a house of correction, and several district and elementary schools. At the north-western end of Ekatarinburg are remains of the fortifications where the garrison is quartered. The number of houses is upwards of 1200, and of inhabitants about 11,000. By the official return of the year 1830 they amounted to 10,695. The population consists of a motley assemblage of Asiatics and Europeans, the latter principally Russians and Germans, among whom are numbers of persons exiled for public offences. There is a public hall for drugs and chemicals, and a botanic garden attached to the hospital. The greater part of the inhabitants depend upon the Ural mining concerns for their subsistence; and as Ekatarinburg lies on the high road from Russia into Siberia, it is a place of transit and of brisk trade. In the neighbourhood lie the gold mines of Beresoff and the iron mines of Niviansk, which extend over a surface of nearly forty square miles: there is also a chalybeate well, which is much used by invalids. A wood of pines encircles the north-western extremity of the town, and about half a mile beyond lies lake Isset.

EKATARINOSLAF, one of the three southern provinces of Russia in Europe, which since 1822 have constituted the government of New Russia. It is bounded on the north by the provinces of Pultava, the Slobodsk-Ukraine, and Voronezh; on the east by the territory of the Don-Cossacks; on the south by the sea of Azof, and the government of Tauria; and on the west by the government of Cherson. There is an isolated district of this province, of which Taganrog is the chief town, lying at the north-western extremity of the sea of Azof, and separated from the remainder of Ekatarinoslaf by the territory of the Don Cossacks. The area of this province is estimated by some at 23,700 square miles; but according to Arsenief, at 28,980. Upwards of two-thirds of this area are an open steppe, destitute of wood, and adapted to pasturage only: this is peculiarly the case with that large tract which is situated east of the Dnieper. The districts west of that river are much more fertile, and are skirted by a range of hills which run northwards from Alexandrofsk along the Dnieper. Here it is principally that the arable lands of Ekatarinoslaf, occupying about one-fourth of the soil, are situated. The whole extent of the woods and forests does not exceed 256,000 acres. The principal river is the Dnieper, which enters the province at its north-western extremity, and, winding through the western parts of it, quits it below Alexandrofsk. The immense blocks of granite which obstruct the course of the river at and below Kidak, give rise to thirteen beautiful falls, here called 'paroghi'; and below them the river is divided by islands into several channels. The Don skirts Ekatarinoslaf only at its mouth; but its tributary, the Donets, waters it partially in the east. The other streams in this province, such

as the Samara, Kalmius, &c., are of no great importance. There are several lakes, the water of which is often much impregnated with salt: swamps are of frequent occurrence. The climate is mild, and not exposed to much variation, and the winter is of short duration. The quantity of grain produced is scarcely adequate to the consumption; in some years it is so scanty that the supply is drawn from foreign parts. Hemp and flax, peas, beans, lentils, vegetables, and fruit, particularly melons, are cultivated. The grape ripens, and some wine is made, but the fruits of the mulberry and walnut do not attain to maturity. The forests do not furnish sufficient timber or fuel; and straw, rushes, and even dung, are substituted for the latter. The chief kinds of trees in the forests west of the Dnieper are the oak, linden, and poplar. In consequence of the scarcity of timber, the houses are built of clay, and roofed with rushes. Cattle-breeding is carried on upon an extended scale, for the steppes are one vast expanse of pasture-ground. The stock of horses, horned cattle, goats, and swine is immense; and numerous flocks of sheep are also kept, the breed of which has been so much ameliorated that 336,835 pure Merinos alone were in stock in the year 1832 all these animals are left to graze in the open fields throughout nearly the whole twelve months. There were, in 1832, between 1480 and 1590 establishments for breeding oxen and cows, and 232 for rearing horses. Cheese and butter are made of sheep's milk. In the same year Ekatarinoslaf possessed 86,100 hives, from which much honey and wax were obtained. The culture of the silkworm is a favourite pursuit with the Greeks at Mariapol and the Armenians at Nakitshevan, and this branch of industry is rapidly on the increase. The chase forms a means of livelihood, as wild animals and game are plentiful: under this head we may enumerate the jerboa, wolf, fox, buffalo, antelope-goat (saiga), wild cat, tiger-martin, musk-rat, pelican, wild duck, and partridge. The fisheries on the Dnieper, Don, Kalmius, and Sea of Azof are very productive, and are estimated to bring in upwards of 20,000*l.* per annum. Among the mineral products of the province, which are few and not of much importance, are lake salt, of which little advantage is taken on account of the scarcity of fuel, granite, chalk in large quantity, clay, and bog iron. The garnet is occasionally met with.

The population is a mixed race, principally of colonists who have gradually transformed a wilderness into a habitable and productive region during the last eighty or ninety years; they are composed of Great and Little Russians, Cossacks, Servians (who migrated hither between the years 1754 and 1760, by thousands at a time,) Walaks, Magyars, Albanians, Greeks, Armenians, Tartars, Germans, and Europeans in general. Of Greeks and Armenians, the numbers are about 30,000 of each; the Germans amount to about 10,000. The inhabitants are classed as follows in the returns for the year 1830:—

| | |
|---|----------------|
| Hereditary nobles | 2555 |
| Superior officers and servants of the crown | 2363 |
| Clergy (including six monks) | 4427 |
| Soldiers on furlough and their families | 3498 |
| Merchants and dealers, mechanics, &c. | 9355 |
| Free peasantry and others attached to the crown lands | 285,777 |
| Peasantry belonging to crown donations | 1956 |
| Peasantry and others, the property of individuals | 236,684 |
| Total | 546,615 |

Arsenief considers this return as much below the real number, and estimates the population at 610,000 for the year in question; but Schubert, in his recent statistics of the Russian empire, states it to have been 826,100 even so far back as the year 1829. Horschelmann, in his new edition of Professor Stein's 'Geography and Statistics,' states it to be 850,000. The numbers given by the two last writers appear to justify Hassel's estimate for 1820, of 761,600. All but the Cossack part of the population, which is semi-nomadic, have fixed abodes. We have no official account of their increase or decrease, excepting for the year 1832, when the births amounted to 40,218, and the deaths to 27,053, showing an increase of 13,165 in that year (Schnitzler). The religion of the majority is Russo-Greek: the province contains 690 parishes, and the ecclesiastical head is the archbishop of Ekatarinoslaf, Cherson, and Tauria.

The 30,000 original Greeks have a bishop of their own at Feodosia; and the Armenians are under the bishop of Nakitshevan. There are a few Mohammedans and Jews.

Ekatarinoslaf is divided into the seven circles of Ekatarinoslaf, on the west side of the Dnieper; Verchne-Dniaprofsk, north of Ekatarinoslaf, also on the west side of the Dnieper; Novo-Moskofsk, on the east side of the Dnieper; Alexandrofsk, on the east side of the Dnieper, which separates it from Ekatarinoslaf; Paulograd, north-east of Ekatarinoslaf; Bakmut, east of Ekatarinoslaf; and Slavenoserfsk, the north-easternmost circle of the province, independently of the isolated district of Rostof, on the Sea of Azof. The principal towns are Ekatarinoslaf; Alexandrofsk, on the left bank of the Dnieper (about 4000 inhabitants); Novo-Moskofsk, on the Samara (3000); Paulograd, on the Voltaga, east of Ekatarinoslaf (9000); Verknébiaprofsk, on the right bank of the Dnieper, (about 250 houses); Bakmut, on the Bakmuta, (about 4500 inhabitants); Slavenoserfsk, on a tributary of the Donecs; and Taganrog, on the Sea of Azof (about 14,000). Besides these towns, which are the capitals of the seven circles, there are several others, the most important of which are Azof, on the sea of that name; Mariapol, at the efflux of the Kalmius into the Sea of Azof, with about 3500 inhabitants; Nakitshevan, on the Don (about 9200); and St. Dmitria Rostofskaye, a fortress at the confluence of the Temernik and Don (about 2500).

The manufactures of Ekatarinoslaf, although gradually extending, are not yet of much importance; in fact, there is still need for a much greater number of hands for the cultivation of the soil. The returns of 1830 show that in the 30 larger manufacturing establishments there were not more than 648 hands employed: these establishments consisted of 3 manufactories of woollen cloths, 6 of tallow and 7 of candles, 10 tanneries, 1 bell foundry, 2 breweries, &c. There were at that time not less than 225 brandy distilleries. The district of Rostof however is not comprised in this enumeration; and here there were 49 manufactories in the year 1832. The principal articles exported are fish, tallow, and other animal products.

The revenue collected by the crown in 1830 amounted to 7,439,704 paper rubles, or about 340,990*l.* sterling. About fifteen years before it was not more than 1,540,000 rubles, or about 70,580*l.*

The province of Ekatarinoslaf was first constituted by the empress Catherine in the year 1784, and was composed of the districts lying next the southern banks of the Dnieper, which were before this held by the Cossacks, of several large districts wrested from the Turks, and of Crimean Tartary as far as the shores of the Sea of Azof. In 1797 the emperor Paul augmented it by the addition of other lands between the Bog and Dniester, which had been ceded by Turkey, and the peninsula of Tauria; and he designated the whole of this extensive country New Russia. In the year 1822, however, the emperor Alexander, his son and successor, reorganised these possessions, and forming them into the governor-generalship of New Russia, divided it into the three provinces of Ekatarinoslaf, Cherson, or Nikolaieff, and Simferopol, or Tauria.

EKATARINOSLAF, the capital of the province, is situated on the right bank of the Dnieper, at the junction of the Kaidak with that river, in 43° 27' N. lat., and 35° 2' E. long. The first stone was laid by the empress Catherine II. in 1787. The town is close to the foot of a mountain, and is built according to an extended and regular plan adapted for a much greater number of inhabitants than the 12,000 which it at present contains. In 1833 they amounted to 11,648. The streets are broad, and laid out in straight lines, but in an unfinished state. There are three churches, a gymnasium, and an ecclesiastical seminary, an imperial manufacture of woollens, and several hospitals. Silk stockings are made, and some retail trade is carried on. The houses are about 900 in number. The navigation of the Dnieper terminates at Ekatarinoslaf, in consequence of the 'peroghi,' or falls, which obstruct its navigation at Kaidak just below it. Prince Potemkin has some gardens and grounds in the vicinity.

ELÆAGNA'CEÆ, a small natural order of Apetalous Exogens, consisting of trees or shrubs, whose leaves are either opposite or alternate, destitute of stipules, and always protected more or less by scurfy scales, which usually give the plants a leprosy aspect. The genera of this order have a tubular 4-lobed calyx, the inside of which is lined with a

fleshy disk, that sometimes almost closes up the tube, there are three, four, or eight stamens, and a superior ovary, containing a single erect ovule. The fruit is soft, succulent, and would be eatable if it were not for its dryness and insipidity. In a few cases, when it is more than usually juicy and acidulated, it is actually considered an excellent fruit. *Elæagnus hortensis* and *Orientalis* bear a brown fruit, about the size of an olive, which is brought to market in Persia under the name of Zinzeyd: in quality it is like a jujube. The red drupes of *Elæagnus conferta*, the large olive-shaped ones of *E. arborea*, and the pale orange-coloured ones of *E. triflora*, are in like manner eaten in India; another occurs among the drawings of Chinese fruits. It is not a little curious, nearly as *Elæagnaceæ* are related to *Thymelæaceæ*, that they do not seem to participate in any degree in the acidity of that deleterious order. The only species found wild in Great Britain is the *Hippophae rhamnoides*, a spiny shrub, with diœcious flowers, small round orange-coloured acid berries, and narrow leaves, like those of rosemary, found growing on cliffs near the sea; its fruit, when the acidity is sufficiently covered by sugar, becomes a rather pleasant preserve. *Elæagnus angustifolia*, called in the gardens the *Olivier de Bohême*, a native of the eastern parts of Europe, is one of the most fragrant of all plants; its dull yellow flowers, hardly remarked among the leaves, fill the atmosphere with a delicious perfume, the source of which is not readily discovered by the passer by.

Elæagnus angustifolia.

1, a section of the tube of the calyx, showing the fleshy disk almost closing up the tube, the carpel, with its style and stigma, and the erect solitary ovule; 2, a ripe fruit; 3, the same cut away to show the single furrowed seed.

ELÆIS, a genus of palms, so named from *elaia*, the olive-tree, because an oil is yielded by the fruit of its principal if not only species. This is *Elæis Guineensis*, or oil-palm, *maba* of the natives of the Congo, and common all along the western coast of Africa. The tree is monœcious, as we are informed that both male and female spadices were obtained from a single plant cut down by Professor Smith. (Brown, in Tuckey's *Congo*). The stem is tall, about ten inches in diameter, rough, and bristling with the persistent bases of the petioles, of which the margins, as in recent leaves, are fringed with spines. The leaves are pinnate, about 15 feet in length, with two rows of sword-shaped leaflets, each 1½ foot long. The fruit is ovoid, about the size of a pigeon's egg, with its outer fleshy covering of a golden yellow colour, and like that of the section *Cocoina*,

to which it belongs, and analogous to the cocoa-nut, has the foramina of its putamen at the apex, and not at the base, as represented by Gærtner and others.

Mr. Brown has observed it as remarkable that *Cocos Indica* and this palm, which is universally, and he relieves justly, considered as having been imported into the West India colonies from the west coast of Africa, should be the only two species of an extensive and very natural section of palms that are not confined to America. The *elæis occidentalis* of Swartz, the *thatch-tree* of Brown's 'Jamaica,' and the *avotira* of Aublet, are probably all identical with the *maba*, or oil-palm, of the African coast.

The oil is obtained by bruising the fleshy part of the fruit (and not the kernel, as sometimes stated), and subjecting the bruised paste to boiling water in wooden mortars; an oil of an orange-yellow colour separates, which concretes when cool to the consistence of butter, and has when fresh the smell of violets or of the root of the Florentine iris, with a very slightly sweetish taste. This oil is used by the Africans in cookery and for anointing the body. It forms a considerable article of commerce to Europe, where it is chiefly employed in perfumery and medicine. *Cocos butyracea* (which is referred by Kunth to the genus *elæis*) is considered by the Edinburgh College to be the plant which yields palm-oil.

Reference has been made from **ALFONSIA** to this article in consequence of Mr. Brown (Tuckey's *Congo*, Appendix, p. 456) having stated, 'It is probable that *alfonsia oleifera* of Humboldt, Bonpland, and Kunth belongs to *elæis*, and possibly may not even differ from the African species. To this the above authors, in the 'Synopsis Plant. Æquinoct.' reply, that in *elæis*, according to the description of Jacquin, both the floral envelopes are sexifid, while in *alfonsia* they are trifid. If this, moreover, be the same as the *corozo* of Jacquin, 'another essential difference may be observed in the structure of the fruit of the two plants, the nut in *elæis* being perforated at the apex, while the *corozo* has its nut perforated with three foramina at its base;' but this might have been inverted, as that of *elæis* was by Gærtner. Humboldt and Bonpland, moreover, found *alfonsia oleifera* always growing wild, while *elæis guineensis*, as they state, is never found except in a cultivated state out of Africa. These two palms require to be carefully re-examined and compared, to ascertain whether, if they are distinct as

Alborea oleifera.

species, as is probable from the figure of the former by Martius, they may not both belong to the same genus. The compressed nut of the alfonsia, like that of the cocoa-nut, is described as yielding an oil, which is obtained by boiling in water the *manteca del corozo*; it is described as a liquid fat employed for ordinary lamps, as well as those of churches.

ELÆOCARPA'CEÆ, a natural order of chiefly Indian trees, having a strong botanical resemblance to our European Lindens, but differing in having fringed petals, and anthers opening by two pores at the apex. The species have not yet received sufficient attention from botanists, especially the few known in South America; and it is doubtful whether this order will not be eventually combined with Tiliaceæ.

In the Indian genera the nuts, cleared of the soft pulp or flesh that covers them, are curiously sculptured, and being bony, and taking a fine polish, they are frequently set in gold and strung into necklaces. The nuts of *Ganitrus sphaericus*, a middle-sized tree, common in various parts of India, as well as the Malay Archipelago, and those of *Monocera tuberculata*, from the forests of Travancore, are what are principally used for this purpose. The fruits of *Elæocarpus serratus*, which are very much like olives when ripe, are said by Roxburgh to be pickled or dried and used in their curries by the natives of India. *Elæocarpus cyaneus* has pure white beautifully fringed petals, and is one of the most ornamental plants of New Holland.

A flowering shoot of *Elæocarpus cyaneus*.

1, a magnified flower; 2, a petal; 3, the stamens; 4, a ripe fruit, 5, the same cut away to show the wrinkled seed.

ELAGABA'LUS, called also **HELIOGABA'LUS**, was the grandson of Mæsa, sister to the empress Julia, the wife of Septimius Severus. Mæsa had two daughters, Sæmis, or Semiamira, the mother of Varius Avitus Bassianus, afterwards called Elagabalus, who was reported to be the illegitimate son of Caracalla and Mammæa, mother of Alexander Severus. Elagabalus was born at Antioch A.D. 204. Mæsa took care of his infancy and placed him, when five years of age, in the temple of the Sun at Emesa to be educated by the priests; and through her influence he was made, while yet a boy, high priest of the Sun. That divinity was called in Syria Elagabal, which name the boy assumed. After the death of Caracalla and the elevation of Macrinus, the latter having incurred by his severity the dislike of the soldiers,

Mæsa availed herself of this feeling to induce the officers to rise in favour of her grandson, whom she presented to them as the son of the murdered Caracalla. Elagabalus, who was then in his fifteenth year, was proclaimed emperor by the legion stationed at Emesa. Having put himself at their head he was attacked by Macrinus, who at first had the advantage, but he and his mother Soëmis with great spirit brought the soldiers again to the charge, and defeated Macrinus, who was overtaken in his flight and put to death A.D. 218. Elagabalus having entered Antioch, wrote a letter to the senate professing to take for his model Marcus Aurelius Antoninus, a name revered at Rome; Elagabalus also assumed that emperor's name. The senate acknowledged him, and he set off for Rome, but tarried several months on his way amidst festivals and amusements, and at last stopped at Nicomedia for the winter. In the following year he arrived at Rome, and began a career of debauchery, extravagance, and cruelty, which lasted the remaining three years of his reign, and the disgusting details of which are given by Lampridius, Herodianus, and Dion. Some critics have imagined, especially from the shortness of his reign, that there must be some exaggeration in these accounts, for he could hardly have done in so short a time all the mischief that is attributed to him. That he was extremely dissolute and totally incapable is certain; and this is not to be wondered at, from his previous eastern education, his extreme youth, the corrupt example of his mother, his sudden elevation, and the general profligacy of the times. He surrounded himself with gladiators, actors, and other base favourites, who made an unworthy use of their influence. He married several wives, among others a vestal. The imperial palace became a scene of debauch and open prostitution. Elagabalus being attached to the superstitions of the East, raised a temple on the Palatine hill to the Syrian god whose name he bore, and plundered the temples of the Roman gods to enrich his own. He put to death many senators; he established a senate of women, under the presidency of his mother Soëmis, which body decided all questions relative to female dresses, visits, precedence, amusements, &c. He wore his pontifical vest as high priest of the Sun, with a rich tiara on his head. His grandmother Mæsa, seeing his folly, thought of conciliating the Romans by associating with him as Cæsar his younger cousin, Alexander Severus, who soon became a favourite with the people. Elagabalus, who had consented to the association, became afterwards jealous of his cousin, and wished to deprive him of his honours, but he could not obtain the consent of the senate. His next measure was to spread the report of Alexander's death, which produced an insurrection among the prætorians, and Elagabalus having repaired to their camp to quell the mutiny, was murdered together with his mother and favourites, and his body was thrown into the Tiber, March, 222. He was succeeded by Alexander Severus. [SEVERUS.] The coins of Elagabalus bear the names of Marcus Aurelius Antoninus, like those of Caracalla, with which they are often confounded. The names of Varius Avitus Bassianus, which he also bore before his elevation to the throne, are not found on his medals.

Coin of Elagabalus.

British Museum. Actual Size. Copper. Weight, 380 grains.

ELAIDINE, a fatty substance produced by the action of nitrous acid upon certain oils, as olive and almond oil, &c. This substance is white, inodorous, insoluble in water, and fusible at 95° Fahr. It is soluble in sulphuric ether, and in 200 times its weight of boiling alcohol; when treated with potash it saponifies, giving rise to glycerin, and a peculiar acid which has been called elaidic acid. This acid is solid, fusible at 112° Fahr., and is partially distilled by exposure to a strong heat.

ELAIN. [OLFIN.]

He took the name of Varius from Sextus Varius Marcellus, who was his mother's husband.

ELAM. [ELYMAIS.]

ELAPS. [VIPERIDE.]

ELASMO'THE'R'IUM. [PACHYDERMATA.]

ELASTICITY (*ἑλαστικότητα*; a spring). When the form of a body is affected by the pressure of another extraneous to it, the re-acting force by which it sustains or tends to remove that pressure is its elasticity. The term has been very loosely used in the most current works, which, instead of furnishing an exact and general idea of this force, are, in general, limited to the phenomena exhibited by elastic solid bodies; and to this imperfect notion of elastic force we are to attribute the discrepancies of treatises, some of which used to represent water as perfectly inelastic, some (as the more modern treatises) as perfectly elastic. The cause of elasticity then belongs to the theory of molecularity, its effects in aggregate masses to mechanics.

The equilibrium of the molecules of solid bodies is almost completely dependent on their own mutual actions and quantity of heat. These forces determine certain mean places for the constituent particles, to which points of stable equilibrium they tend to return when removed a little from them by an external force. This removal may be such as to effect in the mass either compression or extension, inflexion or torsion, and therefore their elastic force is capable of being exhibited in all these ways. It is demonstrated in fluids only by their compressibility, while in gases it arises as a predominant living force which would refuse any position of equilibrium to the constituent particles without external pressure, and is proportional to such pressure uniformly exercised.

When heat is applied to a solid elastic body, that is, when its temperature is raised, the particles seek a different position of equilibrium more remote from each other than before. But while this heat is much below that necessary for friction, or for destroying the fibrous formation of organized matter, the stability of the removable particles is but little affected, and experiment shows that there is scarcely any change of elasticity. In fluids the compressibility obtains a greater range, while in gases, where no countervailing force of attraction is sensible, the increase of temperature is accompanied by a proportional increase of elastic force.

Amongst bodies whose elasticity is very apparent, we may enumerate glass, ivory, caoutchouc, sponges, and fibrous substances, as beams, muscles, and artificial webs, some gums, steel, and all the gases and vapours. In gases and vapours its effects may be produced to any extent, but they are limited in solids by their softness and facility of fusion, as in wax, lead, &c.; by their absorption of moisture, as in clay, feathers, catgut, straw; or by their friability, as in glass, dry resins, and copper or iron which have been exposed to a stream of ammoniacal gas.

Suppose an elastic string, or lamina, to be fixed at one end, and at the other stretched by a force T , which will also represent its tension; if this force be increased by a small quantity t , an additional length l would be given to the string, or lamina; the whole tension now is $T + t$, and if we again add a force t , since the physical condition of the body is sensibly the same as before, the same length l will again be added, and generally the additional extension should be proportional to the additional tension: this law is, however, only approximative, for it is manifest that a force tending to produce either extension or contraction may be applied which would cause the body to break, and near these limits the law would vary considerably from simple proportionality. Let a horizontal elastic lamina AB be fixed by a screw at A , and having been stretched by a known weight G at B , let it be screwed also at that point, when its tension will evidently be equal to the weight appended; let the beam DE of a balance F be sustained at D , the middle of AB through a drilled orifice d , and be attached to a string passing over the fixed pulley C , which string also sustains a weight P , which is an exact counterpoise to the weight of the scale and beam so that they may produce no deflection of themselves in AB ; then if a small weight be put into the scale, the lamina ADB will be bent into the form $A\delta B$, with a deflection $D\delta$ from its original position, which may be estimated with greater accuracy by a hand QR attached to the pulley. An extension $A\delta B - ADB$ will thus be produced, as well as an increase of tension, which may then be compared by the common laws of statics; and the experiments show that as long as the added

weights are small, this extension is proportional to the increase of tension. The apparatus is that employed by S'gravesande.

When a uniform elastic string is suspended vertically it will be stretched by its own weight. The tension varies from point to point, and is every where proportional to the portion of the string of which it supports the weight. If y be a portion of the stretched string corresponding to a portion x of the same unstretched, and $y + \Delta y$, $x + \Delta x$, another corresponding pair of portions greater than the former, and a the whole length of the string in its natural state, the extension $\Delta y - \Delta x$ of the element Δx is proportional to the weight of the remaining portion $a - x - \Delta x$ of the string; hence if g denote the weight of a unit of the string, and e the index of elasticity peculiar to the substance, we

have ultimately [DIFFERENTIAL CALCULUS] $\frac{dy}{dx} - 1 = g e (a - x)$, and therefore by the rules of the *Integral Calculus* $y - x = g e (a x - \frac{x^2}{2})$, to which no arbitrary constant need be added, because y commences at the same point with x

if we now make $x = a$, we find that $g \frac{e}{2} \cdot a^2$ expresses the extension of the entire string.

Similar principles may be easily applied to determine the form of an elastic string suspended from two points, and stretched by its own weight; but in this case the curve which differs from the common catenary cannot be considered as accurately determined without taking into account the elasticity of inflexion as well as that of extension. The mere mathematical problem may be seen in most mechanical treatises. (Whewell's *Mechanics*; Poisson, *Mécanique*; consult also Lagrange, *Mec. Analytique*, for the method of introducing the condition of elasticity in a system at rest.)

An important practical branch of this subject, on the strength of beams, which has been much advanced by Mr. Peter Barlow, and the more recent experiments of Mr. Eaton Hodgkinson, of Manchester, we reserve for a future article. [STRENGTH OF BEAMS.]

When a uniform elastic string, fixed at one extremity and stretched by a force applied at the other extremity, is abandoned to itself, it will return to its original form after a series of contractions and expansions, the force which solicits each point being proportional to its distance from its original place, though the successive oscillations go on rapidly diminishing in extent in consequence of the resistances encountered. The same law applies to the displacements of the molecules of elastic fluids and gases.

For the laws of the mutual impact of elastic bodies see IMPACT. If a body is attached to an elastic string, which at the other extremity is fixed, and be projected in any direction, the resolved part of the centrifugal force which acts in the direction of the length of the string tends to stretch it, and the centripetal force will be proportional to $r - c$, r being the length of the stretched and c of the unstretched string: this force is attractive when r is greater than c , and repulsive when less. Hence if we conceive a

circle, of which the centre is the fixed point, and the radius equal to c , the portions of the orbit described externally to the circle are concave, and those internally are convex relative to the centre of the circle, and there are as many points of contrary flexion (Curva) as intersections of the trajectory and circle. Neither the law of the periodic times nor the form of the orbit is similar to those belonging to the earth and planets: the supposition, therefore, that attraction between the great masses which compose the solar system is conducted through the medium of interposed and invisible elastic strings is unfounded.

When an elastic string, fixed at one end is bent by a weight or other force applied at a given point, the elasticity of inflexion acts normally at each point of the curve, and is some function of the curvature at that point. It is usual to suppose it proportional to the simple curvature. On this supposition the figure of an elastic lamina in a vertical position, fixed at its lower point and bent by a small weight applied at the top, may be determined. This problem has been treated by Euler, Lagrange, and Poisson. The English reader may find the varieties of the elastic curve discussed in the appendix to Whewell's *Mechanics*.

The elastic force of a twisted string follows a law precisely similar to that of one which is only stretched: the latter is proportional to the extension, the former to the torsion. Thus, if a cylindrical elastic thread, fixed at one extremity, be twisted by a force applied perpendicularly to its length, any straight line taken along the surface of the cylinder will be converted into a helix; and with a double torsion the circular arc through which each point has been removed from its original place is doubled. And since the circular arc may be subdivided into any number of equal arcs, the successive resistances of the elasticity to the additional torsions are equal, supposing each preceding resistance to be sustained. Therefore the accumulated force of torsion is proportional to the angle through which an index would move if fixed at any point perpendicularly to the length of the cylinder, or in the prolongation of its radius; but this law has limits as well as that for the elasticity of extension; for the torsion may be continued until a strain is produced, when there will of course be an accompanying diminution of elastic force.

Let AB represent an elastic string, suspended vertically

from the point A , and attached at B to a cylindrical body DE , of which the axis BC is in the direction of the string produced, the string being primitively in an untwisted state. Let the cylinder be turned round its axis through an angle FBG , or α , which measures the torsion generated in AB , and also the elastic force tending to bring the system back to its original state. Let the restraining force be now removed, and the cylinder, abandoned to itself, will return to its original place after a series of isochronous oscillations, which are gradually diminished by the resistance of the air and by the internal resistances of the molecules of AB during the processes of being twisted and untwisted.

Let δm stand for an element of the cylinder, situated at a distance r from its axis, and θ the angle of torsion, at any

time after the commencement of this motion; then $-\frac{d\theta}{dt}$ is the angular velocity; and therefore the linear velocity of δm is $-r\frac{d\theta}{dt}$; the accelerating force or ratio of the increments of velocity and time is $-r\frac{d^2\theta}{dt^2}$; the force of torsion, being proportional to the angle θ , may be represented by $n\theta$ applied at a distance unity from the axis of the

cylinder, perpendicularly to the radius, the constant n being the force of torsion corresponding to an angle unity. Now, by D'Alembert's principle, the impressed force, taken in a reversed direction, would make equilibrium with all the effective forces: that is, the force $-n\theta$, at a distance unity, would produce an equilibrium with the forces such as $-r\delta m\frac{d^2\theta}{dt^2}$ acting on δm at a distance r ; hence the corresponding moments, which are $-n\theta \times 1$, and the sum of all, such as $-r^2\delta m\frac{d^2\theta}{dt^2}$ must be equal, but of contrary signs; and since $\frac{d^2\theta}{dt^2}$ is the common accelerating force on all the particles δm at a unit distance, we need only take the sum of the products $r^2\delta m$, which is easily found in this case by the rules of the integral calculus, and is called the moment of inertia of the cylinder. Representing it by MK^2 , where M is the mass of the cylinder and K its radius of gyration, we have the equation—

$$MK^2 \frac{d^2\theta}{dt^2} = -n\theta.$$

Put for abridgment $c^2 = \frac{n}{MK^2}$; then, by the methods for integrating differential equations, we find $\theta = A \sin. (ct + B)$, where A B are arbitrary constants; and for the velocity $\frac{d\theta}{dt} = Ac \cos. (ct + B)$.

Now, we can determine the constants by the circumstances of the origin of the motion; for when $t = 0$, we have supposed the initial torsion was α , or FBC , and $\frac{d\theta}{dt}$ was then nothing. Hence we have $\alpha = A \sin. B$; $0 = A \cos. B$ therefore $A^2 = \alpha^2$, $B = \frac{\pi}{2}$. The value of θ is therefore expressed at any time by $\alpha \cos. (ct)$.

When the cylinder makes half an oscillation the elastic thread is then perfectly free from torsion; and if T be the time of an entire oscillation, since θ then vanishes, we find

$0 = \alpha \cos. \left(\frac{cT}{2}\right)$; therefore $cT = \pi$, and $T = \frac{\pi}{c}$ which shows

that the successive oscillations are of the same duration, and that the square of the time of one oscillation varies directly as the moment of inertia, and inversely as the force of torsion, estimated at a given distance from the string.

The suspended body may be any other as well as the cylinder we have supposed, with manifestly the same results. For instance, in Coulomb's torsion balance it consists of a needle of gum-lac attached perpendicularly to the string, as BF in the above figure, and a small weight at B to steady the string; the law of the times of oscillation above found is sufficient to give the force of torsion in all cases if we know it in one. It is thus that Coulomb used his balance in finding the law of electrical attractions and repulsions; the electrified ball acted on, being attached to the end of the needle of gum-lac, was subjected to the joint action of electrical and elastic forces. [ELECTRICITY.]

The range of the elastic force of fluids, in consequence of their great resistance to compression, is extremely limited, and therefore few ordinary phenomena of nature are dependent on this cause. The great pressure at considerable depths in the ocean must produce a corresponding increase of density in the lower strata, if it is not in a great measure compensated by the increase of temperature.

There exists one simple and uniform law for the elastic forces of dry air and all the gases. From the experiments of Boyle, Mariotte, and Dalton, it is established, that the elasticity, which is proportional to the pressure, is inversely as the volume, and therefore directly as the density, when the temperature is constant.

But an increase of temperature produces an increase of the elastic force of gases: or, which is the same, under a given pressure it expands the gas into a greater volume. Between the temperature of melting ice and boiling water this increase of volume is proportional sensibly to the additional temperature, measured by a mercurial thermometer, as was well established by the experiments of Gay-Lussac; but by the more recent experiments of MM. Dulong and Petit, it appears that at much higher temperatures the degrees of the mercurial and gas thermometers no longer correspond; for the expansions of the mercury might be

expected to become irregular when it tends to gasefy, and therefore to have greater expansions for each degree of heat than in its liquid state. (*Annales de Chimie et de Physique*.)

In such experiments it is essential that the gas should be perfectly dry; for if not, the elastic force obtained will be that of dry air *plus* that of the contained aqueous vapours. For most observations on the latter we are indebted to the researches of Dalton, who observed that when the inside of a barometer is moistened, the elastic force of the vapours, occupying the space which is a vacuum in ordinary barometers, causes a depression in the column of mercury proportional to itself.

When a space is saturated with aqueous vapour or steam, the elasticity remains the same when the volume is diminished, the only effect of compression being to convert the surplus portion into water. The contrary holds generally in gases, as we have seen that their elasticity is inversely as their volume; but it is probable that with very high pressures, such as that employed by Mr. Faraday to liquefy carbonic acid gas, there exists a limit for each, beyond which it is impossible to render them more elastic by compression.

Moreover, the ratio of the elastic force of dry gas at the temperature of boiling water to that at the freezing point is by no means the same as in aqueous vapours; but at very high temperatures it seems probable that similar ratios would approximate. The following is a table of the elastic forces of the latter, corresponding to degrees of the centigrade thermometer:—

| Temperatures. | Elastic Force in inches. | Successive Ratios. |
|---------------|-----------------------------|-----------------------|
| 0 | 0.2 | |
| 6½ | 0.297 | 1.485 |
| 12½ | 0.435 | 1.465 |
| 18½ | 0.63 | 1.448 |
| 25 | 0.91 | 1.444 |
| 31½ | 1.29 | 1.418 |
| 37½ | 1.82 | 1.411 |
| 43½ | 2.54 | 1.395 |
| 50 | 3.5 | 1.378 |
| 56½ | 4.76 | 1.36 |
| 62½ | 6.45 | 1.355 |
| 68½ | 8.55 | 1.326 |
| 75 | 11.25 | 1.316 |
| 81½ | 14.6 | 1.298 |
| 87½ | 18.8 | 1.288 |
| 93½ | 24 | 1.277 |
| 100 | 30 | 1.25 |

The third column is given incorrectly in Biot's 'Physique'; and it follows from inspection that the elastic force of steam increases nearly in a geometrical progression when the temperature is increased in arithmetical; from which property steam has now become a great mechanical agent.

When vapours are mixed with each other at the same temperature and in the same space, the elastic force of the compound is the sum of the separate elasticities, provided this sum is not sufficiently great to render any of the vapours liquid, and provided these vapours have no chemical affinity.

The vibrations of elastic bodies belong to the subject of acoustics, to which we refer, and to the head VIBRATION. Beside the authorities already quoted in this article, see Pouillet, 'Physique,' and 'Manchester Transactions'.

ELATÆA. [PHOCIS.]

ELATERIDÆ, a family of Coleopterous insects belonging to the section Sternoxi (*Latreille*), and, according to Linnaeus, constituting the genus *Elatæ*.

The insects of this family are of a lengthened form; the head is, in nearly all cases, deeply inserted into the thorax: the thorax is usually of the same width as the elytra, or nearly so, longer than broad, and the posterior angles are acute, and most frequently produced into a pointed spine-like process: the elytra are long and narrow, cover the abdomen, and their external margins are often nearly parallel. The antennæ are of moderate length, either filiform, serrated, or pectinated, and when the insect is at rest they are deposited in two grooves on the under side of the thorax; at least such is the case in very many of the species. The legs are short and rather slender, and the femora and tibiae are generally compressed.

These beetles are found upon flowers and upon the leaves of trees and plants; some species however are most frequently met with upon the ground.

When upon any elevated situation, if approached, they apply the legs and antennæ close to the body, and allow themselves to fall to the ground; if they fall upon their back they regain their natural position by a leap, which is always accompanied by a snapping noise similar to that which may be made by the finger-nails. When about to leap, they bend the thorax backwards, so that the body is arched, or rather forms an angle, the insect then resting upon the apex of the abdomen and the fore part of the thorax. The leap appears to be effected by the sudden relaxation of the muscular effort which kept the thorax bent backwards, there being a peculiarity in its structure which causes it to spring forwards.

Even in a dried specimen, upon attempting to bend the thorax back, we found considerable resistance; but when allowed, it suddenly assumed its natural position, which is a slight inclination forwards.

There is a strong spine, it must be observed, on the under part of the thorax, at its base, which, when the thorax is in its usual position, is deposited in a groove; and it is said that the leap is performed principally by means of this spine, which is at the time forcibly pressed against the margin of the hollow into which it sinks suddenly, as if by a spring. From this opinion we are inclined to differ; for upon removing the spine we found not the slightest alteration in that natural spring in the thorax which we before mentioned. Not however having at this moment the means of investigating the subject, it would be premature to venture any further remarks.

The larvæ of the *Elatæridæ* feed most generally upon vegetable substances: rotten wood affords food to many; others live in the ground, and feed upon the roots of plants: one of them (the larva of *Elatæ striatus* of Fabricius) is said to attack the roots of the wheat, and when in great numbers, to do much injury*.

These larvæ are long, rather slender, generally cylindrical, and covered with a tough skin: the head and terminal joint of the body are of a corneous texture; the latter is very variable in form, and is often depressed and produced into two bluntly-pointed processes: the former is furnished with the usual parts, such as jaws or mandibles, maxillæ, palpi, labrum, labium, and antennæ. The three segments which constitute the thorax are each furnished with a pair of short legs.

Of the insects included by Linnaeus under the generic name of *Elatæ*, and others of similar general characters which have been discovered since that naturalist's time, there are upwards of five hundred species enumerated, and as these species (which are now regarded as constituting a family) are divided into about sixty genera, it will be impossible, consistent with the plan of this Cyclopædia, to enter into the detail of their characters. We will therefore confine ourselves to some of the more important;—in fact to those which are given by Latreille in the 'Règne Animal': these are as follows:—*Galba*, *Eucnemis*, *Adelocera*, *Lissomus*, *Chelonarium*, *Throscus*, *Cerophytum*, *Cryptostoma*, *Nematodes*, *Hemeripus*, *Sternicera*, *Elatæ* (proper), and *Campylus*. These genera are divided by Latreille into two sections, in the first of which the antennæ are lodged (when the insects is at rest) within two grooves situated on the under side of the thorax.

This section includes the six first genera. The genus *Galba* (*Latreille*) has the antennæ filiform, and received into two grooves situated directly under the lateral margins of the thorax: the joints of the tarsi are simple: the thorax is convex: the mandibles are terminated by a simple point: the maxillæ are furnished with a single small lobe: the terminal joint of the palpi is globular, and the body is nearly cylindrical.

The species are all from Brazil. The genus *Eucnemis* (*Ahrens*) differs from *Galba* chiefly, in having the mandibles bifid at the apex, the maxillæ terminated by two lobes, the terminal joint of the palpi securiform, and the body nearly elliptical. Species of this genus are found in Europe and North America.

Genus *Adelocera* (*Latreille*). Here the antennæ are filiform; the joints of the tarsi are simple, and the anterior legs, when contracted, are received into lateral cavities in the under part of the thorax.

Lissomus (*Dalman*.) The species of this genus have

* A larva of one of the *Elatæridæ* (which there were good reasons for believing was that of *Elatæ macr.*) we have found more than once feeding upon worms.

little cushion-like lobes on the under side of each joint of the tarsi.

In the genus *Chelonarium* (Fabricius) the form approaches to an oval, the second and third joints of the antennæ are larger than the following and of a flattened form, and these alone are received into the sternal grooves. The head is almost hidden by the thorax, which is semicircular, and the anterior legs are larger than the rest. All the species are from South America.

Genus *Throscus* (Latreille). This genus is readily distinguished by the antennæ being terminated by a tree-jointed knob: the penultimate joint of each tarsus is bifid; the mandibles are simple.

The species of *Throscus* are very minute. *Throscus dermestoides*, an insect not uncommon in this country, is about one-eighth of an inch in length, of a brown colour, and obscurely covered with an ashy pubescence.

The second section of the Elateridæ comprises those species in which the antennæ are free, or not lodged within grooves on the under part of the thorax.

Cerophytum (Latreille). The principal characters of this genus are: terminal joint of the palpi larger than the following, and almost securiform; tarsi with the four basal joints short and triangular, the penultimate joint bilobed; antennæ serrated in the female, and in the male branched internally.

The *Cerophytum Elateroides* (Latreille), an European species, affords an example of this genus.

Cryptostoma (Dejean). Tarsi simple, small, and slender; anterior extremity of the præsternum projecting beneath the head; the apex of the third and seven following joints of the antennæ prolonged; mandibles unidentate; maxillæ with a single lobe; palpi very short.

Cryptostoma denticornis (Lat.), the only species known, is from Cayenne.

Nematodes (Latreille). Body nearly linear; antennæ with the basal joint elongated; each of the five following joints in the form of a reversed cone; the remaining joints almost perfoliate, with the exception of the last, which is oval.

Species of this genus have been found in Europe and North America.

Hemerhipus (Latreille). In this genus the parts of the mouth are exposed, i. e., not as in the two last genera, hidden by the projecting process of the præsternum; the antennæ are flabellate at the apex in the males.

All the species of this genus are extra-European.

In the genus *Ctenicera* (Latreille) the antennæ are pectinated in the males, and deeply serrated in the females.

The *Ctenicera pectinicornis*, an insect common in some parts of this country, affords an example of this genus. This species is rather more than half an inch in length, and of a brilliant metallic green or copper-like colour: the female is larger and broader than the male.

In the genus *Elater*, as now restricted, the antennæ are simply serrated.

The *Elater æneus* of Linnæus will serve to illustrate this genus. This species, which is common in some parts of England, is generally found under stones on hills of but little elevation, and which are more or less covered with heath. It is about three quarters of an inch in length, and most commonly of a brilliant green colour; some specimens however are blue, and others are of a brassy or bronze hue.

The *Elater noctilucus*, according to Latreille, also belongs to this genus. This species is well known in South America, where it is called the fire-fly.* It is rather more than an inch in length, of a brown colour, and covered with an ashy down: on each side of the thorax there is a round glossy yellow spot. These spots emit by night a light so brilliant as to enable a person to read by it, and it is a common practice to place several of the insects together in a glass jar or bottle for this purpose. This insect (with upwards of twenty other species, all of which emit light by night) is now included in Illiger's genus *Pyrophorus*. The species of this genus are, some of them, from each of the following localities:—Brazil, Peru, Buenos Ayres, Chile, Cuba, St. Domingo, and Guiana.

In the genus *Campylus* (Fischer) the eyes are more prominent than in the other Elateridæ, and the head is pro-

truded from the thorax: the antennæ are inserted beneath a frontal projection on each side, and the body is long and almost linear.

One species of this genus is found in England, the *Campylis dispar*, which is of a yellowish colour. In some specimens the head, legs, and antennæ are black, and sometimes the elytra are black with a broad pale margin.

ELATE/RIUM. [MOMORDICA.]

ELATMA or YELATMA, the chief town of the most northerly circle in the Russian government of Tambof in Great Russia. It is situated at the confluence of the Myksha and Oka, on the left bank of the latter, in 55° 5' N. lat., and 42° 34' E. long. Elatma is an old town, and contains ten churches, eight of wood and two of stone, several government buildings, about 800 houses and thirty-four wooden stores, and about 6000 inhabitants. It has manufactures of linens, vitriol, and sulphur, and a considerable trade in grain, hemp, wax, and honey, chiefly with Moscow, and the provinces on the banks of the Volga, to which parts the Oka gives the means of ready access. The extensive iron works of Yeremshink, which employ nearly a thousand hands, are in its immediate neighbourhood.

ELBA, the Ilva of the Romans, called *Æthalia* (*Αἰθλία*) by Strabo, p. 223, is an island in the Mediterranean sea, near the coast of Tuscany, and divided from it by the channel of Piombino, which is about five miles broad in its narrowest part opposite the town of Piombino, which lies on the main land. The shape of Elba is very irregular; its length is about eighteen miles, from 10° 6' to 10° 25' E. long., and its greatest breadth, which is on its east side, is about ten miles, from Cape Calamita 42° 43' to Cape Vito 42° 52' N. lat.; but in its west part it is six miles broad, and towards the middle of its length it is only three, owing to the coast being indented by gulfs both from the north and south. Its area is about 154 square miles. The island is mountainous; the highest summit, Monte della Capanna, in its west part, is 3600 feet above the sea. The mountains are mostly naked, but the lower ridges and the valleys between are planted with the vine, olive, and mulberry, and other fruit trees. The island produces also some wheat and Indian corn, vegetables, and water melons. Wine, both white and red, is made in considerable quantities; some of it, especially the red sort, is very good, and forms an article of exportation. There is also a kind of muscadell, or dessert wine. Horned cattle and horses are rather scarce, but there are plenty of sheep, goats, pigs, and asses. Fish is plentiful on the coast, and the tunny fishery yields a considerable profit. The salt pans on the sea-shore produce about 50,000 cwts. of salt yearly. Elba is rich in iron, which is of the best quality, and was worked in the time of the Romans. It is found in a mountain, near Rio on the east coast, which is almost entirely a mass of ore, about two miles in circumference, and 500 feet in height. About 120 miners are employed in it, and the ore yields from 50 to 75 per cent. of pure metal. Owing to the scarcity of fuel the ore is embarked and taken to the mainland to be smelted, as it was when Strabo wrote. The annual quantity of metal raised is about 40,000 cwts. The other mineral productions of Elba are loadstone, alum, vitriol, and marble of various kinds. The population of Elba is about 13,500, of which Porto Ferrajo, the capital, has about 3000. Porto Ferrajo lies on the north coast of the island, and is strongly fortified with two citadels on the hill above it, and has an excellent harbour. The town has two parish churches, one hospital, and a lazaretto. It is the residence of the cancelliere, or political governor for the whole island, which is included in the province of Pisa; it has a garrison and military commander, a civil and criminal court, from which appeals are laid before the ruota, or high court of Grosseto. From Porto Ferrajo a good road, five miles in length, made by Napoleon, leads to Porto Longone on the east coast of the island, on a deep bay, where there is good anchorage for vessels. The castle of Porto Longone is on a steep hill, and is regularly fortified. The town or village is small, and reckons about 1000 inhabitants. The other principal villages in the island are Rio, Marciana, Campo, and Capo Liveri. The island of Elba has acquired considerable celebrity in our times, on account of it having been the residence of Napoleon after his first abdication, from May, 1814, to the 26th of February, 1815, when he set sail for Cannes. From that time it has been annexed to the grand duchy of Tuscany. The mountains of Elba form a conspicuous object as seen from Leghorn, which is about fifty

* Other insects having the same power of emitting a light by night are usually confounded with the present species under the name of the fire-fly.

miles north of the nearest point of the island. (Neigeaur, *Gemälde Italiens*; Pini, *Osservazione sulle Miniere di Ferro dell' Isola dell' Elba*.)

ELBE. The, one of the largest rivers in Europe, flows like the Weser entirely within Germany. It originates in the confluence of a number of rivulets and brooks which fall down the western side of the Schneekoppe, or Snowcap, one of the highest mountains in the Riesengebirge, or Giant mountains, of Bohemia, and in that part of them which separates Bohemia from Silesia. Some writers refer the source of this river to the Weissbach (Whitebrook), which springs from the White Meadow, at the foot of the Schneekoppe; others to the Elbe or Narvor Meadow, where eleven springs, called the Wells of the Elbe, are said to rise, and uniting in one stream, which takes the name of the Elbe or Müdelbrunn, fall over a lofty precipice into what is termed the Elbgrund, or region of the Elbe. Here the stream is increased by the Seifen and other rivulets which join it below Krausensbaude, whence it runs towards Hohenelbe under the universally admitted designation of the Elbe. From Hohenelbe, a mountain town in the north-eastern circle of Bidschow, in Bohemia, it flows south-east to Arnau, thence south-west into the circle of Königsgrätz, where it is joined by the Aupa near Yarowitz, the Metau at Josephstadt, and the Adler or Orlitz at Königsgrätz, and afterwards passes into the circle of Chrudim, whence, after receiving the Chrudimka at Pardubitz, it takes a westerly direction. Having passed Elbe-Teinitz, below which it is joined by the Dobrowa, and skirting the northern extremity of the circle of Czaulau, it traverses the most north-eastern part of that of Kaurzim, where it flows past Kolin, and there winding to the north-west re-enters the circle of Bidschow, and crosses its south-westerly districts past Podicbrad. It now pursues a course due west along the southern border of the circle of Bunzlau, re-enters that of Kaurzim, flows north-west from Taurzim past Brandeis, above which it receives the Iser and Elbe-Kostoletz, to Melnik, in the south-western extremity of the circle of Bunzlau, where it is increased by the waters of the Moldau, and from which place (in 50° 20' N. lat. and 14° 28' E. long.) it has an unobstructed navigation to its mouth. From Melnik it forms the boundary for a short distance between the circles of Rakonitz and Leitmeritz, then winds southwards to Kaunnitz, and after entering the last-mentioned circle by again flowing north-westwards from Kaunnitz, is joined by the Eger a few miles above the town of Leitmeritz. From this place it flows northwards to Aussig, takes a winding easterly course past Tetschen where it receives the Pulznitz, bends gradually north-westwards, quits Bohemia near Hernikretschen, or Hirnikretschen, and enters the kingdom of Saxony. At this point the Elbe is 355 feet in width. It thence takes a north-westerly course past Schandau, between which place and Dresden it passes through the Lusatian and Ohre Mountains of Saxony, then flows to Pirna, Dresden, Meissen, Riesa, and Strehla, and enters Prussian Saxony at Loesnitz, about seven miles above Mühlberg. Its whole length from the south-eastern to the northern frontiers of Saxony is between 70 and 75 miles. From Mühlberg its course is north-westerly to Torgau, and thence to Wittenberg, above which it receives the Black Elster; here it takes a westerly direction, leaves for a while the Prussian states, traverses the Duchy of Anhalt from Koswig past Dessau to Barby, during its passage through which it receives the Saale and Mulde, and thence turning northwards, re-enters those states above Aacken, receives the Ohre, and flows on to Magdeburg until it reaches the point below Sandow, where it is joined by the Havel. Here it again has a north-westerly direction, forming first the boundary between Brandenburg and Prussian Saxony till it passes Schneekendorf, and next for a short distance between Brandenburg and Hanover: thence it separates Hanover from Mecklenburg until it enters the north-eastern districts of that kingdom between Dömitz and Hitzacker. After traversing them as far as Boitzenburg, it divides the Hanoverian dominions from the duchies of Lauenburg and Holstein and the Hamburg territory, until it discharges itself into the North Sea. Altogether it traverses Hanover or forms its north-eastern boundary for about 120 miles. Below Winsen, which lies to the south-east of Harburg in Hanover, the Ilmenau falls into it, and below Neuhaus somewhat above Altona, but on the left bank like the former, the Oste. From Hamburg and Altona downwards to Glückstadt in Holstein and thence to the North Sea it be-

comes navigable for large ships. Its mouth lies north of Cuxhaven, about 85 miles below Hamburg.

The Elbe first flows through a deep narrow valley to Josephstadt, the right bank being much higher than the left. This valley widens gradually until the Elbe has passed Nimburg, between Kollin and Brandeis, where it again becomes contracted. From Nimburg to Raudnitz, south of Theresienstadt its banks are lower, but from the last town until it reaches Lowositz they are much more elevated, and thence as far as Pirna in Saxony its bed lies in a deep confined valley. From Pirna the heights on its left bank subside, whilst those on its right accompany the Elbe at a little distance until it has passed Dresden and Meissen. From thence to Torgau a succession of low hills run parallel to both banks, and there entirely disappear. A range of hills approaches the left bank at Dömitz, and occasional heights the right bank near Wittenberg. From the mouth of the Saale until a little above Magdeburg the banks are flat, but in this part high hills command them at several points. From Magdeburg the Elbe flows through a level country into the North Sea, except between Hitzacker and Bleckede on its left and about Altona on its right bank, where the adjacent ground rises to gentle elevations.

In the lower parts of its course, namely, between Harburg on its left bank, and Hamburg and Altona on its right, the Elbe is divided into several arms by five large and seven small islands; these arms, however, unite again in a single channel at Blankenese, about five miles below Hamburg.

The whole length of the Elbe is about 710 miles, and it is navigable for about 470 miles. Its mean depth is 10 feet and its average breadth 900 feet, but it widens at some points to 1000 feet and more, and near its mouth to several miles.

The height of this river above the level of the sea is as follows: near its source 4151 feet; at Königsgrätz 618; at Melnik 426; at Schandau 320; at Pirna 287; at Dresden 262; at Wittenberg 204; at Magdeburg 128; at Tangermünde 87; at Losenrade 48; at Dömitz 26; at Hitzacker 19; at Bleckede 11, and at Boitzenburg 9 feet.

There are 35 bridges across the Elbe between its source and Torgau, below which town the communication between both banks is by ferries. The principal bridges are those at Leitmeritz, which is of wood and stone, and 823 feet in length; Brandeis; Dresden, of stone, 1420 feet long and 36 broad; Meissen; Torgau; Wittenberg, of stone and wood, 1000 feet long; and Magdeburg, where there are three wooden bridges, one across the Old Elbe 76 rods long; another across the main arm of the river, 24 rods; and the third across a side arm 20 rods long.

The waters of the Elbe are increased by the confluence of 17 rivers and upwards of 70 minor streams. Between the years 1801 and 1835 its depth has decreased nearly 8½ inches at Dresden, and about 18½ at Magdeburg. In Bohemia, where less attention has been paid to the clearing of woodlands and drainage of swamps and marshes than in the territories through which the Saale, Mulde, and Black Elster flow, the diminution has been far less. The basin is estimated to occupy about 58,800 miles, and lies between 50° 2' and 53° 54' N. lat., and 8° 41' and 16° 12' E. long.

This river is well stocked with fish, particularly salmon, eels, and sturgeons.

ELBERFELD, a circle in the eastern part of the county or administrative circle of Düsseldorf in the Prussian province of the Rhine. It contains an area of about 125 square miles, three towns (Elberfeld, Gemark or BARMEN, and Mettmann, with about 2100 inhabitants), one market-village, 21 villages, and 135 hamlets, and has a population of about 93,500; which is an increase of 22,750 since the year 1816. About one-fifth are Roman Catholics, and the remainder Protestants. The circle is traversed in all parts by offsets of the Sauerland hills, and is well wooded. Extensive beds of alum lie between Velbert and Langenberg in the northern part of the circle, where a number of alum works are established. Elberfeld is watered by the Ruhr, Wipper or Wupper, Düssel, and 26 minor streams and brooks. The soil is in general but of middling quality; in some of the more elevated districts it is light, and calculated for the cultivation of rye, oats, and potatoes only. In the others, wheat, rye, barley, oats, peas, and flax are raised. There are excellent meadow and grazing lands. The vicinities of Elberfeld, Barmen, Hardenberg, and Kronenberg are crowded with manufactories of cotton yarn and cloths, silks, woollens, linens, ribbons, lace, velvets,

stockings, iron and steel wares, leather, &c. The stock of cattle in 1831 was composed of 1901 horses, 8201 horned cattle, 4386 sheep, 2811 goats, and 1837 swine.

ELBERFELD, the chief town of the circle, lies in a romantic situation upon the right bank of the Wupper, which is 200 feet higher at this spot than at its junction with the Rhine below Opladen: in $51^{\circ} 16' N.$ lat. and $7^{\circ} 8' E.$ long. It is an open well-built town, and stands at an elevation of 405 feet above the level of the sea. The streets are long, but few of them are of any great breadth, as the place is built partly between hills and partly upon them. It is divided into two quarters, the Island and the Liberty, and contains three churches, one of which is Roman Catholic, a gymnasium, a school of trade, a mechanics' school, 15 elementary schools, two orphan asylums, three hospitals and infirmaries, about 650 manufactories, large and small, 2500 private houses, and about 24,200 inhabitants. This is a great increase since the year 1801, when their numbers were 11,720: from which they rose to 15,595 in 1819; 21,027 in 1828, and 23,398 in 1831. Among other establishments in Elberfeld are a museum, a society of the arts and sciences, a bible, a missionary, and a tract society, a savings' bank and loan bank, and a German American mining society. There is no town in the Prussian dominions which carries on such extensive manufactures and none which has a more flourishing trade. The chief manufactures are thread-lace, of which above 20,000*l.* in value are annually made; silks, for the weaving of which with upwards of 1100 looms more than 28,000*l.* a year are paid in wages; cotton cloths, plain and printed, in which 45 factories and above 3600 looms are employed; coverlids to the extent of 30,000 per annum; thread linens, damask cloths, tapes, iron-ware and cutlery, ribbons, stockings, leather, potashes, furniture, &c. There are several bleach-grounds and establishments for dyeing; nearly 300 merchants and manufacturers; and the yearly amount of bills passed on the exchange of the town is said to be upwards of 1,500,000*l.* sterling, in which sum the large manufacturing districts of Barmen, Kronenberg, Langenberg, &c., are comprised.

The earliest historical record of Elberfeld is of the twelfth century, when a burg occupied a small portion of its site, which belonged to the Elverfelds, a family whose descendants established the first manufactures. The Reformation was introduced here in the year 1552. It is the seat of a tribunal of commerce and two courts of arbitration. Elberfeld is also a township (*Bürgermeisterei*) with 32 hamlets, and contained, at the close of the year 1836, 34,257 inhabitants. In that year the births were 1650, the deaths 1132, and the marriages 353. It lies about 19 miles east of Düsseldorf.

ELBING, a circle of the county or administrative circle of Danzig, in Western Prussia, is bounded on the north by the Frisches Haff, the south and west by the circle of Marienburg, and the east by the province of East Prussia. It contains about 268 square miles, two towns, 822 villages, and 5532 dwelling-houses, and had in 1831 a population of 44,406. The north-western part is traversed by a chain of hills, which are connected with East Prussia. The soil is exceedingly fertile, and has luxuriant pastures; it produces an abundance of grain, and fruits and vegetables of the finest sorts, especially in the south-western part. Elbing is well watered by the navigable rivers the Nogat and the Elbing, besides numerous smaller streams and canals. The fishery is productive. Owing to the great scarcity of wood, except in the forest near the town of Elbing, the inhabitants are obliged to use turf. Next to Danzig, Elbing has the most manufactures in the government; the chief are those of tobacco, soap, sugar, vitriol, wood, &c. It also carries on a considerable trade in corn, wood from the Upper Vistula districts, horse-hair bristles, packing cloth, fustian, butter, fruits, wood, potash, &c. The circle, besides Elbing, contains the town of Tolkemit, on the Haff, with 1800 inhabitants.

ELBING (*Elbinga*, Polish *Elbiąg* or *Elbląg*, also called *Urbs Drusinia*), chief town of the circle, and a place of considerable commercial importance, is situated on the navigable river of the same name, which is united to the Nogat by the Kraffuhl canal about four miles north of the town. It lies in $54^{\circ} 10' N.$ lat., and in $19^{\circ} 25' E.$ long., in a very fertile valley, and is surrounded by high walls, towers, and ditches. It is divided into the old and new town, three inner and eleven outer suburbs, and has five land

and two water gates, five Lutheran churches, one reformed, and one Roman Catholic, one synagogue, five hospitals, one convent for elderly females, an orphan asylum, workhouse, house of correction, house of industry, the Pott and Cowle Institute, founded by Richard Cowle, who died in 1821, a savings' bank, a Lutheran gymnasium, with a large library, besides other establishments for the education of the poor. The various benevolent institutions are admirably conducted.

Elbing was founded by the Teutonic knights about the year 1229; in the fourteenth and fifteenth centuries it was a member of the Hanseatic league, but afterwards declined when Danzig engrossed the trade with Poland, and the frequent wars between Poland, Prussia, and Sweden, stopped the intercourse. It however revived during the occupation of West Prussia by Frederick II., and now ranks in the second class of towns in the Prussian monarchy.

The population in 1817 was 18,534, of whom 225 were Jews; in 1831 it was 17,761, of whom 3500 were Roman Catholics, 360 Menonites, and 380 Jews, besides the garrison. The inhabitants carry on manufactures of tobacco, sail-cloth, soap, starch, caviar, stockings, oil, and linen; there are also tan-yards, ship-building, &c. It has a brisk trade with Poland, from which corn, potash, wood, linen, wood, tallow, and wax are obtained; and iron, wine, manufactured and colonial goods, &c., are sent in exchange. The shipping business too is considerable; the townsmen are owners of a great number of large vessels and coasters; and many vessels are built here. By the Kraffuhl canal small vessels can come up to the wharfs, but the larger ones are obliged to unlade in the depth of Pillau, which is the harbour of Elbing. About 1400 vessels enter the port every year; but the greater portion of these are vessels of small burden. There is likewise a considerable fishery, particularly in sturgeon.

ELBŒUF, a town in France, in the department of Seine Inférieure. It is on the left bank of the Seine, seventy-nine miles from Paris by Mantes, Vernon, Louviers, and Pont de l'Arche. The town is situated in a pleasant valley, and may be recognized afar off by the chimneys of its numerous steam-engines. Elbœuf appears to possess little that is worthy of notice, except the choir of the church of St. Etienne. The population of the town in 1832 was 9951, that of the whole commune 10,258: the inhabitants have been engaged since the latter part of the seventeenth century in the manufacture of woollen goods; tapestries were long included in their productions, but this branch of industry has been nearly or quite given up; woollen cloths are now the staple manufacture; and Elbœuf is the centre of a prosperous branch of industry. There were at the publication of M. Dupin's '*Forces Productives et Commerciales de la France*,' (Paris, 1827,) in and round the town 1200 looms, furnishing employment to 2700 weavers, and 4300 workmen of other kinds employed in the various branches of the woollen trade. The cloth is purchased of the small manufacturers by wholesale houses of extensive business (by which the cloths of Louviers are also purchased), and by them sold and sent into various parts of France, especially to Paris, Lyon, Limoges, and Bordeaux. The wool formerly employed by the clothiers of Elbœuf was Spanish; latterly, the wool of the neighbouring country, owing to the improvement of the native sheep by crossing the breed with the Merinos, has to a considerable extent replaced that of Spain. Elbœuf has a large charity-school, in which, in 1823, 400 girls were taught.

ELBORUS, ELBURZ, or ELBROOZ. [*CAUCASUS*, p. 382.]

ELCAJA, an Arabian plant, whose fruit is said to possess emetic properties. Botanists call it *Trichilia emetica*. Forskahl describes it as a large tree, with villous shoots, pinnate leaves, with entire oval-oblong pedicellate leaflets, clustered flowers with five greenish-yellow petals, ten monadelphous stamens, and a downy capsular fruit about an inch long, with three valves, three angles, and three cells, having two plano-convex seeds in each cell. The tree is said to be called Roka, and to be common on the mountains of Yemen. The fruit is sold at Boit el fakih, for mixing with fragrant materials with which the Arab women wash their hair. The fruit called *Djour elki* is reputed an emetic. The ripe seeds mixed with Sesamum oil are formed into an ointment as a cure for the itch.

ELCHE, the *Illici* of the Romans, is a considerable town

in the kingdom of Valencia in Spain, situated on the river Segura, in a fertile plain covered with vines and palm-trees. The latter is the date-palm, with a thick wood of which the town is surrounded to the distance of half a league. Though there are several good streets and squares, the town has on the whole a melancholy aspect. Among the most remarkable buildings is a ducal palace, which is evidently the work of a very remote age. The great church is a beautiful edifice, with a noble dome. The barracks are well built and extensive. There are besides many convents and charitable institutions for the poor. Population, 15,000.

ELDEN HOLE. [DERBYSHIRE.]

ELDER TREE. [SAMBUCUS.]

EL DORA'DO, literally the golden country, was the name given by the Spaniards in the 16th century to an imaginary region somewhere in the interior of South America, south of the Orinoco and between that and the Amazon river, where gold and precious stones were supposed to be as common as rocks and pebbles in other countries, and to be had for merely picking them up. The first notion of this story was communicated by an Indian Cacique to Gonzalo Pizarro, brother of the conqueror, who sent his companion, Francisco Orellana, down the Amazon river to discover this wonderful land. Orellana followed the course of the Amazon down to the sea; but though he did not find El Dorado, still he countenanced the report of its existence. The temper of mind of the Spanish conquerors and discoverers of America seems to have been singularly fitted for credulous belief in all wonderful reports. The story of El Dorado continued to be accredited; a Spanish adventurer was said to have reached the capital of this enchanted region, called Manoa, and wonderful tales were told of its splendour and its wealth, far surpassing those of Peru. The Spanish governor of Guiana was also styled governor of El Dorado, because the latter country was reckoned to belong to his jurisdiction. Raleigh was so persuaded, or pretended to be persuaded, of the existence of this wonderful country, that he fitted out several expeditions for the purpose of discovering and conquering it for England: his last attempt in 1617 involved him in hostilities with the Spaniards of Guiana, which ultimately led to his death on the scaffold. [RALEIGH, WALTER.]

ELEATIC PHILOSOPHY has its name from Elea (called by the Romans, Velia), a Grecian colony on the western coast of Lower Italy, where Xenophanes of Colophon settled in his old age (about 530 B.C.), and founded a school distinguished by its bold attempt to construct a system of the universe upon metaphysical principles. The theory was brought to perfection by Parmenides, but it also reckons among its members Zeno, Melissus, and Empedocles, who however only gave a further development to particular principles; the labour of Melissus being mainly confined to the defence of those positions which were opposed to the Ionian physics, while Zeno and Empedocles exhibit the opposite aspects of the theory, the former confining himself to its doctrine of the supra-sensible, the latter to a detailed application of its physiological views.

In its formation it was subsequent to the Ionian and Pythagorean schools, and was so far a consequence of them as it thought necessary to submit to investigation the legitimacy of the principles upon which they had proceeded. The problem which they had proposed to themselves was, assuming the possibility of a beginning of motion and of production and decay, to determine the first ground or grounds of all that comes into being. This assumption the Eleates attacked as irreconcilable with that idea of the reason which involves the law of causality, the Eleatic expression for which was, 'out of non-being being cannot come,' and its later and more general formula, 'ex nihilo nihil;' and as no distinction had as yet been made between the efficient and material causes, they necessarily arrived at the conclusion that the world had not a beginning.

With the founder of the school religious considerations predominated, and in order to refute the unworthy conceptions of the Deity to which polytheism had given rise, he showed from the very notion of God that he is necessarily one. The notion of Deity, he argued, implies his infinity and eternity, but there cannot be many infinite beings; the eternal and infinite God is therefore one. But from the denial of production it followed that the world is eternal. Now an eternal world would equally limit the eternal God: the co-existence, therefore, of the two, separately and independently of each other, is impossible. con-

sequently the world and the Deity are one. This result is the foundation of the so-called error of Pantheism; but it was only by such an error that man could arrive at a right and worthy conception of the Deity, which it is the merit of the Eleates to have distinctly propounded.

From the position that God or the world is one, it necessarily followed that our conceptions of sensible things are imperfect and insufficient to bring us to a knowledge of the All or of God. Man, consequently, is placed in a painful situation, desiring on the one hand to know God, on the other to look to individual phenomena. Attention was thus awakened to the opposition which exists between the pure truth and the sensible appearance, and the Eleates were the first to advance a systematic theory of human knowledge; and although its object was to deny the validity of the testimony of sense and experience, and to ascribe to the reason exclusively the merit of arriving at the truth without any attempt to reconcile appearance and reality, it nevertheless constituted a most important advancement of the philosophy of the period, and so completed its edifice as a system by contributing the dialectical or logical portion; the Ionians and Pythagoreans having respectively constructed the physical and moral parts.

In conclusion, we must observe that the history of this as well as of the other early schools of Grecian philosophy is both obscure and imperfect, since of the written works of its several members we only possess a few and unconnected fragments.

ELECAMPANE, the herbalist's name of the plant called *Inula Helenium*. Mr. Burnett speaks of it thus:—It is by some persons esteemed as a grateful stomachic; its leaves are aromatic and bitter, but its root much more so. The former were used by the Romans as pot-herbs, and it would appear were held in no mean repute in after times, from the monkish line, 'Enula campana, reddit præcordia sana.' When preserved, it is still eaten as a cordial by Eastern nations, and the root is used in Europe to flavour certain sorts of confectionary that bear its name; and it enters into the composition of several continental carminatives. It is seldom used in England except in veterinary practice, or by fraudulent druggists to make an emetic powder, by the addition of tartate of antimony, and then sold as a substitute for ipecacuanha. A peculiar proximate principle, something resembling starch, was first detected in the roots of this plant, and hence called Inulin; it has since been discovered in the tubers of the Jerusalem artichoke, the roots of the common pellitory, the angelicum, the cornus of the colchicum, &c. [INULA.]

ELECTION (Lat. *electio*), in divinity, is a doctrine which, on the authority of Scripture, and as a consequence of the omniscient and prescient attributes of God, teaches that from all eternity the destiny of every individual of mankind was determined by an immutable decree, some (the elect) being ordained to eternal salvation, while others (the reprobate) are left to inevitable and eternal damnation. The term election is often considered as but another name for the doctrine of predestination, both implying that man is subject to a certain predetermined fate. This doctrine in modern times is associated constantly with the name of Calvin, though similar notions were maintained or opposed among the philosophical and religious sects of the ancient Gentiles, Jews, and Christians. The Essenes were believers in absolute preordination. The Sadducees rejected it, and adopted the doctrine of moral freedom. The Pharisees, in a theory of syncretism, endeavoured to reconcile and combine the two extremes. (Josephus, *Antiq. Jud.*) The Stoics insisted upon the doctrine of predestination or necessitarianism; while the rival sect of Epicureans maintained that of the perfect free agency of man and the contingent nature of events. The Gnostics taught that human souls, according as they emanated from the good or bad principle, were destined to happiness or misery. In the systems of Manes (Manichæism), Marcion, Cerdon, and others of the second century, similar doctrines were enforced concerning the fixed inevitable fate of men. Throughout the first four centuries the pagan philosophers, especially those of the Stoical school, opposed the dogmas and miracles of Christianity by alleging the principle of necessity as exhibited in the immutable series of causes and effects, or antecedents and consequents, in the physical and mental phenomena of nature, and the ignorant populace were confirmed believers in the influence of fortune and

fatality. Justin Martyr, Irenæus, and most of the Greek fathers, in defending the Christian system, resorted therefore to arguments tending to establish anti-predestinarian doctrines. Origen, in the third century, had taught that man, in his moral and religious agency, is not necessitated by omnipotent decrees of God. His tenets were adopted in Palestine, and throughout the East, especially by Chrysostom, Isidorus, Theodoret, and the other Greek fathers; and Pelagius, an English monk, proceeding on their authority, promulgated in the first half of the fifth century the sectarian theory designated Pelagianism, which asserts free agency, moral responsibility and perfectibility, making good works meritorious, and denouncing the predestinarian doctrine of imputed guilt and inherited depravity. (Pelagius in Pluquet's *Dict. des Hérésies*.) St. Augustin was among the most strenuous opponents of Pelagius, and adduced abundances of scriptural authority to show the absolute omnipotence, the omnipresence, and consequently the preordination of God, with respect to the characters and destiny of men; showing some to be elected by the divine will as objects of especial grace, and others to be abandoned to the perdition which through Adam is merited by all. (St. Augustin, *De Gratia, De Peccat. orig., De lib. arbit., De Dono Perseverantiae*.) The arguments of St. Augustin occasioned the formation in the fifth century of a sect in Africa called Predestinarians, the tenets of which were zealously propagated in Gaul by a priest named Lucidus, who was excommunicated and anathematized by the church in council. (See the treatise of Père Sirmond on this heresy, and the replies of the Jansenists and divines of Port Royal.) In the ninth century, the Predestinarian controversy was revived with great enthusiasm by Gottescalque, a French Benedictine monk, who was condemned, and terminated his life in a dungeon, for teaching the 'five points' concerning election, which subsequently gained for Calvin so much celebrity. Gottescalque was answered by Scotus Erigena, and many others. (Dufresnoy, *Tablettes Chronolog.*) This incomprehensible subject formed one of the great points of subtle disputation in the scholastic theology; it was discussed by 'the Angelic Doctor,' Thomas Aquinas, and others, in the thirteenth century. Whether God's election was before or after the prevision of human merits was a standard thesis for the exercise of syllogistic skill (*electio ante vel post prævisa merita*). Aquinas sustained the doctrines of Augustin, and the controversy was subsequently carried on in the sixteenth century between his followers (the Thomists) and the adherents of Louis Molina (the Molinists). When Luther began to form his opinions, he perceived that nothing could so effectually demolish the Catholic doctrine of justification by works as the predestinarian theory of St. Augustin, which he therefore enforced in his writings; but finally he was induced by Melancthon to mitigate the rigour of his opinions concerning man's passive subjection to God's eternal decrees. By the Socinians the certain prescience of future events by the Deity is denied, and the divine decrees are maintained to be merely general, and not specially relative to particular persons. The system of Calvin is set forth in his great work entitled 'Institutes of the Christian Religion' (*Institutiones, &c.*), in which he states that 'no one desirous of the credit of piety can dare to deny God's predestination of some to eternal happiness, and of others to eternal damnation; that 'every man is created for one or the other of these purposes,' God having from all eternity fixed the destiny of every individual of the human race, all of whom, in consequence of Adam's offence, have been, are, and to the end of time will be, under the curse and wrath of God, and justly subject to everlasting punishment; that salvation depends wholly on God's will; that particular persons, without any regard whatever to their merits or demerits, are elected, or rejected for ever; and that God is an absolute, tremendous, and incomprehensible Judge. Such propositions, it must be confessed, are sufficiently mysterious and fearful to overwhelm the timid with despair, and excite the bold to inquire if they are founded in truth. One of the ablest works in confutation of Calvin is Dr. Whitby's discourse on the five points of his system, which are as follows:—1. God, before the creation, was pleased to choose, without prevision of merit, some of mankind to enjoy everlasting happiness, and others to suffer everlasting misery. What was certainly foreseen must certainly come to pass, as the prescience of the omnipotent and omniscient Being must be coincident with.

and not by possibility antecedent to, his decrees. 2. Atone-ment was made by Christ only for the sins of the elect. His death did not make the salvation of all possible, and dependent on the performance of certain conditions; for if God intended salvation for all, doubtless all must be saved; and if Christ died for all, he died in vain for many, which is a supposition absurd and impious. 3. By original sin, that is, the imputation of Adam's guilt, all are by nature in total depravity, which justifies the consignment of the whole human race to eternal misery, and makes the election of some to happiness an act of God's especial grace and good pleasure. 4. All the elect are effectually called at some point of time in life when the influence of the divine grace is first communicated. 5. As all who are not elected must be damned, so all those who are elected must be saved: irremissible grace necessitates all their actions, and inevitable salvation must terminate their 'final perseverance.'

The following are some of the scriptural authorities alleged in support of these doctrines: Ephesians i. 4, 5, 11, some chosen before the foundation of the world; predestinated according to God's pleasure: Acts xv. 18. God's foreknowledge: Rom. viii. 29, 30, 33, those foreknown, predestinated, called, justified, and glorified, are God's elect. Math. xxv. 34, to inherit a kingdom eternally prepared for them: Acts xiii. 48, those ordained to eternal life believe. Rom. ix. 11, 18, 21, 22, 23, election before birth, and not according to works; God's power absolute; mercifully favours some and hardens others. Divine election is considered to be shown in the acceptance of Abel, and the rejection of Cain; in God's love of Jacob, and hatred of Esau (Malachi i. 2, 3); in the two men in the field; the two women at the mill; and the two in a bed, of whom one was taken and the other left (Luke xvii. 34; Matth. xxiv. 40).

Arminius, a professor in the University of Leyden, became, at the commencement of the seventeenth century, the chief of Calvin's opponents, who were thence called Arminians, and Remonstrants, from the remonstrance which they addressed to the Dutch government against Calvinistic intolerance. But the rigid Calvinists, headed by Goar (Goarites), being by far the most powerful party, Arminius and his adherents were condemned at the general synod of Dordrecht, convened for the purpose in 1619. (Scott's *Synod of Dort*, pp. 112-124.) At this synod the standard points of strict Calvinism, with respect to election, were determined upon and established. That the homilies and articles of the English church, especially the seventeenth, are confirmatory of the Calvinistic views of election, is beyond dispute, though many Arminian expositors have made laborious efforts to explain away their obvious original purport. Bishop Burnet, in his exposition of the articles, observes that the seventeenth, on Election and Predestination, 'has given occasion to one of the longest, the subtlest, and the most intricate of all the questions in divinity.' It displays in fact the *medulla* of Calvin's Institutes, precisely involving all the doctrinal particulars of his 'five points,' and asserting that, to the elect predestination 'is full of sweet, pleasant, and unspeakable comfort; while to the *reprobate* it is a most dangerous downfall, whereby the devil doth thrust them into desperation and wretchedness.' Baxter endeavoured to reconcile the doctrines of Calvin and Arminius. Arnauld, in his treatise on the subject, contends that the Calvinistic predestination directly overthrows all the principles of morality; though many others, including Dr. Chalmers, in his recent course of lectures on Predestination, assert the contrary. To enumerate the various modifications of this doctrine, which at different times have been maintained by distinguished theologians, would be endless. Some, as Origen and the Catabaptists, have denied that any one is predestined to perdition, and contended that salvation will be finally extended to every one of God's creatures, including the devil and all his angels. (Bullinger, *Contra Catabap.*) The following references, in addition to those already given, may be useful to the studious inquirer.—

(Cudworth's *Free Thoughts on Election*; Diderot, *Encyclop.*, articles Predestination, &c.; Bossuet, *Hist. des Variations*, liv. 14; *Westminster Assembly's Confession of Faith* (Calvinistic); Mosheim's *Eccles. Hist.*, vols. iii. and iv.; *Authentic Documents relating to the Predestinarian Controversy under Queen Mary*, by Archbishop Lawrence, 1819; Finch's *Examination of Cudworth's Free Thoughts on Elect.*, 1755.—A list of numerous treatises on Election, written in the sixteenth and seventeenth centuries, and of

sermons for and against the doctrine, may be seen in Watt's *Bibliotheca*, and Du Pin's *Study of Divinity*.)

ELECTION (law) is when a man is left to his own free will to take or do one thing or another which he pleases (*Termes de la Ley*); and he who is to do the first act shall have the election. As, if A covenants to pay B a pound of pepper or saffron before Whitsuntide, it is at the election of A at all times before Whitsuntide which of them he will pay; but if he does not pay either before the time fixed, then it is at the election of B to sue for which he pleases. So, if a man give to another one of his horses, the donee may take which he chooses; but if the donation be that he will give one of his horses (in the future tense), then the election is in the donor.

Courts of equity frequently apply the principle of election in cases where a party has inconsistent rights, and compel him to elect which he will enforce: as, if A by his will assumes to give an estate belonging to B to C, and gives other benefits to B, B cannot obtain the benefits given to him by the will unless he gives effect to the testator's disposition to C. It does not appear to be quite settled whether the party electing to retain his own property in opposition to the instrument is bound to relinquish only so much of the property given to him as will be sufficient to compensate the disappointed parties, or whether his election will be followed by absolute forfeiture of the whole. The arguments on both sides are ably stated 1 Roper, *Husb. and Wife*, 566 n.; 1 Swanst. Reports, 441; 2 Coke's Repts., 35 b., Thomas's note. The principle of election is equally recognized in courts of law, though they are seldom called to adjudicate upon it, except where the alternative is very distinct, or the party has already elected. Indeed this principle is of universal application, and prevails in the laws of all countries; it is applicable to all interests, whether of married women or of infants; to interests immediate, remote, or contingent; to copyhold as well as to freehold estates; to personalty as well as to realty; to deeds as well as to wills.

Courts of equity also will compel a plaintiff suing at law as well as in equity, or in a foreign court as well as in the court in England, for the same matter, at the same time, to elect in which court he will proceed, and will restrain him from pursuing his rights in all others. There are some exceptions to this doctrine, as in the case of a mortgagee, who may proceed in equity for a foreclosure, and on his bond or covenant at law at the same time; but this arises from the difference of the remedy, and from the original agreement to give the concurrent remedies: and even in such a case a court of equity will restrain a mortgagee from enforcing his judgment at law upon the bond or covenant, if he is not prepared to deliver up the mortgaged property and the title-deeds belonging to it.

On Election under a will in the Roman Law see *Dig. xxxiii. tit. 5, De Optione vel Electione Legata*: and as to the French Law, see the *Code Napoléon*, art. 1189, &c., *Des Obligations Alternatives*.

ELECTOR. [BOROUGH OF ENGLAND; COMMONS, HOUSE OF.]

ELECTRA. [CELLARIEA, vol. vi. p. 401.]

ELECTRICITY (ἤλεκτρον, amber). The electric phenomena, connected as they are now known to be by certain well-ascertained laws, form together the most complete and important addition to the physical sciences which has been made since the time of Newton.

The simplest and most usual mode of producing electricity is by friction. When any two substances are rubbed against each other briskly it is always produced; but it is only a particular description of bodies called non-conductors that retain it after it is thus produced so as to exhibit its primary effects of attraction and repulsion.

The production of electricity may be observed in a very familiar manner thus:—Tear up a piece of paper into small fragments, and place them on a table; then take a stick of sealing-wax, and rub it briskly with a piece of flannel, or against the sleeve of a cloth coat, and immediately after hold it near the fragments of paper; these small pieces will be soon observed to be agitated and the smaller to fly with considerable velocity to the wax, to which having adhered for some time, some will suddenly jump off, others which have touched the stick edgewise will dangle from it a considerable interval, and then fall off by their own gravitation when the electrical force has sufficiently subsided. It was by observing amber produce similar effects after friction

to those we have described that electricity obtained its name.

Glass is now more commonly employed to produce electricity than any wax or gum; and there is a striking difference in the kind of electricity then generated, which we shall afterwards notice more at length. These bodies are non-conductors, as they manifestly retain their electricity beyond the moment of its production, and they are isolators, because a conducting substance will also retain its electricity when communication with the earth, or other conducting substances, is cut off by means of non-conducting supports or envelopes.

Water is a conductor of electricity; for if you immerse a conducting isolated and electrified substance in water, it will completely lose its electrical properties. Perfectly dry air or gases, on the other hand, are non-conductors; for if not, none of the phenomena mentioned could have been observed, as the experiments are not made in vacuo. We are not aware that it has yet been established whether the vapours of all substances are conductors (or all the gases non-conductors). Aqueous vapour certainly is a conductor; and therefore when the air is impregnated with moisture it is difficult to perform any electrical experiments which require duration.

Hence a conductor constitutes a channel by which the electricity produced on a non-conductor will gradually escape, and a non-conductor constitutes an isolator by which the electricity communicated to a conductor may be retained.

Thus, place an electrified glass tube on a tin stand, and the metals being conductors, the electricity will be gradually dissipated; on the contrary, place an electrified tin cylinder on a glass support in dry air, and the electricity will be retained for a very long time.

Nevertheless it is far from improbable that this is a question only of degree; that all substances are conductors; and that the usual terms conductor and non-conductor strictly mean quick conductor and slow conductor.

When an electrified body is brought near the skin where the power of touch is delicate, a sensation is produced which has been compared to that produced by the touch of a cobweb; but instruments founded on the laws of electric action have been constructed, which indicate the presence of electricity in its most feeble state, and measure its tension. [ELECTROMETER.]

Previous to our study of the properties of electricity, on which the construction of the best machines for procuring it in large quantities depends, it will be useful to describe a simple apparatus, and one easily constructed or procured, by which we may learn the first laws of electrical action.

A represents a glass cylinder of which the axis is supported on a frame, and which is pressed against by a cushion stuffed with horse-hair, and covered by an amalgam of zinc and mercury spread over its surface; this cushion is attached to a conducting bar C, such as a lamina of iron connected with the frame, and with it communicating with a table or the ground.

At one extremity of the axis of the cylinder is attached a handle by which it may be rapidly turned round, and the friction which is generated against the cushion will produce electricity on the surface of the glass, to guard which

against the action of the moisture of the air, the upper side of the cylinder may be lapped over by a piece of glazed taffeta in the direction of the rotatory motion of the cylinder.

B is a long narrow and hollow metallic cylinder standing on a glass support, and having at the extremity near A a small cross bar garnished with points or teeth presented towards the cylinder. B is called the conductor in this apparatus.

When the cylinder A is turned briskly round, the motion will be accompanied by a crackling noise, and if in the dark, streams of light of a blueish hue will be perceived directed to the several points on the projecting bar of the conductor.

B may be thus charged with electricity, and when removed from the presence of the cylinder (taking it away by its isolating support), it will retain its electrical properties (the longer as the air is more free from moisture), and will by simple contact communicate a portion of its electricity to another isolated conducting substance, or be discharged by touching one not isolated: if, with a feeble charge, it is touched by the finger, a sensation like the pricking of a needle is felt, accompanied by a faint spark apparently penetrating the fingers.

It is useful to cover the glass supports at their points of contact with gum-lac, which is an excellent isolator.

Glass plates are now in more general use than cylinders for the production of electricity by friction. It would be impossible here to describe the varieties of electrical machines which have been constructed. Perhaps the most perfect apparatus for producing electricity, and also measuring its quantity, is that employed by Mr. Snow Harris, and which is described in his paper on Electricity in the Philosophical Transactions; a valuable memoir, which deserves also to be consulted for the electrical data, which are there established with much accuracy, in the mode of performing the experiments on which they are founded; though we do not acquiesce with some of the inferences drawn by the author.

We shall now observe, as our first phenomenon, that neither the cylinder which has generated and given out electricity, nor the conductor which has acquired it, exhibits the least alteration of weight, nor will the greatest possible accumulation of electricity produce the least perceptible alteration in this way. Those who suppose that electricity is a distinct species of matter, an all-pervading fluid, have therefore denominated it *imponderable*. Facts do not, however, authorize us yet to take this view of it, or to regard it as essentially different from the forces which the molecules of matter exercise, which, though neutralized for external bodies when these molecules are in positions of equilibrium or stability relative to their mean places, may become sensible by impressed forces, such as friction, which would alter the position of their poles, or by sudden concussion forcibly altering their relative situations. There is a convenience of language, however, in speaking of it as a fluid, which can lead to no error by its adoption until the phenomena of molecular actions are more studied, and the views of Mesotti and many other natural philosophers with respect to the identity of these forces better established. Adopting, therefore, this hypothesis, the sense in which we speak of its quantity, its accumulation, its density, or its partition between bodies, may be readily translated into the hypothesis founded on the views of molecular action if we should find any occasion for it.

The next phenomenon to notice is the limit to the quantity of electricity we can communicate to a perfect conductor. If, from different sources of electricity, we charge a metallic ball, and so continue to charge, we shall find that there is a limit beyond which we cannot communicate more; for on attempting so to do, the ball will discharge itself through the air into the nearest conducting body, when a spark, describing apparently a zigzag course, will be observed, the colour of the light being dependent on the medium it traverses. This spark travels with immense velocity, and is accompanied by a very audible sound; and if received by the body of a man or animal, it produces through a part or the whole of the system an instantaneous muscular contraction, which may be rendered sufficiently strong to cause death, but in more moderation has been used in some diseases, as deafness, though its use has become by no means general.

Two points determine this limit, or fix the charge of

which a perfect conductor is susceptible. The first is the extent of its surface; for if two bodies have similar figures, the quantities of electricity of which they are capable are proportional, not to their solid content or weight, but to their surfaces; that is, to the square of their linear dimensions. The second is the pressure of the non-conducting medium by which they are encompassed. The quantity of electricity is then as the square root of the pressure. When placed in an artificial vacuum, an electrical light is observed along the sides of the machine. Mr. Harris has shown that dry air, considerably rarefied by the action of the pump, will suffice to retain the electricity of a body for a long time; but it should be remembered that the square root of two quantities gives a much lower ratio than the quantities themselves; and this ratio cannot be considered very small in any artificially-formed vacuum.

That the quantities of electricity should follow the law of proportionality to the surfaces, and not to the content or weight of the body, will not excite surprise when we state that no developed electricity exists within a body, at least to any appreciable depth below its surface. This fact has been repeatedly confirmed experimentally; and in consequence of this law we see the advantage of using a long cylindrical form for a conductor, and perceive the proportions in which the partition of electricity takes place when several similar conductors communicate.

We come now to the third and very important phenomenon of the mutual repulsion of the different parts of developed electricity: these parts repel each other with forces which vary inversely as the square of the distance. We may easily witness this repulsion in the following familiar manner. Take a small well-dried ball of elder-pith, and suspend it from the hand by a fine silk thread, which is a good non-conductor; then bring it near the conductor of an electrical machine, or to a body to which this conductor has communicated electricity. The ball will at first be attracted to this body; but when it has touched it and shared a small portion of its electricity, it will be repelled from it and will stretch the string by which it is suspended in a slant direction, until the obliquity is sufficiently great for its own gravity and the tension of the string to counterpoise the repulsion of the electricity on the conductor. Let two pith balls be suspended by parallel strings

so as to touch each other, as A, B, and if a portion of electricity be communicated to them by temporary contact with a body already charged, the strings will diverge in consequence of the mutual repulsion, and the balls will come into the positions a, b, where, notwithstanding their gravitation, they will remain a considerable time, if the air be very free from moisture. They will be observed gradually to close in towards each other as they lose their electricity from the contact of the surrounding medium.

That the law of force in this case is, as in gravitation expressed by the inverse square of the distance, was satisfactorily demonstrated by Coulomb by means of his torsion balance, the principle of which we have before explained [ELASTICITY], and has been lately confirmed by Mr. Harris's experiments: and a remarkable fact arises from it, namely, if the electrified pith-ball A be placed any where within the concavity of a spherical shell, it will not be moved in any direction by the repulsion of the electricity on the surface of the shell; for the electricity being then uniformly distributed, the intensity of the force of any small portion DC is at its extent, or proportional to the square of the arc DC, and is therefore destroyed by the action of an opposite portion dc, cut off by a conical surface having A as vertex, and DC as base; for $DC^2 : dc^2 :: DA^2 : cA^2$, that is, what the portion gains in extent it loses in its distance from A. This law was first demonstrated by Newton (*Principia*, book 12); and it was afterwards shown by other analysts, that for no other law of force but that stated could the same mutual destruction of forces occur (Laplace, *Mécanique Céleste*).

tom. ..., liv 2; Murphy's *Electricity*, chap. iii.); and Poisson, from other considerations which we shall afterwards notice, made this condition, for a body of any figure, the ground of his calculations on the distribution of electricity over the surfaces of bodies.

When electricity is produced, as above described, and a conductor charged, if the conductor be removed, and another conductor replace it, the latter will become charged by repeating the operation: thus the cylinder and every substance is an inexhaustible source of electricity.

We have supposed the cushion by which the cylinder is rubbed to be in communication with the ground by a conductor; but if two substances both isolated be electrified by friction, and when separated the electricities belonging to each surface be examined, we find the following results:—

Let two isolated pith-balls A and B, as before, be electrified by communication with one of the surfaces, and two other balls *a* *b* in like manner electrified by the other surface.

Then when A is presented to B, or *a* to *b*, repulsion takes place as before described; but when A is presented to *a*, or B to *b*, they will attract each other; and if A, *a* have equal charges from the different surfaces which have been rubbed against each other, when contact takes place between A and *a*, all signs of developed electricity will depart from each, and the bodies will take their natural positions, neither attracting nor repelling each other; but if A has a greater electrical charge than *a*, a surplus of the electricity of A will remain, and will be partly communicated to *a* when a consequent repulsion arises.

The same results would occur if two machines were used, in one of which the cylinder is glass, and in the other resin or a gummed substance: the pith-ball which receives its electricity from the glass cylinder will attract that which has been in communication with the other machine.

Hence arise the terms *vitreous* electricity and *resinous* electricity, or, as they are now more usually and properly called, positive electricity and negative; for whatever two substances they may be which are rubbed together when electricity is produced, it will be found positive on one substance, and negative on the other, even if the substances are of the same nature; for instance, both glass.

The phenomenon above noticed may be then announced as follows: 'Like electricities mutually repel, unlike mutually attract;' and the law of force between particle and particle is in both cases the inverse square of the distance.

Moreover, we have seen that the addition of quantities of unlike electricities is similar to the addition of quantities with unlike signs in algebra: when equal the sum is zero, when unequal it is the excess, and of the same name as the greater charge.

Franklin's theory makes only one electric fluid in excess above its natural state in bodies positively electrified, and in defect in those said to be negatively electrified.

Epinus, and most of the continental philosophers after him, suppose two distinct electrical fluids, the particles of each of which repel those of the same kind, but attract those of the contrary, and therefore the opposite electricities always seek combination or neutralization, so that in natural bodies the two fluids exist in equal quantity, by which the presence of neither is indicated.

Mosotti has in some degree revived the theory of Franklin in his memoir on the forces which determine the state of bodies. We adopt at present the theory of two fluids, out all the phenomena may be readily expressed also on Franklin's theory.

The pressure of the electricity on the surrounding medium, when the body is perfectly conducting, determines the direction of the motion under the influence of foreign

electrified or non-electrified substances, which, by rendering this pressure unequal on the different parts of the surface, produce motion by the unequal reaction of the medium. But imperfectly conducting bodies have in themselves a certain retentive or coercive force, and the electrical particles, instead of then freely obeying the external impressed force by a corresponding law of arrangement or accumulation amongst themselves, communicate the forces impressed to the particles of matter by which they are restrained. In imperfect conductors the force is partially exercised in each of these ways. The circumstances of the motions of electrified substances therefore vary with their conducting faculty.

We can now understand the mode in which light substances are attracted to a stick of sealing-wax which has been made electrical by friction: the electricity of the wax is in this case negative; and when brought near a small piece of paper, which is a conductor, it acts upon the neutral fluid of the paper, attracting some of its positive electricity to the side next it, and forcing the negative to the farther surface, which, being in communication with the ground or a conductor, is carried off; so that the paper is thus *by influence* made positively electrical, which, being of a contrary kind to that of the wax, is attracted by it, and therefore the paper flies to the wax, and having touched it communicates its positive electricity to it, thereby neutralizing a portion of its free fluid; after which it shares a part of the surplus of negative electricity remaining on the wax, when it is of course repelled; and if it become neutral by again touching the ground, and the electrical force has sufficient energy, it will again fly to the wax and the same results will be repeated.

When a body is of an irregular figure, and is electrified, the electricity of its surface will be differently accumulated at the different parts, projecting points having the most, and portions of small curvature the least in convex surfaces; and it is a mathematical problem of considerable difficulty in some cases 'to find the law of the distribution of free electricity on the surface of a perfectly conducting body of a given form.' The datum for the solution is, that the whole action of the electric envelope on any point interior to the body is zero: we have shown that it would be so in the case of a sphere by a uniform distribution on the surface; but in other bodies this distribution cannot be uniform to produce the same effect. The next case in the order of simplicity is the spheroid, or more generally the ellipsoid, for a spheroidal shell, bounded by two similar and concentric spheroidal surfaces, and attracting by the law of the inverse square of the distance, will exercise no action on an internal point; hence the accumulation of electricity on the surface of a spheroid at any point is proportional to the normal breadth of the stratum at that point, which it may be easily proved is proportional to the perpendicular drawn from the centre on the tangent plane, or inversely as the diameter parallel to the tangent at that point.

Hence we see why the accumulation of electricity at points is so great, which are therefore part of the armature of prime conductors; for if we conceive the axis minor of an ellipse to diminish indefinitely, while the axis major remains invariable, the breadth of the spheroid generated will be correspondingly diminished while the length remains the same, and ultimately it will approximate to the form of a needle pointed at the extremities of its axis major, the breadth of the electricity at the point is then to that at the middle of the needle as the length of the needle to its greatest breadth. Now, in consequence of the law of force being the inverse square of the distance, we find the pressure against the air is as the square of the accumulation, and consequently is very much greater at either extremity of the needle than at or towards the middle; and therefore, on being overcharged, the electrical spark is given from the extremity, when not otherwise determined by the influence of external bodies.

Moreover, when several conducting bodies, some or all of which are electrified, are placed near each other, a new distribution of electricity takes place on their surfaces, caused by the decomposition of the neutral fluid of each by the action of the extraneous substances: thus, the principle for calculating the distribution in this case on every body is to suppose it such that the total action on any point within each of the conductors shall be zero; for if not, the neutral fluid at that point would be decomposed, and the separated fluids proceeding to the surface of the body would alter the distribution. When the distribution is ascertained, then the

motions of the bodies may be calculated according to the laws of dynamics, the pressure against the surrounding medium being as the square of the accumulation.

Two spheres placed in contact and electrised will have the point of contact neutral. This result of theory (founded on the principles above detailed), with many others, has been fully confirmed by experiment. Those who wish to follow up the mathematical principle here noticed, may see Poisson's *Memoirs on Electricity* (*Mémoires de l'Institut*), and an English treatise expressly on this subject by Mr. Murphy of Cambridge.

When electricity is generated by the friction of two substances, one acquires positive, the other negative electricity, but it is difficult to judge *a priori*, from the nature of the substances employed, the character of the electricity which each will take; and though most treatises contain tables of substances in which each is positive to that which precedes and negative to the succeeding, yet the nature of the electricity is so liable to alteration, from very minute circumstances of the friction, that it is better, even in each case, to try direct experiment. The friction produced by liquids also produces electricity, the electric light, when a barometer well freed from air is first filled with mercury, having been remarked from the earliest dates of the use of that instrument; and when a current of air is directed against a plate of glass the latter will acquire positive electricity, and therefore the air negative, and the rapid agitation of a piece of silk in the air communicates to the latter positive electricity while the silk acquires negative.

The difference of temperature of a substance often determines the species of electricity it acquires by friction. Generally an increase of temperature disposes to negative electricity, and polish or smoothness to positive; pressure on many crystals will produce opposite electricities, as will also heat (as in tourmaline), and even the slight adherence which a piece of glazed taffeta would have to an isolated metallic plate which it covers is sufficient to give the plate negative electricity, which is the more remarkable from the fact that the friction of the two would have made the taffeta negative and the plate positive.

Moreover, both the electricities are produced in most of the chemical compositions and decompositions, in the sudden fracture of substances, in evaporations, &c.; and the higher couches of the air are in a state of positive electricity when unoccupied by clouds, which are found indifferently charged with either.

When a body is positively electrised, we can procure the negative electrification of another conducting substance by the influence of the former on the neutral electricity of the latter. Let the conductor be placed in the vicinity of the influencing body, but not so close as to receive any positive electricity by sparks or other direct communication. The natural electricities of the conductor will be then separated by the influence of the positively electrised body, towards which the negative electricity must be attracted and the positive repelled; the part of the conductor nearest the influencing body must therefore be covered with negative electricity, and that more remote with positive. If now this end of the conductor be made to communicate with the ground, the positive electricity will escape into this great reservoir, and moreover sufficient negative electricity will be communicated from the ground to the conductor to render the point of contact neutral: thus the conductor acquires a double change of negative electricity, and when isolated will be found negatively electrised after it has been removed from the vicinity of the isolating body.

The effects of influence, as above described, may be easily observed in the following manner: Place a long and narrow isolated conducting cylinder before a body strongly electrised, and from different equi-distant points of the cylinder suspend pairs of pith-balls by cotton threads, which will acquire the electricities of the parts of the cylinder with which they are connected. We shall observe a considerable divergence in the pair suspended nearest the influencing body, because they are strongly charged with an electricity of a contrary nature to that of the body: going along the cylinder, the divergence diminishes, and at a point not as remote as the middle of the cylinder there will be no divergence. Beyond this neutral line the cylinder has an electricity of the same kind as the influencing body, increasing in intensity towards its farthest extremity, and therefore the strings commence to diverge more and more as we approach that end. In making this experiment a single pair of pith-

balls moved along the cylinder will be sufficient if we secure them from the direct influence of the body by a piece of glass interposed near them.

This is the direct influence the electrised body has on a neutral body, but the neutral body must again re-act on the original body, sensibly decomposing its electricity if it be a conductor; and thus the true arrangement of the electricity, in two surfaces influencing each other, although instantaneously effected, may be regarded as the final effect of a succession of direct and reflected influences between the bodies. This principle has been shown by Mr. Murphy materially to facilitate the actual calculation of the distribution of electricity on two electrised surfaces in presence of each other.

The effect of the influence of a near electrised cloud has been felt by several persons; among others by the writer; and in many cases fatal results have followed, not from the direct discharge of the electricity or, as it is called, the lightning, but from the sudden reunion of the electricities which had been separated by influence, and which, upon the discharge of the cloud, is effected by means of a corresponding electric charge brought through the body from the ground.

From the power of separation of the neutral fluid in bodies at a distance which is exercised by electricity, an easy means has presented itself by which a much greater quantity of electricity may be collected upon a conducting plate than that which could be directly communicated by a conductor. We shall therefore now endeavour to explain the principle of the condenser, which we think very inaccurately stated in Biot's *Physique*, in which the subject of electricity is treated, generally speaking, in a very luminous manner.

The following investigation the author of this article gives, on his own responsibility, with the desire of placing the power of the condenser on its true basis—

Suppose two equal conducting plates, of which the axes are AB, CD, to communicate respectively at A and D with known sources of electricity, and have their opposite faces B, C near to each other and parallel, the whole being surrounded by a non-conducting medium, the known sources of electricity communicate quantities E, E' of electricity to the bases B, D, and the mutual influences of the system generate other quantities X, X' on the second bases B, C, these quantities are dependent on E, E', on AB, CD, which for simplicity we shall suppose both equal to c, and on the mutual distance B, C of the plates, which we shall call a. Our problem is to find X and X' from these data.

Consider the total action on a point P, taken anywhere within the first plate and on its axis; this must be equal to zero, in order that the neutral electricity at that point may not be further decomposed. Let PB = z.

The action arising from the base A and the adjoining portion of the sides of the plate included between A and a parallel drawn through P is $E f(c-z)$; the form of the function f is unknown, since it depends on the law of the distribution of the fluid at the different parts of the base and sides.

Similarly, the action arising from the base B = $X f(z)$

$$\begin{aligned} \therefore \quad & \therefore \quad \therefore \quad \therefore \quad C = X' f(a+z) \\ \therefore \quad & \therefore \quad \therefore \quad \therefore \quad D = E' f(a+c+z). \end{aligned}$$

Our first equation of condition must therefore be—

$$X f(z) + X' f(a+z) - E f(c-z) + E' f(a+c+z) = 0 \dots (1);$$

and if we consider in precisely the same way the equilibrium of a point Q within the second plate and in its axis, we obtain (putting CQ = z')

$$X' f(z') + X f(a+z') - E' f(c-z') + E f(a+c+z') = 0 \dots (2).$$

The equations (1) and (2) must hold true for all values of z and z' between 0 and c, and they serve to determine the form of the function and the values of X, X'.

If the bases were infinite, f(z) would be constant. (*Principia*, book xiv.)

Now $f(x) = f(o) + f'(o) \cdot x + \frac{f''(o)}{1.2} \cdot x^2 + \&c.$ by Maclaurin's Theorem $= f(o) \left\{ 1 + \frac{x}{c} \right\}$ nearly;

for x being very small, we reject the powers higher than the first, and put $\frac{x}{c}$ for abridgment, instead of $\frac{f''(o)}{f(o)}$; c is introduced for homogeneity.

We may observe that n is necessarily a very small fraction in the actual case; for it depends on $\frac{c}{R}$, R being the linear dimension of the base, and it vanishes when R is infinite.

The equations may be thus simplified; and dividing them by $f(o)$ they become—

$$X + X' \left(1 + \frac{na}{c} \right) - E(1+n) + E' \left(1 + \frac{na}{c} + n \right)$$

$$+ \frac{nx}{c} (X + X' + E + E') = 0 \dots (3)$$

$$X' + X \left(1 + \frac{na}{c} \right) - E'(1+n) + E \left(1 + \frac{na}{c} + n \right)$$

$$+ \frac{nx'}{c} (X + X' + E + E') = 0 \dots (4)$$

Hence, by subtraction and dividing by $\frac{na}{c}$, we obtain—

$$X' + X + (E' - E) \left(1 + \frac{2c}{na} + \frac{2c}{a} \right) + \frac{x-x'}{a} (X + X' + E + E') = 0 \dots (5)$$

Since $x-x'$ may be positive, negative, or zero, and yet this equation always true, we must have separately—

$$X' - X = (E - E') \left(1 + \frac{2c}{na} + \frac{2c}{a} \right) \dots (6)$$

$$X' + X = -(E + E') \dots (7)$$

It will be useful to make a few remarks before proceeding further. The expression which we have put for the action of the plane C on P in equation (3) is in reality the action not only of that plane but also of the side of the prism or cylinder, of which the base is C and altitude CP; and a similar remark applies to the action of the plane D; therefore the total action given in that equation is too great by twice the action of the side of the prism or cylinder included between the plates B and C. For the same reasons we have a like excess in the equation (4); wherefore we have subtracted these equations, when that excess disappears; whereas, if we had added them, an error would arise, small with respect to X and X' , but comparable to $E + E'$.

Also, from equation (7), the apparatus would be discharged by making the two plates communicate.

In the actual case the lower plate communicates with the ground; therefore $E' = 0$.

Adding now the two equations, we find—

$$X' = \frac{cE}{a} \left(1 + \frac{1}{n} \right),$$

and subtracting—

$$X = -\frac{cE}{a} \left(1 + \frac{1}{n} + \frac{a}{c} \right).$$

n is a very small quantity and negative, since the attractive force diminishes as the point acted on becomes more remote. Hence X is very great and positive compared with E , and it follows—

First, that the greater the extent of the plates, the less n will be, being zero when that extent is infinite; therefore the power of the condenser is increased by the extent of the surfaces being enlarged.

Second, that another source of increase of the condensing power is the diminution of a , the space occupied by the non-conducting medium interposed between the parallel conducting plates.

These results are perfectly accordant with experience.

In practice, the conducting plates are generally separated by a plate of glass or a cover of varnish, the latter being used when the electrical charge is feeble; for the attractive forces of the two opposite electricities X, X' would be too powerful for such an obstacle if E were great, and the elec-

tricity would penetrate it, and unite; but in chemical operations, where the electricity developed is of weak tension, the diminution of a is of great advantage, the quantity of electricity acquired by the plates becoming very sensible to the electrometer. [ELECTROMETER.]

The Leyden jar is an instrument founded on these principles. A glass bottle is coated within and without with tin-foil. The conductor of an electrical machine communicates with the foil on the inside by means of a metallic chain, while the outside is in communication with the ground. The opposite electricities are therefore accumulated on the internal and external sides of the glass; hence a flash and a powerful shock is produced, when the two fluids combine, by touching the outside foil with one hand, while the conductor or chain communicating with the inside is touched by the other.

It was ascertained by Cavendish that the quantity of electricity produced in the Leyden jar, with given surfaces, was inversely proportional to the breadth of the glass; this completely corresponds with the results which we have above obtained by theoretical considerations.

There seems little doubt, from the experiments of Wolaston, that much of the electricity produced by the common machine is attributable to chemical action; for the best amalgam to use with the rubber is that which oxidizes most readily, such as tin and zinc, and scarcely any quantity of electricity is produced if, by the nature of the amalgam, there is no sensible oxidation, or if we envelope the apparatus in a medium which will not communicate oxygen, as carbonic acid gas. As the quantity taken by the conductors is proportional, *ceteris paribus*, to their surfaces, it is usual to employ several narrow cylindrical conductors placed parallel to each other; the total surface in this case being the same as that of a single cylinder of the same length, and of which the radius would be the sum of all their radii.

The electrophorus is founded on a principle nearly similar to that of the condenser; but in this case it is the non-isolated body which acquires electricity by the influence of that which is isolated.

It should be observed that the non-conducting plates employed in the condenser and Leyden jar have a certain retentive power on the electricity, and which is of the same origin as its non-conducting faculty; hence it will happen generally in experiments that the whole of the electricity will not be discharged at once, when the opposite electricities of the two plates are made to communicate by a conductor, and frequently not after several repetitions.

The same principle of the separation of the neutral electricity of remote bodies by influence is only varied in the number of electrical machines which have been at different times constructed, such as electrical batteries, electrical piles, &c. The construction of such apparatus is continually varying, as frequently from caprice as from experience. Those which are most commonly employed in laboratories will be found (by such as cannot actually see them) described in most popular treatises on electricity.

In the best conducted experiments there will be a loss of electricity, arising either from the hygrometric state of the atmosphere or the imperfect insulation of the supporters employed. When, for instance, the moist particles of vapour floating in the air come in contact with the conductor of an electrical machine, they acquire by their own conducting power a small portion of the electricity developed in the conductor; being similarly electrified they are repelled; and new particles of moisture arising, repeat the same process of exhaustion, each tiny robber carrying away as much electricity, not as it can hold, but as it may hold without being itself held. The quantity thus lost in a small given time is proportional to the whole charge, and therefore the latter must diminish in a geometrical progression when the time increases in arithmetical.

For atmospheric electricity, see METEOROLOGY.

The electrical light produced in a discharge, whether in an artificial vacuum, in air, or in water, which is susceptible of decomposition by the prism, and varies its tint with the substances between which it is discharged, has been a subject of controversy among physical philosophers; but the opinion most generally received is, that it is the effect of the compression of the traversed medium, which, under such circumstances, would give out light and heat. Mr. Wheatstone has recently exhibited some ingenious experiments to show the velocity of the electric fluid, an account

of which may be seen in a paper communicated to the Royal Society. Its immense velocity has been demonstrated 'ong since by the instantaneousness of its arrival at different parts of long metallic tubes, or a series of them, such as are used in pipes for conducting gas. The chemical and other effects of electricity will be found under their proper heads.

ELECTRICITY, LATENT. [MOLECULARITY.]

ELECTRICITY, Medical application of. A supposed analogy between electricity and the nervous power has led to the employment of this agent, particularly in diseases connected with defective nervous energy, and also in cases of defective secretion, perhaps originating in a similar cause. The influence of electricity on the human system differs much according to the manner in which it is applied, the length of time during which it is continued, and the degree of intensity. It also differs in its action according as it is abstracted from, or communicated to, the individual. When applied in a moderate degree of intensity, it occasions an increase of nervous action, of sensibility and irritability, more vigorous circulation of the blood, augmented warmth, and secretion, especially cutaneous transpiration: even the exhalation of plants is much increased by electricity. When the electric principle is more intense, all these actions are heightened, often to a painful degree; while such a degree of concentration as occurs during certain atmospheric changes can occasion instant death. Death occasioned by this means is always followed by rapid decomposition of the body. The diseased states in which electricity has been found most useful are—in asphyxia, from any cause (except organic disease of the heart), but particularly from exposure to irrespirable gases; in certain asthmatic diseases; and dyspepsia, dependent on irregular or defective supply of nervous energy to the lungs and stomach. It is however much inferior to galvanism as a remedial agent in these diseases. (Wilson Philip *on the Vital Functions*.) In local paralytic affections, when of a chronic character, electricity, duly persevered with, has been found very useful: in a case of dysphagia, from paralysis of the œsophagus, the patient could only swallow when placed on a seat resting on nonconductors and electrified. In deafness and loss of sight, when directed by a competent judge, it has restored the functions of seeing and hearing. Lastly, in defective secretion, especially amenorrhœa, it has proved of service.

ELECTRO-CHEMISTRY. The effects of electricity, whether produced by the common electrical machine or the galvanic apparatus, when applied to substances with sufficient intensity, are recognized in their composition or decomposition, their fusion, phosphorescence, &c.; this class of phenomena have been successively investigated by Franklin, Priestley, Cavendish, Wollaston, Cuthbertson, Davy, Van Marum, Gay-Lussac, and Thénard, Becquerel, Faraday, &c., and form an important branch of science closely connected with the nature of chemical affinities, and called electro-chemistry.

Though the decomposition of water by common electricity was effected before Wollaston, yet the remarkable simplifications which this celebrated man introduced into every chemical subject with which he was connected accompanied his electro-chemical researches, we shall therefore confine ourselves to the description of the mode he adopted to decompose water.

Finely-pointed wires of gold or platina are introduced into capillary tubes, the glass is then heated by a lamp until it becomes soft and completely covers the metal, the uncovered part of the wire is then cut off with a sharp instrument, or else the glass may be ground away until the very point of the wire commences to project; sometimes the platina is first silvered, and when the uncovered part has been cut away, the whole is plunged in nitric acid, which dissolves the silver envelope, leaving only a very fine point of platina.

Two wires thus prepared are placed in a vessel containing water, bringing the metallic points very close to each other; one wire is now put in communication with the ground, the other with one of the conductors of an electrical machine; when the electricity of the machine is evolved, a series of sparks passes through the water between the metallic

points, the water becomes decomposed into its constituent gases at the points of the wires, and being collected in glass vessels filled with water, they are found in the ratio of 2 to 1 in volume, which is the known proportion of hydrogen and oxygen combined to form water: the finer the metallic points, the greater will be this decomposition; some of those used by Wollaston were of only the 1600th of an inch in diameter.

The decomposition of æther, alcohol, oils, &c., have also been effected in nearly a similar manner, by the electrical spark, and the correct proportions of the constituent gases have invariably been obtained; the oxygen in such cases is always found at the negative pole, and the same result is obtained if we use only a single wire, and do not insulate the vessel containing the fluid operated on.

In metallic solutions the precipitate on the electrified wire shows visibly the decomposition; thus in a solution of copper, if we employ a silver wire, protected by an envelope of sealing-wax, when the electrical discharge is communicated we find the copper precipitated on the negative wire.

When solid substances are enclosed in tubes of glass, such as the oxides of gold, tin, &c., and a strong electrical discharge passed through them, a similar decomposition takes place, the products being deposited on the sides of the glass.

When a gas is thus to be decomposed, a glass vessel is filled with mercury, and the wires introduced; the vessel is then inverted in a reservoir of mercury, and the vacuum is sufficiently filled with the gas that the wire points project above the surface of the mercury; the discharge is then effected, and the required decomposition is produced.

Example.—Sulphuretted hydrogen. Hydrogen is disengaged, the sulphur deposited, and the volume remains unaltered.

Conversely, the composition of compound bodies from their elements in many cases is effected by the electrical spark, two volumes of hydrogen, and one of oxygen gas being introduced into a stout glass tube filled with mercury, and an electrical spark passed through them by means of the wires, water is formed, accompanied with a loud detonation, and the rising of the mercury in the tube in consequence of the diminution of volume. The instruments used for the combustion of gas are called eudiometers, the principle of their construction, particularly that of Mitscherlich, is particularly simple; the object being generally to measure the quantity of oxygen contained in air.

The electrical spark will re-light a candle which has been just blown out by the carburetted hydrogen of the smoke with the oxygen of the air, which are then easily inflamed.

When electrical sparks are transmitted incessantly through a small given portion of atmospheric air, its volume becomes compressed, and nitric acid formed. (*Phil. Trans.*, vol. 75.)

By adding oxygen, we can decompose gaseous bodies (by means of the spark) which contain hydrogen: however, it has been found that there is a limit in such mixtures, beyond which the burning will no longer take place. A table of these limits is given by Turner.

Table of mixed Gases and their Products when decomposed.

| Names of the gases. | Products. |
|-----------------------------|---|
| Deuto-carbonate of hydrogen | Carbon and hydrogen; volume of hydrogen double |
| Olefeant gas | Carbon and hydrogen |
| Gas ammoniacal | Hydrogen and azote; volume doubled |
| Phosphoretted hydrogen | Phosphorus precipitated; volume of hydrogen unaltered |
| Carbonic acid gas | Imperfect decomposition |
| Hydro-chloric acid gas | Hydrogen and chlorine (Henry) |
| Azoteprotoxide | Oxygen and azote |
| Nitrous gas | Nitric acid and azote |

A species of phosphorescence is produced in different bodies by subjecting them to the action of a powerful electrical machine. Calcareous spar, carbonate of barytes, Derbyshire bitumen, &c. become luminous by the shock, while other substances give great sparks, and do not become luminous, as mica, dry peat, plumbago, &c.

We shall now consider the electro-chemical effects of the voltaic pile. In general, if two rods of platina in communication with the poles of a voltaic battery be immersed in

a saline solution, it will cause a separation of its constituent parts; when the current passes through solutions of neutral salt, coloured with vegetable blues, the part of the liquid at the negative pole is green, at the positive, red.

When the water contains a solution of a metallic salt, as of zinc, lead, or copper, the negative wire receives a coating of the particular metal; and in the general electro-chemical decompositions, oxygen and the oxides are found at the positive pole, hydrogen and the bases at the negative. Bodies thus susceptible of decomposition by the pile have been lately distinguished by the term electrolytes ($\eta\lambda\epsilon\kappa\tau\rho\omicron\nu\ \lambda\upsilon\omega$): thus hydro-chloric acid, water, &c. are electrolytes; boric acid is not such; substances are said to be electrolysable when capable of being thus decomposed. These terms have been introduced by Mr. Faraday.

This is the place to notice the decomposition of the alcahis by means of a powerful galvanic battery. These substances had been previously taken as simple or elementary, but upon being introduced into the circuit of the battery, at the positive pole oxygen was disengaged, while at the negative pole was found the metallic base of the alcali, as sodium or potassium, according to the nature of the alcali employed; these substances burn at the temperature of the air, in oxygen or air, and are even capable of being inflamed in water. To preserve them therefore from the contact of the air, Seabec adopted a process by which they are made to combine with mercury, in proportion as they become disengaged; the amalgam thus produced is afterwards separated by the evaporation of the mercury.

Gold-leaf, carbon, &c. placed in the voltaic current between the points of the positive and negative wires of a pile become inflamed, yielding a light of the greatest brilliancy often so intense as to be painful to the eyes.

All the chemical effects of voltaic electricity are *cæteris paribus* proportional to the extent of surface of the plates employed, and are also increased by augmenting the number of plates. (For further information on this subject, the reader is referred to the actual memoirs of Davy, Wollaston, and Faraday, in the Transactions of the Royal Society; to the *Annales de Chimie*; and to the *Traité de l'Electricité*, par Becquerel. Several isolated and interesting facts on the same subject will be found in the *Annals of Philosophy*, and the *Edinburgh Journal of Science*. See also GALVANISM.)

ELECTRO-DYNAMICS. In ordinary electricity, that fluid when developed takes a position of equilibrium, dependent on the conducting power of the medium on which it is disposed, on the non-conducting power of the medium by which it is enveloped, and on the law of force, whether of attraction or repulsion, between the elementary portions of electricity. The motions of electrified bodies are only results of the statical equilibrium of this fluid, and do not therefore belong to electro-dynamics. The mode of calculating such effects may be found under the head **ELECTRICITY**. These effects are moreover of the same nature whether the source of electricity be by means of friction, or by chemical action, as in the voltaic pile, the nature of the electricities in these cases differing from each other only in the mode of their production; but when the contrary, electricities are no sooner produced than re-combined, again reproduced and again re-combined, a new class of phenomena is produced belonging to electricity as it were in motion. Suppose, for example, that the plate A is a constant source of positive

electricity, the plate B in like manner a constant source of negative electricity of equal intensity; that AC, BC are two conducting rods communicating with each; the electricities immediately combine when the conductors are made to touch at C, and for an instant the whole may be conceived to be in the neutral state, but A being the next instant replenished with positive and B with negative electricity, the same combination takes place over again, the same neutrality succeeds, and so on indefinitely. The rod ACB is in a different condition from one in its natural state, since electrical charges are continually pouring through it from A and B; and again it is in a different condition from an electrified rod, since we cannot at any moment say that it is charged positively rather than negatively. Hence we cannot infer that it should attract rather than repel an electrified ball D, since there is as much reason for one event as the

other, and in point of fact we find that it neither will attract nor repel D. We have here a positive current of electricity issuing from A and a negative from B, and no effect of attraction or repulsion is produced on an electrified point as in statical electricity. How then is its state recognized? First by touch; for if we touch the rod ACB, a series of shocks is felt, the interval between two succeeding ones being inappreciable; and secondly, powerful chemical decomposition may be effected. [GALVANISM, ELECTRO-CHEMISTRY.] But thirdly, we may recognise it mechanically by presenting to AB another rod A'B' under exactly similar circumstances,

when the effects of the currents in AB, A'B' will be recognized by the visible motions of the rods, provided they be free to move while their communication with the proper sources of electricity remains unbroken: for example, if their extremities be immersed in cups of mercury communicating with the constant sources of the positive and negative electricities. The laws of the mutual action of electrical currents constitute the science of electro-dynamics; and previous to its study it would be desirable that the reader should be acquainted with the construction and applications of the galvanic apparatus, the opposite poles of which afford the two constant sources A, B of electricity which we have supposed. These will be found under the head GALVANISM.

To discover the laws of the mutual actions of electrical currents we must have recourse to experiment. An apparatus similar to that employed by Ampère will be found in Professor Cumming's translation of Dumoufferrand's treatise on this subject; together with a description of the mode of performing the various experiments by which these laws have become known. The term *direction of a current* is convenient when speaking of more than one; for instance, the zinc end of the pile being a constant source of positive electricity and the copper end of negative, a rod communicating with wires connected respectively with these extremities will have a current of positive electricity from the zinc to the copper, and a negative current in a contrary direction; but as it is simultaneously permeated by both, when we speak of the direction of a current we shall understand that of the positive current to avoid ambiguity.

Two parallel currents which are directed in the same way attract each other, but when directed in opposite ways, they repel.

When rectilinear currents form mutually an angle, the species of action which they exercise may be thus defined: 'Two portions of currents will attract if they are both approaching or both receding from the vertex of the angle which they form; but when one approaches and the other recedes from that angle, then they repel:' the same law holds in the limiting case of parallelism.

Let two currents cross each other, as AEB, CED, and suppose the directions of the currents to be those indicated by the arrows in the figure; then, according to this law, the force between CE, EB, is repulsive; and that between CE, EA, attractive; if, therefore, AB is fixed, and CED moveable, we ought to have CE tending towards AE, and for the same reason, DE tending towards EB; the rod CED, therefore, has a rotatory motion impressed on it until it is placed parallel with AB: this is confirmed by experiment.

If we now consider two currents to form a very obtuse angle, one of them approaching, and the other receding

from the vertex, we have repulsion; let the obtuse angle be increased to 180° , and in this extreme case the two currents merge into one: hence it follows that the consecutive parts of one and the same current exercise a mutual repulsion on each other.

The actions exercised by a rectilinear current and by a sinuous current, which have generally the same direction and are terminated at the same extremities, are equal, the intensity of action being supposed the same in both cases; thus, if we suspend a moveable conductor between a rectilinear and a sinuous conductor disposed so as to repel the first, this, after a little oscillation about its mean place, will finally rest in the middle of the interval between the conductors.

Let us now consider the action of an indefinite current AB, on a terminated current CE, which is directed towards E; the direction of AB being that indicated in the figure.

The portion BE of the indefinite current repels EC, in consequence of the contrary direction of the current in the latter. Let us represent this force in magnitude and direction by $Cg = CG$; also AE attracts CE; the force may be represented by CF, similarly situated with CG; but Cg, the repulsive force of BE, is drawn without the angle BEC; and CF, or the attractive force of AE, must be drawn within the angle AEC. If we now compound the forces CF, CG, they will manifestly produce a resultant CH parallel to the indefinite current AB. Hence the terminated current will be urged by a force parallel to the other, and in a contrary direction; and by similar reasoning it is easily seen that if the direction of the current CE were contrary to that indicated by the arrow, or receded from AB, then the whole force in CE would be in the same direction as the current AB, and parallel to it.

Let us suppose CD to be a conductor moveable round an axis at C in the plane DD'D'', and suppose the direction of its current to be from C towards D, and that of an indefinite conductor AB to be similar and parallel; then AB attracting CD will turn it round C into the position CD', and the force on the angle CE'B is then repulsive, and in CE'A attractive; hence CD' will further turn round, and the same direction of rotation will be continued in the upper semicircle; for the force is attractive in the angle D''E''B, and repulsive in D'''E'''A. Hence a continued rotation will be produced. This rotation will be in the contrary direction if we change the direction of the current either in AB or CD; or if, without changing the current, we transfer AB to the opposite side of CD: hence if AB be placed so as to meet the axis C, there will be no rotation; hence also if the terminated current be moveable round its middle point there will be no rotation, since both its halves tend to rotate in contrary ways. It is easy to analyse in the same manner the action of an indefinite conductor on a closed current by considering its action on each of the parts, the general effect being to bring the moveable conductor into a position

of equilibrium in a plane parallel to the indefinite conductor.

Instead of a single closed circuit we may suppose any number of them connected together after an invariable manner. The action of an indefinite current will still tend to bring that system into a plane parallel to its direction. These systems have been called electro-dynamic cylinders and also canals of currents.

In consequence of the electro-chemical causes which are so widely diffused through the globe, electrical currents are generated, which give its polarity to the magnet, and which, as is well known, are sufficient to generate continued rotation of given currents.

It has been found by Ampère that the actions of similar conductors on points similarly situated are equal; and that a closed conductor exercises no action on a circular conductor moveable round a central axis.

In seeking for the true laws of elementary action of currents, a decomposition similar to that of the parallelepiped of forces may be employed; that is, for the action of an elementary current we may substitute the actions of the three sides of a parallelepiped terminated at the same extremities; for, as before stated, if we preserve the direction of the currents we shall not alter the action by substituting any sinuous for a plane conductor with the same extremities.

We will now show how the law of force between the elements of currents may be obtained, which, when once known, will reduce all the phenomena to mathematical calculation.

To determine the law of force tending to or from any element of an electrical current, when points of another current are taken at different distances but in a given direction:—

Let $\delta s, \delta s'$ be the elements of two electrical currents, of which the intensities are i, i' , their distance a unit, and f the force mutually exercised in the line forming their middle points; hence $f = ii' \delta s \delta s'$.

Let $\delta \sigma, \delta \sigma'$ be portions of similar currents to the former, but of which the linear dimensions are ν times as great, and since their mutual distance is also ν times as great; this force is diminished in proportion to some function of ν , as $\phi(\nu)$: hence $f' = ii' \delta \sigma, \delta \sigma', \phi(\nu)$.

$$\text{Now } \delta \sigma = \nu \delta s \quad \delta \sigma' = \nu \delta s'; \text{ therefore} \\ f' = ii' \nu^2 \delta s \delta s', \phi(\nu).$$

$$\text{Hence } \frac{f'}{f} = \frac{1}{\nu^2 \phi(\nu)}$$

We should have the same proportions if, instead of elements, we took conductors of any lengths but still similar, for this is equivalent merely to integrating the above expressions after decomposing the forces in fixed directions; and since we have experimentally in this case $f = f'$, it

follows that $\phi(\nu) = \frac{1}{\nu^2}$; that is, the law is the inverse square of the distance, as in statical electricity; but we must observe that the directions of the currents are here supposed to make given angles with the joining line ν .

The following theorems are taken from Mr. Murphy's 'Electricity,' to which we refer for the demonstrations, which are by no means difficult to persons a little acquainted with the differential and integral calculus.

Let a right line ν join the middles of the elements $\delta s, \delta s'$ of two currents, being inclined respectively to those elements at the angles θ, θ' , the planes of which angles are mutually inclined at an angle ϕ , and let ρ, ρ' be the intensities of the currents; the mutual action of these two elements will then be represented in all cases by the formula

$$\frac{\rho \rho' \delta s \delta s'}{\nu^2} \left\{ \sin \theta, \sin \theta' \cos \phi - \frac{1}{2} \cos \theta \cos \theta' \right\} \\ = \rho \rho' \delta s \delta s' \cdot \frac{-\frac{1}{2} \frac{d}{ds} \left(-\frac{1}{2} \frac{dr}{ds'} \right)}{\nu}$$

Let R, R_1, θ_1 be the final values of ν and θ for any given current of which δs is an element, $\delta s'$ remaining as before; then the total action of this electrical current on the element δs in the direction of its length will be

$$\frac{1}{2} \rho \rho' \delta s' \left(\frac{\cos^2 \theta_1}{R_1} - \frac{\cos^2 \theta}{R} \right).$$

This may be easily deduced from the preceding formula.

Hence an indefinite current, for which R, R_1 are infinite,

exerts no longitudinal action on $\delta\delta'$; only a normal force. This coincides with what has been before shown for the action of an indefinite current on a terminated conductor. The same property holds true for a closed current, since in this case $\Theta = \Theta$, $R = R$.

From hence it is easy to find the total action of a fixed current, or a moveable rectilinear current.

The action of a closed current, or an element of another current, which is turned in all possible positions round its middle point, lies in an invariable plane.

The mutual action of two small closed conductors, containing areas λ, λ' , the centres of which are at a distance v , exercise on each other a force directly as the plane areas, and inversely as the fourth power of the distance.

The action of a uniform canal of currents indefinitely extended in one way varies inversely as the square of the distance of its extremity from the element acted on, and directly as the sine of the angle which that distance forms with the element, and is in a direction perpendicular to the plane passing through the element and the extremity of the canal.

When two uniform and indefinite canals of currents act on each other, the canals being supposed terminated at one extremity only, the resultant is in the line joining their extremities, and the force is inversely as the square of this line; hence the action of finite canals may be easily estimated, as being the difference between two indefinite canals. With respect to the nature of the force, it will be attractive or repulsive as before described. The simplest mode of observing the actions of a canal of closed currents is by twisting a wire in the form of a helix having but small intervals between the successive convolutions, the action of each portion of the helix being then very nearly the same force as that of a portion of a circle or closed current.

Ampère imagined an ingenious manner of calculating the actions of any plane closed conductors. Conceive one such to be divided into an infinity of small compartments by right lines parallel to the rectangular axes of co-ordinates, and the periphery of each compartment to be traversed by currents, in the same manner as the whole curvilinear side which encloses the area; then it is easily seen that all the internal sides of the compartments, being traversed by two currents in opposite directions, will have no electro-dynamical action, and therefore the sole remaining current is that which circulates in the periphery of the given figure; but by this division into compartments we can calculate the mutual actions of the two closed conductors from the very simple law which we have already given for the action of small closed conductors on each other.

Voltaic conductors, of which the centres of gravity are supported, undergo terrestrial action, similar to that produced by a canal of currents. We should infer, by the position which the moveable conductor takes, that the direction of the terrestrial currents is nearly from east to west, having the north magnetic pole situated on their right.

Since the action of closed currents on an element of a conductor is perpendicular to that element, hence a straight conductor fixed at one extremity, and free to move in a horizontal plane, will receive a continued rotation from the influence of the currents of the earth; but if the conductor were supported by its centre of gravity, it would be brought by their action into a fixed plane, and an electro-dynamic cylinder would come into a position perpendicular to that plane.

All these results of theory are confirmed by experiments, and are shown in the lecture-rooms of gentlemen who profess this branch of science.

There are few works expressly on this subject beside those quoted, the subject being itself the most modern addition to the exact sciences.

ELECTRO-MAGNETISM. The first important discovery in point of time, which laid the foundation of this new science, was made by Professor Oersted of Copenhagen. By reference to the article **ELECTRO-DYNAMICS** it will be seen that when the wires which communicate with the poles of a galvanic battery are connected by a conductor or by being brought into contact with each other, the opposite electricities thus continually made to combine acquire a power of action on another conductor under similar circumstances, though latent with respect to common electrical action; but this discovery of Ampère was preceded by that of Oersted, who found that the electrical current thus generated acted upon a magnetised bar, and tended to turn it round as if exer-

cising a tangential force. Before this time a connexion between electricity and magnetism had been suspected, or rather believed, by Franklin, Beccaria, and others, from the well-known circumstance that the poles of the compass-needle had been frequently reversed during thunder-storms, and that the same effect could be produced by electrical discharges. In most experiments which were then made these discharges were unnecessarily strong; but to Oersted's discovery, followed up as it has been by Ampère, Faraday, Barlow, Arago, &c., we must ascribe the source of those accurate data by which the actions of the earth on magnets, of magnets on each other, of conducting wires on magnets, and of the earth on conducting wires, are reducible to similar and simple principles of action.

When a magnetic needle is placed near a conducting wire in the plane of the magnetic meridian, and the battery is powerful, it is observed that the needle will turn round, placing itself at right angles to the direction of the current; the same effect, which we have seen in the preceding article, would be produced by the same conductor on a canal of currents. If we suppose that a man with his face turned to the needle is himself the conductor, with his feet at the positive pole, the north pole of the needle will turn towards his right. This must be understood as only meant to illustrate the direction of rotation.

In order to discover the law of action of a current on a magnetic element, Biot and Savart used a small magnetic needle, guarded from the agitations of the air, and having the action of terrestrial magnetism neutralized by a bar, thus subjected only to the immediate action of the conductor. Having acquired the position indicated by Oersted, the times of its small oscillations were observed, which we know by the principles of Dynamics must be inversely proportional, *ceteris paribus*, to the square root of the accelerating force impressed. By observing the times in which, for instance, ten oscillations of the needle took place, at different distances, it was deduced, without difficulty, that the electro-magnetic force exercised by the whole conductor was inversely as the distance of the needle from the conductor: this of course supposes that the current may be regarded as indefinite, compared with the dimensions of the needle. Hence it easily followed, as was shown by Laplace, that the force exercised by each element of the conductor on the magnetic needle must, like all known forces, vary inversely as the square of the distance; and Biot showed that, when the distance was given, the force was then proportional to the sine of the angle formed by each element of the current with the right line joining the middle of that element with the middle of the needle.

It has been shown by means of the multiplier that the electrical intensity of the current at different points of the same conductor is constant. We may observe that the principle of the multiplier consists in bending the wire in the form of a helix, but returning upon itself so as to form a closed circuit, the wire being covered with silk to prevent communication at the crossings; the action of such a spiral being similar to that of closed circular currents equal in number to the spiral convolutions.

It was afterwards found that the magnetic needle of the multiplier could be acted on by electrical discharges from a Leyden jar; and Mr. Faraday showed conclusively that, with the condition of time, ordinary electricity can produce a continued deviation of the needle; this condition he fulfilled by making the electricity pass through imperfect conductors.

Arago observed that small fragments of soft iron were attracted by the conductor of the galvanic pile, and the same current imparted permanent magnetism to small needles of steel. The needle should be placed perpendicularly to the joining wire or current, or, which is better, be introduced in a helix, the discharge of the current through which instantaneously magnetises the needle.

Nobili observed that needles placed between the isolated spires of a plane spiral of copper wire were, by an electrical discharge, magnetised in opposite ways, when near the centre and when near the circumference. Savary also observed that when needles were placed horizontally with their middle points vertical over a horizontal current and the needles perpendicular to the direction of the current, they were differently magnetised according to their distances. These experiments he has varied relatively to the length of the needles, the length and diameter of the conductor, &c.

The magnetising force of the current is transmitted without sensible loss through isolating media, as glass, wood, &c., but is much altered by the interposition of conducting plates, a result similar to the development of ordinary electricity by the influence of electrified bodies. Thus —

A large plate interposed between the conductor and the needles weakens the magnetising effect of feeble discharges, while it augments strong ones; and for a given charge, a thin and a broad interposed conducting plate may produce contrary effects, and with a certain determinate breadth the effect would be unaltered, and in general the two surfaces of the same plate exercise contrary actions. (Savary.)

When a bar of soft iron, bent in a horse-shoe shape, is encompassed by a helix covered with silk and always turned in the same way, it may be made to receive a powerful magnetism under the influence of a current through the helix discharged from a voltaic battery. Mr. Watkins has made some valuable experiments on the conservation of the magnetic power in soft iron, for which see *Phil. Trans.*, 1833.

The discovery of the currents produced by volta-electric induction is due to Mr. Faraday. With about 203 feet of copper wire he formed each of two helices, and twisted them about a cylinder of wood, making one in communication with a galvanometer and the other with a powerful voltaic pile. The moment the communication was established, the galvanometer deviated; then, after some oscillations, returned to its place, and again deviated the instant this communication was broken: hence the directions of the inducing and induced currents are contrary, while that generated at the interruption of communication or cessation of the inducing current is directed the same way with the latter.

The same philosopher has also succeeded in producing currents by the influence of magnets, his experiments with the great magnets of the Royal Society proving most manifestly the disengagement of electricity by the influence of ordinary magnetism. The extraction of the electrical spark from the magnet is now pretty generally exhibited, as also the continued rotations produced by terrestrial magnetism. The theory of Ampère, which supposes electrical currents to exist round the component particles of magnetised substances, and round the mass of the earth, is perhaps the most satisfactory explanation yet given of the cause of magnetic action, and has been greatly strengthened by the discoveries of Faraday on electro-magnetic induction, by which many objections that had been urged against this theory are removed.

This branch of science is daily receiving constant accessions, and it is gratifying that much of its progress is eminently due to our countrymen. The labours of the French and German philosophers have also been far from unfruitful.

The following works may be consulted on this subject: Gilbert's *Annalen*; *Memoirs* by Erman of Berlin, Prechtel, Hansteen, &c.; and in *Poggendorff* the papers by Seebeck, Kupffer, &c.; the recent volumes of the *Philosophical Transactions*, containing Faraday's *Researches*, Professor Cumming's *Electro-Dynamics*, and his papers in the *Annals of Philosophy*; Barlow's labours described by himself in an article of the *Encyclopædia Metropolitana*, &c.

ELECTRO-METER. This term strictly applies only to instruments adapted to measure electricity; it has however been applied in a more extended sense to those which only indicate the presence of that fluid; but these are more correctly denominated electrosopes.

Of the former kind is the Balance of Torsion invented by

Coulomb, to which we have had occasion to refer in the articles **ELASTICITY** and **ELECTRICITY**. The following is a description of this delicate instrument.

A very fine metallic wire, or, which is better, a single thread of silk taken from the cocoon, is fixed at the upper extremity, and at the lower it supports horizontally a fine needle made of a good non-conducting substance, as gum lac, to one of the ends of which is attached the body to be electrified, as for instance a small ball of elder-pith; at the top of the suspended string there is placed a plate moveable with friction on a glass cylinder, in which the thread is contained, by which any requisite torsion may be given to the thread, which is shewn by an index on a micrometer screw; the body of the large cylinder which encloses the needle is also surmounted with a graduated brass circle. In electrical experiments the index of the micrometer is on its division zero, and the plate is turned round to bring the needle and pith-ball to the zero of the graduated circle on the string. Again a second ball is attached to the extremity of a fine isolating cylinder inserted in the apparatus so that both balls may be in contact without pressure. The balls are then electrified by communication with some isolated and electrified body, and acquiring similar electricities repulsion immediately takes place. That attached to the needle being moveable with it, carries it round through a certain angle, and after some oscillations settles at a definite position with respect to the fixed ball, this angle being indicated by the graduated arc; the elastic force of torsion is then in equilibrium with the moving force of repulsion between the balls, and hence a measure of the latter can be obtained. In such experiments only a very small electrical charge is communicated to the balls.

Coulomb, in seeking the law of electrical action, found that in the first instance of his experiment the needle deviated by 36° . Then, communicating a torsion to the thread in a direction tending to diminish this deviation, he found that the micrometer index traversed 126° to reduce the angle of deviation to 18° , and 567° of torsion was necessary to bring it to $8\frac{1}{2}^\circ$; the thread being twisted by forces applied at both ends it is evident that the entire torsions in the two latter cases are $126^\circ + 18^\circ = 144^\circ$ and $567 + 8\frac{1}{2} = 575\frac{1}{2}^\circ$, while in the first case it is only 36° . By comparing the deviations with the torsions, it was easily seen that the force of repulsion varied inversely as the square of the distance between the balls. It should be remembered in such experiments that if the torsion of the thread be too great, its elasticity will act imperfectly, and be no longer proportional to the angle of torsion. [ELASTICITY.]

In like manner the law of attraction of differently electrified balls was ascertained, the torsion being then employed in resisting the attraction. We may observe here that the results thus deduced are necessarily approximative, and not exact, because the neutral electricity of the balls being partly decomposed by the mutual influence of the electricities communicated, the small forces thus arising interfere with the actions which should be due to the latter only. The attractive and repulsive forces may also be estimated by disturbing the needle a little from its position of equilibrium, and observing the number of oscillations which it makes in a given time, as was adopted by Biot in determining the law of electro-magnetic action of a galvanic current.

The proof-plane also used by Coulomb was merely a small disc of gilt paper fastened to an isolating handle; this he employed to discover the distribution of electricity on the surfaces of bodies by touching them with the plane at various points, and observing by means of the torsion-balance the quantity of electricity taken up by contact, which he assumed to be proportional to the quantity of electricity at the point touched. Mr. S. Harris has lately thrown doubt on the exactness of this assumption.

Various instruments have been constructed for estimating approximatively the total quantity of electricity in the charge of an electrified body, such as Lane's, Henley's, and Cuthbertson's electrometers. The most precise instrument of this description is one recently invented by Mr. Harris, who is always distinguished by the beautiful precision of his experiments; its description will be found in his paper on electricity in the *Philosophical Transactions*.

Electrosopes indicate the presence of very small quantities of electricity, and therefore are generally used with a condenser; as the gold-leaf electroscope, consisting of two small portions of gold-leaf laid flat together; and when

made to communicate by a conducting stem, with a condenser which has acquired electricity from a very feeble source, they diverge from each other. They have been also employed to indicate atmospheric electricity. [METEOR-
OLOGY.]

Similar instruments have been constructed for the purpose of indicating the existence of electrical currents of but slight intensity, such for instance as those generated by inequality of temperature. [GALVANOMETER and THERMO-ELECTRICITY.]

ELECTRUM, from the Greek *electron* (ἤλεκτρον). Pliny says this term denotes two substances, namely, amber and a metallic alloy composed of four parts of gold and one part of silver. 'Ubicumque quinta argenti portio est electrum vocatur.' (*Hist. Nat.*, lib. xxxiii., section 23; *Hardouin*, tom. ii., p. 619.) The term *electron*, in the *Odyssey* of Homer, is supposed to mean amber.

The metallic *electrum* was in use in the Roman times: it is uncertain whether it was known to the Greeks. The Romans were partial to it for its brilliancy. Pliny, a few sentences lower down than the passage just quoted, says, 'Electri natura est ad Lucernarum lumina clarius argento splendere.' The Romans used it frequently for what we term plate.

Lampridius, in his *Life of Alexander Severus*, remarks, that this prince caused coins to be struck in honour of Alexander the Great, both of *electrum* and gold. 'Alexandri habitu nummos plurimos figuravit: et quidem electreos aliquantos: sed plurimos tamen aureos.' (*Hist. Aug. Scriptores*, p. 922.)

Isidorus, in his *Origines* (li. xvi., c. 23), speaks of three sorts of *electrum*:—1, amber; 2, a metal so called, found in a natural state; and 3, a metal compounded of three parts of gold and one of silver.

ELECTUARY, a term applied to a compound of various medicines, united by means of syrup, or wine, and formed into a soft mass, nearly of the consistence of honey. Substances in the state of powder or extract were thus combined, and rendered capable of being swallowed without their natural taste, which might be unpleasant, being perceived. Formerly *electuaries* consisted of a great variety of ingredients, often very unsuitable to be taken together. In the present day the few *electuaries* which are prescribed are much simpler in their composition. Many compounds which were formerly preserved in a soft state are now kept in a hard dry condition, and termed *confections*.

ELEDONE. [CEPHALOPODA; SEPIADÆ.]

ELEGIT, so called from the entry of its award upon the roll, 'quod elegit sibi executionem' (because the plaintiff hath chosen the writ of execution), is a writ of execution given by the statute 13th Edw. I., cap. 18, to parties recovering upon judgments for debt or damages, or upon the forfeiture of a recognizance in the king's courts. It is directed to the sheriff of the county where the defendant's property lies, commanding him to make delivery of a moiety of the debtor's lands and all his goods (except oxen and beasts of the plough) to the plaintiff.

The sheriff, immediately upon the receipt of this writ, empanels a jury, who appraise the debtor's lands as well as his goods, and if the goods alone are insufficient to pay the debt, then the sheriff, upon the finding of the jury, sets out one-half of the lands by metes and bounds, and delivers them over to the party suing out the writ, who thereupon becomes what in law is termed a *tenant by elegit*, and continues to occupy them until the whole of his debt and damages are satisfied. The tenant's interest in the land is only a chattel, and as such goes to his personal representatives.

In like manner every subsequent judgment creditor takes a moiety of what is left; the last moiety being reserved according to the feudal law for the lord to distrain for his services.

Previously to the passing of the statute above referred to, a judgment creditor could only have obtained satisfaction of his debtor's goods by the writ of *fiery facias*, and of the present profits of his lands by a *levari facias*; but as the latter writ did not extend to the possession of the lands themselves, a defendant might, if he thought proper, alien the property, and thus oust the plaintiff of his remedy.

Copyhold lands are not liable to be extended under an *elegit*; but all estates in fee-simple in possession, all estates in reversion, expectation, leases for lives or years (in which case the creditor takes half the rents), an estate tail during

the life of the tenant in tail, who is the debtor, a rent charge, and a term of years, are liable to an *elegit*.

When the judgment is satisfied out of the extended, that is, estimated value of the estate, the defendant may recover his lands either by an action of ejectment, or by a suit in equity. If the lands are recovered by ejectment, the plaintiff only accounts for the extended value of the land, which is usually below the real value; and he is not entitled to any interest on his judgment. If, on the other hand, a bill in equity is filed, the plaintiff is allowed interest, and accounts not merely for the extended value, but for the actual profits of the lands during his possession, and it is referred to a master of the Court of Chancery to ascertain the exact amount of such profits. (*Reeves's History of the English Law*; *Archbold's Practice*.)

ELEGY, from the Greek, *elegos* (ἔλεος, whence *ἔλεος*), in English commonly means a short poem composed on some person's death; also, in a more general sense, any mournful or serious poem, as, for instance, Gray's 'Elegy in a Country Church-yard.' The Greek word, *elegos*, is properly a strain of lament; *elegion*, the form of versification in which such strains were first composed by the Greeks; i. e., the combination of an hexameter and a pentameter (commonly called long and short) verse; *elegia*, a poem made up of such verses. (*Müller, Hist. of Lit. of Greece*.) The elegiac was the first variation from the hexameter, or epic, measure; and this change of form corresponded with a change of subject: the poet in epic composition keeping himself and the workings of his own mind out of sight; while, on the contrary, the free and full expression of the poet's feelings, as affected by external circumstances, constituted the essence of the Greek elegy. Hence arises its variety; the elegies of Callinus and Tyrtæus (the earliest) being political and warlike; of Mimnermus, contemplative and melancholy; of Theognis and Solon, moral and political, &c. It was at first more peculiarly appropriated to social meetings, and therefore equally fit for topics of political and local interest, and for those which refer to the common feelings of our nature, as love, regret for the perishableness of human things, exhortations to the enjoyment of the present hour, and the like. The elegiac was also a favourite measure for epigrams, that is, taking the word in its proper sense, inscriptions. [EPIGRAM.]

Catullus is the first Latin elegiac writer of any note; he was followed by Tibullus, Propertius, and Ovid, with many others of the Augustan age, whose poems are either totally lost, or have only come down to us in fragments. With them political and moral subjects find no place; the elegiac verses of Catullus (a small part of his poems) are, for the most part, either mournful or satirical; those of the other poets above named are chiefly devoted to love, fortunate and unfortunate. Ovid, however, has taken a wider scope of personal feelings in his *Epistles* from Pontus, and of historical and mythological learning in his *Fasts*.

ELEMI, a resin, of which there are two or more sorts, brought from different parts of the world, and apparently produced by different kinds of trees. The West Indian or American *elemi* is commonly referred to the *Amyris elemifera* (Linn.), but the very existence of such a species is doubtful, unless it be synonymous with the *Amyris Plumieri* (Dec.) The East Indian *elemi* is obtained from the *Amyris zeylanica* (Retz.), while a third sort, called African, or *elemi verum*, is referred to the *Eleagnus hortensis*. A substance resembling *elemi*, and capable of being applied to similar purposes, may be procured from several plants. West Indian *elemi* occurs in irregular-shaped small pieces, which run into masses, of a yellowish colour, of an agreeable odour, which is most perfectly developed by the application of heat. The consistence is at first soft, but it hardens with age, and even becomes brittle, losing some of its odour. Specific gravity 1.083. It seems to contain a principle termed *Elemine*. *Elemi* is recommended as an ointment, but it is chiefly used to form pastilles, or to burn as incense.

ELEMENTARY ORGANS, in plants, are those minute internal parts out of which all the visible organs are constructed; they are always too small to be seen without the assistance of the microscope, and often require very high magnifying powers to be distinctly observed. When of a spheroidal figure 5000 of them have been sometimes computed to lie in half a square inch; and when tubular they are often not more than $\frac{1}{100}$ of an inch in diameter; their size is however extremely variable, and their magnitudes are given only to convey an idea of their smallness.

These organs may be defined to be closed, transparent, thin-sided membranous sacs, varying in form according to the part of the plant in which they are placed, and the purpose they serve.

If for the conveyance of fluid matter equally in all directions, and for the general purposes of digestion and respiration, they have a spheroidal figure shaped into a polygon by the pressure of the sacs upon each other, and constitute *common cellular tissue*; if fluid is to be conveyed more in one direction than another the spheroids are lengthened in that direction, and *prismatical cellular tissue* is the result, or *muriform* if they are placed horizontally and strongly compressed from the side; sometimes instead of being prismatical they are lengthened into bags acute at each end, the *clostres* of some French botanists, and the tissue thus formed is named *prosenchyma*, in contradistinction to *parenchyma*, which is a collective name for all cellular tissue the ends of whose sacs are truncated. Now and then a fibre is generated spirally in the inside of a sac of cellular tissue, but for what purpose is unknown.

If the elementary organs are for the conveyance of air they are lengthened into tubes, the sides of which are protected in the inside by a fibre, or fibres twisted spirally, so that the threads touch each other, thus forming a lining to the membrane and preventing the ingress of fluid through the sides. Such organs are called *spiral vessels*, and are exclusively (except in a very few cases) stationed around the pith of exogens, in the woody bundles of endogens, and in the veins of the leaves and of all the parts of the flower. They unroll with elasticity when stretched; and even uncoil with the growth of the membranous tube in which they have been generated so as to leave spaces between the threads through which fluid percolates; they then become *ducts*, and probably cease to convey air, but become passages for fluid.

If they are required to serve the two purposes at once of conveying fluid along the plant and of strengthening and protecting the parts in which they are placed, the sacs become fine tubes, thick-sided, elastic, tough, and collected in bundles so as to bend any way without breaking; this occurs in wood, which is composed principally of them, and which gives them the name of *woody tissue*, in the liber, and in the veins of the leaves where they are placed around the spiral vessels.

For an explanation of the many varieties of the elementary organs, and for a more particular account of their nature and uses, see Lindley's *Introduction to Botany*, 2nd edit., book i.

ELENCHUS, the Latin form of the Greek *elenchos* (ἐλεγχος), and commonly translated by the words *argumentum*, *inquisitio*, *confutatio*, and *demonstratio*, is a term of frequent use in the Aristotelian system of logic, and signifies argument, replication, refutation, or the point, subject, or nature, of dispute or demonstration. (See the authorities cited in Valpy's edition of Stephens's Greek Thesaurus under Ἐλεγχω.) Aristotle defines *elenchos* as 'a syllogism of contradiction,' that is, an argument alleged in opposition to another; and Mr. Thomas Taylor, in his translation of the *Organon*, considers the Greek term to be precisely equivalent to *Redargutio* in Latin. By some of the early English authors the noun *elench* is used in a similar sense, and also the verb *elenchize*, meaning to argue with captious or sophistical opposition. (Johnson's *Dict.*) In the two last books of the *Organon*, entitled Περὶ τῶν Σοφιστικῶν Ἐλεγχῶν, Aristotle minutely classifies and discusses the various kinds of sophistical elenchi, or modes of argument used by contentious sophists. The sophism which, in scholastic phraseology, is designated *Ignoratio elenchi*, that is, a real ignorance of, a mistaking, or sinister deviation from, the argument, or question under discussion, consists in proving something irrelevant, and which, as it may be true without affecting the truth of the real proposition, with which it has no necessary connexion, does not determine, though it may seem to determine, the question. Aristotle includes under this designation the introduction of anything extraneous to the point in dispute, (ὅτι τοῦ πράγματος); the disproving of what is not asserted, as well as the proving of what is not denied. Examples of this species of sophism are of very frequent occurrence in discourses which display the rhetorical artifice of appealing to passions and prejudices, and resort to injurious imputations, or ludicrous and satirical illustration; especially in religious, political, and forensic disputations, which affect individual in-

terests and feelings, and in which the predominant desire is not the exhibition of truth, but merely the obtaining of victory; for a disingenuous disputant when excited, and conscious of the superiority of his adversary's argument, strives to elude conviction by the stratagem of *de-ploting*, and seeks to gain a sinister advantage and triumph, by proving or disproving, not the real proposition in question, but one or more which in some way are apparently involved or implied, so as to create the assumption of identity. The following instance is given by Dr. Kirwan (*Essay on Logic*, vol. ii., p. 440): 'Paschal arguing against atheism insists that it is *more dangerous* than theism, whereas the point in debate is the *truth*, and not the *prudence* of either system. Some Christian sects use similar arguments. Mistake or misrepresentation of the question to be determined, and the consequent proving of what is not to the purpose, are also common in didactic and conversational discussions, and the sophisms of *Petitio principii* and *non causa pro causa* are frequently combined with the *Ignoratio elenchi*. In all cases of irrelevant conclusion, when something is proved which does not in reality contradict the adversary's proposition, the latent fallacy is best exposed by showing that both propositions may be equally true (Archbishop Whateley's *Logic*, p. 235, 5th ed. 1834); and the best means of preventing sophistical deception of this nature is to keep the attention constantly fixed upon the precise point of dispute, neither wandering ourselves, nor suffering our opponent to wander or make any substitution. (Dr. Watts's *Logic*.) In dramatical writing the *Ignoratio elenchi*, or as it is otherwise called, the *quid pro quo*, is frequently adopted as a very effective expedient for the production of laughter. Numerous and long continued instances of consistent dialogue, displaying the most ingenious and amusing *équivoque* or cross-purposes, are to be found in the comedies of Molière, the source of amusement being in each party's 'ignorance of the question' about which the other is concerned.

ELEPHANT, in Latin *Elephas* and *Elephantus*; in Greek Ἐλεφας; in Spanish *Elefante*; in Italian *Elefante*, in French *Elephant*; in German *Olyphant*; the name of the well-known genus which forms the only living type of the family of *true Proboscidiæ* or *Pachydermatous Mammifera*, with a proboscis and tusks, and presents the largest of existing terrestrial animals.

The *proboscis* or *trunk*, from which the name of the family is derived, demands some attention previous to our inquiry into the rest of the structure, habits, and history of the elephants.

The great size of the alveoli necessary for the lodgment of the tusks renders, as Cuvier observes, the upper jaw so high and shortens the nasal bones to such a degree, that in the skeleton the nostrils are placed towards the upper part of the face; but in the living animal they are prolonged into a cylindrical trunk or proboscis composed of thousands* of small muscles variously interlaced, so as to bestow on it the most complicated powers of mobility in all the varieties of extension, contraction, and motion in every direction. It is of a tapering subconical form, and has internally two perforations. On the upper side of the extremity, immediately above the partition of the nostrils, is an elongated process, which may be considered as a finger; and on the under edge is a sort of tubercle, which acts as an opposable point; in short, as a thumb. Endowed with exquisite sensibility, nearly 8 ft. in length, and stout in proportion to the massive size of the whole animal, this organ, at the volition of the elephant, will uproot trees or gather grass—raise a piece of artillery or pick up a comfit—kill a man or brush off a fly. It conveys the food to the mouth and pumps up the enormous draughts of water, which by its recurvature are turned into and driven down the capacious throat, or showered over the body. Its length supplies the place of a long neck, which would have been incompatible with the support of the large head and weighty tusks. A glance at the head of an elephant will show the thickness and strength of the trunk at its insertion; and the massy arched bones of the face and thick muscular neck are admirably adapted for supporting and working this powerful and wonderful instrument.

The following cuts will convey some idea of the form and action of the termination of the proboscis:—

* Cuvier gives the number of muscles having the power of distinct action as not far short of 40,000.

Anterior termination of elephant's trunk (profile).

Anterior extremities of the trunks of male (A) and female elephants (B).

Action of anterior extremity of proboscis in gathering long herbage.

Mode of holding herbage when gathered.

Mode of holding a roof full enough is collected for a mouthful.

Carried action, when a powerful grasp and much force is required.

Dental Formula.—African elephant, incisors $\frac{2}{0}$, molars $\frac{4}{4} = 10$. Asiatic elephant, incisors $\frac{2}{0}$, molars $\frac{3}{2} = 6$.

Dentition and osseous Structure.—The succession of molar teeth in the elephants takes place in a direction from behind forwards; and the tooth last developed pushing against that which preceded it, and in time replacing it, gives as a result that there are never more than two molar teeth on each side of each jaw, and that sometimes there is only one. The last case happens immediately after the shedding of the anterior tooth, which has been pushed out by its successor, and which, in its turn, is to be replaced in like manner. This succession happens many times during the life of the animal, and Mr. Corse noticed it eight times in an Asiatic elephant. Now, as these teeth show their anterior extremity first, long before the other extremity appears, and as they begin to be worn down anteriorly, it follows that the anterior tooth, when it is shed, is infinitely smaller in size than it once was, and that its form is entirely changed.

In the molar teeth of most graminivorous quadrupeds there is, besides the bony substance and enamel, a third component part, differing in appearance from both the others, but resembling the bone more than the enamel. Blake and others have distinguished this substance by the name of *crusta petrosa*; Cuvier calls it *cement*. The distinction of these three substances is, perhaps, better seen in the molar tooth of an elephant than in any other animal.

If a longitudinal vertical section be made and the surface be polished, the *crusta petrosa* will be distinguished by a greater yellowness and opacity, as well as by a uniformity of appearance, there being no apparent laminae nor fibres. 'The grinding teeth of the elephant,' writes Lawrence in his 'Additions' to Blumenbach, 'contain the most complete intermixture of these three substances, and have a greater proportion of *crusta petrosa* than those of any other animal. The pulp forms a number of broad flat processes lying parallel to each other, and placed transversely between the inner and outer laminae of the alveoli. The bone of the tooth is formed on these in separate shells, commencing at their loose extremities and extending towards the basis, where they are connected together. The capsule sends an equal number of membranous productions, which first cover the bony shells with enamel and then invest them with *crusta petrosa*, which latter substance unites and consolidates the different portions. The bony shells vary in number from four to twenty-three, according to the size of the tooth and the age of the animal; they have been described under the name of denticuli, and have been represented as separate teeth in the first instance. It must, however, be remembered that they are formed on processes of one single pulp. When the *crusta petrosa* is completely deposited, the different denticuli are consolidated together. The bony shells are united at the base to the neighbouring ones; the investments of enamel are joined in like manner; and the intervals are filled with the third substance, which really deserves the name bestowed on it by Cuvier of *cement*. The pulp is then elongated for the purpose of forming the roots or fangs of the tooth. From the peculiar mode of dentition of this animal, the front portion of the tooth has cut the gum and is employed in mastication before the back part is completely formed; even before some of the posterior denticuli have been consolidated. The back of the tooth does not appear in the mouth until the anterior part has been worn down even to the fang. A horizontal section of the elephant's tooth presents a series of narrow bands of bone of the tooth, surrounded by corresponding portions of enamel. Between these are portions of *crusta petrosa*; and the whole circumference of the section is composed of a thick layer of the same substance. A vertical section in the longitudinal direction exhibits the processes of bone upon the different denticuli, running up from the fangs; a vertical layer of enamel is placed before and another behind each of these. If the tooth is not yet worn by mastication, the two layers of enamel are continuous at the part where the bone terminates in a point; and the front layer of one denticulus is continuous with the back layer of the succeeding one, at the root of the tooth. *Crusta petrosa* intervenes between the ascending and descending portions of the enamel. As the surface of the tooth is worn down in mastication, the processes of enamel, resisting by their superior hardness, form prominent ridges on the grinding surface, which must adapt it excellently for bruising and comminuting any hard substance. The grinding bases, when worn sufficiently to expose the enamel, in the Asiatic species, represent flattened ovals placed across the tooth. In the African they form a series of lozenges, which touch each other in the middle of the tooth.' In the Museum of the Royal College of Surgeons are a series of preparations (Nos. 350 to 354, both inclusive) illustrative of the structure and physiology of the molar teeth of elephants, preceded by an interesting extract from the Hunterian MS. catalogue. No. 375 B. is a portion of the cementum of an elephant's grinder, which has been steeped in an acid, dried, and preserved in oil of turpentine, for the purpose of showing the proportion of animal matter which it contains.

Nos. 262 to 264, both inclusive, show the interarticular ligamentous substance from the joint of the lower jaw of the elephant, and the adaptation of the structure for applying two convex surfaces to each other.

More than one molar tooth and part of another are never to be seen through the gum in the elephant. When the anterior tooth is gradually worn away by mastication, the absorption of its fangs and alveolus takes place, while the posterior tooth advances to occupy its position; then comes a third to take the place of the second tooth, which undergoes the same process, and so on as we have stated for at least eight times. Each succeeding tooth is larger than its predecessor. Thus the first or milk grinder, which cuts the gum soon after birth, has but four transverse plates (denticuli); the second is composed of eight or nine, and

appears completely when the animal is two years old; the third consists of twelve or thirteen, and comes at the age of six years; and in the fourth up to the eighth grinder both inclusive, the number of plates varies from fifteen to twenty-three. It would seem that every new tooth takes at least a year more for its formation than its predecessor. As the tooth advances gradually, a comparatively small portion only is through the gum at once. A molar tooth, composed of twelve or fourteen plates, shows only two or three of these through the gum, the others being imbedded in the jaw, and in fact the tooth is complete anteriorly, where it is required for mastication, while, posteriorly it is very incomplete. As the laminae advance, they are successively perfected. An elephant's molar tooth is therefore never to be seen in a perfect state; for if it is not worn at all anteriorly, the posterior part is not formed, and the fangs are wanting; nor is the structure of the back part of the tooth perfected until the anterior portion is gone.

Elephants have no canine teeth; but in the upper jaw there are two incisors better known by the name of *tusks*. These enormous weapons are round, arched, and terminating in a point, and their capsule is always free, so that the tusk continues to grow as long as the animal lives. The structure of the ivory of which it is composed differs from other tusks; and a transverse section presents striae forming the arc of a circle from the centre to the circumference, and, in crossing each other, curvilinear lozenges which occupy the whole surface. The tusk is hollow within for a great part of its length, and the cavity contains a vascular pulp, which supplies successive layers internally as the tusk is worn down externally. Blumenbach, in his 'Comparative Anatomy,' observes, that not to mention other peculiarities of ivory, which have induced some modern naturalists to consider it as a species of horn, the difference between its structure and that of the bone of teeth is evinced in the remarkable pathological phenomenon resulting from balls, with which the animal has been shot when young, being found, on sawing through the tooth, imbedded in its substance in a peculiar manner. Haller employed this fact, both to refute Duhamel's opinion of the formation of bones by the periosteum, like that of wood by the bark of a tree, as well as to prove the constant renovation of the hard parts of the animal machine. It is still more important in explanation of that '*nutritio ultra vasa*,' which is particularly known through the Petersburg prize dissertation. Blumenbach further states that the fact above mentioned may be seen in Buffon (4to. ed., tom. xi., p. 161); in Galandat *over de Olyphants Tanden*; in the *Verhandeligen der Genootsch.* te Vlissingen, p. 352, tom. ix.; and in Bonn. *descr. thesauri Hoviani*, p. 146. In all these cases, according to Blumenbach, the balls were of iron; and he adds that he possesses a similar specimen. In the cases we have seen the balls were also of iron. 'But,' continues Blumenbach, 'there is a still more curious example in my collection, of a leaden bullet contained in the tusk of an East Indian elephant, which must have been equal in size to a man's thigh, without having been flattened. It lies close to the cavity of the tooth; its entrance from without is closed, as it were, by means of a cicatrix; and the ball itself is surrounded apparently by a peculiar covering. The bony matter has been poured out on the side of the cavity in a stalactitic form.' Upon this Lawrence well remarks that the facts here recounted have been sometimes brought forward in order to prove the vascularity of the teeth; a doctrine which is refuted by every circumstance in the formation, structure, and diseases of these organs. When a bullet has entered the substance of the body, the surrounding lacerated and contused parts do not grow to the metal and become firmly attached to its surface, but they inflame and suppurate in order to get rid of the offending matter. If the ivory be vascular, asks Mr. Lawrence, why do not the same processes take place in it? 'We can explain very satisfactorily,' writes Mr. Lawrence in continuation, 'how a bullet may enter the tusk of an elephant, and become imbedded in the ivory without any opening for its admission being perceptible. These tusks are constantly growing during the animal's life by a deposition of successive laminae within the cavity, while the outer surface and the point are gradually worn away; and the cavity is filled for this purpose with a vascular pulp, similar to that on which teeth are originally formed. If a ball penetrate the side of a tusk, cross its cavity, and lodge in the slightest way on the opposite side, it will become covered towards the cavity by

the newly-deposited layers of ivory, while no opening will exist between it and the surface to account for its entrance. If it have only sufficient force to enter, it will probably sink by its own weight between the pulp and the tooth, until it rests at the bottom of the cavity. It there becomes surrounded by new layers of ivory; and as the tusk is gradually worn away and supplied by new depositions, it will soon be found in the centre of the solid part of the tooth. Lastly, a foreign body may enter the tusk from above, as the plate of bone which forms its socket is thin: if this descends to the lower part of the cavity, it may become imbedded by the subsequent formations of ivory. This must have happened in a case where a spear-head was found in an elephant's tooth. The long axis of the foreign body corresponded to that of the cavity. No opening for its admission could be discovered, and it is very clear that no human strength could drive such a body through the side of a tusk.' 'Phil. Trans.' 1801, part 1.

The great size to which these tusks grow may be judged of by examining the table published by Cuvier in his 'Ossements Fossiles,' tome i., p. 57. It is generally considered that the tusks of the African elephant are the largest; but with regard to the table, Cuvier observes that the African tusks could not be distinguished from those of the Indies, and that there is not the certainty that could be wished in the measures employed. According to Mr. Corse, the tusks of the Indian elephant seldom exceed 72 lbs. in weight, and do not weigh beyond 50 lbs. in the province of Tiperah, which produces thousands of elephants. There are however, in London, tusks which weigh 150 lbs., probably from Pegu; for it is from Pegu and Cochin China that the largest Indian elephants and tusks are brought. The largest recorded in Cuvier's table was a tusk sold at Amsterdam, according to Klokner, which weighed 350 lbs.: this is stated on the authority of Camper; and one possessed by a merchant of Venice, which was 14 feet in length, and resting on the authority of Hartensfeld, in his *Elephantographia*. The largest in the Paris Museum is nearly 7 feet long, and about 5½ inches in diameter at the large end. These tusks have different degrees of curvature.

Mr. Corse, speaking of the Asiatic elephant, states that the first or milk tusks of an elephant never grow to any size, but are shed between the first and second year. These, as well as the first grinders, are named by the natives *dood-kau-dawnt*, which literally signifies milk teeth. The tusks which are shed have a considerable part of the root or fang absorbed before this happens. The time at which the tusk cuts the gum seems to vary. Mr. Corse knew a young one which had his tusks when about five months old, while those of another did not cut the gum till he was seven months old. Those tusks, which are deciduous, observes the same author, are perfect and without any hollow at the root, in a status which is come to its full time, and at this period the socket of the permanent tusk begins to be formed on the inner side of the deciduous tusk: he gives the following examples of the progress of this part of the dentition. A young elephant shed one of his milk tusks on the 6th of November, 1790, when near thirteen months old, and the other on the 27th of December, when about fourteen months old: they were merely two black-coloured stumps, when shed; but, two months afterwards, the permanent tusks cut the gum, and on the 10th of April, 1791, they were an inch long, but black and ragged at the ends. When they became longer and projected beyond the lip, they soon were worn smooth by the motion and friction of the trunk. Another young elephant did not shed his milk tusks till he was sixteen months old. The permanent tusks of the female are very small in comparison with those of the male, and do not take their rise so deep in the jaw; but they use them as weapons of offence in the same manner as the male named *Mooknah*, that is by putting their head above another elephant, and pressing their tusks down into the animal.

In the lower jaw there are neither incisors nor canines, and the molar teeth resemble those to which they are opposed.

Cuvier comes to the conclusion that the females of the African species have large tusks, and that the difference between the sexes in this respect is much less than in the Indian elephants; but Burchell attributes the want of success of the elephant hunters whom he met with to their having only fallen in with females whose tusks were small.

Teeth of African Elephant, from F. Cuvier.

a, Upper jaw; *b*, lower jaw; *c*, original state of the tooth when the laminae which compose it are free; *d*, the laminae as they are attached in parallel one to the other by the cortical substance in a subsequent state of dentition, but before the crown of the tooth has been worn by mastication, and when it only presents on its surface blunt tubercles.

Teeth of Asiatic Elephant, from F. Cuvier.

a, Upper molar tooth; *b*, lower molar tooth.

Pursuing our inquiry into the general structure of the skeleton, we shall find a marked difference in the external appearance of the skulls of the African and Indian species.

Skull of Indian Elephant.

Skull of African Elephant.

Section of the Skull of Indian Elephant.

a, shows the opening of the nostrils; *b*, the cellula sinus which separates the external from the internal table of the skull; *c*, the cavity where the brain is lodged.

Here we see that the almost pyramidal form of the skull in the Indian species is strongly contrasted with the more rounded form and contour of that of the African species. The front of the head is concave in the Indian species, while in the African it is rather convex; there are besides other differences.

Internally we find a beautiful provision for increasing the surface necessary for the attachment of muscles combined with strength and lightness.

The other parts of the skull most worthy of note are the nasal bones, of which the elephant possesses only a kind of imitation: the lachrymal bones are entirely wanting. The cervical vertebræ form a short and stiff series, allowing hardly more than a limited motion of the head from side to side, a more extended action being rendered unnecessary by the flexibility of the trunk, and a firm support for the head being the principal object to be attained. The spinous processes of the anterior dorsal vertebræ are exceedingly long for the attachment of the great suspensory ligament of the neck (*ligamentum nuchæ* or pax-wax). Blumenbach puts the number of ribs, and consequently of dorsal vertebræ, at 19 pairs, observing that this, at least, is

the case in the skeleton of the Asiatic elephant at Cassel Blair, he remarks, found the same number in the individuals of which he has given an account; and a manuscript Italian description of the elephant which died at Florence in 1657 confirms this statement. Allen Moulins, on the contrary (*Anatomical Account of the Elephant burned in Dublin*, London, 1682, 4to.), and Daubenton, represent the number of pairs as 20. The elephant in the Museum of the Royal College of Surgeons (Chunee, formerly of Exeter Change) has 19 pairs of ribs; and that in the British Museum has the same number, 14 true and 5 false; but Mr. Gray informs us that, in a second specimen of a young one, the bones of which have not been separated, there are 20 pairs, 15 true and 5 false. There are only three lumbar vertebræ. The margin of the scapula, which is turned towards the spine, and is shortest in most of the proper quadrupeds, is the longest in the elephant, as it is in the *Cheiroptera*, most of the *Quadrumanæ*, and especially in man. There is no *ligamentum teres*, and consequently no impression on the head of the *femur* or thigh-bone.

Skeleton of Elephant.

Structure of internal soft parts.—The following internal soft parts are more particularly worthy of remark in the elephant. *Brain, &c.*—A portion of the *dura mater* from an Asiatic elephant may be seen in the Museum of the Royal College of Surgeons, in London (Gallery No. 1346), where the termination of the falx and the commencement of the tentorium or process which separates the cerebrum from the cerebellum are shown. The two fibrous layers of the *dura mater* are separated by a softer cellular substance, in which the vessels ramify; and it may be observed that the thickness of the *dura mater* is in proportion to the size of the skull, and of the entire animal, but not to the size of the brain, which does not much exceed that of the human brain, as will be seen in the preparation of the brain of a young Asiatic elephant (No. 1331). For though the absolute size of the organ exceeds that of man, the proportion which the cerebrum bears to the rest of the brain, and especially that part of the hemisphere which forms the roof and sides of the lateral ventricle, is much less. The hemispheres are broad and short, with a considerable development of the natiform protuberance. The convolutions are comparatively small and numerous. A lateral section has been removed from the left hemisphere, which shows that the anfractuosités are also deep, extending in some cases more than two-thirds of an inch into the substance of the brain. The hippocampus is comparatively

smaller than in the ass, and the corpus striatum larger. The ventricle is seen to be continued into the olfactory bulb. The cerebellum is of considerable width, and its surface, as shown by the lateral section, is increased by numerous and complex anfractuosités. The tuber annulare corresponds in size to the development of the lateral lobes of the cerebellum. The corpora olivaria are remarkably prominent. The origins of all the cerebral nerves are shown, among which the olfactory nerves of the fifth pair, which supplies the proboscis, are remarkable for their prodigious size; whilst the optic nerves, and those which supply the muscles of the eye, are remarkable for their small size. The *pia mater* is left on with the vessels at the base of the brain. A bristle is placed in the infundibulum. (Cat. Gallery, vol. iii.) The brain in man is from $\frac{1}{2}$ to $\frac{1}{3}$ of the body, that of the elephant $\frac{1}{10}$. The *stomach* is simple, the intestines are very voluminous, and the cæcum enormous. In the sanguiferous system the *heart* is worthy of note, and a section of the right auricle and ventricle of that of an Asiatic elephant may be seen in the museum last mentioned (Gallery, No. 924). In this animal, which, in some other respects, singularly resembles the *Rodentia*, three venæ cavae terminate in the right auricle. Besides the Eustachian valve, which projects between the orifices of the inferior and left superior cavae, there is also, as in the Porcupine, a rudiment of a superior valve, ex-

tending from the posterior side of the orifice of the right superior cava. The tricuspid valve, and its chordæ tendinæ and columnæ carnæ, are also well displayed. (Cat. Gallery, vol. ii.)

Reproduction, &c.—Romantic stories were formerly told of the extreme modesty of elephants; but Mr. Corse has disproved these and others which asserted that they would only reproduce the species in a state of nature, by showing that captivity and numerous witnesses formed no obstacle: but it must be remembered that the experiments recorded by him were made in India. Copulation more equino. The period of gestation is twenty months and some days. The female mentioned by Mr. Corse produced a fine male, which was thirty-five inches and a half high just twenty months and eighteen days after she was first covered. The breasts of the female are placed under the chest, and the young one sucks, not with the trunk, but with the mouth. 'The young of the elephant, at least all those I have seen,' writes Mr. Corse, 'begin to nibble and suck the breast soon after birth; pressing it with the trunk, which, by natural instinct, they know will make the milk flow more readily into the mouth while sucking. Elephants never lie down to give their young ones suck; and it often happens, when the dam is tall, that she is obliged for some time to bend her body towards her young to enable him to reach the nipple with his mouth; consequently, if ever the trunk was used to lay hold of the nipple, it would be at this period, when he is making laborious efforts to reach it with his mouth, but which he could always easily do with his trunk if it answered the purpose. In sucking, the young elephant always grasps the nipple (which projects horizontally from the breast) with the side of his mouth. I have very often observed this; and so sensible are the attendants of it, that, with them, it is a common practice to raise a small mound of earth, about six or eight inches high, for the young one to stand on, and thus save the mother the trouble of bending her body every time she gives suck, which she cannot readily do when tied to her picket.' The maternal affection does not seem to be very strong in the female elephant, at least in captivity; for the same author states that tame elephants are never suffered to remain loose, as instances occur of the mother leaving her young and escaping into the woods; and he says that if a wild elephant happens to be separated from her young, for only two days, though giving suck, she never afterwards recognises or acknowledges it. 'This separation,' adds Mr. Corse, 'sometimes happened unavoidably, when they were enticed separately into the outlet of the *Keddah*. I have been much mortified at such unnatural conduct in the mother, particularly when it was evident the young elephant knew its dam, and, by its plaintive cries and submissive approaches, solicited her assistance.'

LIVING SPECIES.

Elephas Indicus. The Asiatic elephant differs from the African species, not only in its greater size and in the characters of the teeth and skull, but also in the comparative smallness of the ears, the paler brown colour of the skin, and in having four nails on the hind feet instead of three. The sagacity of this species is also supposed to be greater than that of the African elephants; but though many wonderful stories are told, and some of them are as true as they are wonderful, of the grateful remembrance which it long retains of benefits conferred, or of the tenacity with which it 'treasures up a wrong,' and though the instances of its docility, both antient and modern are very extraordinary, we agree, upon the whole, with Baron Cuvier, who observes, that after having studied these animals a long time, he never found their intelligence surpass that of a dog nor of many other carnivorous animals. It is imposing to see such a mountain of vitality obedient to the voice of its keeper and performing feats at his dictation; and the massive gravity of its physiognomy assists the impression.

The following is Mr. Corse's description of a perfect *Asiatic Elephant*. An elephant is said to be perfect when his ears are large and rounded, not ragged or indented at the margin; his eyes of a dark hazle colour free from specks; the roof of his mouth and his tongue without dark or black spots of any considerable size; his trunk large, and his tail long, with a tuft of hair reaching nearly to the ground. There must be five nails on each of his fore-feet, and four on each of the hind ones, making eighteen in all; his head

well set on and carried rather high; the arch or curve of his back rising gradually from the shoulder to the middle, and thence descending to the insertion of the tail, and all his joints firm and strong.

The following are the castes (*Zat*) or varieties of the Asiatic elephant noticed by Mr. Corse. Both males and females are divided into two castes, by the natives of Bengal, viz., the *Koomareah* (of a princely race) and the *Mergheah* (hunting elephant, from *mrighah* a deer, or hunting, or from its slender make), and this without any regard to the appearance, shape, or size of the tusks in the male, as these serve merely to characterize some varieties in the species. The *Koomareah* is deep-bodied, strong, and compact, with a large trunk and short but thick legs. The *Mergheah* is generally taller but is not so compact nor so strong: he travels faster, has a lighter body, and his trunk is both short and slender in proportion to his height. As a large trunk is considered a great beauty in an elephant, the *Koomareah* is preferred, but not only for this, but for its superior strength, and greater capability of sustaining fatigue. The mixed breed is held in greater or less estimation in proportion as it partakes of the qualities of the *Koomareah* or *Mergheah*. A breed from a pure *Koomareah* and *Mergheah* is termed *Sunkareah* (from *sunkarah*, a mixture), or *Mergheah bauliah* (for the most part *Mergheah*); but a farther mixture or crossing of the breed renders it extremely difficult for the hunters to ascertain the variety. Besides the *Koomareah*, *Mergheah*, and *Sunkareah* breeds, several varieties are generally to be found in the same herd; but the nearer an elephant approaches to the true *Koomareah* the more he is preferred, especially by the natives, and the higher will be his price; though Europeans are not so particular, and will sometimes prefer a female *Mergheah* for hunting and riding when she has good paces and is mild and tractable.

The variety of male termed *Damtelah* (toothy, having large fine teeth,) produces the largest tusks and the finest ivory: his head is strongly contrasted with that of the *Mooknah* (probably from *mookh*, the mouth or face), which can hardly be distinguished in this respect from a female elephant, and the tusks of some of the females are so small as not to appear beyond the lip, while in others they are almost as large as in the variety of male called *Mooknah*. The *Damtelah* is generally more daring and less manageable than the *Mooknah*; and for this reason, until the temper and disposition are ascertained, the Europeans prefer the *Mooknah*; but the natives who are fond of show generally take their chance, and prefer the *Damtelah*: although there is a material difference in their appearance as well as in the value of their tusks, yet, if they are of the same caste, size, and disposition, and perfect, there is scarcely any difference in their price.

There are many varieties between the *Mooknah* and *Damtelah*, and these are varied according to the variation of the form of the tusks from the projecting horizontal, but rather elevated, curve of the *Pulling-Damtelah* of the true *Damtelah*, to the nearly straight tusks of the *Mooknah* which point directly downwards.

Thus the *Goneish* or *Ganesa*, which is a *Damtelah* that has never had but one tusk and this of the *Pulling* sort and which is so called from *Ganesa*, the Hindu god of wisdom, who is represented with a head like an elephant with only one tooth, was sold in Mr. Corse's time to the Hindu princes for a very high price, to be kept in state and worshipped as a divinity. Another variety of the *Damtelah* has the large tusks pointing downwards and projecting only a little beyond the trunk: he is then said to have *Soor* or *Choomdant* (Hog's teeth). A third is the *Putte damtee*, whose tusks are straight like those of the *Mooknah* only much longer and thicker. The *Ankoos Damtee* is fourth, and has one tusk growing nearly horizontal, like the *Pulling-Damtelah*, and the other like the *Puttul-Damtelah*, at there are other less distinct varieties.

The term *Goondah* seems to be used to designate the wandering male elephants which are much larger and stronger than the males generally taken with the herd, the *Goondah* departing from it or returning to it according to his desire. The *Goondahs* are supposed to be rarely taken with the herd: when they are so taken, their violence and ferocity renders them most destructive. Mr. Corse relates an instance of the ungovernable passions and terrible havoc

* *Pulling* signifies a bed or cot, and *damtelah* teeth; and, from the tusks projecting so regularly, and being a little curved and elevated at the extremity the natives suppose a man might lie on them at his ease, as on a bed. (Corse)

occasioned by the savage disposition of one, or at least a large male that was supposed to be one, when in the *Keddah**. He was at length tied and led out, but his untameable spirit could not brook restraint, and after languishing about 40 days he died.

Mr. Hodgson in his paper 'on the Mammalia of Nepál' (*Zool. Proc.* 1834) suggests that there are two varieties, or perhaps rather species of the Indian elephant, *Elephas Indicus*, viz., the Ceylonese, and that of the Saul Forest. The Ceylonese has a smaller, lighter head, which is carried more elevated; it has also higher fore-quarters. The elephant of the Saul Forest has sometimes nails on its hinder feet.

The height to which the Asiatic elephant will attain has been variously stated: but upon a strict examination of alleged great heights, the natural disposition among men to exaggerate has generally been detected.

A male elephant recorded by Mr. Corse was at its birth 35 inches high.

| | | Feet. | Inches. |
|---------------------|--------------------------|-------|----------|
| In one year he grew | 11 inches, and was . . . | 3 | 10 high. |
| In the 2nd year | 8 " | 4 | 6 " |
| In the 3rd year | 6 " | 5 | 0 " |
| In the 4th year | 6 " | 5 | 6 " |
| In the 5th year | 5 " | 5 | 10 " |
| In the 6th year | 3½ " | 6 | 1½ " |
| In the 7th year | 2½ " | 6 | 4 " |

A female elephant was six feet nine inches high at the time she came to Mr. Corse's possession, and was supposed to be 14 years old according to the hunters; but, according to the belief of Mr. Corse, she was only 11 years of age. During the next five years, before she was covered, she grew only six inches, but, while pregnant, she grew five inches in 21 months, and in the following 17 months, though again pregnant, she grew only half an inch. Mr. Corse then lost sight of her. She was at this time about 19 years old and had perhaps attained her full growth. Her young one was then not 20 months old, yet he was four feet five inches and a half high, having grown 18 inches since his birth. It thus appears that no certain standard of growth, for captive elephants, at least, can be depended on: nor do there seem to be any satisfactory data for defining the age at which the animal ceases to grow. Mr. Corse conjectures that elephants attain their full growth between the ages of 18 and 24. With regard to the height, the East India Company's standard for serviceable elephants was, in Mr. Corse's time, seven feet and upwards, measured at the shoulder in the same manner as horses are. At the middle of the back, they are considerably higher; and the curve or arch, particularly in young elephants, makes a difference of several inches. The lessening of this curve is a sign of old age when not brought on by disease or violence. During the war with Tippoo Sultaun, of the 150 elephants under the management of Captain Sandys, not one was ten feet high, and only a few males nine feet and a half. Mr. Corse was very particular in ascertaining the height of the elephants employed at Madras, and with the army under Marquis Cornwallis, where there were both Ceylon and Bengal elephants, and he was assured that those of Ceylon were neither higher nor superior, in any respect, to those of Bengal: nay, some officers asserted that they were considerably inferior in point of utility.

The only elephant ever heard of by Mr. Corse as exceeding 10 feet, on good authority, was a male belonging to Asaph Ul Dowlah, formerly vizier of Oude. The following were his dimensions:—

| | Feet. | Inches. |
|---|-------|---------|
| From foot to foot over the shoulder | 22 | 10½ |
| From the top of the shoulder, perpendicular height 10 | 6 | |
| From the top of the head, when set up as he ought to march in state | 12 | 2 |
| From the front of the face to the insertion of the tail | 15 | 11 |

And yet the Madras elephants have been said to be from 17 to 20 feet high. Now let us see how dimensions shrink before the severity of measurement. Mr. Corse heard from several gentlemen who had been at Dacca, that the Nabob there had an elephant about 14 feet high. Mr. Corse was desirous to measure him, especially as he had seen the elephant often at a former period, and then supposed him to

be 12 feet high. He accordingly went to Dacca. At first he sent for the mahote or driver, who without hesitation assured him that the elephant was from 10 to 12 cubits, that is from 15 to 18 feet high; but added that he could not bring the elephant for Mr. Corse's examination without the Nabob's permission. Permission was asked and granted. Mr. Corse measured the elephant exactly, and was rather surprised to find that the animal did not exceed 10 feet in height.

Variety. The white elephants so much esteemed by the Indian sovereigns are merely Albinos.

Geographical Distribution.—The Asiatic elephant inhabits the greater part of the warm countries of Asia, and the large islands of the Indian archipelago. Mr. Corse states that the elephants for the service of the East India Company are generally taken in the provinces of Chittagong and Tipperah; but from what he had heard, those to the southward of Chittagong, in the Burmah territories and kingdom of Pegu, are of a superior breed. In confirmation of this opinion, he observes that the elephants taken to the south of the Goomty river, which divides the province of Tipperah from east to west, were generally better than those taken to the north of that river; and though elephants were taken at Pilibet as far north as lat. 29° in the vizier of Oude's territories, yet the vizier, and also the officers of his court, gave those taken in Chittagong and Tipperah a decided preference, they being much larger and stronger than the Pilibet elephant. Till the year 1790 Tipperah was a part of the Chittagong province; and so sensible was the Bengal government of the superiority of the southern elephants for carrying burdens, enduring fatigue, and being less liable to casualties, that in the then late contracts* for supplying the army, the contractor was bound not to send any elephant to the military stations taken north of the Chittagong province. Hence Mr. Corse concludes the torrid zone to be the natural clime, and the most favourable for producing the largest, the best, and the hardest elephant; and that when this animal migrates beyond the tropics the species degenerates. He speaks of elephants being taken on the coast of Malabar as far north as the territories of the Coorgah rajah; but adds that these were much inferior to the Ceylon elephant, and that from this circumstance the report of the superiority of the Ceylon elephant to all others probably originated. He remarks that most of the previous accounts respecting the Asiatic elephant had been given by gentlemen who resided many years ago on the coast of Malabar or Coromandel, where, at that time, they had but few opportunities of seeing the Chittagong or the Pegu elephant.

Mr. Hodgson, in the paper above noticed, states that *Elephas Indicus* and *Rhinoceros unicornis* are both abundant in the forests and hills of the lower region of Nepál, whence, in the rainy season, they issue into the cultivated parts of the Tará to feed upon the rice crops.

Habits, Utility to Man, &c.—In a state of nature the Asiatic elephant lives in great herds, which are generally said to be under the conduct of the old males, or bulls, as they are sometimes termed. From time immemorial the species has been brought under the dominion of man† and trained to swell the pomp of pageants, and add to the terrors of war, as well as to perform the more useful offices of a beast of burthen and draught, and the more dreadful one of executing the sentence of death on criminals. It has been long made the companion of the sports of the Orientalist in the great hunting parties; and from the same early period has been made to minister to the wanton and cruel pleasures of Eastern princes by being stimulated to combat not only with other elephants but with various wild animals. Our limits will not allow us to enter into the highly interesting detail of the mode of capturing this enormous animal, &c., &c.; and we must refer the reader to the second volume of the *Menageries*‡, where he will find an abundant and amusing collection of anecdotes connected with this subject, as well as a complete history of the elephant, both in the wild state and as the servant of man.

The tusks of both species still form, as they did from the earliest periods, a valuable article of commerce. The ivory which is now sought for useful purposes and ornaments of minor importance, was in great request with the antient

* Mr. Corse's paper was read before the Royal Society in 1799.

† The earliest extant account in any European language of the mode of capturing the Indian elephant is in Arrian, *Indike*, chap. 13.

‡ Library of Entertaining Knowledge, 8vo., London, 1831.

* *Keddah* is the name of the enclosure into which the wild elephants are driven and then captured.

Greeks and Romans for various domestic uses, as well as for the Chrys-elephantine statuary rendered so famous by Phidias. Of these rich statues the Minerva of the Parthenon, and especially the Olympian Jupiter, appear to have been the master-pieces.

Elephas Indicus—Asiatic Elephant.

Elephas Africanus.—The African elephant is less than the Asiatic. The head is rounded; the front convex instead of concave; the ears are much larger than those of the Asiatic species; and the general number of nails on each hind foot is only three instead of four.

Geographical Distribution.—From Senegal to the Cape of Good Hope. Cuvier says that it is not known whether the species is found up the whole oriental side of Africa, or whether it is there replaced by the preceding species.

Habits, Utility to Man, &c.—The flesh is relished by the inhabitants of many districts of Africa. Major Denham speaks of it as being esteemed by all, and even eaten in secret by the first people about the sheikh; and he says that though it looked coarse it was better flavoured than any beef he found in the country. The ancient Romans considered the trunk as the most delicious part; but Le Vaillant speaks of the foot as a dish for a king. The disposition of this species is supposed to be more ferocious than that of the Asiatic elephant; though its habits in a state of nature do not greatly differ. It is not now tamed; but

Elephas Africanus. African Elephant.

there is good ground for believing that the Carthaginians availed themselves of the services of this species as the Indians did of those of the Asiatic elephant. The elephants exhibited in the Roman arena by Cæsar and Pompey appear to have been Africans; and from them principally, if not entirely, the ivory for ornamental purposes and the statues above alluded to, seems to have been taken. The tusks of this species are of great size.

Fossil Species.

The third and fourth divisions of the tertiary fresh-water deposits (Pliocene period of Lyell) abound in extinct species of recent genera, and among them the remains of fossil elephants are very numerous. The alluvium, the crag, the ossiferous caverns, the osseous breccias, and the subappennine formations afford the most numerous examples. Cuvier ('Règne Animal,' last edit.) observes that there are found under the earth, in almost all parts of both continents, the bones of a species of elephant approximating to the existing Asiatic species, but whose grinders have the ribbands of enamel narrower and straiter, the alveoli of the tusks longer in proportion, and the lower jaw more obtuse. An individual, he adds, found in the ice on the coasts of Siberia appeared to have been covered with hair of two sorts, so that it might have been possible for this species to have lived in cold climates. The species has, he concludes, long since disappeared from the face of the globe. This species he characterizes (*Ossements Fossiles*) as having an elongated skull, a concave front, very long alveoli for the tusks, the lower jaw obtuse, the grinders larger, parallel, and marked with closer set ribbands of enamel, and he designates it as *The fossil Elephant*, *Elephas primigenius* of Blumenbach, *Elephas Mammonteus*, Fischer, *The Mammoth* of the Russians.

Skull of *Elephas Primigenius*.

Mammoth's, or elephant's bones and tusks occur throughout Russia, and more particularly in Eastern Siberia and the Arctic marshes, &c. The tusks are very numerous, and in so high a state of preservation that they form an article of commerce, and are employed in the same works as what may be termed the living ivory of Asia and Africa, though the fossil tusks fetch an inferior price. Siberian fossil ivory forms the principal material on which the Russian ivory-turner works. The tusks most abundant in the Laichovian Isles and on the shores of the Frozen Sea; and the best are found in the countries near the Arctic circle, and in the most eastern regions, where the soil in the very short summer is thawed only at the surface: in some years not at all. In 1799 a Tungusian, named Schumachoff, who generally went to hunt and fish at the peninsula of Tamut, after the fishing season of the Lena was over, had constructed for his wife some cabins on the banks of the lake Oncoul, and had embarked to seek along the coasts for Mammoth horns (tusks). One day he saw among the blocks of ice a shapeless mass, but did not then discover what it was. In 1800 he perceived that this object was more disengaged from the ice, and that it had two projecting parts; and towards the end of the summer of 1801 the entire side of the animal and one of his tusks were quite free from ice. The summer of 1802 was cold, but in 1803 part of the ice between the earth and the Mammoth, for such was the object, having melted more rapidly than the rest, the plane of its support became inclined, and the enormous mass fell by its own weight on a bank of sand. In March, 1804, Schumachoff came to his mammoth, and having cut off the tusks, exchanged them with a merchant for goods of the value of fifty rubles. We shall now let

Mr. Adams, from whose account these particulars are abridged, speak for himself.

'Two years afterwards, or the seventh after the discovery of the mammoth, I fortunately traversed these distant and desert regions, and I congratulate myself in being able to prove a fact which appears so improbable. I found the mammoth still in the same place, but altogether mutilated. The prejudices being dissipated because the Tungusian chief had recovered his health,* there was no obstacle to prevent approach to the carcass of the mammoth; the proprietor was content with his profit from the tusks, and the Jakutski of the neighbourhood had cut off the flesh, with which they fed their dogs during the scarcity. Wild beasts, such as white bears, wolves, wolverines, and foxes, also fed upon it, and the traces of their footsteps were seen around. The skeleton, almost entirely cleared of its flesh, remained whole, with the exception of one fore-leg. The spine from the head to the os coccygis,† one scapula, the basir and the other three extremities were still held together by the ligaments and by parts of the skin. The head was covered with a dry skin: one of the ears well preserved was furnished with a tuft of hairs. All these parts have necessarily been injured in transporting them a distance of 11,000 wersts (7330 miles); yet the eyes have been preserved, and the pupil of the eye can still be distinguished.‡ This mammoth was a male, with a long mane on the neck, but without tail or proboscis.' (The places of the insertion of the muscles of the proboscis are, it is asserted, visible on the skull, and it was probably devoured as well as the end of the tail.) 'The skin, of which I possess three-fourths, is of a dark grey colour, covered with a reddish wool and black hairs. The dampness of the spot, where the animal had lain so long, had in some degree destroyed the hair. The entire carcass, of which I collected the bones on the spot, is four archines (9 feet 4 inches) high, and seven archines (16 feet 4 inches) long from the point of the nose to the end of the tail, without including the tusks, which are a toise and a half (9 feet 6 inches, measuring along the curve; the distance from the base or root of the tusk to the point is 3 feet 7 inches) in length; the two together weighed 360 lbs. avoirdupois; the head alone, with the tusks, weighs 11 poods and a half (414 lbs. avoirdupois.) The principal object of my care was to separate the bones, to arrange them, and put them up safely, which was done with particular attention. I had the satisfaction to find the other scapula, which had remained not far off. I next detached the skin of the side on which the animal had lain, which was well preserved. This skin was of such extraordinary weight that ten persons found great difficulty in transporting it to the shore. After this I dug the ground in different places to ascertain whether any of its bones were buried, but principally to collect all the hairs which the white bears had trod into the ground while devouring

the flesh. Although this was difficult from the want of proper instruments, I succeeded in collecting more than a pood (36 pounds) of hair. In a few days the work was completed, and I found myself in possession of a treasure which amply recompensed me for the fatigues and dangers of the journey, and the considerable expenses of the enterprise. The place where I found the mammoth is about 60 paces distant from the shore, and nearly 100 paces from the escarpment of the ice from which it had fallen. This escarpment occupies exactly the middle between the two points of the peninsula, and is three wersts long (two miles), and in the place where the mammoth was found this rock has a perpendicular elevation of 30 or 40 toises. Its substance is a clear pure ice; it inclines towards the sea; its top is covered with a layer of moss and friable earth, half an archine (14 inches) in thickness. During the heat of the month of July, a part of this crust is melted, but the rest remains frozen. Curiosity induced me to ascend two other hills at some distance from the sea; they were of the same substance, and less covered with moss. In various places were seen enormous pieces of wood of all the kinds produced in Siberia; and also mammoths' horns (tusks) in great numbers appeared between the hollows of the rocks; they all were of astonishing freshness. How all these things could become collected there, is a question as curious as it is difficult to resolve. The inhabitants of the coast call this kind of wood *Adamschina*, and distinguish it from the floating pieces of wood which are brought down by the large rivers to the ocean, and collect in masses on the shores of the frozen sea. The latter are called *Noachina*. I have seen, when the ice melts, large lumps of earth detached from the hills mix with the water, and form thick muddy torrents which roll slowly towards the sea. This earth forms wedges which fill up the spaces between the blocks of ice. The escarpment of ice was 35 to 40 toises high; and, according to the report of the Tungusians, the animal was, when they first saw it, seven toises below the surface of the ice, &c. On arriving with the mammoth at Borchaya, our first care was to separate the remaining flesh and ligaments from the bones, which were then packed up. When I arrived at Jakutsk, I had the good fortune to repurchase the tusks, and from thence expedited the whole to St. Petersburg.' The skeleton is now in the Museum of the Academy, and the skin still remains attached to the head and feet. A part of the skin and some of the hair of this animal were sent by Mr. Adams to Sir Joseph Banks, who presented them to the Museum of the Royal College of Surgeons. The hair is entirely separated from the skin, excepting in one very small part, where it still remains attached. It consists of two sorts, common hair and bristles, and of each there are several varieties, differing in length and thickness. That remaining fixed on the skin is of the colour of the camel, an inch and a half long, very thick set, and curled

Mammoth found in Siberia. Reduced from the lithographic plate above mentioned.

* He had fallen sick from alarm, on first hearing of the discovery, as it was considered a bad omen.

† An error, as of 38 or 39 caudal vertebrae only 8 remained.

‡ This is doubted; a dried substance is visible.

in locks. It is interspersed with a few bristles about three inches long, of a dark reddish colour. Among the separate parcels of hair are some rather redder than the short hair just mentioned, about four inches long; and some bristles nearly black, much thicker than horse hair, and from 12 to 18 inches long. The skin when first brought to the Museum was offensive; it is now quite dry and hard, and where most compact is half an inch thick. Its colour is the dull black of the living elephants. (*On the Mammoth, or Fossil Elephant, found in the Ice at the Mouth of the river Lena, in Siberia, with a lithographic Plate of the Skeleton.* From the 5th vol. of the Memoirs of the Imperial Acad. of Sciences of St. Petersburg, London, 1819, 4to.)

Fischer indicates the following species of fossil elephants resting principally on the difference of form in the molar teeth. 1. *Elephas mammuticus* (*E. primigenius*, Blumenb.) 2. *Elephas panicus*. 3. *Elephas proboscides*. 4. *Elephas pygmaeus*. 5. *Elephas campylotes*. 6. *Elephas Kamenskii*. M. Nesti proposes a species under the name of *Elephas Meridionalis*, whose remains have been found in a freshwater formation in many places in Italy, and especially in the Val d'Arno. M. Nesti rests principally on the difference of the conformation of the cranium, and especially on an apophysis in form of a beak which terminates the lower jaw.

Dr. Harlan is of opinion that there are two species of fossil elephants peculiar to the United States.

Captain Cautley mentions the remains of elephants among those of mammalia found by him in the Sewalik mountains, at the southern foot of the Himalayas, between the Sutluj and the Ganges, partly lying on the slopes among the ruins of fallen cliffs, and partly in situ in the sandstone.

ELEPHANTA, a small island about seven miles in circumference, situated between the island of Bombay and the Maharatta shore, distant five miles from the latter and seven miles from the castle of Bombay. Its name among the natives is Gorapori; that by which it is known to Europeans was derived from the figure of an elephant cut out of the solid black rock on the acclivity of a hill about 250 yards from the landing-place, and which is a conspicuous object in approaching the island. This figure has been split in two, apparently by means of gunpowder, which injury is attributed to the religious zeal of the Portuguese invaders of Hindustan, which prompted them to destroy whatever they considered to be objects of pagan worship. In 1814 the head and neck of the elephant dropped off, and the figure is otherwise in such a state of decay as to threaten its speedy fall. At a short distance from the elephant stands the figure of a horse, also cut out of the rock. Mr. Dalrymple, in a description inserted in the *Archæologia* (vol. vii., page 324), says that this figure is still called the horse of Alexander, in memory of Alexander the Great, to whom has been attributed, without the least foundation, the excavation to which this island owes its celebrity. The construction of this cave has also been attributed, with no greater probability, to Semiramis; its origin is, in fact, involved in the greatest obscurity, although the rapidity with which its decay is seen to go forward seems to preclude the idea of its being the work of any very remote age. The entrance to this cave, or temple, occurs about half way up the steep ascent of the mountain or rock out of which it is excavated.

The length of this temple, measuring from the entrance, which is on the north side, is 130 feet, and its breadth 123 feet; the floor not being level the height varies from 15 feet to 17½ feet. The roof was supported by 26 pillars and 8 pilasters, disposed in four rows; but several of the pillars are broken. Each column stands upon a square pedestal, and is fluted, but instead of being cylindrical is gradually enlarged towards the middle. Above the tops of the columns a kind of ridge has been cut to resemble a beam about 12 inches square, and this is richly carved. Along the sides of the temple are cut between forty and fifty colossal figures varying in height from 12 to 15 feet; none of them are entirely detached from the wall. Some of these figures have on their heads a kind of helmet; others wear crowns with rich devices, and others again are without any other covering than curled or flowing hair. Some of them have four and others six hands, holding 'aceptres, shields, symbols of justice, ensigns of religion, weapons of war, and trophies of peace. On the south side, facing the main entrance, is an enormous bust with three faces, representing the triple deity, Brahma, Vishnu, and Siva.

Brahma, the creator, occupies the centre position. This face measures 5 feet in length; the width from the ear to the middle of the nose is 3 feet 4 inches; the breadth of the whole figure is near 20 feet. On the right is the preserver, Vishnu; and Siva, the destroyer, is on the left, having in his hand a cobra capella, or hooded snake, and on his cap a human skull. To the left of this bust, amid a group of uncouth figures, is one, a female figure, to which Niebuhr has given the name of Amazon, from the fact of its being without the right breast. This figure has four arms. The right fore-arm rests upon the head of a bull; the left fore-arm hangs down, and once contained something which is now mutilated and undistinguishable. The hand of the hinder right arm grasps a cobra capella, and that of the hinder left arm holds a shield. At the west side of the temple is a recess, 20 feet square, having in the centre an altar, upon which are placed symbols of a worship offensive to European notions of delicacy. The entrance to this recess is guarded by eight naked figures, each 13½ feet high, sculptured in a manner which shows that the people by whom they were executed must have made considerable progress in the statuary's art.

The cave is not at present used as a temple, nor has it any establishment of priests connected with it, although it is frequently visited by devotees for the purpose of offering prayers and oblations.

(Captain Hamilton's *Account of India*, 1744; Maurice's *Indian Antiquities*; Niebuhr's *Voyage en Arabie*; *Archæologia*, vol. vii.; *Asiatic Researches*, vol. i.)

ELEPHANTIASIS (ἑλεφαντίασις and ἑλεφαντίασις), elephant and elephant disease, so called partly on account of some supposed resemblance of the diseased skin to that of the elephant, but principally from the formidable nature of the malady. It is disgusting to the sight, says Aretæus, and in all respects terrible, like the beast of similar name.

The term is now commonly applied to two different diseases; first to a peculiar disease of the skin, one of the most formidable of the dreadful cutaneous affections which occur in hot climates, and more particularly where agriculture and the arts of civilization are imperfectly advanced; and secondly to a peculiar disease of the leg, which becoming enormously tumid, is conceived to bear some resemblance to the leg of an elephant.

The first distemper, elephantiasis properly so called, is a tubercular disease of the skin. The tubercles present a shining appearance; they are of different sizes, and are of a dusky red or livid colour on the face, ears, and extremities. The tubercles are accompanied with a thickened and rugous state of the skin, a diminution or total loss of its sensibility, and a falling off of all the hair excepting that of the scalp.

The disease is wholly unknown in this country. It is described as slow in its progress, sometimes continuing several years without materially deranging the functions, but gradually producing an extraordinary degree of deformity. The following is the description commonly given of this formidable malady; but there is reason to believe that the picture is much exaggerated.

The alæ of the nose become swelled and scabrous; the nostrils are dilated; the lips are tumid; the external ears, particularly the lobes, are enlarged and thickened, and beset with tubercles; the skin of the forehead and cheeks grows thick and tumid, and forms large and prominent rugæ, especially over the eyes; the hair of the eye-brows, the beard, the pubes, axillæ, &c., falls off; the voice becomes hoarse and obscure; and the sensibility of the parts affected is obtuse or totally abolished, so that pinching or puncturing them gives no uneasiness. This disfiguration of the countenance suggested the idea of the features of a satyr or a wild beast; whence the disease was by some called *Satyriasis*, and partly also on account of the excessive libidinous disposition said to be connected with it; and by others *Leontiasis*, from the laxity and wrinkles of the skin of the forehead, which resembles the prominent and flexible front of the lion.

As the malady proceeds, the tubercles begin to crack, and at length to ulcerate; ulcerations also appear in the throat and in the nose, which sometimes destroy the palate and the cartilaginous septum; the nose falls; and the breath is intolerably offensive; the thickened and tuberculated skin of the extremities becomes divided by fissures, and ulcerates, or is corroded under dry sordid scabs, so that the fingers and toes gangrene and separate joint after joint

The large misshapen leg, which is also often termed elephantiasis, arises from a repeated effusion and collection of a lymphatic and gelatinous matter in the cellular membrane under the skin, in consequence of inflammation of the lymphatic glands and vessels. The skin itself is much thickened in the protracted stages of the disease, and its vessels become greatly enlarged; its surface grows dark, rough, and sometimes scaly. As the effusion first takes place after a febrile paroxysm, in which the inguinal glands of the side about to be affected are inflamed, and the limb is subsequently augmented in bulk by a repetition of those attacks, Dr. Hendy termed the malady the glandular disease of Barbadoes, in which island it is endemial. In England it is often called the Barbadoes leg. Except when these paroxysms occur, the functions and constitution of the patients are not mainly injured, and they often live many years, incommoded only by carrying about 'such a troublesome load of leg.'

In this country the disease is only seen in its inveterate stage, after repeated attacks of the fever and effusion have completely altered the organization of the integuments of the limb, and rendered it altogether incurable. In this state the swelling is hard and firm, does not pit on pressure, and is entirely free from pain. The skin is thickened and much hardened; its blood vessels are enlarged, particularly the external veins, and the lymphatics distended; and the cellular substance is flaccid and sometimes thickened, and its cells much loaded with a gelatinous fluid. The muscles, tendons, ligaments, and bones are generally in a sound state.

In this advanced stage the disease is altogether irremediable. Little success indeed seems to have attended the practice employed in the earlier stages, which has chiefly been directed to alleviate the febrile paroxysms by laxatives and diaphoretics, and subsequently to strengthen the system by cinchona. Local bleeding has not been employed; but after the fever and inflammation have subsided, the practice of binding the limb in a strong bandage is strongly recommended as the best means of exciting absorption, and of reducing the swelling. (Dr. Bateman's *Practical Synopsis of Cutaneous Diseases*.)

ELEPHANTINE. [EGYPT.]

ELETTARIA, a genus established by the late Dr. Maton of the plant yielding the lesser cardamoms. The name is that (elettari) under which it was first figured by Rheede, *Hort. Mal.* xi. t. 4, 5, and is softened into *elachee* (Sanskrit *ela*), the common appellation of this substance over all India. The genus belongs to the natural family of Scitamineæ, or Zingiberaceæ of some authors; besides this it includes three other species, of which one *E. cardamomum* medium, is a native of the hilly countries in the vicinity of Silhet. Dr. Roxburgh concludes, from the form of the capsule and its acrid, aromatic taste, that it is the plant which produces the Cardamomum medium of the writers on materia medica. The whole of the species, differing chiefly in their radical inflorescence, are however by Dr. Roxburgh and some other botanists, referred to the genus *Alpinia*.

Elettaria Cardamomum is a native of the mountainous districts of the coast of Malabar, especially above Calicut, in the Wynad district, between 11° and 12° of N. lat. where the best are produced. It is therefore well placed; for cardamoms formed a portion of the early commerce, which subsisted between this part of India and Arabia, whence they must have been made known to the Greeks, as they are described by Dioscorides and mentioned as early as the time of Hippocrates.

The cardamom plant delights in moist and shady places on the declivities of the hills. It is cultivated from partings of the root in the district of Soonda Balaghat, but the fruit is very inferior; but the best grows in a wild state, at least where no other measures are adopted, than clearing away the weeds from under the largest trees, which are felled close to the roots. The earth being loosened by the force of the fallen tree, young cardamom plants shoot forth in a month's time, and are sheltered by the shade of the branches. The tree-like herbaceous plants attain a height of from 9 to 12 feet. The root is as tortuous and tuberous as that of the ginger, and the leaves, with long sheathing footstalks, are from one to two feet in length, placed in two rows, and lanceolate in shape, like those of the Indian shot (*Canna indica*) common in English gardens. The scapes, or flower- and fruit-bearing stalks, make their appearance in

Februray of the 4th year, from the base of the stems, are three to four in number, and from one to two feet long, lax, and resting on the ground. The fruit is ripe in November, and requires nothing but drying in the sun to be fit for commerce.

Species of *Amomum*, q. v., yield the other kinds of cardamom.

ELEVATION, ANGLE OF ELEVATION. [ALTITUDE.]

ELEVATION (Architecture). [DESIGN, ARCHITECTURAL.]

ELEUSIS, a celebrated town of Attica, on the borders of Megaris. In very antient times it is said to have been an independent state of some importance, and carried on a war with Athens, by the result of which it became subject to that city. (Thucyd. ii., 15.) Eleusis owed its celebrity in the historical age to its being the principal seat of the mystical worship of Demeter, who, in search of her daughter, was said to have rested by the well Callichorus, at Eleusis, and to have taught Triptolemus the use of corn on the Rharian plain, near the city. This worship subsisted at Eleusis from the earliest period of history to the time of Alaric. Eleusis stood near the northern shore of the Gulf of Salamis. Its port was small and circular, and formed by two piers running out into the sea. Traces of a theatre have been found on a hill about half a mile from the sea. The temple of Demeter was commenced by Ictinus, in the administration of Pericles, and finished by Philo under the auspices of Demetrius Phalereus. It was originally a Doric building in antis, but was afterwards changed into a decastyle temple, with fluted columns. The upper part of an admirably executed colossal statue of Ceres, or Proserpine, brought from Eleusis by Dr. E. D. Clarke, is now in the vestibule of the public library at Cambridge. A modern village on the site is called Lefaina.

Coin of Eleusis.

British Museum. Actual Size. Copper. Weight, 59 grains.

ELEUSINIA, the great mystic festival of Demeter celebrated at Eleusis in the month Boëdromion. The lesser mysteries were celebrated in Elaphebolion at Agræ, on the Ilissus, and were a sort of preparation for the Eleusinia. The great festival began on the 15th Boëdromion, and lasted nine days. The first day was called the assembling (*ἀγυρμός*); on it all who had been initiated in Elaphebolion were invited to complete their sacred duty. The second day was named *ἀλάδε μύσται*, 'to the sea ye initiated!' from the words of the proclamation by which they were admonished to purify themselves. This purification took place in the *petrol*, two streamlets of salt water running into the gulf of Salamis, and which separated the territory of Eleusis from the rest of Attica. The third day was called *εἰς λήχην μύσται*, from some ceremonies imitative of the marriage of Proserpine, which took place on that day. What was the name or employment of the fourth day is unknown. The fifth was called the 'day of the torches,' *λαμπάδων ἡμέρα*, on account of a lampadephoría, or torch-procession, in which the initiated marched two and two round the temple. The initiation took place on the sixth and seventh days of the feast. The sixth day, which was called Iacchus, was the chief day of the Eleusinia. On this day the statue of Iacchus was carried in procession from the Cerameicus to Eleusis, and back again on the following day, which was named the return of the fully-initiated (*νοστούσιν οἱ ἐκέρται*). The seventh day was called Epidauria, in honour of Æsculapius who did not arrive from Epidaurus to be initiated until after the return of the Epoptæ. The ninth day was called *πληροχόη*. The ceremony of this day consisted in the symbolic overturning of two vessels filled with wine. Those initiated at the lesser mysteries were called *μύσται*, from *μύω* 'to close up,' because they were bound to strict silence; those who had passed through the Eleusinian ceremonies were called *ἐκέρται* or *ἐκέρπαι*, 'contemplators,' because they had been admitted to see the sacred objects; they were also hailed as happy and fortunate (*εὐδαίμονες, δαίμον*). The initiation consisted in a set of rites not very different, it is

believed, from the free-masonry of modern Europe, though the effects were far from the same, and the initiated were not supposed to be bound to one another by any particular tie. Every Athenian was obliged to pass through these ceremonies once in the course of his life. Bastards, slaves, and prostitutes, as well as strangers, and in later time Christians and Epicureans, were excluded from the Eleusinia. To reveal any of the mysteries, or to apply to private purposes any of the hallowed solemnities, was considered a capital crime. The priests at Eleusis belonged to the house of the Eumolpidae. The chief priest was called the Hierophant, the second in rank the Torch-bearer (*δαδούχος*), the third the Sacred Herald (*λεπορίτης*), and the fourth the Altar-priest (*ἀνὰ βωμῶν*). The other two festivals of Demeter, the Demetria and the Thesmophoria, must be distinguished from the Eleusinia. (Jul. Poll. i., § 37.)

ELGINSHIRE, formerly and by some still called MORAYSHIRE, a small county of Scotland lying between 57° and 58° N. lat., and between 3° and 4° W. long. It is bounded on the north by the Moray Frith (*Æstuarium Varar* of Ptolemy); on the south by Inverness-shire and Banffshire; on the east by Banffshire; and on the west by Nairnshire and Inverness-shire. A portion of Inverness-shire intersects and divides Elginshire into two separate parts to the north and south. The north part approaches to a circular figure, in diameter nearly 25 miles. The south part has about half this extent of area, and a very irregular outline. The line of sea-coast measures about 35 miles, and presents in some parts precipitous rocks, in others a beach of level sands. The low country forms a plain varying from five to twelve miles in width from the sea-shore to the mountainous district, and extending from the river Spey to the western boundary. It is intersected by small ridges running nearly parallel with the line of coast. On the southern course of the Spey are some considerable plains. The rest of the country, including the distinct southern part, is hilly, and the cultivated land lies chiefly on the banks of the streams in the valleys. The number of entire parishes is fifteen; of eight others, five partially belong to Banffshire, three partially to Inverness, and one partially to Nairn. The soil of the eastern part of the large northern plain is principally sandy, with small fields of clay and peat. The middle and western parts are chiefly clay and loam. The arable and pasture lands of the mountainous district are for the most part sand and sandy loam. Considerable tracts of peat moss occur in the south-east part, and patches of it here and there throughout the country. In the Agricultural Survey, published in 1811, the proportion of waste land is stated to be about three times the amount of that in cultivation, but since that time some extension of and improvements in agriculture have been made, though a great deal yet remains to be done.

The rivers are the Spey, the Lossie, and the Findhorn, which flow in a north-east and nearly parallel course to the sea. The Spey, one of the most productive fishing rivers in Scotland, has its source in the south west part of Inverness-shire, and forms a great portion of the boundary line between Elgin and Banff. In the upper part of its course its branches extend 15 miles on each side, and it drains about 800,000 acres. It is not navigable except for floating timber-rafts from the large forests of Strathspey; but its salmon fishery is of great importance and rents for more than 8000*l.* a year. Since 1815 the depth of water to the extent of two miles out in the Speymouth Bay has diminished six feet, in consequence of the deposit of gravel carried down by the stream, the velocity of which is four or five miles an hour. This river is said to discharge into the sea a greater quantity of water than the Thames. The devastation occasioned by its great overflows in 1829 is described by Sir T. D. Lauder in the work on the Great Floods in Moray.

The Findhorn rises also in Inverness-shire, and passes through Elginshire near the western boundary. Fir timber from the extensive forests on its banks is floated down in separate logs. The entrance from the sea to the large estuary at its mouth is rendered difficult by a bar of sand, though the port and quay at the village of Findhorn are commodious for small vessels. The salmon fishery is valuable, but inferior to that of the Spey.

The Lossie is formed by the confluence of numerous streams in the centre of the shire; it passes to the north of the town of Elgin and falls into the sea on the eastern side of Loch Spynie. In a course of twenty miles it turns

numerous corn-mills and some manufacturing machinery near Elgin. There was formerly a salmon fishery on this river, but at present the number of fish which enter is too small to offer any encouragement to the fishers. There is a port for small shipping at the Lossiemouth, five miles north-east of Elgin. Large embankments of earth have been raised at great expense along each side of this river through the low plains between Elgin and the sea, in order to prevent a recurrence of the calamitous inundation which happened in 1829, of which a very interesting description is given in Sir Thomas Dick Lauder's 'Account of the Great Floods in Moray,' a work containing much valuable information respecting this county.

Near Lossiemouth is the large Loch Spynie, the drainage of which has been imperfectly made at an expense of 10,800*l.*; but the expectation of finding its bed suitable for cultivation has been disappointed. The drainage of two or three small lakes between Elgin and Alves has also been proposed. The south portion of the county contains several lakes surrounded with picturesque mountain scenery. That of Glenmore is circular, and two miles in diameter; and Loughnadurb, in the south-west extremity, is four miles in length. Chalybeate springs are found in all parts of the county, but none are much distinguished for medicinal qualities; and it is remarked as a curious fact that the old holy wells are of pure water exempt from any mineral tinge.

The principal roads are, one which intersects the northern part of the county from Fochabers on the east to Burg Head on the north and Forres on the west, passing through the town of Elgin; one from Elgin to Craig-Elachie bridge, on the Spey; and two, one on the east from Fochabers, the other on the west from Forres, which communicate with the south portion of the county. A large proportion of Elginshire is covered with forests and plantations, chiefly of Scotch fir and larch. Many thousands of acres which, fifty years ago, were naked moor, are now clothed with various kinds of firs, interspersed with oaks, ash, and beeches. The aspect of the northern low country, although generally fertile and well-cultivated, is dull, flat, and unvaried; but in the southern highlands, especially in the parish of Knockando, on the banks of the Spey, the scenery is often highly picturesque and romantic; having mountains covered with broom and heather, richly wooded slopes, deep and gloomy glens, with lofty rocks, torrents, and waterfalls, and mossy banks abounding in many varieties of beautiful flowers, overhung by the honeysuckle and the wild rose. This woody district is a sheltered resort of all the ordinary kinds of singing and game birds; of the roe-deer, fox, hare, rabbit, badger, &c. The summits of Cairngorm (blue mountains), in the southern extremity of the south division of the county, are seldom free from snow: the highest point is 4080 feet above the sea. James Roy's Cairn, in the south part of the north division, is considered the highest elevation in the county, and commands, in clear weather, a very extensive prospect.

Geology and Mineralogy.—The rocks in the south consist of granite, felspar, mica, sandstone, slate, gravel, and rock crystal. The banks of the Spey towards its mouth exhibit secondary rocks of red sandstone which dip into the basin of the Moray Frith, and extend westward throughout the northern plain of the county. The upper beds are soft, and are cut into ravines by the rivulets. The rocks are covered with a great depth of sand, gravel, and other alluvial matter, so that the soil often on the same farm varies from strong clay to rich loam and light and gravelly sand. Numerous large granitic boulder stones, which are used for building, are found far from their parent rocks. (*New Statistical Account of Scotland*, part viii. p. 83.) Many large and inexhaustible quarries of freestone are worked, especially near the coast. Those on Quarrywood Hill, near Elgin, have supplied the stone for the handsome public edifices in that town. It is there found in large blocks adapted for pillars, millstones, and pavements; the colour is yellow and white, and it takes a fine polish. One or two quarries of slate supply the county with roofing materials. Neither coal nor any metallic ores of importance are found; but peat occurs in various places. The beds of peat, which are generally from four to twelve feet in thickness, lie on gravelly sand or clay, and are covered at the surface with a mossy turf about ten inches deep. This peat is in general use for fuel, but when burning, it often emits a disagreeable smell of sulphur. A similar smell rises from the surface of the fields of peat when

heated by the sun. It changes the colour of silver to a leaden hue, and corrodes utensils of copper or iron. Numerous trunks of oak and fir trees, many of them large, intermixed with boughs of birch and alder and hazel nuts, are found deeply imbedded in the peat mosses. These are considered by the old bishop of Ross, in his description of Moray, to have been thus deposited by the Deluge; but closer observation shows this fossil timber to have fallen by the action of fire, and in some instances by the axe; and geologists, judging from the quantities of marine shells and other fossil exuviae discovered beneath the surface, believe the northern plain to have been once the bed of the sea.

Antiquities, Buildings, Bridges.—In the parish of St. Andrew's Lhanbryd is a small Druidical structure, supposed to have been standing nearly 3000 years; another has been broken up to macadamize a piece of road. The ruins of the castle of the lords of Duffus stand on the margin of Loch Spynie; the tumuli or cairns, the supposed tombs of ancient warriors, which are remaining on the heights along the shore, and the ruins of the Roman, or, according to others, the Danish, fortifications at Burghead; all deserve the attention of the antiquarian. In the parish of Urquhart are the remains of Druidical *lithoi*, forming a circular temple. The magnificent priory of Pluscarden, near Elgin, is sufficiently entire to show the plan of the structure and its numerous offices. The surrounding wall encloses nearly twelve acres. The church at Birnie is of great antiquity, and contains vestiges of Druidical and Scandinavian art. It was one of the earliest consecrated places of the Roman hierarchy in the north of Scotland. The curious old bell is described by Sir Thomas Dick Lauder. The ruins of the ancient palace of the bishops of Moray, on the south bank of Loch Spynie, are those of a magnificent castle, whose lofty halls and deep vaults were fortified by towers, gates, and ditches. The fortified castle on the lonely lake called Loughnadurb, in the mountain wilds of the south-west extremity, is a romantic ruin of a place besieged by King Edward I. in his war with Bruce. Many more ruins and fragments of feudal castles and strongholds and monasteries are remaining, some of them famous in the legends of chivalry; also several of the artificial hills of sand, on which the *blaze*, or signal fires, antiently flamed to summon the warriors to battle. In barrows, cairns, and caves, and on the site of camps, have been found skeletons, stone coffins, and Danish and Lochaber dirks and battle-axes made of copper. Near the town of Forres is 'King Sueno's Stone,' a large column or obelisk with many curiously-sculptured historical figures, representing the expulsion of the Danes from Scotland, or, as others think, the murder of Macduff; and a wooded hill, called the Knock of Alves, near the town of that name, is famous in tradition as being the place where the usurper Macbeth consulted 'the Weird Sisters,' when, according to Shakespeare, he inquired—

'How far's it called to Forres? What are these,
So wither'd and so wild in their attire,
That look not like the inhabitants of the earth,
And yet are on it?'

The foundations of the castle of Forres, in which Macduff was murdered, have been removed, and the green mound on which it stood has been levelled for the erection of a modern mansion. On a mount near the obelisk is an octagonal tower, raised to the memory of Nelson. Its diameter is 24 ft. and the height 70 ft., and the top is finished with a battlement, surmounted with a mast, ropes, and flag.

One of the finest and most useful of the public structures in this county is the bridge erected over the Spey, in 1801, from Fochabers to Elgin. The strength required to resist the impetuous force of the river when swollen with mountain-torrents is well provided for by massive piers deeply based on the rock and supporting four circular arches, of which the two smallest have each a span of 75 ft., and the two in the middle a span each of 95 ft.: that is, 19 ft. wider than the central arch of Westminster Bridge. The cost was 15,000*l*. The Spey is also crossed by an elegant bridge of cast iron at Craig Elachie, a very picturesque point of its course, in the eastern extremity of the parish of Knockando. The banks of the river are here formed by lofty rocks, and the centre of the span of the arch is more than 150 ft. above the water. This bridge was constructed in 1814 at a cost of about 10,000*l*. The following are some of the principal mansions of the nobility and gentry.—Darnway Castle, near Forres, is a magnificent

palace, containing a spacious old hall of the fourteenth century, capable of entertaining 1000 men. The building is beautifully encompassed by several thousand acres of antient forest and plantations. Brodie House is an elegant mansion in a very extensive park. The Grange, near Alves, and Burgie Castle adjoining it, are large and elegant edifices. Innes House, in the parish of Urquhart, was the noble residence of the lairds of Innes. The spacious mansions of West and East Elchies are in the old manorial and castellated style. Knockando House is beautifully situated near the river Spey. Many more might be enumerated, this county being particularly rich in manorial mansions and seats of the opulent classes.

Agriculture, Climate.—This county was antiently reputed 'the Granary of Scotland.' In the great famine at the end of the sixteenth century, oatmeal was procured from Elgin for the districts south of the Grampian Hills, and at present it furnishes some of the best samples of wheat in the London market. (Mac Culloch's *Statistics of the British Empire*.) The soil of the lowland district about the latitude of Elgin is remarkably fertile, and especially adapted for the growth of wheat, oats, and barley, of which it produces many heavy and luxurious crops, a great portion of which is shipped at Speymouth, Burghead, Lossiemouth, and Findhorn, for the Scotch and English markets. The climate of this part of the country is noted for its general mildness, dryness, and salubrity, owing, it is thought, to the low level of the surface, which is little above that of the sea, and to the absorbent sandy nature of the soil. Instances occur of extraordinary longevity, and, as a winter residence for invalids, some physicians have considered it preferable to Devonshire. However, at the beginning of spring, a bleak easterly wind generally prevails for several weeks, blasting throughout the country the germinating corn and budding trees, and severely affecting sickly and delicate constitutions. (*Agricultural Survey*, 1811.) In the summer the wind is gentle from west-south-west, and in winter occasionally violent from west-north-west. The soil and climate of the southern highlands are less favourable for the cultivation of grain; and a great portion of the surface is still covered with native forests, or with unclosed commons of furze and broom, abounding in rabbits, which greatly damage the crops. Oats and barley were formerly the only kinds of grain produced; wheat, though now one of the staple articles of commerce, is of comparatively recent introduction, and still more recent is the cultivation of peas, beans, clover, grasses, turnips, and potatoes; yet the turnip husbandry is very extensively and successfully adopted, and potatoes are as common as in Ireland. No uniform course of cropping is pursued; yet, on each of the larger farms, a six-shift rotation is generally used, by which it is divided into one-sixth in green crop, one-third in grass or clover, and one-half in corn, but the succession of each crop is more dependent on individual opinion and convenience than on any principles of experimental science. The land is in the possession of a few large proprietors. The annual rent of the arable kind varies from 7*s*. to 40*s*. per acre, and leases are taken commonly for nineteen years. The average produce of an acre of wheat or oats, of very superior quality, is from three to four quarters. Several mills are established for the preparation of pot-barley. [BARLEY, p. 466.] Oats being the principal article of food consumed by the peasantry, they are given very sparingly to horses. All the bread used by the labouring classes is wholly of oatmeal made simply with water into flat cakes, and baked over a wood fire in a pan. Their breakfast invariably, and frequently their other meals, consists of various preparations of oatmeal. In the form of porridge it is flavoured with onions, butter, pepper, sugar, milk, beer, or whiskey, and for supper it receives an addition of shredded kail or turnips. The farinaceous solution obtained by steeping oat-bran is called *sourens*. It is thick and gelatinous, and slightly acidulated by fermentation. Among servants and farm labourers it is consumed in large quantities. This paste is also dried and preserved in lumps for the convenience of those who require a portable breakfast. Sheep and horses are reared, for the most part, only for domestic use. The cheviot breed of sheep has been extensively introduced to cross that of the old white-faced and the small brown-faced breeds of Moray. The breed of native cattle has been improved by importations from Skye, Aberdeen, and Argyle. Stock of this kind are bred for, and sold to,

the graziers of the southern counties. During the last thirty years numerous agricultural improvements have been attempted, and many with success, which, in part, is justly attributable to the premiums offered by the Farmers' Club at Elgin. New roads have been opened and some old ones made conveniently passable; large tracts of waste have been planted with trees; good horses and implements have been procured; many wretched farm-houses and offices have been rebuilt on superior plans; draining, over and under, has been adopted; inclosures have been made; and lime is much used for manuring, &c. The peasantry, who are naturally hardy and thrifty, have become in the same period considerably improved in knowledge, habits, manners, dress, and mode of living; still, it is truly asserted that Elgin, as to improvement, is greatly in the rear of many other counties of Scotland. Inclosures, for instance, are not general, and are made chiefly by dikes of loose stones: rent is yet partially paid in produce and labour, and such customs as night-wakes for the dead are still superstitiously observed. The Gaelic language is used among a few of the highlanders, but the peasantry in general speak a barbarous dialect of the English, of which a glossary, containing several hundred specimens, is given at the end of Mr. Leslie's 'Agricultural Survey.'

Education.—The people of this county, as in most parts of Scotland, highly appreciate the advantages of early instruction. A well-attended and well-conducted parochial school exists in every parish, and it is a rare occurrence to meet with a youth of either sex, however humble, who is not able at least to read and write. At several of these parochial establishments the masters, though their salaries seldom exceed 30*l.* a year, teach Latin, Greek, mathematics, geography, book-keeping; in short all the knowledge requisite either for entering upon a course of collegiate studies or commercial business. The more populous parishes have each one or more private schools, of which some are of superior character. Several Sunday-schools have been established, and a few small circulating libraries. This county, with the exception of the royal burghs of Elgin and Forres, shares in Mr. Dick's bequest. [BANFFSHIRE, p. 370.]

Commerce and Manufactures.—The chief articles exported are corn, timber, whiskey, and salmon. Of 204 vessels which in 1834 sailed from the Speymouth, 50 were laden with 18,000 quarters of oats and wheat, chiefly for Leith and London. Large quantities are also shipped at the ports of Findhorn, Burghhead, and Lossiemouth, whence trading vessels and steam-packets regularly sail for London. At the Speymouth since 1793, 150 vessels, several above 750 tons burden, have been built entirely of natural fir from the forests on the bank of this river. It is greatly superior to that which is planted, and for ships appears to be no less durable than oak, as they are insured at Lloyd's on similar terms, and some of the largest dimensions have been employed in the trade with China and India.

Though the great flood of 1829 greatly damaged the harbour at the mouth of the Spey, the sales of timber thence exported still amount to 10,000*l.* or 11,000*l.* per annum. In the last war, when foreign timber was excluded, the annual amount commonly exceeded 40,000*l.* About 300 rafts are annually floated down the Spey from the parish of Abernethy, a distance of forty miles; and 100 men are employed at saw-mills in cutting timber into planks.

From eight to twelve smacks are employed by the Salmon Fishery Company of the Spey, in conveying salmon to London. In 1834, seventy-two cargoes were shipped, each on an average containing 280 boxes, the weight of each box being 112 lbs., and its value 5*l.* The fishing commences on the 1st of February, and ends on the 14th of September. About eighty boats are employed in the herring fishery off the port of Burghhead. The salmon fishery on the river Findhorn is of less extent. At Linkwood, near Loch Spynie, the principal manufacture of whiskey is carried on in a spacious range of buildings erected for the business of malting, grinding, and distilling. The capacity of the stills is from 170 to 400 gallons each. The annual quantity of barley manufactured is 1200 quarters; and the annual quantity of liquor produced about 20,000 gallons. It is of great strength and purity, and is almost wholly consumed in this and the adjoining county of Nairn. Two other fine distilleries are in the highland parish of Knockando. From 70 to 100 cargoes of coals, Scotch and English, are annually imported for limekilns, distilleries, and domestic fires.

Besides the county town of Elgin, there is but the town

of Forres which can be properly so designated: all other places in the county being merely villages, each with a population less than a thousand. That of Forres amounted, in 1831, to 3895. In the middle of the 10th century, under the reign of King Macduff, this town was a place of more importance than Elgin, from which it is distant twelve miles to the west. King James IV. of Scotland, in 1496, made it a royal burgh with separate jurisdiction. One street, extending about a mile from east to west, having the town-hall, church, and gaol in the centre, comprises the whole town. It is pleasantly and picturesquely situated on elevated ground, surrounded by verdant fields and wooded heights. The houses are neat and of modern construction, though some of an antient date present here and there their pointed gables. At the western extremity, half-encircled by a brook, is the green hill on which stood the castle of Macbeth, which, with the adjoining obelisk, and Nelson's monument, have already been noticed. The salmon fishery on the Findhorn gives employment to a few of the inhabitants; the rest belong chiefly to the agricultural class. The grammar-school maintains a good reputation, and there are several superior private academies. A well supplied market is held on Wednesdays, and several small fairs in the course of the year. Fochabers is a small modern-built market town, with a population of about 800, situated on the east bank of the Spey, about five miles from the mouth. The inhabitants are employed for the most part in manufacturing cotton, thread, and worsted. The site of the antient town was a mile to the north of its present position, and near the noble mansion of the duke of Gordon, of which the extensive park is only partly in the shire of Elgin. Burghhead is a pretty village, with neat accommodation for sea-bathers. Its port is frequented by numerous vessels of about 80 tons burden.

The population of the county in 1831 was 34,231. In conjunction with Nairnshire, it sends one member to parliament.

(*New Statistical Account of Scotland*, 1835; Leslie's *Agricultural Survey of Moray*, 1811; Dr. Lachlan Shaw's *History of Moray*, 1775.)

ELGIN, the county town of the shire of Elgin, is agreeably situated in the north lowland plain of corn-fields, on the road which connects, and nearly at an equal distance from, Forres on the west, and Fochabers on the east. The small river Lossie passes near, in a winding course on the western and northern sides, and is crossed at five different points by substantial stone bridges. The town consists of one main street, extending nearly a mile, and numerous narrow lanes which intersect the main street at right angles and contain houses of antient date and construction. Elgin at the end of the tenth century was an important place, with a royal fort. The earliest charter was granted by Alexander II. in 1234. Various grants were ratified by Charles I. in a charter issued in 1633; but none of the lands and privileges thus conferred have ever been possessed. At a remote æra the neighbourhood was adorned with ecclesiastical palaces and other extensive establishments of monks and friars. The civic arms represent St. Giles in sacerdotal attire with crozier and book, and the motto 'sic itur ad astra.' The most interesting and magnificent ruins in this county are those of the cathedral of Elgin, which was founded in 1244. In 1390 the original structure was destroyed by fire to gratify the revenge of 'The Wolf of Badenóch' against the bishop of Moray. It was immediately rebuilt on a model similar to that of the cathedral of Lichfield; but on a scale of much greater magnitude, and with far more elaborate ornaments. The regent Morton, in 1568, having stripped off the lead of the roof to procure money for the payment of his troops, this venerable specimen of architecture and sculpture was left to decay as a monument only of popish superstition. In 1711 the great central tower fell to the ground; but the two western turrets, the walls of the choir, and parts of the nave and transept are still standing. The loftiness of the fabric, the symmetry and unity of design, and the great profusion of laboured sculpture, grotesque and elegant, must excite the greatest admiration of the skill and perseverance of the artists. A college was attached to the cathedral, and included within its walls the house and gardens of the bishop, and those of 22 canons. Part of the wall, which had four gateways, and was 900 yards in circuit and four yards in height, yet remains, with the eastern gateway, formerly secured by an iron grate, a portcullis, and a watchman's lodge. On the

scuth side of the town are the ruins of a convent of Grey Friars, and on a hill at the west are the remains of an antient fort. The Elgin institution for the support of old age and the education of youth, is a handsome quadrangular building, at the eastern entrance, surmounted with a circular tower and a dome. The whole is constructed of beautiful freestone and ornamented with Doric columns and sculptured figures; and the interior is very conveniently laid out in school-rooms, eating-halls, dormitories, wards for the sick, a chapel, and various other offices. The building, playgrounds, and shrubbery cover an area of about three acres. The objects of this excellent charity are threefold: an almshouse for age and indigence; a school for the support and education of labourers' children, and a free-school solely for education. The inmates of the first class are 10 in number, of the second class 40, of the third class 230.

The new church in the centre of the town is one of the most elegant in the north of Scotland. It has a richly ornamented cupola, and a Doric portico. Grey's Hospital, at the western extremity, is a similar structure, with a Grecian portico and a central dome.

The sectarian places of public worship are numerous, and include an episcopal and a Catholic chapel. The schools within the town, endowed and private, are ten in number, and are generally well-conducted and efficient establishments. The Elgin Academy consists of three parochial schools of very superior character. The subjects taught are English reading, writing, grammar, and composition, arithmetic, geography, mathematics, French, Latin, and Greek. Courses of lectures on natural philosophy are occasionally delivered and illustrated by an experimental apparatus. The salaries of the teachers are each about 45*l*. per annum. A literary society for the purpose of procuring reviews and other periodical publications was established in 1818, and is still in prosperous existence; and also an extensive and valuable circulating library. There are many endowed charities, and various other religious and benevolent institutions. The Morayshire Farmer's Club was instituted in 1799. The members have subscribed the sum of 2250*l*., which is very judiciously appropriated to the improvement of agricultural science, and the collection of valuable books on every department of rural economy.

The following observation on the progress of improvement in Elgin is made in the *New Statistical Account of Scotland*, No. VIII., p. 27: 'Forty years ago there were no turnpike-roads leading to or from it; no stage-coaches, no gas lights, indeed no lighting, nor any side pavement to the streets, no hospital for the sick, no institution for the support of old age or the education of youth, no academy, no printing-press, and no newspaper.' All these desiderata are now possessed. Many new and more convenient houses have been built, and the progress of knowledge and comfort are very apparent; improvements however are still wanting in the efficiency of the police, in the supply of water by pipes, and in the removal from the heart of the town of that greatest of nuisances, the butchers' shambles. The population of the town in 1831 was 6130.

The burgh, in conjunction with Banff, Cullen, Inverary, and Kintore, sends one member to parliament.

ELGIN MARBLES, the designation given to a collection of antient sculpture, chiefly from the Acropolis of Athens, whence it was obtained by the Earl of Elgin (who had been the English ambassador to Turkey) between the years 1801 and 1812. This collection was purchased in pursuance of an act of the legislature, dated July 1st, 1816, for the sum of 35,000*l*., and is now deposited in the British Museum, in a room built especially for its reception.

The Parthenon, or Temple of Minerva, at Athens, whence the more important of these sculptures were obtained, was built during the administration of Pericles, about the year a.c. 448. It was constructed entirely of white marble from Mount Pentelicus; Callicrates and Ictinus were its architects; and its sculptures were produced partly by the hand and partly under the direction of Phidias.

The sculptures of the Parthenon in the Elgin collection are of three descriptions: Metopes; a portion of the Frieze of the cella; and Statues and their parts from the tympana or pediments.

The *Metopes* are fifteen in number, from the frieze of the peristyle on the southern side of the building, and bear reference to the contest between the Centaurs and the Lapithæ. The Centaurs were invited to the nuptials of Pirithous, king of the Lapithæ. During the marriage-feast

one of them, named Eurytion or Eurytus, elated by wine, offered violence to the person of Hippodamia, the bride. This outrageous act was immediately resented by Theseus, the friend of Pirithous, who, hurling a large vessel of wine at the head of the offender, brought him lifeless to the ground. A general engagement then ensued between the two parties; and the Centaurs not only sought to revenge the death of their companion Eurytus, but likewise attempted to carry off all the females who were guests at the nuptials. In this conflict, sustained on both sides with great fury, the Centaurs were finally vanquished. Such is the general outline of the mythic history represented in the *Metopes*. There is a sixteenth *Metope*, placed as No. 9; but it is a cast from one now in the Louvre gallery at Paris, the original of which, formerly belonging to the same series, was purchased for that collection in 1818, at the sale of the Count de Choiseul Gouffier, who before the French Revolution had been his king's ambassador in Turkey. The most interesting of the Elgin *Metopes* are Nos. 3, 11, 12, and 13. The three last mentioned are the finest in point of execution.

In an uninterrupted series of very low relief, placed round the cella, immediately below the ceiling of the porticoes of the Parthenon, was the *Frieze*, representing the solemn quinquennial procession, called the Panathenæa. The procession was represented as advancing in two parallel columns from west to east, one along the northern, the other along the southern side of the temple, and facing inwards after turning the two angles of the eastern front, and meeting towards its centre. Such was the frieze in its original position. Of its remains the Elgin collection possesses an extent, in slabs and fragments of marble, beginning at No. 17, of rather more than 249 ft., with a continuation of plaster casts of more than 76 ft. The greater part of the last are from portions of the sculpture which were not brought away, including a single slab, No. 23, which likewise belonged to the Count de Choiseul, now in the gallery of the Louvre; all forming a total of representation from the frieze of very near 326 ft. The bas-reliefs which at present compose the frieze in the Elgin Room, as far as they extend, are placed in the same order in which they were originally seen upon the Parthenon. Those on the principal front of the temple, namely, the east, are placed first, then follow those of the north, and lastly those of the west and south. They are arranged, in short, in the same manner in which the spectator viewed them as he approached the temple by the east and walked round it by the north, west, and south. But the spectator in the Elgin Room has to keep in mind that what formerly surrounded an exterior wall now lines the interior of a room.

The slabs 17 to 25, on the left of the entrance into the room, form the eastern frieze, the portion which occupied the east end of the temple. The figures on slab 17, the Virgins of Attica, head the procession from the southern frieze. The slab 19, the longest in the collection, stood immediately above the eastern entrance or door, and was the centre of the composition. In this slab, upon the left, a Priestess is represented, supposed to be the wife of the principal archon, or chief magistrate of Athens, in the act of receiving from two canephoræ, or bearers of the mystic baskets, the articles serving for the rites of sacrifice. To her left stands the Archon, in a drapery which reaches from the head to the feet, receiving from the hands of a youth a piece of cloth folded in a square form in numerous thicknesses, conjectured to be the peplos, or embroidered veil, the sail of the Panathenæic ship, and the principal ornament of the procession. On each side of the groups which represent the priestess and archon are various seated figures, among which Jupiter, Minerva, Triptolemus, Æsculapius, and Hygeia are the most conspicuous. Another train of females head the procession as it comes from the northern frieze; and here the sculptures which adorned the eastern front of the Parthenon terminate. This part of the frieze is greatly mutilated; but the explanation of it is aided by some drawings of the Parthenon made in 1674 by Jacques Carrey for the Marquis de Nointel, at a time when the sculptures were a little more perfect. These drawings are in the Royal Library at Paris, and copies of them are in the British Museum.

From the Nointel drawings it appears that the virgins who led the procession from the northern frieze, like those on the southern side, were followed by oxen led as victims; the foreigners settled in Athens were likewise represented,

with the players on the flute and lyre; and a troop of citizens closed the train of persons on foot. But all these have disappeared. Nineteen metopes and a large portion of the northern frieze fell when the Acropolis was besieged by the Venetians in 1687, and these subjects were amongst them. The slabs with which the remains of this frieze now open, No. 26 to 31, consist of chariots and charioteers in action, followed by a train of horsemen, Athenian citizens of the second class, who served in the cavalry. This, the most beautiful portion of the whole frieze, extends from No. 32 to 45; in the forms and actions of the horses, in the attitudes and costumes of the riders, and in the distribution of the figures, the sculptors seem to have reached the highest excellence of their art in the department of low relief. The bridles of the horses, in many of the slabs here referred to, were originally of gilded bronze, as appears by the holes left in the marble. Small pieces of the bronze itself were found by lord Elgin's formatori when taking moulds for him from this part of the frieze in its original position.

A single slab of the western frieze (but of exquisite beauty, No. 47), is all which the Museum possesses in marble. Plaster casts of fourteen slabs, which form the remainder of the western frieze, and which are still attached to the Temple, follow it, numbered 48 to 61. The western frieze extended over the front, and over the ante of the opisthodomos, or back chamber. The direction of the figures is the same as that on the north side, namely, from right to left. There is a peculiarity, too, in the frieze of the west end, which distinguishes it from that on the north and south sides of the temple. The subjects represented on the slabs of those two sides run one into another: that is, what was left imperfect in one slab is completed in the next; whereas in the west end the subjects are nearly complete on each piece of marble. The western frieze is likewise distinguished from those of the two sides of the temple by the comparatively few figures introduced into it.

We now come to that portion of the frieze which enriched the southern side of the Temple. The direction of the figures which form it is from left to right, and the numbers being in continuity from the western frieze, begin with the end of the procession, and extend from 62 to 90, round to the door of entrance into the Elgin room. In this, as in the western frieze, the spectator is supposed to have his face turned respectively to the north and south sides of the temple. A considerable number of the slabs, No. 62 to 77, represent horsemen; 78 to 82 consist of chariots; a collection of citizens and old men, corresponding with those of the northern frieze, but more numerous, preceded these; all, however, but a single fragment of four women (No. 83) have disappeared. In the slabs and fragments numbered 84 to 90 we see the sacrificial oxen, and upon the turn of the slab 90 is a figure, believed to be that of a magistrate looking round upon the procession which follows him. He is interposed between the end of the procession on the northern, and the beginning of that upon the eastern frieze.

Of the *Statues* and fragments from the tympana, or pediments, of the Parthenon, those toward the southern end of the Elgin Room, No. 91 to 98, are from the eastern pediment, the allegory of which represented the Birth of Minerva; these consist of the neck, the shoulders, and the arms of the figure of Hyperion rising from the sea, the Horses of Hyperion, the recumbent statue called Theseus, the goddesses, supposed to be Ceres and Proserpine, Iris with her veil inflated, Victory winged, the Fates, and the head of one of the Horses of Night. Those toward the northern end, No. 99 to 106, are from the western pediment, the allegory of which represented the Contest of Minerva and Neptune for the guardianship of Attica. With the exception of the first figure, the Ilissus, or River God, they are fragments, and were broken in an effort to remove them from the pediment after the siege of 1687. The greater part were recovered by lord Elgin by excavating below a house which had been built out of the ruins beneath the pediment, and which he had purchased. They consist of the torso of Cecrops, a fragment of the face and the chest of Minerva, the upper part of the torso of Neptune, a fragment of the Erichonian Serpent, the torso of Apteral Victory, and the lower part, or rather lap, of the figure of Latona. M. Quatremère de Quincy, in his *Monumens et Ouvrages d'Art Antique*, fol., Par., 1829, has given two plates of the pediments of the Parthenon in which all the figures are conjecturally restored.

Between, and separating the sculptures of the two pediments (No. 119), stands an imperfect statue of a youth of the size of life, of exquisite workmanship, supposed to have formed part of a group of Dædalus and Icarus: all that is certainly known of it, is, that it came in fragments, and from the Acropolis.

Casts from the temple of Theseus, and others from the bas-reliefs of the choragic monument of Lysicrates, are let into the eastern wall of the Elgin Room, the first above; the latter, at the northern end, below the Panathenaic frieze.

Of the remainder of the Elgin collection, it may be sufficient to name a few marbles of highest character, such as the colossal statue of Bacchus, from the choragic monument of Thrasylus, No. 111, and the Caryatide, from the Temple of Pandrosus, No. 128. Of architectural fragments, the pieces of frieze, from the treasury of Atreus, at Mycenæ, Nos. 177, 180, are the most antient; the capital and portion of a shaft, No. 112, give a notion of the magnitude of the columns of the Parthenon: and the capital and shaft from the temple of Eretheus, No. 126, present the most beautiful example of the Ionic order now known. The frieze of the temple of Eretheus is also one of the most valuable parts of the collection. Among the inscriptions, the Sigeian, written in the most antient Greek characters, and in the Boustrophedon manner, No. 107, claims the first place, followed by numerous others relating to the temples and buildings of Athens, some containing decrees or treaties, and a few inventories of the treasurers of the Parthenon: sepulchral inscriptions, urns, and stelæ abound in the collection; and among these the epitaph on the warriors who fell at Potidæa. (Thucyd. i. 63.) Votive bas-reliefs and offerings are also preserved in it in large number. The last article we shall name is a vessel of beautiful form, an urn of bronze; it was found in a tumulus situated on the road which leads from the Piræus to the Salaminian ferry and Eleusis, enclosed within the marble vase in which it now stands, and in it was a deposit of burnt bones, a lacrymatory of alabaster, and a sprig of myrtle in gold. It is supposed, from the last article, to have contained the ashes of some amatory poet.

The possession of the Elgin collection has established a national school of sculpture in our country, founded on the noblest models which human art has ever produced. A tribute of thanks is due to the nobleman to whose exertions the nation is indebted for it. If Lord Elgin had not removed them, the greater part would long since have been totally destroyed. In the last siege of Athens the Parthenon suffered additional damage.

ELIMINATION (Algebra), the process of reducing a number of equations, containing certain letters, to a smaller number, in which one or more of the letters shall not be found. The simplest case of elimination, and therefore the best adapted for the explanation of the term, is the following: if A be equal to B and B be equal to C , then A is equal to C . In the result, B is eliminated. Any operation of algebra may produce elimination. We give four instances in which such a result is obtained by addition, subtraction, multiplication, and division.

1. $x+y=12$, $x-y=8$; add, $2x=20$: y is eliminated.

2. $x+z=a$, $y+z=b$; subtract, $x-y=a-b$: z is eliminated.

3. $xy=a$, $\frac{2x}{3y}=b$; multiply, $\frac{2}{3}x^2=ab$: y is eliminated.

4. $xy=a$, $yz=b$; divide, $\frac{x}{z}=\frac{a}{b}$: y is eliminated.

The process of elimination, in the case of more complicated equations, becomes difficult and frequently impracticable. So much is this subject connected with the theory of equations, that a treatise on the first would be the largest portion of one on the second. The writings on this subject are scattered, but most works on algebra contain all that is absolutely necessary.

ELIOT, JOHN, often called the apostle of the Indians, was a native of England, born in 1604. He was educated at the university of Cambridge, and distinguished himself by proficiency in theology and in antient languages. Having seceded from the established church and embraced the ministry, he emigrated, like many other sufferers for conscience, to New England, and arrived at Boston in 1631. In the following year he married, and finally established

his abode at Roxbury, only a mile distant, as minister of a small congregation, composed chiefly of friends to whose religious service he had previously engaged himself, in case they should follow him across the Atlantic. In discharging the duties of his function he was zealous and efficient; and he was also earnest in spreading the blessings of education, by promoting the establishment of schools.

Having qualified himself, by learning their language, to become a preacher to the Indians, he commenced his missionary labours, October 28, 1646, before a large assembly collected by his invitation a few miles from Roxbury. Many, it is said, on this and on a subsequent occasion, seemed deeply touched; and it is evident, by the questions asked of the preacher, that the understandings, as well as the feelings of his audience, were roused. From the chiefs and priests, or conjurors, both of whom felt interested in maintaining ancient manners and superstitions, he usually met with opposition. Still no small number were converted; and these, abandoning their savage life, united in communities, to which lands were granted by the provincial government. In 1674 there were seven Indian praying-towns, containing near 500 persons, thus settled in Massachusetts, under the care of Eliot, besides a still greater number of converts, to whom land had not been thus assigned.

In travelling among the woods Eliot underwent great physical labour and hardship, and his mental labour was unremitting. He translated the Old and New Testament and several religious treatises into the Indian tongue which were printed for distribution chiefly at the expense of the Society for Propagating the Gospel; he composed an Indian grammar, and several treatises on subjects not directly religious, for the use of his converts and pupils, and also wrote a number of English works. Nevertheless he lived to the age of 86, and resigned his pastoral charge at Roxbury only two years before his death, which took place in 1690. A colleague had been appointed to assist him in 1650, in consequence of his necessary and frequent absence. His private character appears to have been very beautiful: he was not only disinterested and zealous, but benevolent, self-denying, and humble. Baxter says, in one of his letters, 'There was no man on earth whom I honoured above him.' (Cotton Mather, *Eccles. Hist.* b. iii., and *Life of John Elliot*. A modern *Life of John Elliot*, Edinburgh, 1828, 12mo., contains a good deal of information concerning the early attempts to convert the Indians.)

ELIOTT, GEORGE AUGUSTUS, was born at Stobbs in Scotland, in 1718. He studied the mathematics and other sciences at Edinburgh, and afterwards went to the University of Leyden, where he made great proficiency in classical literature, and was remarkable for the elegance and fluency with which he spoke the French and German languages. His knowledge of tactics was acquired in the celebrated school at La Fère. Having attained the rank of lieutenant-colonel, he accompanied George II. to Germany in 1743 as his Majesty's aid-de-camp, and was wounded in the battle of Dettingen. In the Seven Years' War, he fought in 1757 under the duke of Cumberland and Prince Ferdinand of Brunswick, and greatly distinguished himself at the head of his celebrated regiment of light-horse, raised and formed by himself, and called by his name. He was second in command in the expedition against the Havannah, the capture of which important place was highly honourable to the courage and perseverance of the British troops. After the peace he obtained the rank of lieutenant-general, and was appointed in 1775 to the government of Gibraltar. His memorable defence of that important fortress against the combined efforts of France and Spain was the last exploit of his life, the splendour of which so far eclipsed all that had preceded it, that he is most familiarly known as 'the gallant defender of Gibraltar.' After the peace he was created a peer by the title of Lord Heathfield. His lordship died at his favourite country seat Kalkofen, near Aix-la-Chapelle, whither he had gone for the benefit of the waters, July 6, 1790, in the seventy-third year of his age. [GIBRALTAR.]

ELIQUATION, an operation by means of which a more fusible substance is separated from another which is less fusible. It was formerly employed in the purification of silver, but is now little used.

ELIS or ELEA, a district of the Peloponnese, included between Achaia, Arcadia, Messenia, and the sea. Its coast line extended from the promontory Araxus to the P. C., No. 576.

mouth of the river Neda. Elis was originally divided into three parts, the northern, called hollow Elis (κοιλὴ Ἠλίας), the southern, Triphylia; and that in the middle, Pisatis. The earliest inhabitants of this territory were the Epeans and Pylians, who occupied the whole western coast of the Peloponnese from Araxus to Taygetus, the line of demarcation between these two tribes being on a line with Cape Ichthys. (Leake's *Morea*, ii., p. 182.) The chief towns of the Epeans were, in the time of Homer, Elis and Buprasium. (*Iliad*, B. 615, v. 630.) The Eleans were the first people in the Peloponnese who experienced the effects of the Dorian invasion, as their territory was the landing-place of the invaders, and was assigned by them to their ally the Ætolian Oxylyus, who claimed to be descended from Ætolus, the son of Endymion, a mythical king of the Epeans. Oxylyus and his new subjects conquered Pisa and Olympia, where the Olympian games were established about 1104 B.C., though they were not regularly celebrated till Coræbus gained the prize in 776 B.C. Those games exercised a most important influence on the subsequent destinies of Elis. The reverence with which the Greeks in general regarded this festival was extended to the country in which it took place, and the districts in the neighbourhood of the cities of Olympia and Elis were always free from the ravages of war so long as the games maintained their respectability. In the earlier periods the people of Pisa, which was in the immediate neighbourhood of Olympia, sometimes presided over the celebration of the games; but the wars between Messenia and Sparta enabled the Eleans to form a very intimate connexion with the Spartans, which ended in a tacit understanding that the intervening sea-coast should be divided between the two powers; the resistance of the Pisatæ only brought upon them the destruction of their city and the annexation of all Triphylia to Elis. This happened as early as the 48th Olympiad; and when Agis invaded Elis and occupied Olympia in the 95th Olympiad (400 B.C.), the power of the Pisatæ was so entirely overthrown that the Spartan king would not take the administration of the games from the Eleans, on the ground that those who claimed it were mere peasants and not fit for so great a charge. (Xen. *Hellenica*, iii., c. 2.) The harmony between Elis and Sparta was interrupted during the Peloponnesian war by the countenance which the Spartans afforded to the Lepreatæ, and the Eleans endeavoured to avenge this interference by excluding the Spartans from the Olympic games. After some years of misunderstanding, they were compelled to return to the Spartan alliance by the invasion of Agis, mentioned above. In 365 B.C. they were engaged in a war with the Arcadians, which deprived them of almost all their southern territories. The Eleans were firm supporters of the Ætolians during the social war, and never joined the Achæan league.

The city of Elis was originally called Ephyra, and, according to Colonel Leake, changed its name in the time of Oxylyus. (*Travels in the Morea*, i., p. 6.) The site of the ancient capital is now called Paleopoli. 'The ruins consist of several masses of Roman tile and mortar, with many wrought blocks of stone and fragments of sculpture scattered over a space of two or three miles in circumference.' (Leake, i., p. 5.) The soil was sandy, argillaceous, or a rich mould, and stone was found only in the mountains. (Leake, ii., p. 179.) The territory was very fertile and populous, and is said to have been the only one in Greece which produced flax. Its principal rivers are the Alpheius (Rofea) and the Peneius (Gastuni). Its chief mountain, Pholoe, was celebrated in ancient poetry and mythology. This name appears to have been given to all the high lands of Elis north of the river Alpheius. The principal sea-port of Elis was Cyllene, which Colonel Leake supposes to be the modern Chiarenza. (*Travels in the Morea*, ii., p. 174.)

Coin of Elis.

British Museum. Actual Size. Silver. Weight, 183½ grains.

VOL. IX.—3 A

ELIXIR OF VITRIOL. [SULPHURIC ACID.]

ELIZABETH, queen of England, the daughter of Henry VIII. by his second wife, Anne Boleyn, was born at Greenwich, 7th September, 1533. She was not three years old therefore when her mother was brought to the block, in May, 1536. Very soon after her birth it was declared, by the Act 25 Henry VIII., c. 22, that if Queen Anne should decessae without issue male, to be begotten of the body of the king, then the crown, on the death of the king, should go 'to the Lady Elizabeth, now princess, and to the heirs of her body lawfully begotten.' By this act therefore Henry's female issue by his present queen was placed in the order of succession before the male issue he might have by any future wife. By the 28 Henry VIII., c. 7, however, passed after his marriage with Jane Seymour, his two former marriages were declared to be unlawful and void, and both Elizabeth and her elder sister Mary were bastardized. But finally, by the 35 Henry VIII., c. 1, passed soon after his marriage with his last wife, Catharine Parr, it was declared that if Prince Edward should die without heirs, then the crown should remain first to the Lady Mary, and, failing her, to the Lady Elizabeth. This was the last legal settlement of the crown, by which her position was affected, made previous to Elizabeth's accession; unless indeed she might be considered to be excluded by implication by the Act 1 Mary, st. 2, c. 1, which legitimized her sister Mary, declared the validity of Henry's first marriage, and pronounced his divorce from Catherine of Aragon to be void.

In 1535 a negotiation was entered into for the marriage of Elizabeth to the duke of Angoulême, the third son of Francis I. of France; but it was broken off before any agreement was come to. In 1546 also Henry proposed to the Emperor Charles V., with the view of breaking off a match then contemplated between the emperor's son, the prince of Spain, afterwards Philip II., with a daughter of the French king, that Philip should marry the Princess Elizabeth; but neither alliance took place. Elizabeth's next suitor, though he does not seem to have formally declared his pretensions, was the protector Somerset's unfortunate brother, the Lord Seymour of Sudley. He is said to have made some advances to her even before his marriage with Queen Catharine Parr, although Elizabeth was then only in her fourteenth year. Catharine, who died a few months after her marriage (poisoned, as many supposed, by her husband), appears to have been made somewhat uncomfortable while she lived by the freedoms the princess continued to allow Sudley to take with her, which went beyond ordinary flirtation; the scandal of the day indeed was, that 'the Lady Elizabeth did bear some affection to the admiral.' After his wife's death he was accused of having renewed his designs upon her hand; and it was part of the charge on which he was attainted that he had plotted to seize the king's person and to force the princess to marry him; but his execution in the course of a few months stopped this and all his other ambitious schemes.

In 1550, in the reign of Edward VI., it was proposed that Elizabeth should be married to the eldest son of Christian III. of Denmark; but the negotiation seems to have been stopped by her refusal to consent to the match. She was a favourite with her brother, who used to call her his 'sweet sister Temperance'; but he was nevertheless prevailed upon by the artful and interested representations of Dudley to pass over her, as well as Mary, in the settlement of the crown which he made by will a short time before his death. [EDWARD VI.]

Camden gives the following account of the situation and employments of Elizabeth at this period of her life, in the introduction to his history of her reign. She was both, he says, 'in great grace and favour with King Edward, her brother, as likewise in singular esteem with the nobility and people; for she was of admirable beauty, and well deserving a crown, of a modest gravity, excellent wit, royal soul, happy memory, and indefatigably given to the study of learning; insomuch, as before she was seventeen years of age she understood well the Latin, French, and Italian tongues, and had an indifferent knowledge of the Greek. Neither did she neglect music, so far as it became a princess, being able to sing sweetly, and play handsomely on the lute. With Roger Ascham, who was her tutor, she read over Me-
lanchthon's Common-Places, all Tully, a great part of the histories of Titus Livius, certain select orations of Isocrates (whereof two she turned into Latin), Sophocles's Tragedies,

and the New Testament in Greek, by which means she both framed her tongue to a pure and elegant way of speaking, &c.' (*English Translation in Kennet's Collection.*)

It appears from what Ascham himself tells us in his 'Schoolmaster' that Elizabeth continued her Greek studies after she ascended the throne: 'after dinner' (at Windsor Castle, 10th December, 1563), he says, 'I went up to read with the Queen's Majesty: we read there together in the Greek tongue, as I well remember, that noble oration of Demosthenes against Æschines for his false dealing in his embassy to King Philip of Macedonia.'

On the death of Edward, Camden says that an attempt was made by Dudley to induce Elizabeth to resign her title to the crown for a sum of money, and certain lands to be settled on her: her reply was, 'that her elder sister, the Lady Mary, was first to be agreed withal; for as long as the said Lady Mary lived she, for her part, could challenge no right at all.' Burnett says that both she and Mary, having been allured by messages from Dudley, who no doubt wished to get them into his hands, were on their way to town, when the news of Edward's approaching end induced them to turn back. When Mary came to London after being proclaimed queen, the Lady Elizabeth went to meet her with 500 horse, according to Camden, others say with 2000. Fox, the martyrologist, relates that 'Queen Mary, when she was first queen, before she was crowned, would go no whither, but would have her by the hand, and send for her to dinner and supper.' At Mary's coronation, in October, 1553, according to Holinshed, as the queen rode through the city towards Westminster, the chariot in which she sat was followed by another 'having a covering of cloth of silver, all white, and six horses trapped with the like, wherein sate the Lady Elizabeth and the Lady Anne of Cleve.' Another account says that Elizabeth carried the crown on this occasion.

From this time Elizabeth, who had been brought up in their religion, became the hope of the Protestant party. Her position however was one of great difficulty. At first she refused to attend her sister to mass, endeavouring to soothe Mary by appealing to her compassion: after some time however she yielded an outward compliance. The Act passed by the parliament, which, although it did not mention her by name, bastardized her by implication, by annulling her father's divorce from his first wife, could not fail to give her deep offence. Availing herself of an order of Mary, assigning her a rank below what her birth entitled her to, as an excuse for wishing to retire from court, she obtained leave to go to her house at Ashridge, in Buckinghamshire, in the beginning of December. About the same time Mary is supposed to have been irritated against her sister by the preference shown for Elizabeth by her kinsman Edward Courtenay, whom, after releasing from the Tower, the queen had restored to his father's title of earl of Devon, and is said to have had some thoughts of marrying. It appears to have been part of the design of the rash and unfortunate attempt of Wyatt, in the beginning of the following year, to bring about a marriage between Elizabeth and Courtenay, who was one of those engaged in the revolt. This affair involved Elizabeth in the greatest danger. On the 8th of February, the day after the suppression of the insurrection, certain members of the council were sent with a party of 250 (other accounts say 600) horse to Ashridge, with orders to bring her to London 'quick or dead.' They arrived during the night, and although they found her sick in bed, they immediately forced their way into her chamber, and informed her that she must 'prepare against the morning, at nine of the clock, to go with them, declaring that they had brought with them the queen's litter for her.' She was so ill however that it was not till the fourth night that she reached Highgate. Here, says Fox, 'she being very sick, tarried that night and the next day; during which time of her abode there came many pursuivants and messengers from the court, but for what purpose I cannot tell.' When she entered London great multitudes of people came flocking about her litter, which she ordered to be opened to show herself. The city was at this time covered with gibbets; fifteen had been erected in different places, on which fifty-two persons were hanged; and it appears to have been the general belief that Elizabeth would suffer, as Lady Jane Grey had done a few days before. From the time of her arrival in town she was kept in close confinement in Whitehall. It appears that her case was twice debated in

council; and although no evidence had been obtained by all the exertions of the crown lawyers which went farther than to make it probable that Wyatt and Courtenay had solicited her to give her assent to their projects of revolt, her immediate destruction was strongly advised by some of the members. Elizabeth long afterwards used to declare that she fully expected death, and that she knew her sister thirsted for her blood. It was at last determined however that for the present she should only be committed to the Tower, although she seems herself still to have been left in doubt as to her fate. She was conveyed to her prison by water on the morning of the 11th of March, being Palm Sunday, orders being issued that, in the mean time, 'every one should keep the church and carry their palms.' In attempting to shoot the bridge the boat was nearly swamped. She at first refused to land at the stairs leading to the Traitor's Gate; but one of the lords with her told her she should have no choice; 'and because it did then rain,' continues Fox, 'he offered to her his cloak, which she (putting it back with her hand with a good dash) refused. So she coming out, having one foot upon the stair, said, "Here landeth as true a subject as ever landed at these stairs; and before thee, O God, I speak it, having none other friends but thee alone." ' She remained in close custody for about a month, after which she was allowed to walk in a small garden within the walls of the fortress. On the 19th of May she was removed, in charge of Sir Henry Bedingfield, to Woodstock. Here she was guarded with great strictness and severity by her new jailor. Camden says that at this time she received private letters both from Henry II. of France, inviting her to that country, and from Christian III. of Denmark (who had lately embraced the Protestant religion), soliciting her hand for his son Frederick. When these things came to the ears of her enemies, her life was again threatened: 'The Lady Elizabeth,' adds the historian, 'now guiding herself as a ship in blustering weather, both heard divine service after the Romish manner, and was frequently confessed; and at the pressing instances and menaces of Cardinal Pole, professed herself, for fear of death, a Roman Catholic. Yet did not Queen Mary believe her.' She remained at Woodstock till April, 1555, when she was, on the interposition, as it was made to appear, of King Philip, allowed to take up her residence at the royal palace of Hatfield, under the superintendence of a Catholic gentleman, Sir Thomas Pope, by whom she was treated with respect and kindness. Philip was anxious to have the credit of advising mild measures in regard to the princess, and perhaps he was really more disposed to treat her with indulgence than his wife. According to Camden, some of the Roman Catholic party wished to remove her to a distance from England, and to marry her to Emanuel Philibert, duke of Savoy; but Philip opposed this scheme, designing her for his eldest son Charles (the unfortunate Don Carlos). Elizabeth also was herself averse to a marriage with the Savoyard.

She continued to reside at Hatfield till the death of Mary, which took place on the 17th November, 1558. The news was communicated the same day, but not till after the lapse of some hours, to the House of Lords, which was sitting at the time. 'They were seized at first,' says Camden (or rather his translator), 'with a mighty grief and surprise, but soon wore off those impressions, and, with an handsome mixture of joy and sorrow, upon the loss of a deceased and the prospect of a succeeding princess, they betook themselves to public business, and, with one consent, agreed that the Lady Elizabeth should be declared the true and lawful heir of the kingdom according to the act of succession made 35 Henry VIII.' It is probable that Elizabeth's outward compliance in the matter of religion had considerable effect in producing this unanimity, for the majority of the lords were Catholics, and certainly both the bishops and many of the lay peers would have been strongly inclined to oppose her accession if they had expected that she would venture to disturb the established order of things. The members of the lower house were now called up, and informed of what had been done by Archbishop Heath, the chancellor. He concluded by saying that, 'since no doubt could or ought to be made of the Lady Elizabeth's right of succession, the House of Peers only wanted their consent to proclaim her queen. A vote to that effect immediately passed by acclamation; and, as soon as the houses rose, the proclamation took place. Elizabeth came to London on Wednesday, the 23rd: she was met by all the bishops in a body at Highgate, and

escorted by an immense multitude of people of all ranks to the metropolis, where she took up her lodgings at the residence of Lord North, in the Charter House. On the afternoon of Monday the 28th she made a progress through the city in a chariot to the royal palace of the Tower: here she continued till Monday the 5th of December, on the morning of which day she removed by water to Somerset House.

One of Elizabeth's earliest acts of royalty, by which, as Camden remarks, she gave proof of a prudence above her years, was what we should now call the appointment of her ministers. She retained of her privy council thirteen Catholics, who had been of that of her sister, including Heath, archbishop of York and lord chancellor; William Paulet, marquis of Winchester, the lord high treasurer; Edward, Lord Clinton, the lord high admiral; and William, Lord Howard of Effingham, the lord chamberlain. But with these she associated seven others of her own religion, the most eminent of whom was the celebrated William Cecil, afterwards Lord Burleigh, whom she appointed to the office of secretary of state, which he had already held under Edward VI. Soon after, Nicholas Bacon (the father of the great chancellor) was added to the number of the privy councillors, and made at first lord privy seal, and next year lord keeper of the great seal, on the resignation of Archbishop Heath. Cecil became lord high treasurer on the death of the marquis of Winchester in 1572, and continued to be Elizabeth's principal adviser till his death in 1598, when he was succeeded by Thomas Sackville, Lord Buckhurst (afterwards made earl of Dorset by James I.). Of the other persons who served as ministers during Elizabeth's long reign, by far the most worthy of note were Sir Francis Walsingham (who was principal secretary of state from 1573 till his death in 1590, and was all the time they were in office together the confidential friend and chief assistant of Cecil the premier, under whose patronage he had entered public life), and Burleigh's son, Robert Cecil (afterwards earl of Salisbury), who succeeded Walsingham as secretary of state, and held that office till the end of the reign. Among the other persons of ability that were employed in the course of the reign, in different capacities, may be mentioned Sir Nicholas Throckmorton; 'a man,' says Camden, 'of a large experience, piercing judgment, and singular prudence, who discharged several embassies with a great deal of diligence and much to his praise, yet could he not be master of much wealth, nor rise higher than to those small dignities (though glorious in title) of chief cupbearer of England and chamberlain of the Exchequer; and this because he acted in favour of Leicester against Cecil, whose greatness he envied; Sir Thomas Smith, the learned friend of Cheke, who had been one of the secretaries of state along with him under Edward VI., and held the same office again under Elizabeth for some years before his death, in 1577; and Sir Christopher Hatton, who was lord chancellor from 1587 till his death in 1591, and whom Camden, after having related his singular rise from being one of the band of gentlemen pensioners, to which he was appointed by the queen, who was taken with his handsome shape and elegant dancing at a court masque, characterizes as 'a great patron of learning and good sense, and one that managed that weighty part of lord chancellor with that equity and clearness of principle as to be able to satisfy his conscience and the world too.'

The affair to which Elizabeth first applied her attention on coming to the throne, and that in connexion with which all the transactions of her reign must be viewed, was the settlement of the national religion. The opinions of Cecil strongly concurred with her own in favour of the reformed doctrines, to which also undoubtedly the great mass of the people was attached. For a short time however she kept her intentions a secret from the majority of the council, taking her measures in concert only with Cecil and the few others who might be said to form her cabinet. She began by giving permission, by proclamation, to read part of the church service in English, but at the same time strictly prohibited the addition of any comments, and all preaching on controversial points. This however was enough to show the Catholic party what was coming; accordingly, at her coronation, on the 15th January, 1559, the bishops in general refused to assist, and it was with difficulty that one of them, Oglethorp of Carlisle, was prevailed upon to set the crown on her head. The principal alterations were reserved to be made by the parliament, which met on the 25th of this month. Of the acts which were passed, one

restored to the crown the jurisdiction established in the reign of Henry VIII. over the estate ecclesiastical and spiritual, and abolished all foreign powers repugnant to the same; and another restored the use of King Edward's book of common prayer, with certain alterations, that had been suggested by a royal commission over which Parker (afterwards archbishop of Canterbury) presided. In accordance with this last statute public worship began to be performed in English throughout the kingdom on Whitsunday, which fell on the 8th of May. By a third act the first fruits and tenths of benefices were restored to the crown, and by a fourth, her majesty was authorized, upon the avoidance of any archbishopric or bishopric, to take certain of the revenues into her own hands; and conveyances of the temporalities by the holder for a longer term than twenty-one years or three lives were made void. The effect of these laws was generally to restore the church to the state in which it was in the reign of Edward VI., the royal supremacy sufficing for such further necessary alterations as were not expressly provided for by statute. A strong opposition was made to the bills in the House of Lords by the bishops; and fourteen of them, being the whole number, with the exception of Anthony, bishop of Llandaff, who, Camden says, 'was the scourge of his diocese,' were now deprived for refusing to take the oath of supremacy. About 100 prebendaries, deans, archdeacons, and heads of colleges, were also ejected. The number of the inferior clergy however that held out was very small, amounting to no more than 80 rectors and other parochial ministers, out of between nine and ten thousand. On this subject it is only necessary farther to state that the frame of ecclesiastical polity now set up, being in all essential particulars the same that still subsists, was zealously and steadily maintained by Elizabeth and her ministers to the end of her reign. The church of England has good reason to look upon her and Cecil as the true planters and rearers of its authority. They had soon to defend it against the Puritans on the one hand, as well as against the Catholics on the other; and they yielded to the former as little as to the latter. The Puritans had been growing in the country ever since the dawn of the Reformation; but they first made their appearance in any considerable force in the parliament which met in 1570. At first their attempts were met on the part of the crown by evasive measures and slight checks; but, in 1587, on four members of the House of Commons presenting to the house a bill for establishing a new Directory of public worship, Elizabeth at once gave orders that they should be seized and sent to the Tower, where they were kept some time. The High Commission Court also, which was established by a clause in one of the acts for the settlement of religion passed in the first year of her reign, was, occasionally at least, prompted or permitted to exercise its authority in the punishment of what was called heresy, and in enforcing uniformity of worship with great strictness. The determination upon which the queen acted in these matters, as she expressed it in a letter to the archbishop of Canterbury, was, 'that no man should be suffered to decline either to the left or to the right hand, from the drawn line limited by authority, and by her laws and injunctions.' Besides the deprivation of their livings, which many of the clergy underwent for their refusal to comply with certain particulars of the established ritual, many other persons suffered imprisonment for violations of the statute of uniformity. It was against the Catholics however that the most severe measures were taken. By an act passed in 1585 (the 27 Eliz. c. 2) every Jesuit or other popish priest was commanded to depart from the realm within forty days, on pain of death as a traitor, and every person receiving or relieving any such priest was declared guilty of felony. Many priests were afterwards executed under this Act.

It was the struggle with popery that moved and directed nearly the whole policy of the reign, foreign as well as domestic. When Elizabeth came to the throne, she found the country at peace with Spain, the head of which kingdom had been her predecessor's husband, but at war with France, the great continental opponent of Spain and the Empire. Philip, with the view of preserving his English alliance, almost immediately after her accession, offered himself to Elizabeth in marriage; but, after deliberating on the proposal, she determined upon declining it, swayed by various considerations, and especially, as it would appear, by the feeling that by consenting to marry her sister's husband on a dispensation from the pope, she would in a manner be affirming the lawfulness of her

father's marriage with Catharine of Aragon, the widow of his brother Arthur, and condemning his subsequent marriage with her own mother, the sole validity of which rested on the alleged illegality of that previous connexion. A general peace, however, comprehending all the three powers, and also Scotland, was established in April, 1559, by the treaty of Cateau Cambresis. By this treaty it was agreed that Calais, which had been taken by France in the time of Queen Mary, and formed the only difficult subject of negotiation, should be restored to England in eight years, if no hostile act should be committed by Elizabeth within that period. Scarcely however had this compact been signed when the war was suddenly rekindled, in consequence of the assumption by the new French king, Francis II., of the arms and royal titles of England, in right, as was pretended, of his wife, the young Mary, queen of Scots. Elizabeth instantly resented this act of hostility by sending a body of 5000 troops to Scotland, to act there with the duke of Chatelherault and the lords of the congregation, as the leaders of the Protestant party called themselves, against the government of the queen and her mother, the Regent, Mary of Guise. The town of Leith soon yielded to this force; and the French king was speedily compelled both to renounce his wife's pretensions to the English throne and to withdraw his own troops from Scotland, by the treaty of Edinburgh, executed 7th July, 1560. The treaty however never was ratified either by Francis or his queen; and in consequence the relations between the three countries continued in an unsatisfactory state. Charles IX. succeeded his brother on the throne of France before the end of this year; and in a few months afterwards Mary of Scotland returned to her own country. Meanwhile, although the two countries continued at peace, Elizabeth's proceedings in regard to the church had wholly alienated Philip of Spain. The whole course of events and the position which she occupied had already in fact caused the English queen to be looked upon as the head of the Protestant interest throughout Europe as much as she was at home. When the dispute therefore between the Catholics and the Huguenots or reformed party in France came to a contest of arms, in 1562, the latter immediately applied for assistance to Elizabeth, who concluded a treaty with them, and sent them succour both in men and money. The war that followed produced no events of importance in so far as England was concerned, and was terminated by a treaty signed at Troyes, 11th April, 1564. A long period followed, during which England preserved in appearance the ordinary relations of peace both with France and Spain, though interferences repeatedly took place on each side that all but amounted to actual hostilities. The Protestants alike in Scotland, in France, and in the Netherlands (then subject to the dominion of Philip), regarded Elizabeth as firmly bound to their cause by her own interests; and she on her part kept a watchful eye on the religious and political contentions of all these countries, with a view to the maintenance and support of the Protestant party, by every species of countenance and aid short of actually making war in their behalf. With the Protestant government in Scotland, which had deposed and imprisoned the queen, she was in open and intimate alliance; in favour of the French Huguenots she at one time negotiated or threatened, at another even went the length, scarcely with any concealment, of affording them pecuniary assistance; and when the people of the Netherlands at length rose in revolt against the oppressive government of Philip, although she refused the sovereignty of their country, which they offered to her, she lent them money, and in various other ways openly expressed her sympathy and good will. On the other hand, Philip, although he refrained from any declaration of war, and the usual intercourse both commercial and political long went on between the two countries without interruption, was incessant in his endeavours to undermine the throne of the English queen and the order of things at the head of which she stood, by instigating plots and commotions against her authority within her own dominions. He attempted to turn to account in this way the Catholic interest, which was still so powerful both in England and in Ireland—the intrigues of the Scottish queen and her partisans materially contributing to the same end. The history of Mary Stewart and of the affairs of Scotland during her reign and that of her son must be reserved for a separate article. But it is necessary to observe here, that Mary was not merely the head of the

Catholic party in Scotland, but as the descendant of the eldest daughter of Henry VII., had pretensions to the English crown which were of a very formidable kind. Although she was kept in confinement by the English government after her flight from the hands of her own subjects in 1568, the imprisonment of her person did not extinguish the hopes or put an end to the efforts of her adherents. Repeated rebellions in Ireland, in some instances openly aided by supplies from Spain—the attempt made by the duke of Alva in 1569, through the agency of Vitelli, to concert with the Catholic party the scheme of an invasion of England—the rising of the Catholics of the northern counties under the earls of Northumberland and Westmoreland the same year—the plot of the duke of Norfolk with Ridolfi in 1571, for which that unfortunate nobleman lost his head—the plots of Throgmorton and Creighton in 1584, and of Babington in 1586—to omit several minor attempts of the same kind—all testified the restless zeal with which the various enemies of the established order of things pursued their common end. Meanwhile, however, events were tending to a crisis which was to put an end to the outward show of friendship that had been so long kept up between parties that were not only fiercely hostile in their hearts, but had even been constantly working for each other's overthrow behind the thin screen of their professions and courtesies. The queen of Scots was put to death in 1587, by an act of which it is easier to defend the state policy than either the justice or the legality. By this time also, although no actual declaration of war had yet proceeded either from England or Spain, the cause of the people of the Netherlands had been openly espoused by Elizabeth, whose general, the earl of Leicester, was now at the head of the troops of the United Provinces, as the revolted states called themselves. An English fleet at the same time attacked and ravaged the Spanish settlements in the West Indies. At last, in the summer of 1588, the great Spanish fleet, arrogantly styled the Invincible Armada, sailed for the invasion of England, and was in the greater part dashed to pieces on the coasts which it came to assail. [ARMADA.] From this time hostilities proceeded with more or less activity between the two countries during the remainder of the reign of Elizabeth. Meanwhile Henry III., and, after his assassination in 1589, the young king of Navarre, assuming the title of Henry IV., at the head of the Huguenots, had been maintaining a desperate contest in France with the duke of Guise and the League. For some years Elizabeth and Philip remained only spectators of the struggle; but at length they were both drawn to take a principal part in it. The French war, however, in so far as Elizabeth was concerned, must be considered as only another appendage to the war with Spain; it was Philip chiefly, and not the League, that she opposed in France; just as in the Netherlands, and formerly in Scotland, it was not the cause of liberty against despotism, or of revolted subjects against their legitimate sovereign, that she supported, or even the cause of Protestantism against Catholicism, but her own cause against Philip, her own right to the English throne against his, or that of the competitor with whom he took part. Since the death of Mary of Scotland, Philip professed to consider himself as the rightful king of England, partly on the ground of his descent from John of Gaunt, partly in consequence of Mary having by her will bequeathed her pretensions to him should her son persist in remaining a heretic. Henry IV. having previously embraced Catholicism, made peace with Philip by the treaty of Vervins, concluded in May, 1598; and the death of Philip followed in September of the same year. But the war between England and Spain was nevertheless still kept up. In 1601 Philip III. sent a force to Ireland, which landed in that country and took the town of Kinsale; and the following year Elizabeth retaliated by fitting out a naval expedition against her adversary, which captured some rich prizes, and otherwise annoyed the Spaniard. Her forces continued to act in conjunction with those of the Seven United Provinces both by sea and land.

Elizabeth died on the 24th of March, 1603, in the 70th year of her age and the 45th of her reign. In the very general account to which we have necessarily confined ourselves of the course of public transactions during the long period of the English annals with which her name is associated, we have omitted all reference to many subordinate particulars, which yet strongly illustrate both her personal

conduct and character and the history of her government. One of the first requests addressed to her by the parliament after she came to the throne was that she would marry; but for reasons which were probably various, though with regard to their precise nature we are rather left to speculation and conjecture than possessed of any satisfactory information, she persisted in remaining single to the end of her days. Yet she coquetted with many suitors almost to the last. In the beginning of her reign, among those who aspired to her hand, after she had rejected the offer of Philip of Spain, were Charles, archduke of Austria (a younger son of the Emperor Ferdinand I.); James Hamilton, earl of Arran, the head of the Protestant party in Scotland; Erick XIV., king of Sweden (whom she had refused in the reign of her sister Mary); and Adolphus, duke of Holstein (uncle to Ferdinand II. of Denmark). 'Nor were there wanting at home,' adds Camden, 'some persons who fed themselves (as lovers use to do) with golden dreams of marrying their sovereign;' and he mentions particularly Sir William Pickering, 'a gentleman well born, of a narrow estate, but much esteemed for his learning, his handsome way of living, and the management of some embassies into France and Germany;' Henry earl of Arundel; and Robert Dudley (afterwards the notorious earl of Leicester), a younger son of the duke of Northumberland, 'restored by Queen Mary to his honour and estate; a person of youth and vigour, and of a fine shape and proportion, whose father and grandfather were not so much hated by the people, but he was as high in the favour of Queen Elizabeth, who out of her royal and princely clemency heaped honours upon him, and saved his life whose father would have destroyed hers.' Leicester continued the royal favourite till his death in 1588, disgracing by his profligacy the honours and grants that were lavished upon him by Elizabeth, who, having appointed him commander-in-chief of the forces which she sent to the assistance of the Dutch, insisted upon maintaining him in that situation, notwithstanding the mischiefs produced by his incapacity and misconduct, and, at the perilous crisis of the Spanish invasion, was on the point of constituting him lieutenant-governor of England and Ireland. Camden says that the letters patent were already drawn, when Burghley and Hatton interfered, and put a stop to the matter. Of the foreign princes that have been mentioned, the archduke Charles persisted longest in his suit: a serious negotiation took place on the subject of the match in 1567, but it came to nothing. In 1571 proposals were made by Catherine de' Medici for a marriage between Elizabeth and her son Charles IX., and afterwards in succession with her two younger sons, Henry duke of Anjou (afterwards Henry III.), and Francis duke of Alençon (afterwards duke of Anjou). The last match was again strongly pressed some years after; and in 1581 the arrangement for it had been all but brought to a conclusion, when, at the last moment, Elizabeth drew back, declining to sign the marriage articles after she had taken up the pen for the purpose. Very soon after the death of Leicester the young Robert Devereux, earl of Essex, whose mother Leicester had married, was taken into the same favour that had been so long enjoyed by the deceased nobleman; and his tenure of the royal partiality lasted, with some intermissions, till he destroyed himself by his own hot-headedness and violence. He was executed for a frantic attempt to excite an insurrection against the government in 1601. Elizabeth, however, never recovered from this shock; and she may be said to have sealed her own sentence of death in signing the death-warrant of Essex.

Both the personal character of Elizabeth and the character of her government have been estimated very differently by writers of opposite parties. That she had great qualities will hardly be disputed by any one who duly reflects on the difficulties of the position she occupied, the consummate policy and success with which she directed her course through the dangers that beset her on all sides, the courage and strength of heart that never failed her, the imposing attitude she maintained in the eyes of foreign nations, and the admiration and pride of which she was the object at home. She was undeniably endowed with great good sense, and with a true feeling of what became her place. The weaknesses, and also the more forbidding features of her character, on the other hand, are so obvious as scarcely to require to be specified. Many of the least respectable mental peculiarities of her own sex were mixed

in her with some of the least attractive among those of the other. Her selfishness and her vanity were both intense—and of the sympathetic affections and finer sensibilities of every kind she was nearly destitute.

Her literary knowledge was certainly very considerable; but of her compositions (a few of which are in verse) none are of much value, nor evidence any very superior ability, with the exception perhaps of some of her speeches to the parliament. A list of the pieces attributed to her may be found in Walpole's 'Royal and Noble Authors.'

There has been a good deal of controversy as to the proportion in which the elements of liberty and despotism were combined in the English constitution, or in the practice of the government, in the reign of Elizabeth; the object of one party being to convict the Stewarts of deviating into a new course in those exertions of the prerogative and that resistance to the popular demands which led to the civil wars of the seventeenth century,—of the other, to vindicate them from that charge, by showing that the previous government of Elizabeth had been as arbitrary as theirs. Upon this question the reader may consult the elaborate exposition with which Hume closes his account of this reign, along with the remarks upon it in the Introduction to Mr. Brodie's 'History of the British Empire, from the Accession of Charles I. to the Restoration.' There can be no doubt that the first James and the first Charles pursued their object with much less art, and much less knowledge and skill in managing the national character, as well as in less advantageous circumstances, than Elizabeth and her ministers; they did not know nearly so well when to resist and when to yield as she did; but it may notwithstanding be reasonably questioned if her notion of the rightful supremacy of the crown was very different from theirs. However constitutional also (in the modern sense of the term) may have been the general course of her government, her occasional practice was certainly despotic enough. She never threw aside the sword of the prerogative, although she may have usually kept it in its scabbard.

Her reign, however, take it all in all, was a happy as well as a glorious one for England. The kingdom, under her government, acquired and maintained a higher and more influential place among the states of Europe, principally by policy, than it had ever been raised to by the most successful military exertions of former ages. Commerce flourished and made great advances, and wealth was much more extensively and more rapidly diffused among the body of the people than at any former period. It is the feeling of progress, rather than any degree of actual attainment, that keeps a nation in spirits; and this feeling every thing conspired to keep alive in the hearts of the English in the age of Elizabeth; even the remembrance of the stormy times of their fathers, from which they had escaped, lending its aid to heighten the charm of the present calm. To these happy circumstances of the national condition was owing, above all, and destined to survive all their other products, the rich native literature, more especially in poetry and the drama, which now rushed up, as if from the tillage of a virgin soil, covering the land with its perennial fruit and flowers. Spenser and Shakspeare, Beaumont and Fletcher, Raleigh and Bacon, and many other distinguished names, gained their earliest celebrity in the Elizabethan age.

ELIZABETH PETROWNA, daughter of Peter the Great and of Catherine I., was born in the year 1709. After the death of her nephew, Peter II., in 1730, she was urged to assert her claims to the crown, but she declined to do so through indolence or timidity, and her cousin Anna, duchess of Courland, was raised to the throne. After the death of Anna in 1740, Iwan, the infant son of the duke of Brunswick and of Ann, niece to the late empress, was proclaimed emperor under the tutelage of his mother, in conformity to the will of the defunct sovereign. A conspiracy however was soon after hatched by some of Elizabeth's attendants, especially a surgeon of the name of Lestok, who found great difficulty in conquering her irresolution: the officers of the guards were drawn into the plot, and a military insurrection followed in 1741, when Elizabeth was proclaimed empress, and Ann and her husband, the duke of Brunswick, and the child Iwan, were put in confinement. Several noblemen were sent into Siberia. Bestucheff, who had been minister under the Empress Anna, was retained in office and appointed chancellor. Elizabeth took an active part in the war of the Austrian succession, and sent troops to the assistance of Maria Theresa, and she

afterwards concurred in the peace of Aix la Chapelle in 1748. During the Seven Years' War, Elizabeth took part against Frederick of Prussia, it was said, from personal pique at some sarcastic reflections of the Prussian king. The Russian army invaded Prussia, won the hard-fought battle of Kunnersdorf, crossed the Oder, entered Berlin, and reduced Frederick to the verge of ruin and despair. But the illness and death of Elizabeth soon retrieved his fortunes. She died in December, 1761, after a reign of twenty years, and was succeeded by the duke of Holstein Gottorp, son of her sister Anna Petrowna, duchess of Holstein: he assumed the title of Peter III.

The government of Elizabeth was directed in great measure by favorites, who succeeded one another. The empress herself was good-natured and even amiable, but indolent and sensual, and many acts of oppression and cruelty were perpetrated under her reign. She was averse to the punishment of death, but numerous persons were sentenced to the knout and to exile in Siberia. Several ladies, among others Madame Lapoukin, a handsome and clever woman, who had given offence to Elizabeth, experienced the same fate. Elizabeth exerted herself to forward the compilation of a code of laws for the Russian empire, a task begun under Peter the Great, but which was not completed till the reign of Catherine II. She was never married, but left several natural children.

ELIZABETHGRAD or YELISAVETGRAD, a circle in the northern part of the province of Cherson, and in the south of Russia in Europe, lying between 47° 30' and 49° 4' N. lat., and 30° 50' and 33° 8' E. long. It is bounded on the north by Kieff, on the south by Cherson, and on the west by Podolia. According to Georgi, Elizabethgrad contains 696,490 acres of land fit for the plough, 438,460 of meadows and pastures, and 24,330 of woods and forests. The forests principally consist of pines, occasionally intermixed with limes and beeches. The surface in the northern districts is traversed by a branch of the mountains of the Dnieper, where there are extensive forests, such as the Tshuta, Tshernoylez, &c. The remaining part of the circle is a steppe. On the whole the soil is rich and fertile, but most cultivated in the north. It produces much grain, and saffron grows in a wild state. The Ingul is the principal river in the circle. It contains one town, and about 180 villages and hamlets. Wild beasts, particularly bears, and in the south wild horses abound: game is plentiful. There are many quarries of millstones, which form a considerable article of export. The population is about 35,000.

ELIZABETHGRAD, the chief town of the circle, is in 48° 30' N. lat., and 32° 28' E. long., in a beautiful plain on the banks of the Ingul. It is of an hexagonal shape, defended by six bastions, and was built in 1754. The town and a large arsenal are situated within its walls; but it has besides four suburbs; the whole is regularly built, and has straight broad streets, planted with avenues of trees. There are five churches, a large hospital, numerous magazines, above 1000 houses, and about 12,000 inhabitants, many of whom are Greeks or of Servian origin; but the majority are Rostolnicks, who observe the rites of the primitive Russo-Greek church. The inhabitants depend much upon a large traffic in the produce of the neighbouring parts, and carry on considerable trade with Poland and Moldavia. There is an annual fair at Elizabethgrad, which being the largest in the whole province of Cherson, is attended by many thousand dealers and others. There are no less than thirty-two windmills round the town.

ELK. [DEER, vol. viii. p. 351.]

ELL (Ulna), a measure of length now almost disused. 'It is properly,' says Ducange, 'the length between the ends of both the extended hands, though Suetonius makes it to be only one cubit.' It is not worth while to attempt to follow a measure of secondary importance through its various changes, and this measure in particular has denoted very different lengths in different countries. The three ells which have preserved a place in our arithmetical works, namely the Flemish, English, and French ells, are respectively three, five, and six quarters of a yard.

ELLAGIC ACID. This acid exists in the gall-nut along with gallic acid; and they separate from the aqueous infusion in the state of a yellowish crystalline mass. They are separated by boiling water, which dissolves the gallic acid, and leaves the ellagic unacted upon, but mixed with a little gallate of lime. By treatment with a weak solution of potash the ellagic acid is dissolved, and the gallate of lime

remains insoluble; the ellagate of potash is then treated with hydrochloric acid, which uniting with the potash, precipitates the ellagic acid in a pulverulent state.

The properties of this acid are the following. It is of a light fawn colour. It is insipid, slightly soluble in boiling water, and reddens litmus paper slightly. When heated in close vessels it decomposes, yielding a yellow vapour, which condenses in crystals of the same colour. This acid becomes of a blood-red colour by digestion in nitric acid, and is converted afterwards into oxalic acid. It unites with potash, soda, and ammonia, to form neutral salts; the two first are insoluble in water, except when an excess of base is present; and the ellagate of ammonia does not dissolve under any circumstances. Its acid powers are weak, for it is incapable of decomposing the alkaline carbonates.

It is composed of

| | | | |
|-----------------------------|----|----|------|
| Two equivalents of hydrogen | 2 | or | 2.6 |
| Seven " carbon | 42 | | 55.2 |

ELLEBORIN, a resin, of an extremely acrid taste, which has been found in the *helleborus hyemalis*. It is obtained by making a tincture of the root with alcohol, and subjecting it to distillation, when the elleborin remains in the state of a nearly white mass, which is soft and granular, and readily melts into an oily fluid. Its taste is extremely acrid, but it has no smell; it dissolves in alcohol, and imparts to it a red-brown colour; it is but little dissolved by water; the spirituous solution precipitates the persalts of iron of a purple colour.

ELLENBOGEN, ELNBOGEN, or ELBOGEN, the most westerly circle of the kingdom of Bohemia, bounded on the north by Saxony, and on the west by Bavaria, consists of four districts, Ellenbogen (nine-tenths of the whole circle), Eger, Asch, and the small territory of the Fraiss in the south-west. Its area is about 1186 square miles, and it has 27 towns, 13 market-villages, 609 villages and hamlets, and about 220,500 inhabitants: in 1816, 188,427. The great range of the Bohemian Ore mountains (Erzgebirge), which separate it on the north and west from Saxony and Bavaria, spreads its branches over every part but the south-east; between those offsets are numerous small fertile plains, and many large valleys. The principal streams are the Eger, which traverses it from south-west to north-east, the Tepl and Striela in the south, and the Zwoda and Weistriz in the north. The forests produce good timber, &c., but on the whole neither the soil nor climate is well adapted for agriculture; mining, manufactures, and a brisk trade are the chief occupations of the people. The principal mineral productions are silver, tin, lead, iron, sulphur, alum, and saltpetre; and there are several valuable mineral springs, such as those of Carlsbad, Franzensbrunnen (near Eger), Schaben, &c. The chief manufactures consist of woollens, cottons, stockings and hosiery, paper, and iron and steel wares; and nearly three-fourths of the Bohemian lace are made in this circle. Ellenbogen (2100 inhabitants), Carlsbad, Joachimsthal (a mining town of 4400 inhabitants in the north-east), Weipert (3000), Grasslitz (4700), a manufacturing town, Königsberg (3300), Schlaggenwald (3600), Schönfeld (2530), and Schönbach (2230), are the principal towns in the district of Ellenbogen: in that of Eger are Eger, Franzensbrunnen or Egerbrunnen, and Wildstein and Haslau, manufacturing places. In that of Asch are Asch, the chief town, which has considerable manufactures, and about 500 inhabitants, and Rossbach, a manufacturing place.

ELLESMERE. [SHROPSHIRE.]

ELLICHPORE, a principal city in the province of Berar in $21^{\circ} 14' N.$ lat. and $77^{\circ} 36' E.$ long. It is only in part surrounded by a wall, and is not a place of any strength. It lies in the Doab, between the Sarpan and the Beechun rivers, which form a junction near Ellichpore, and afterwards fall into the Poorna. This city is held, together with a small surrounding territory, by a petty chief, who is nominally dependent upon the Nizam, but is under the protection of the English. The palace of the chief is a handsome and commodious building, and the bazaars and houses in the vicinity are built of brick, but the rest of the city consists of mud houses, and has a very mean appearance. Ellichpore is 121 miles from Nagpore; 319 miles from Hyderabad; 380 miles from Delhi; 671 from Madras, and 844 miles from Calcutta, all travelling distances

ELLIPSE (*ἔλλειψις*). This curve, which is one of the CONIC SECTIONS, ranks next in importance to the circle (which is itself an extreme form of the ellipse) and the straight line. We shall here consider the ellipse independently of the other conic sections, and simply state some of the most remarkable properties which can be exhibited without algebraical symbols.

1. Let any two points S and H be taken, and their distance bisected in C. Set off CA and CM, equal lines, each greater than CS, and let a point P move in such a manner that HP and PS together are always equal to AM. The curve described by the point P is an ellipse.

2. CA is called the *semi-axis major*, CB the *semi-axis minor*, C the *centre*, S and H the *foci*, SP and HP the *focal distances* of the point P, CP the *semi-diameter* of the point P, and CD (drawn parallel to the tangent PT) the *conjugate semi-diameter*, or *semi-conjugate* of CP. Also the fraction which CS is of CA is called the *eccentricity* of the ellipse.

3. Let SA be to AK as CS to CA. Then KR is called the *directrix* of the ellipse, and SP is to PR as SA to AK.

4. The tangent PT bisects the angle made by SP and the continuation of HP.

5. CA is a mean proportional between CN and CT.

6. If, A and M remaining the same, the figure of the ellipse be altered by varying S and H, the tangents drawn through the several points in which the ellipses cut NQ will all pass through the same point T of the axis. The circle AQM is the extreme form of the ellipse, when S and H meet in C, and the tangent at Q passes through T.

7. Wherever the point P may be taken, NP bears to NQ the same proportion as CB to CA, and so does the area ANP to the area ANQ.

8. The perpendicular let fall from S upon PT must cut it in a point of the circle AQM.

9. If CD be parallel to the tangent at P, then CP is parallel to the tangent at D.

10. The parallelogram PCDK is equal to the rectangle of BC and CA, and the sum of the squares on PC and CD is equal to the sum of the squares on AC and CB.

11. The square on PN is less than the rectangle contained by AN and NM in the proportion of the square on CB to the square on CA. From this *deficiency* the ellipse derives its name, as does the *HYPERBOLA* (*ὑπερβολή*) from a corresponding *excess*.

12. PG bisects every line parallel to CD which is bounded at both ends by the ellipse, and the square on XY is to the rectangle contained by GY and YP in the proportion of the square on CD to that on CP.

13. The square on CD is equal to the rectangle contained by SP and PH.

Such are a few of the countless properties which might be exhibited. But it is to be noticed that the most common and elegant theorems are not those which are found most useful. The striking use of this curve lies in its being the nearest representative of a planetary orbit which can be given in a simple manner. If the planets did not attract each other, but were only attracted by the sun, they would describe absolute ellipses. Their mutual actions being small, compared with that which the sun exerts, they consequently move in ellipses *very nearly*. Hence the utility of the ellipse in astronomy: but at the same time the properties of the curve which facilitate the

investigation of the heavenly motions present nothing so striking as those which we have given.

The reader who is not versed in geometry must remember that though an ellipse be an *oval*, yet an oval is not necessarily an ellipse. A figure may be formed by arcs of circles which shall have the appearance of an ellipse, without possessing any of its properties.

ELLIPSOID. [SURFACES OF THE SECOND DEGREE.] See also SPHEROID for the most useful part of the subject.

ELLIPSOLITES. [CORNU AMMONIS, vol. viii. p. 26.]

ELLIPSOSTOMATA. M. de Blainville's name for a family (the third) of his second order, *Asiphonobranchiata*, of his first sub-class, *Paracephalophora Dioica*, of his second class, *Paracephalophora*, of his *Malacozoa*. The *Ellipsostomata* of De Blainville comprehend the genera *Melania*, *Rissoa*, *Phasianella*, *Ampullaria*, *Helicina* (including *Ampulleira* De Blainv. and *Olygira*, Say), and *Pleurocerus*. Of these all but *Pleurocerus* are included under the Pectinibranchiate Gasteropods of Cuvier; and as the habits of the included genera are by no means uniform, the genera will be treated of under their several titles. For AMPULLARIA see vol. i. p. 473.

ELLIPTIC COMPASSES, the name given to any machine for describing an ellipse. We shall only mention two contrivances of the kind out of a large number which have been proposed. The first is the simple and rough method suggested by the first property in the article ELLIPSE. Let two pins be fastened to the paper at the points in which the foci are to lie, and let a thread, equal in length to the proposed major axis, have one end tied to each pin. Then if a pencil move in such a way as to keep the thread always stretched, it will describe an ellipse.

The second method is as follows: it is known that if any two fixed points in a straight line A be made to move along two other straight lines, B and C, then every other point in A will describe an ellipse. If then two grooves be made (at right angles to each other, for convenience), and if two pins attached to a ruler be made to travel in the grooves, the motion of the ruler will make any pencil attached to it trace out an ellipse. The distances of the pencil from the two pins will be the semiaxes of the

ellipse. If the pins be attached to the ruler by clamping screws their distance may be altered, and the instrument may be made to describe any ellipse within limits depending on the length of the ruler and of the grooves.

ELLIPTICITY, a term used in the theory of the figure of the earth. It means the fraction which the excess of the axis major over the axis minor of an ellipse is of the axis minor itself. Thus if the axis major be 9 and the axis minor 7, the ellipticity is $\frac{2}{7}$. This term must not be con-

founded with the *eccentricity*, a word in much more common use. If *a* and *b* be the semiaxes major and minor, and if *e* be the eccentricity and *E* the ellipticity, then

$$E = \frac{a-b}{b}, e = \sqrt{1 - \frac{b^2}{a^2}}$$

if *b* and *a* be nearly equal, $e^2 = 2E$ nearly.

ELLORE, a district forming part of the collectorate of Musulipatam, one of the subdivisions of the Northern Circars, situated between the Krishna and Godavery rivers, and comprising an area of about 2700 square miles exclusive of a mountainous tract on the west whose limits have not been defined. The town of Ellore, which is the place of residence of the Masulipatam collector, is a place of considerable size, lying in $16^\circ 43' N.$ lat. and $81^\circ 15' E.$ long. It is 183 miles from Hyderabad, travelling distance.

ELM. [ULMUS.]

ELMINA. [COAST, GOLD.]

ELMSLEY, PETER, was born in the year 1773, and educated at Westminster and Oxford. In 1798 he was presented to the chapelry of Little Horkesley, in Essex. By the death of his uncle Elmsley, the well-known bookseller, he succeeded to a competent fortune, which enabled him to live in independence, and devote his whole time to literary pursuits. For some time after his uncle's death he resided in Edinburgh, and was one of the earliest contributors to the Edinburgh Review. The articles on Wyttenbach's Plutarch, Schweighäuser's Athenæus, Blomfield's Æschylus, and Porson's Hecuba are generally understood to have been written by him. While at Edinburgh he superintended an edition of Herodotus (1804, 6 vols. 12mo), in which he gave the first proof of the love of Atticisms which always distinguished him, by introducing into the text the Attic forms of the tenses, in spite of all the MSS. He was also an early contributor to the 'Quarterly Review': his paper on Markland's Euripides (in the seventh volume) is well known to scholars. As soon as the state of Europe permitted, Elmsley went abroad, and collated MSS. in the continental libraries. He spent the whole of the winter of 1818 in the Laurentian library at Florence. In 1819 Elmsley was appointed by the government to assist Sir Humphrey Davy in unravelling and deciphering the papyrus at Herculaneum; but the attempt was not attended with success, and in the prosecution of his duties Elmsley caught a fever, from which he never fully recovered.

On his return to Oxford he became Principal of St. Alban's Hall, and Camden Professor of Modern History in that university. He died of a disease of the heart on the 8th of March, 1825. Elmsley's acknowledged works were editions of Greek plays. He published the Acharnians of Aristophanes in 1809: the Œdipus Tyrannus of Sophocles in 1811: the Heracleidæ, Medæ, and Bacchæ of Euripides in the years 1815, 1818, and 1821; and the Œdipus Coloneus of Sophocles in 1823. His transcript of the Florentine Scholia on Sophocles was published after his death. As a scholar, Elmsley did not pretend to be more than a follower of Porson, but he did far more for Greek scholarship than any English scholar who followed that great critic. His character has been drawn with great truth by the celebrated G. Hermann of Leipzig (in the Wien. Jahrbücher, vol. liv., p. 236). 'The way laid open by Porson was pursued and enlarged by P. Elmsley, a man worthy of all honorable mention as well on account of his sound scholarship, as his great fairness and earnest love of truth. We owe to his unweariable accuracy and great application a rich treasure of excellent observations on the Attic dialect; and if he was too fond of making general rules, and for the sake of these rules introducing many wrong or unnecessary emendations, we should remember how easily diligent observation induces one to form a rule, and how easily the adoption of a general rule inclines one to set aside all deviations from it. But Elmsley had too much good sense and too sincere a love of truth not to turn back from his error, and to use it only for a confirmation of the truth and a new advance on the right way: and of this he has given many proofs.'

ELOCUTION. [ORATORY.]

ÉLOGE, in the French language means praise, being derived from the Latin *elogium*, and that from the Greek *eulogia* (εὐλογία). It has become the name of a considerable branch of French literature, which comprehends panegyric orations in honour of distinguished deceased persons. It is the custom when one of the members of the French or

other academies dies, and a new member is appointed in his place, for the new member to deliver a panegyric oration on the labours and other merits of his predecessor. These éloges are generally printed and published, and although they are mostly written in a florid rhetorical style, still many of them are really interesting biographies. Such, for example, are the éloges written by Cuvier on several of his brother naturalists. [CUVIER.] The custom of writing éloges of deceased persons is not confined to members of academies. Bailly wrote *Eloges de Charles V., de Molière, de Corneille, de l'Abbé de la Caille, et de Leibnitz*, Berlin, 1770. The Italians have also *Elogii degli Uomini Illustri Toscani*, 3 vols., fol., Firenze, 1766-70, and many other similar compositions.

ELONGATION, an astronomical term for the angular distance between two heavenly bodies as seen from the earth. Custom has confined it to the case in which both bodies are in the solar system, and one of them is generally the sun. Thus we speak of the *distance* of two fixed stars, and of the *elongation* of Mercury from the sun.

ELOQUENCE. [ORATORY.]

ELORA, or **ELLORA**, a town situated near the city of Dowlatabad, in 19° 58' N. lat. and 75° 23' E. long. This place, although it is now nearly depopulated, was once of considerable importance. The ruins surrounded by the wall of the town occupy a great space; but it is to the excavations near to the town that it owes its present celebrity. These excavations, which occur in a mountain about a mile to the east of Elora, were formerly Hindu temples of great sanctity, although they are now never visited except from curiosity. They are cut out of the solid rock, and the labour which they cost must have been prodigiously great. The largest cave, which is called the Kailasa, is 247 ft. long, and 150 ft. wide. It contains sculptures of almost every deity of the Hindu mythology, and most of them of colossal size. This chamber contains the Great Temple, which is a monolith or solid piece of rock hollowed out: it is 103 ft. long, and its greatest breadth 61 ft.; its interior height is 18 ft.; but its exterior rises in a pyramidal form to the height of more than 100 feet.

There are several other large temple-caves in different parts of the mountain. Those towards the north and the south have evidently been devoted to Buddhist rites, while those in the centre have been the scenes of Brahminical worship. In different parts of the mountain there are found a great number of smaller excavations cut in the face of the rock. These are not ornamented with sculptures, and are supposed to have been the residences of the officiating priests and officers of the temples.

The Brahmins who reside on the spot assert that the whole of the caves were made by Keloo, rajah of Ellichpore, who lived upwards of 7900 years ago—an assertion incapable of proof, and which does not bear the stamp of probability. Elora being in the immediate neighbourhood of Deoghur (Devagiri), now called Dowlatabad, which, previously to the Mohammedan conquest, was the metropolitan city of a powerful state, these temples were most probably constructed at various times and by different princes.

The town of Elora was acquired by the English from Holkar; but in 1820 was, together with the lands attached to it, including the mountain wherein these cave-temples are situated, made over to the Nizam in exchange for other lands situated more conveniently for the British interest. (Seely, *Wonders of Ellora*, London, 1824; *Asiat. Researches*, vol. vi.)

ELPHIN, a bishop's see in the ecclesiastical province of Tuam in Ireland. The chapter consists of dean, precentor, archdeacon, and eight prebendaries. The diocese embraces the greater part of the county of Roscommon, and portions of the counties of Galway and Sligo, with one parish in King's county; and extends in length about thirty English miles, and in breadth from three to thirty. It contains seventy-four parishes, constituting thirty-two benefices. In 1792 there were in this diocese twenty-six churches of the establishment: in 1834 the numbers were, churches of the establishment, thirty-nine; other places of worship in connexion therewith, three; Roman Catholic chapels, eighty; Presbyterian ditto, one; other places of Protestant dissenting worship, eight. The total population of the diocese in the same year was 327,624, of whom there were 16,417 members of the established church, 310,822 Roman Catholics, 250 Presbyterians, and 135 other Protestant dissenters; being in the proportion of nineteen Roman Ca-

P. C., No. 577.

tholics to one Protestant of whatever denomination, nearly. In the same year there were in this diocese 388 schools, of which fourteen were in connexion with the National Board of Education, educating 24,076 young persons, being in the proportion of 7 $\frac{1}{2}$ per cent. of the entire population under daily instruction; in which respect this diocese stands eighteenth among the thirty-two dioceses of Ireland.

This see was founded about the end of the fifth century, by St. Patrick, who set over it Asic as its first bishop. Asic, like many others of the primitive Irish bishops, was a distinguished worker in metals, and is said to have bequeathed to his successors several specimens of his skill, which were long preserved with great veneration. There is nothing of importance in the subsequent history of the see. Elphin, when void, is to be united to the diocese of Kilmore, by section 32 of the Church Temporalities' Act of the 3rd and 4th Wm. IV.

ELPHINSTONE, WILLIAM, founder of King's College, Aberdeen, was born at Glasgow in 1437. His father, whose name he bore, entered into holy orders on the death of his wife, and was first rector of Kirkmichael, and at length archdeacon of Teviotdale, in which station he died in 1486, being then also, as it seems, provost of the collegiate church of St. Mary's, Glasgow.

At the head of those who in *congregatione* confirmed the statutes of the faculty of arts in Glasgow college, on the erection of that seminary in 1451, stands the name of William Elphinstone, Dean of Faculty. This was, no doubt, the archdeacon of Teviotdale. Among those incorporated in the university the same year appears also the name "Willus. Elphinstoun." Some* have thought this was the same individual; but it would rather seem, as the learned author of the life of Melville supposes (M'Crie's *Melv.* i. 432), that it was the youthful Elphinstone, who, it is admitted on all hands, was educated at the university of Glasgow. Here he passed A.M. probably in the 20th year of his age. (Keith's Bishops, p. 116.) Afterwards, applying himself to theology, he was made priest of St. Michael's, or Kirkmichael, Glasgow, in which place he served four years, and then proceeded to France, where, after three years' study of the laws, he was appointed professor of law, first at Paris and then at Orleans. He continued abroad till the year 1471, when he returned home at the earnest request of his friends, particularly Bishop Muirhead, who thereupon made him parson of Glasgow and official of the diocese.

On Muirhead's decease, in the end of 1473, the archbishop of St. Andrews made him official of Lothian, which he continued to be till the year 1478. In the spring of that year we find John Otterburn in the office; yet in June following Mr. Elphinstone is marked in the parliament rolls as official of Lothian, and in that capacity elected *ad causas*. He was also made a privy councillor. About the same time he was joined in an embassy to France with the earl of Buchan and the bishop of Dunblane, to compose some differences which had arisen between the two crowns; and on his return, in 1479, he was made archdeacon of Argyle, and then bishop of Ross, whence, in 1484, he was translated to the diocese of Aberdeen.

The same year, as bishop of the latter see, he was one of the commissioners from Scotland to treat of a truce and matrimonial alliance with England, whither he was again dispatched as an ambassador on the accession of King Henry VII. When affairs at home came to be troubled between the king and his nobles, he took the part of the former; and when the Earl of Argyll was sent on an embassy into England, he was, on the 21st February, 1488, constituted lord chancellor of the kingdom, in which place however he continued only till the king's demise in June following. In October of the same year he was in the parliament then held at Edinburgh, where we also find him assisting at the coronation of the new king. He was afterwards sent on an embassy to Germany; and on his return thence was appointed to the office of lord privy seal, where he seems to have remained till his death, which happened at Edinburgh on the 25th October, 1514, while negotiations were pending with the court of Rome for his elevation to the primacy of St. Andrews.

Besides a book of canons, extracted out of the ancient canons, Elphinstone wrote a history of Scotland, chiefly out of Fordun. He wrote also some lives of Scotch saints; and in the college of Aberdeen are preserved several large folio volumes of his compilations on the canon law. The civil and

* Report of Commis. on Scots universities, 1831, p. 232.

canon laws indeed were his favourite studies, and to their establishment as the laws of Scotland he long and steadily directed his attention. It is to him we may in all probability ascribe the crafty acts 1487, c. 105, seq. to recover the former large jurisdiction of the chancellor and court of session, as well as the act 1494, c. 54, the object of which appears to have been to enforce in the courts the study of the Roman laws; and we shall not perhaps greatly err in conceiving his zeal to have been employed in the erection of the Court of Daily Council in 1503. It was moreover at his solicitation that the convent of Grey Friars at Stirling and the Chapel Royal were founded in 1494, the same year in which he also obtained a papal bull for the erection of a university at Aberdeen, in place of the narrow seminary previously existing there. To Bishop Elphinstone Aberdeen also owes another great work, namely the bridge across the river Dee: to the completion of his plans the prelate left 10,000 pounds Scots in money lying in his coffers at his death.

ELSHEIMER, or ELZHEIMER, ADAM, was born at Frankfurt in 1574, and, according to the most probable account, died in 1620; but the statements of writers on the subject differ extremely. Finding that he was not likely to acquire in his own country that knowledge of the art which he saw to be necessary, he resolved to go to Rome, where he soon formed an intimacy with Pinas, Lastman, Thomas of Landau, and other eminent painters. Having carefully examined the curiosities of Rome and the works of the greatest artists, both ancient and modern, he resolved to adopt a style of painting peculiar to himself; this was the designing of landscapes with historical figures on a small scale, which he finished in so exquisite a manner that he was not only far superior to all his contemporaries, but is probably unrivalled in his own line by any artist of subsequent times. He designed entirely after nature; and a most retentive memory enabled him to recollect everything that had struck him, and to make the most judicious use of it in his compositions. It is scarcely possible to speak in too high terms of the rare union of excellences in the works of Elsheimer; he is equally admirable for the fine taste of his design, the correct drawing of his figures, the lightness, spirit, and delicacy of his touch, the beauty of his colouring, the high finishing of his works, so that the minutest parts will bear the closest inspection, and, above all, his admirable management and distribution of light and shade, and perfect knowledge of the principles of chiaroscuro, which was manifested in his pieces representing scenes by torch or candlelight, moonlight, sunrise, or sunset. Even during his lifetime his pictures bore a very high price, which was considerably increased after his death. It is lamentable to add, that he was unable to acquire affluence or even comfort by the exercise of his talents. He had a large family; and though he received very high prices for his works, he spent so much time and labour upon them, that he could not subsist by what he earned. He was at length cast into prison for debt; and though very soon released, the disgrace even of that short confinement preyed on his spirits, and he sunk under his misfortunes. The Italians, who highly honoured and esteemed him, deeply regretted his untimely death; and his friend Thomas of Landau was so grieved at his loss that he could no longer bear Rome, but retired to his own country.

Old Teniers and Bamboccio were indebted for great part of their excellence to their study of the works of Elsheimer.

ELSNORE (in Danish, *Helsingør*), a considerable seaport and town in the bailiwick of Frederiksborg, in the Danish island of Seeland, and at the narrowest point of the strait between the Kattegat and the Baltic. It is opposite to Helsingborg, a Swedish seaport, and lies in 56° 2' N. lat. and 12° 37' E. long. It is the spot where the Danish government collect certain dues on every vessel passing through the Sound. On a tongue of land east of it is the castle and fortress of Kronborg, and there is a handsome palace, called Marienlyst, with an hospital for seamen, built upon a commanding eminence close to it. Elsinore itself is an open town, and has been much improved of late years. It consists of a main street of considerable length, with several lateral streets; has a harbour accessible to ships of small draught, and contains 2 churches, about 650 houses, a town-hall and high-school, an infirmary and hospital, a theatre, a quarantine establishment, and about 7000 inhabitants. Independently of a good foreign trade, the townsmen are employed in making straw hats, arms, refined sugar, brandy, &c., printing cottons, and carrying on fish-

eries. The harbour is formed by what is here called a bridge, or wooden pier. Elsinore is about twenty miles north of Copenhagen. It was the birthplace of Saxo Grammaticus, a celebrated writer of the twelfth century. The number of vessels which have paid the Sound-dues was in 1777, 9053; 1783, 11,233; 1787, 9758; 1792, 12,114; 1799, 7844; 1802, 12,181; 1817, 13,148; 1823, 9203; 1830, 13,212; and 1833, 10,986, of which last 3195 were British. The average for the three years, 1831 to 1833, was 12,045; and of British, 3766.

ELSTER. [ELBE.]

ELSTOB, WILLIAM, descended from an ancient family in the bishopric of Durham, was born at Newcastle-upon-Tyne, January 1, 1673. His father was Mr. Ralph Elstob, a merchant of that place. He received his earliest education in his native town, but was afterwards sent to Eton, and thence to Catherine Hall, Cambridge. Being of a consumptive habit, and the air of the place not agreeing with him, he removed to Queen's College, Oxford, whence, in 1696, he was chosen fellow of University College. In 1701 he translated the Saxon Homily of Lupus into Latin, with notes, for Dr. Hickes; and about the same time he translated Sir John Cheke's Latin version of Plutarch's Treatise on Superstition, which was printed at the end of Strype's Life of Cheke. In 1702 he was presented by the dean and chapter of Canterbury to the rectory of the united parishes of St. Swithin and St. Mary Bothaw, in London, where he continued till his death. In 1703 he published, at Oxford, an edition of Roger Ascham's Letters; and in 1709, in the Saxon language, with a Latin translation, the Homily on St. Gregory's day. He intended the publication of several other works in Saxon literature, more particularly the Saxon laws, and Alfred's paraphrastic version of Orosius. He died March 3rd, 1714-15. He published one or two other works, but of less consequence than his Saxon labours. (Pegge's *Hist. Account of the Textus Roffensis*; and of Mr. Elstob and his sister, in the *Bibl. Topogr. Britan.*, No. XXV.: Kippis's *Biogr. Brit.*)

ELSTOB, ELIZABETH, sister of the above, was born at Newcastle, September 29th, 1683. During her brother's continuance at Oxford, she resided chiefly in that city with him, and afterwards removed with him to London, where she joined him in his Saxon studies. The first public proof she gave of this was in 1709, when, upon his printing the Homily upon St. Gregory's day, she accompanied it by an English translation and a Preface. Her next publication was a translation of Madame Scudery's Essay on Glory. By the encouragement of Dr. Hickes, she undertook a Saxon Homiliarium, with an English translation, notes, and various readings, of which a few sheets only were printed at Oxford, in folio, when the work was abandoned. Her transcript of the Saxon Homilies, in preparation for this work is preserved in the Lansdowne Collection of MSS. in the British Museum. In 1716 she published a Saxon grammar, in 4to, the types for which were cut at the expense of Lord Chief Justice Parker, afterwards earl of Macclesfield. After her brother's death, Mrs. Elstob retired to Evesham in Worcestershire, where she subsisted with difficulty by keeping a small school. Each scholar paid her 4d. a week. She was subsequently patronized by Queen Caroline, who granted her a pension of 20l. a year; but this bounty died with the queen. In 1739 the duchess dowager of Portland took Mrs. Elstob into her family as governess to her children, where she continued till her death, May 30th, 1756. She was buried at St. Margaret's, Westminster. (Pegge's *Account of the Textus Roff.* ut sup.; Tindal's *Hist. of Evesham*; Nichols's *Lit. Anecd.*)

ELTHAM. [KENT.]

ELUTRIATION, the process of separating substances reduced to powder, when of different specific gravities, by means of water. It is also employed as a method of reducing any one substance to a fine powder; thus the creta præparata, or prepared chalk, of the London Pharmacopœia, is prepared by mixing finely-powdered chalk with water, stirring the mixture, and while it is yet turbid allowing the upper portion of the water to run off; and when this is allowed to settle, the chalk or any other substance similarly treated settles in a very fine powder. By the process of elutriation ores, especially those of tin, are separated from earthy matter.

ELVAS, a strongly-fortified town in the province of Alentejo in Portugal, about 126 miles east of Lisbon, situated on a hill in the midst of a plain, which extends to the

east as far as the Guadiana. It is a frontier town, being about 13 miles west of Badajoz, the first Spanish town on that side, and on the high road from Lisbon to Madrid. Elvas is the strongest fortress of Portugal: the town is situated between two castles, Fort Santa Lucia and Fort la Lippe, which stand on two summits commanding the town. Elvas is a bishop's see, and the head town of a comarca, or district, of the same name. The town contains about 13,000 inhabitants, and has a fine cathedral, six parish churches, several convents and hospitals, and very extensive barracks, which are bomb-proof. A handsome aqueduct brings water to the town from a distance of about 4 miles, and supplies the various fountains. The country around is productive in corn, wine, and oil. (Mariano, *Diccionario Geografico; Views of Elvas*, by H. Smith, London, 1813.)

ELWUND. [ECBATANA.]

ELY, a city in the Isle of Ely in the northern part of the county of Cambridge, 16 miles N.N.E. from Cambridge and of N. by E. from London.

According to Bede, the word Ely, which was given to a large district of fens in which the city is situated as well as to the city itself, is derived from Elge or Elig an 'eel,' and consequently has reference to the abundance of eels in the neighbourhood. But most antiquarians derive the appellation from Helig, a British name for the willow, which grows in great quantities in the isle. Etheldreda, daughter of Anna king of East Anglia, and wife of Oswy king of Northumberland, preferring cloistered seclusion to courtly splendour, retired here about the year 670, and soon after founded a monastery, which was dedicated to the Virgin Mary, and of which she became the abbess. In 870 the whole abbey was pillaged and destroyed by the Danes, and all its revenues were annexed to the crown, which retained them till the reign of Edgar. In 970 that king granted the isle with all its appurtenances, privileges, &c., to Ethelwold, bishop of Winchester, who rebuilt the monastery, and provided it with monks. The charter of Edgar was confirmed by Canute and Edward the Confessor, and subsequently by the Pope. The isle was gallantly defended against William the Conqueror, but after repeated attacks the inhabitants were obliged to surrender, many of them were put to the sword, and most of the valuable furniture and jewels of the monastery were seized, but through the firmness of Æthelwin, who had been made abbot, the property was restored. In 1107 Ely was erected into a bishopric by Henry I., and Hervey, bishop of Bangor, was appointed to the see. The lands of the monastery were divided between the bishopric and the monks, and the monastery was governed by the prior, who was called the Lord Prior. After the surrender of the monastery to Henry VIII., he granted a charter to convert the conventual church into a cathedral by the title of the Cathedral Church of the Undivided Trinity. The cathedral of Ely is the workmanship of many different periods, and displays a singular mixture of various styles of architecture, but taken as a whole it is a noble structure. The most ancient part is the transept, which was erected in the reigns of William Rufus and Henry I. The nave and great western tower were built in 1174, and the other parts of the edifice, which consists of a nave, transept, an octagon tower, choir, antichoir, Trinity chapel, Galilee porch, &c., were erected at different periods between the time and the year 1534.

The interior is exceedingly beautiful; the nave is supported by lofty columns, almost without ornament, which perhaps adds to the imposing effect. The octagon tower combines solidity with gracefulness probably more than any other building of the kind in Great Britain; and the choir is a perfect specimen of the early English style of pointed architecture. The stalls are beautiful specimens of wood carving. The whole length of the edifice, including the Galilee porch, is 517 feet; and the western tower, which is of exquisite workmanship, is 270 feet high.

There are many interesting monuments, among which are the tomb and effigies of Bishop Alcock, and that of the earl of Worcester. The bishops of Ely, like those of Durham, formerly possessed, by grant of Henry I., Jura regalia, and appointed their own chief justice, chief bailiff, &c. but their secular jurisdiction is taken away by the 6th and 7th Will. IV., c. 87, and vested in the king, who is empowered to appoint a Custos Rotulorum for the isle. The office is also abolished, and committals are made to the

county gaol at Cambridge. The quarter sessions are still held by the justices of the peace of the isle, but the assizes are now held by her majesty's judges who join the Norfolk circuit.

The bishop has considerable patronage at Cambridge; he is visitor of four colleges, appoints absolutely to the mastership and one fellowship of Jesus College chooses one out of two nominated by the society to be master of St. Peter's college, and has besides nearly 100 livings in his gift.

The city is situated on a considerable eminence near the river Ouse, which is navigable for barges from Lynn to Ely. It consists principally of one long street partially paved; in the centre of the town is a spacious market-place. The soil in the vicinity is exceedingly fertile, and supplies great quantities of fruit, vegetables, and butter to the London market. There is a considerable manufactory for earthenware and tobacco-pipes, and there are several mills in the isle for the preparation of oil from flax, hemp, and cole-seed. The market is on Thursday for corn and cattle. The fairs are on Ascension-day and the eight following days and October 29th for horses, cattle, hops, and Cottenham cheese. The population of the city is 6189, of whom 3132 are females. there were in 1831 1246 inhabited houses, and 718 families employed in trade and agriculture. The isle of Ely contains a population of 47,152.

The city, exclusively of the liberty of the college, which is extra-parochial, comprises the parishes of St. Mary and the Holy Trinity, in the peculiar jurisdiction and patronage of the dean and chapter. The living of St. Mary's is a perpetual curacy of the clear yearly value of 94*l*. The church is a handsome building, partly in the Norman and partly in the early English style of architecture. The Church of the Holy Trinity is attached to the cathedral, and is what formerly was the Lady Chapel. It was commenced in the reign of Edward II., and is one of the most perfect buildings of that age. It is 200 feet in length, 46 in breadth, and 60 in height; it has neither pillars nor side-aisles, but is supported by strong spiring buttresses, surmounted with pinnacles. The living is of the yearly value of 116*l*. There are places of worship for Baptists, Independents, and Wesleyan Methodists. The grammar-school, founded by Henry VIII. in 1541 is under the control of the dean and chapter, who appoint the master. There is also a national school for boys and girls supported by voluntary contributions. A charity school was founded in 1730 by Mrs. Catherine Needham, who endowed it with lands worth nearly 400*l*. per annum for the instruction and clothing of thirty boys, with each of whom an apprentice fee of 20*l*. is given, issuing out of lands bequeathed by Bishop Lancy for that purpose. James Bentham, whose history of Ely is not only interesting as a local history, but valuable for the observations which it contains on the Saxon, Norman, and Gothic styles of architecture, was educated at the grammar-school of this city. [BENTHAM.]

ELYMA'IS, the name of a district of Persia between Susis and Media, and of a city, its capital, situated on the river Eulæus. The name seems to be the same with Elam, which is used in the sacred writings as a general designation for Persia. According to Strabo (p. 744), the population consisted of husbandmen, who cultivated the plains, and a numerous army, principally archers, who occupied the high lands. The king of Elymais was so powerful in the time of Strabo that he could assert his independence in spite of the Parthians, though it appears from the same writer that the Parthians on one occasion invaded Elymais, and carried off a spoil of 10,000 talents from the Elymæan temple of Artemis at Azara. Antiochus Epiphanes had previously made an unsuccessful attempt to rob the same wealthy temple (Joseph. *Antiq.* xii. c. 13; Justin. lib. xxxii., and *Maccabees* i. vi. 1.) Strabo attributes this attempt to Antiochus the Great, but he is perhaps in error. The author of the second book of the *Maccabees* (ix. 2) calls the chief city of this district Persepolis, probably from having by mistake confused Elymais with Elam, for Persepolis stood upon the Araxes. (Strabo p. 729.)

ELYOT, SIR THOMAS, one of the best writers of the time of Henry VIII., was the son of Sir Richard Elyot of the county of Suffolk. He received his university education at St. Mary's Hall in Oxford. He afterwards travelled through Europe, and upon his return was introduced at the court of Henry VIII., who conferred upon him the honour of knighthood, and subsequently employed him in several embassies, particularly to Rome in 1532 in the affair of the

* There is an account of the constitution of the court of Ely in Grant's *12th Kent's Reports*, 129.

divorce, and afterwards in 1536 to the emperor Charles V. Sir Thomas Elyot's literary and philosophical attainments were various; and he was courted by most of the learned men of his time, and by none in a more friendly manner than by Sir Thomas More. He died in 1546, and was buried in the church of Carleton in Cambridgeshire, of which county he had been sheriff.

From a letter of Sir Thomas Elyot to secretary Cromwell, among the Cottonian MSS. in the British Museum, it appears that Wolsey made him clerk of the king's council.

Sir Thomas Elyot's works of greatest note were his book named the Governor, his Castle of Health, and his Dictionary, all of which went through numerous editions between 1531 and 1580. He also published a small treatise 'Of the Knowledge which maketh a Wise Man,' 8vo., London, 1533; and 'The Banquet of Sapience,' 8vo., 1545; besides several translations from Plutarch, Isocrates, St. Cyprian, &c.

ELY'SIA. (Zoology.) [PLACOBANCHIATA.]

ELYSIUM, the name given by the antient Greeks and Romans to the abode of the righteous after death. They fancied that there was, somewhere to the west, a region blessed with perpetual spring, clothed with continual verdure, enamelled with flowers, shaded by pleasant groves, and refreshed by never-failing springs, where the souls of the good repaired, and where they enjoyed each other's society. (Virgil, *Aeneid* vi., with which compare the notion of Elysium in the *Odyssey*, iv. 563.) The 'islands of the blest' was another name for this favoured region, which some placed in the midst of the ocean in the farthest west, others in some inaccessible spot in the middle of Asia or Africa. From this notion the appellation of Elysian Fields has been given to certain delightful secluded spots, such as the strip of land on the northern shore of the Mare Morto, or the inner part of the harbour of Misenum near Naples, which is sheltered from the winds by the surrounding hills, and where no winter is felt. It seems to have been originally a vast cemetery, planted with trees and adorned with tombs; but the imagination of the poets confounded the repository of the perishable bodies with the abode of the immortal souls. [BAIÆ.] Those antient philosophers who had more spiritual notions of the nature of souls discarded the vulgar idea of the Elysium being in any part of our globe, and placed the abode of the departed in the heavens or firmament. (Cicero, *Somnium Scipionis*.) The Parisians have given the name of Champs Elysées to a much-frequented walk planted with trees, at the western extremity of Paris, extending from the Place Louis XV. to the Barrière de l'Etoile, and which, with the exception of the shade which the trees afford, has none of the attributes ascribed to the true Elysium; for it is dusty, noisy, and vulgar, and very inferior in point of comfort to the neighbouring gardens of the Tuileries.

ELZERIANA. [CELLARIAE, vol. vi. p. 402.]

ELZEVIRS, the name of a family of celebrated printers and publishers at Amsterdam, Leyden, the Hague, and Utrecht, who adorned the republic of letters with many beautiful editions of the best authors of antiquity. The right name of the family was Elzevir. They are believed to have come originally either from Liege or Louvain. In neatness and in the elegance of small type they exceeded even the family of the Stephens. [ESTIENNE.] Their Virgil, their Terence, and their Greek Testament are considered the master-pieces of their productions; but the Virgil is said to be incorrect.

The first trace of the name of Elzevir is found in an edition of Eutropius, printed in 1592, published at Leyden by Louis Elzevir, who was still living there in 1617. Matthew, his eldest son, died at Leyden in 1640. Giles, his second son, was a bookseller at the Hague in 1599. Isaac, the eldest son of Matthew, was the first printer of his family, and printed from 1617 to 1628. Abraham and Bonaventure, the third and fourth sons of Matthew, were printers and booksellers. Bonaventure was a partner with his father in 1618, and occurs associated with his brother Abraham in 1626. The set of Elzevirs which the French call 'Les Petites Républiques,' the Accounts of the Nations of the World, were published by Abraham and Bonaventure; and, in fact, gave to the family their celebrity. Their brother Jacob printed at the Hague in 1626. Both Abraham and Bonaventure died at Leyden in 1652. Louis, the second of the name, the son of Isaac, was established as a printer at Amsterdam from 1640 to his death in 1662.

Peter, son of Arnout, the second son of Matthew Elzevir, printed at Utrecht in 1669, and was living in 1680. John and Daniel were sons of Abraham, and printed in partnership in 1652: but John printed alone in 1655, when Daniel appears to have been associated with his cousin Louis. John died in 1661; Daniel in 1680. Daniel left children who carried on the business, but passes for the last of the family who excelled in it.

The Elzevirs printed several catalogues of their editions; but the best, as being the latest lists and accounts of them, are contained in the 'Notice de la Collection d'Auteurs Latin, Français, et Italiens, imprimée de format petit en 12mo, par les Elzevier' in Brunet's 'Manuel du Libraire,' 3rd edit., 8vo., Paris, 1820, vol. iv. p. 533-567; and in 'Essai Bibliographique sur les Editions des Elzevirs; précédé d'une Notice sur ces imprimeurs célèbres,' 8vo., Paris, Didot, 1822.

The usual imprint upon the Elzevir editions is either 'Apud Elzeviro,' or 'Ex officina Elzeviriorum' or 'Elzeviriana.' the names of the different branches of this family are rarely found in the title pages of their editions. *Eise*, in Dutch, signifies an elm, and by extension of signification, wood in general; *vuur*, is fire. These words explain a device of a wood-pile burning in the title-pages of some of the Elzevir productions, as in that of the Sleidanus, 1631, of Cuneus de Republica Hebræorum, 1632, the Cæsar and Terence of 1635, the Memoirs of Comines, &c.

EMANCIPATION, Emancipatio. To understand the legal effect of emancipation by the Roman law, it must be premised that all children born in lawful marriage were said to be in the father's power, as well as all his son's children so born before the son was emancipated; and no person who was in the power of another could acquire any property of his own. (Gaius, ii. 86, &c.) Whatever property, then, a son acquired while in his father's power strictly belonged to his father. If the son was by will appointed heir (heres in the Roman sense), he could not accept without his father's consent, and all that he took was for the benefit of his father: the same rule held as to a legacy. It is unnecessary here to mention the exceptions to the general rule above laid down, or to describe the father's power over the son's person. 'There is hardly any nation,' observes Gaius (i. 55), 'in which fathers have such power over their children as we have.' The rigour of the antient Roman law, however, was gradually relaxed, though the remarks of Gaius, who wrote at least after the time of Antoninus Pius, show that it was not then entirely fallen into disuse. The father's power was dissolved by his natural death, and also by the civil death of the father or the son. (Gaius, i. 128.)

Emancipation was the act by which the power was dissolved or released in the lifetime of the father; and it required the consent of both parties. The emancipation, which was made according to the Laws of the Twelve Tables, was effected by an imaginary sale from the father to another person. In the case of a son, this sale was made three times, as if the father were selling a slave, and the person to whom the sale was made, who of course was some friend, manumitted the son after each sale. After each of the first two sales, the son, being manumitted, became again in his father's power; but the last manumission was final, and extinguished all the father's paternal rights. It was however usual for the son, after the third sale, to be resold to his natural father, who then manumitted him, and thus acquired the rights of a patronus over his emancipated son, which would otherwise have belonged to the purchaser who gave him his final manumission. In the case of a daughter or a grandson, a single sale and manumission was sufficient. (Gaius, i. 132; *Dig.*, lib. 28, tit. 3, l. 8; *Cod.*, lib. 8, tit. 49, l. 6; *Instit.*, lib. i., tit. 12, §. 6.)

The Emancipatio Anastasiana, or that introduced by the Emperor Anastasius, was by Imperial Rescript. (*Cod.*, lib. viii., tit. 49, l. 6.)

The Emancipatio Justiniana was effected by a simple declaration of a father before the proper magistrate, that he released his son from the paternal authority; but the father still retained the rights of a patronus over his emancipated son. (*Ibid.* l. 6.)

The immediate legal effect of emancipation was, that the person emancipated possessed over his own children the paternal right: he could acquire property, and bequeath it by will. If a son married and had children before he was emancipated, his children were in the power of their grand father, who could emancipate them without emancipating

their father; and such emancipation continued in force after the grandfather's death.

It was also a consequence of emancipation that the emancipated children stood to their father in the relation of strangers, and consequently, in case of intestacy, could not take the parent's property, which could only be claimed by those who corresponded to the legal description of *heredes sui, agnati, and gentiles*. But this injustice of the civil law (*juris iniquitates*), observes Gaius, was remedied by the prætor's edict, or, as we should term it, the equity, which was gradually introduced in order to soften the rigour and strict rules of the civil law. [EDICT.] The prætor's edict, however, did not extend to give the same advantage to an emancipated son in succeeding to the property of an intestate brother. The Emperor Anastasius remedied this under certain restrictions; and finally Justinian put emancipated and non-emancipated brothers and sisters and their children on the same footing in all respects as to sharing in the property of a deceased parent or brother or sister. (*Cod.*, lib. vi., tit. 57, l. 15; *Instit.*, lib. v., tit. 5.)

As to emancipation under the Code Napoléon, see liv. i., chap. 3, tit. 10.

EMARGINULA. [CERVICOBRANCHIATA, vol. vi. p. 444.]

EMBALMING. [MUMMY.]

EMBANKMENT. It is often necessary to raise mounds or dykes along the course of rivers to keep them within their channels, and prevent their flooding the lands which lie near them, when the waters rise above their usual level. Those alluvial lands which lie near the mouths of rivers and are below the line of high water cannot be cultivated to advantage unless they are secured from inundation by proper embankments; and as these alluvial deposits are generally very fertile, it amply repays the expense of constructing dykes and keeping them in repair. The whole of the provinces of Holland and Zeeland and several other districts in the Low Countries could not be inhabited if the sea were not kept out by strong embankments; and the destruction of a dyke frequently desolates great tracts of country. The art of constructing dykes and of keeping them in repair is therefore one of the greatest importance to the proprietors of low lands situated as above described.

The first thing to be attended to in forming embankments is to enable them to resist the pressure of the highest floods which are likely to occur, and to prevent the effect of the waves and currents in washing them away. When it is the simple pressure of a column of water which is to be withstood, a simple earthen bank made of the soil immediately at hand, provided it be not of a porous nature, is sufficient. Its form should be a very broad base with sloping sides and with a flat top, which may serve as a path or even a carriage-road, if the bank be of considerable dimensions. The side towards the water should slope more gradually than towards the land, where it may form an angle of 45° with the horizon. A ditch is usually dug along the inside of the bank, and sometimes on both sides, when the dyke is at some distance from the usual channel

sight it would seem that a straight channel is the natural course of a stream; but this is far from being the case. A straight course can never be maintained without artificial means; water never flows in a straight line, but always in curves. The slightest inequality in the bottom or sides partially obstructs its course and produces a circular motion in the water; and this, acting on soft banks, soon hollows them out, which, increasing the eddies, accelerates the change in the current. When a river is turned into a new channel, the banks must be strengthened with piles or masonry, and the foundations of the works must be laid below the gravel or stones which may have accumulated, that they may not be undermined by the percolation of the water.

When the dykes are only intended to check the waters at the time when they flow over their natural banks, it is best to raise them at some distance from the river on each side and parallel to its course; because, in sudden floods, the water, having a greater space to flow through, will not rise so high, and will sooner recede. The natural banks must be carefully attended to in this case, that they may remain nearly the same, without being subjected to that continual change which we have noticed before. Those who have long attended to these changes and their immediate causes will find no difficulty in checking them in the outset by very easy and simple means. Whenever a bank begins to be undermined, a few piles driven in judiciously, and some stones thrown into the river above the place where its banks begin to wear away, will cause a change in the current, and throw it over to the opposite side. Indeed, if this is done injudiciously, the banks opposite will begin to wear away; but by continued attention and prevention, rather than correction, any river having a moderate current may be kept within its proper bed.

It sometimes happens that rivers near their mouths form shallow estuaries, and occupy much ground which might be usefully employed. In this case an entirely new outlet may sometimes be made, through which the river may at once discharge itself into the sea; and the whole course will probably be soon filled up by the deposition of soil and mud brought in by the tides; for it is the current which clears the channel, and when this is taken away the channel soon fills up. In the course of a short time the old mouth of the river will be so filled up as scarcely to admit the tide; and an embankment across it may lay a large fertile tract of land quite dry.

Where embankments are made against the sea, greater skill is required to resist the force of the waves. If there are materials at hand to lay a bank of stones imbedded in clay, with a broad base, and the sides sloping very gradually upwards, a very safe barrier may be opposed to the waters. It is not the direct impulse which is the most destructive, waves striking against a sloping surface lose their force and rise over it; but it is in returning that they draw the materials with them, and scoop out the foundations. If the stones are well joined together, the retiring wave will have no effect in loosening them; but if any one of them can be singly removed from its place, they will soon disappear one after another, till a breach is made; after which a single storm may destroy the whole embankment. There are many parts of the coast of England where whole estates would soon be swept away, if it were not for continual attention to the embankments. Near the mouth of the Thames, in particular, on the north side, and all along the coast of Essex, the sea is only kept out by incessant attention to the sea-walls. In various places the ingenuity of scientific men has been exercised to invent various modes of resisting the force of the sea. In some exposed points piers of solid oak have been made, which oppose a smooth surface obliquely to the force of the waves; in others, rows of piles have been driven in, forming lines at right or oblique angles to the line of the shore, in order to intercept the waves, and break their force before they reach the bank. In a place where the rounded stones called shingles were usually thrown up by the waves, and the bottom was a strong clay, their retreat has been intercepted by rows of strong piles driven in a line along and parallel to the shore, and covered with boards nailed to them on the land side. By this means the sea has been made to provide the materials of the embankment, and to lay them down. In one night the shingles have been thrown over the piles; and being retained by the board ing, have formed a perfect wall. A second row of piles between the first and the sea, and a third if required, forms a sea wall which might defy any storms. We mention this

of the water, and is only a precaution against unusual floods. The inner ditch collects the water which is produced by rains or may find its way by filtration through the bank or the soil.

To raise these simple dykes nothing is requisite but to carry the earth from below, and consolidate it by treading it in a moist state, that no interstices be left. Such are the dykes along the slow-running rivers and canals in Holland. But where a considerable river winds through an extensive plain and is apt to change its bed by the wearing away of the banks in some places and the deposition of mud in others, more skill and more expensive works are required to keep it within its banks and to prevent the effects of a rapid current in destroying them. In this case strong piles are driven deep into the ground, and instead of earthen dykes, stone walls are opposed to the force of the water.

The embanking of a considerable river often requires the course of the stream to be changed, and instead of the winding course which rivers naturally take through plains, straight channels are artificially made for them. At first

an example of the advantage which may be taken of particular circumstances by which a great expense may sometimes be saved. In other situations where the shingle is not thrown up, and the wall is not so immediately exposed to the action of the waves, an excellent facing of the wall is made by several rows of piles from five to fifteen feet long, driven along the side of the earthen bank in the form of steps rising above each other. These piles are driven very close together, and the distance between the rows is about two feet. This interval is filled with stones, and bushes are pinned down over them by means of wooden pins driven horizontally through holes made in the piles. This contrivance effectually prevents the washing away of the bank.

Where the land lies very flat for a considerable distance from the shore, it is of advantage to have two complete banks, one within the other; so that if the outer bank is broken through, the second will keep back the waters, until the first can be repaired. The ground between the two lines of banks is usually left in pasture. In this case the damage done by an inundation of salt-water will not be so great as if the land were arable; and unless it remain flooded for a considerable time, the herbage suffers little, if anything, from it.

The water which accumulates within the banks and is collected in the internal ditch and those which divide the marshes must be let off occasionally by means of channels and sluices at the time when the tide is out, and the water outside the bank is lower than that which is within it. In small embankments a wooden trunk or pipe may be laid through the bank, with a valve opening outwards, by which means the superfluous water may flow out, and none flow back. It is useful to carry this trunk a considerable way outside the bank, if it empties itself immediately into the sea, in order that it may not be choked up with sand or shingles. Cast-iron pipes are conveniently used for this purpose, and they may be carried out so far as to empty themselves below low-water mark. But when the embankment is very extensive, and there are streams flowing through the part which is embanked, larger flood-gates and more extensive works are necessary. These being opened and shut as occasion may require, serve to keep the channel clear, by producing occasionally a considerable rush of water to carry away mud and sand which would otherwise have accumulated at the mouth of it. When the level of the land which is embanked is below the usual level of the waters which are without, the water is raised by means of engines over the banks, as is the case in the fens. [DRAINING.]

In the forming of the banks, where the soil may not be quite impervious to water, it is useful to begin by digging a ditch in the line of the intended bank, of such a depth as to reach an impervious subsoil. This ditch is to be filled up with clay or tempered earth, and as the bank is raised, the middle of the bank should be composed of the same materials, which will thus form a vertical wall A B up to the top; and the more porous earth being heaped up against the sides of this wall will form the slopes of the bank: thus the whole will be perfectly impenetrable to the water. The

clay should be well trod in with the feet in a moist state, and no pieces of wood, or even straw should be in it; for a

straw may be the cause of the water finding a passage through a bank, and this passage gradually widening will soon produce a hole, which may in the end cause the destruction of the bank. Moles and worms are great enemies to dykes. In Holland the storks are held in great veneration, and are never molested, because they are supposed to destroy a worm which often does great mischief to the dykes by perforating them.

EMBARGO, the word used to denote the act by which the public authorities of a country lay an arrest on ships to prevent their leaving its ports. On the breaking out of war with any nation it has been usual for the government of each country to lay an embargo upon such of the enemy's ships as are within reach, with a view to their being declared good and lawful prize. During the progress of war, when any expedition is on foot against the enemy, and it is desirable to keep the circumstance from the knowledge of the party to be attacked, it is usual to lay an embargo upon all private vessels, as well those under the national flag as foreign vessels, until the object to be attained by secrecy is accomplished. An embargo may also be laid by the government upon ships belonging to its subjects with a view to their employment for the service and defence of the nation. In all these cases it is clear that embargoes are detrimental to commerce; the only case in which they have an opposite character is when a foreign vessel of war or privateer frequents a neutral port, and is restrained from quitting the same until a certain time shall have elapsed after the departure from the port of any vessel of which it might otherwise make prize.

EMBER-DAYS and **WEEKS**, certain seasons of the year set apart for imploring the blessing of the Almighty on the produce of the earth by prayer and fasting, observed in the Christian church as early as the third century. Pope Calixtus, who first directed them to be observed, also ordained that the same seasons should be especially devoted to the preparation of the clergy before their ordination. These seasons are mentioned in the laws both of Alfred and Canute. At first the Ember-days were not uniformly observed by different churches at the same time; but the Council of Placentia, A.D. 1095, fixed the spring and summer Ember-days to be the Wednesdays, Fridays, and Saturdays after the first Sunday in Lent and Whitsunday; those of autumn and winter upon the same days after the feast of the holy cross (September 14th) and St. Lucia (December 13th). The Sundays immediately following all these seasons are still appointed by the thirty-first canon of the Church of England for the ordination of ministers. The four weeks in which the Ember-days severally occur are called *Ember-weeks*. Shakspeare speaks of *Ember-eves*. The etymology of *Ember-days* is uncertain. Some have derived the term from *ember*, ashes; others from *ημεραι*, days; and others from *ymbren*, which in the Anglo-Saxon means a circle or revolution, the *Ember-days* being set seasons in the course or circuit of the year. (Broughton's *Dict. of all Religions*, p. 357; Brady's *Clavis Calendaria*, 8vo. Lond. 1812, vol. i. p. 223-226.)

EMBERI'ZIDÆ. (Zoology.) The Latin name for the birds, popularly known in England by the name of Buntings. [FRINGILLIDÆ.]

EMBEZZLEMENT, from the old French word *besler* or *embesler*, to flich, is the fraudulent appropriation by servants and others of money or goods entrusted to their care, or received by them on account of their employers.

By Clerks and Servants. Is an indictable offence under the 7th and 8th Geo. IV., cap. 29, sect. 46, and by that statute is declared to be larceny, and punishable with transportation for a term not exceeding fourteen or less than seven years, or by imprisonment for any term not exceeding three years. If the offender be a male he is liable to be once, twice, or thrice publicly or privately whipped (if the court shall so think fit) in addition to such imprisonment. This statute extends to the clerks and servants (both male and female) of all persons, whether in or out of trade, provided they are entrusted to receive moneys for their employers.

By Agents, Bankers, Attorneys, &c. Of moneys and securities, when entrusted to them for any special purpose, is constituted a misdemeanour by the same statute, cap. 49, and subjects the offender to transportation, as in the case of clerks and servants, or to fine and imprisonment, in the discretion of the court.

By Public Servants. Under the 2nd Wm. IV., cap. 4.

sect. 1, persons employed in the public service and embezzling any moneys or securities entrusted to them are to be deemed guilty of felony, and are punishable in the same manner as clerks and servants for the like offence, except being whipped.

As to bankrupts and insolvents, see **BANKRUPT** and **INSOLVENT**.

EMBLEM: in Greek, *ἔμβλημα* (from *ἐν* and *βάλλειν*, to cast in), a thing inserted, inlaid work, Mosaic, or the like. In English, an emblem is a figurative representation; a representation which by virtue of association suggests to our minds something not expressed to our senses. For instance, a lion is the emblem of courage, a cock of watchfulness, because watchfulness and courage are qualities commonly associated in our minds with those animals, as their characteristics. So by historical association, without any intrinsic fitness, one thing may become the emblem of another, as the wheel and other instruments of torture are emblems of saints who have perished by them. Any device, however arbitrary, when established by usage as a distinctive mark, may become the emblem and be put for that which assumes it, either in writing or in imitative art; as for instance in Wordsworth's lines:—

From town to town, from tower to tower,
The red rose is a gladsome flower, &c.

The red rose is the emblem of, and is universally understood to mean, the house of Lancaster, though no mention of that house has been made.

EMBLEMENTS, from the French words *emblance de bled* (corn sprung or put above ground), in its strict signification means the profits of land sown, but in its usual sense it extends to roots planted and other annual artificial profits which arise from the soil, as for example, standing corn, hemp, saffron, flax, hops, and garden produce growing above ground, as melons and cucumbers, all of which annually require either sowing, planting, or manuring at the expense of the tenant, and are not a permanent or natural product of the soil.

By a rule of law founded on public policy, and for the encouragement of husbandry, all persons are entitled to the emblements of land sown by themselves in which they have an uncertain interest, and which is determined either by the act of God, or of the law, between the time of sowing or planting and the severance of the crop.

Thus the representatives of a tenant for life, who dies previous to harvest, are entitled to the growing crops as a compensation for the labour and tillage bestowed on the lands by the deceased. The same rule also exists with regard to a strict tenant at will, if his tenancy is determined by the landlord previously to the corn being reaped, and for this reason, that as the tenant could not know when the landlord would determine his will, he could not therefore make any provision against it, and having sown the land upon a reasonable presumption of taking the produce, the law will not suffer him to be a loser by it. If, on the other hand, a tenant for life or at will puts an end to his occupation by his own act, he will not be entitled to the crops, as no uncertainty can exist on his part, which is the point upon which all cases of emblements rest.

The parochial clergy and their under-tenants, being also tenants for lives, and their representatives, are in like manner entitled to all the advantages of emblements by the 28th Henry VIII., c. 11, sect. 6; and under that statute they are enabled to bequeath by will grain growing upon the glebe land, manured and sown at their own cost; but for the reason above mentioned, a person who resigns his living is not entitled to the emblements.

Fruit trees which cannot be presumed to be planted in contemplation of present profit, but rather of being permanently useful to a succession of tenants, and grass which grows of itself without annual expense and labour on the part of the tenant are not included within the meaning of emblements. (Godolphin's *Orphan's Legacy*; Woodfall's *Landlord and Tenant*.)

EMBRACERY, an attempt to influence or corrupt a jury, or induce them to favour one of the parties in a cause. It is punished by fine and imprisonment. [ATTAINT.] The crime of embracery is completed whether the jury on whom the attempt is made give any verdict or not, or whether the verdict given be true or false.

EMBRASURE (in Architecture) is the indent of a battlement. [BATTLEMENT.] It signifies also the splay of

a door or window. In walls of some thickness the apertures are splayed on the inside or outside, or both, in order to admit more light, thus making the angles of the wall obtuse instead of rectangular: thus—

AA are splays forming the embrasure. The term is derived from the French.

EMBRASURE (in fortification) is an opening made in an epaulement or parapet for the purpose of allowing a gun to be fired through it. Embrasures are usually two feet wide at the neck, or interior extremity; and, at the mouth or exterior extremity, their width is equal to half the thickness of the epaulement, that is about nine feet. The cheeks or sides are frequently formed vertically at the neck, that the men who serve the guns may be covered as much as possible; but, beyond that part, each side declines gradually from a vertical plane outwards, in order that it may be less injured by the fire of the piece; and, at the mouth, this deviation amounts to one foot. The sole or lower surface of the embrasure is five feet below the top of the epaulement, or two feet six inches above the platform on which the gun-carriage is placed; and it is either parallel or inclined to the horizon, according to the position of the fixed object against which the fire is to be directed.

In general the axis of the embrasure is perpendicular to the length of the epaulement, but when the confined nature of the ground does not permit the epaulement to have the required direction, the embrasure is necessarily cut obliquely, in which case the breadths above given are still set out perpendicularly to the axis.

In permanent fortifications the sides of the embrasures are generally reveted or lined with brickwork; but in field-batteries the earth at the sides is either without support, or is kept up, about the neck, only by gabions or fascines.

EMBROCATION (from *Embroche*, *ἐμβροχή*), a moistening, a term employed to denote certain external applications, which had for their object to soften and dissipate swellings: in this sense they do not differ from fomentations; but the word has been extended beyond its original meaning, and signifies oleaginous or spirituous compounds, which may excite the vessels of the skin to increased action, and produce all the effects of counter-irritants, or by their influence on the extremities of the nerves may assist in resolving spasm, and so act as antispasmodics.

EMBRUN, a frontier fortress of France in the department of Hautes Alpes, on the north-west bank of the Durance, about 353 miles in a straight line south-south-east of Paris.

Embrun was known to the Romans by the name of Ebrodunum, Eburodunum, Hebridunum, or Eburonum. It obtained various privileges from the Roman emperors; and in the division which was made of Gaul in the later period of the Roman domination was included in the province of Alpes Maritimæ (the Maritime Alps), of which it was one of the chief towns. It became early the seat of a bishopric; afterwards of an archbishopric. The see continued to exist up to the period of the French revolution.

The archbishop of Aix still takes the additional title of archbishop of Embrun, but the diocese has not been restored. Embrun was in the middle ages the capital of the district of Embrunois, in Dauphiné. The town suffered in the religious wars of the sixteenth century, and was taken in 1693 by the duke of Savoy.

Embrun is fortified and tolerably well built. Among the most remarkable buildings are the former cathedral, the foundation of which is ascribed to Charlemagne, and the archiepiscopal palace. There is a central house of correction, the buildings of which were formerly occupied as a seminary for the priesthood. The population in 1832 was 2392 for the town, or 3062 for the whole commune. The chief trade carried on is in sheep: there are several tan-yards, and some hat manufactories. Excellent slates are quarried near Embrun, and there are orchards and vineyards near it. The site is at a considerable elevation above the level of the sea.

Embrun is the capital of an *arrondissement*, which had in 1832 a population of 30,828.

EMBRYO. [FÆTUS.]

EMDEN, or **EMBDEN**, the chief town of a *balliwick*, in

the north-western part of the province of Aurich, formerly East Friesland, in the kingdom of Hanover. It lies in 53° 22' N. lat. and 7° 12' E. long., a little below the efflux of the Ems into the Dollart, a bay of the German Ocean, and is connected with that river by a canal about two miles long, called the Delf Canal, which was constructed at the expense of the town in 1769. Emden is surrounded with walls and towers, and consists of Faldern, the old town, and two suburbs, which contain about 2250 houses and 12,500 inhabitants, of whom about 450 are Jews. It has all the appearance of a Dutch town, and is intersected by canals, over which there are thirty bridges. Its spacious townhall, with an old armoury and library, is one of the finest buildings in East Friesland. There are six churches, of which three belong to the Dutch form of worship, one to the French Protestant, one to the Lutheran, and one to the Roman Catholic; there are also a synagogue and Menonite chapel, a gymnasium, schools of navigation and design, elementary schools, a richly-endowed orphan asylum, a castle and custom-house, and societies of the fine arts and national antiquities.

Emden owes its prosperity to a colony of Dutchmen, who sought refuge in it, and communicated so great an impulse to its commercial enterprise that in the year 1652 the population amounted to 20,000, and owned upwards of 600 vessels. A century afterwards viz., in 1749, the town had so much declined that the population did not exceed 8000. It came into the hands of Holland in 1808, was made the chief town of the French department of Ostern in 1810, and on the 15th of December, 1815, was, with the whole of East Friesland, incorporated with the kingdom of Hanover. It would rival Hamburg and Bremen in trade but for the shallowness of its harbour. It has been a free port ever since the year 1751; but the Delf canal, which unites the harbour with the town, and is drained and cleansed by means of five inland canals, has frequently no water in it, and can be entered at high water only; and even then it is not navigable by vessels which draw more than 13 or 14 feet of water. All ships of greater draught are obliged to discharge their cargoes in the fine roadstead called Delf, into which the canal opens. There is a treckshuyt, or towing canal, about 14 miles in length, between Emden and Aurich.

Emden is the chief commercial place in Hanover; and ship-building is carried on to a considerable extent. As early as the year 1682 it had an African trading company, and in the middle of the last century an East India company. The herring fishery off Scotland, which is a source of great profit to the place, is carried on by four companies, who send out between fifty and sixty ships. This branch of its fishery alone employs above 1500 individuals, and produces annually from 12,000 to 13,000 tons of fish. Emden has brandy distilleries and sawing and oil-crushing mills, besides manufactures of fustian, cottons, stockings, sail-cloth, cordage, needles, leather, soap, tobacco, &c. It has considerable trade in linens, thread, grain, butter, and cheese (Embder kaese), the last of which is in much repute. Between 900 and 1000 vessels enter the port every year. The dykes and sluices, which protect the neighbouring country from inundation, are a cause of great expense to the municipality; it is estimated that they gain about two miles square of soil every forty years by pushing out the embankments into the Dollart. Emden is the birthplace of Backhuysen, the celebrated marine painter. Opposite the harbour, in the Dollart, are the small remains of the Island of Nessa, or Nesserland. It is separated from Delf by a swampy arm of the Ems, and previously to the inundations which overwhelmed it between the years 1277 and 1287, formed a beautiful spot of about 80 square miles, with a town called Torum, 2 market-towns, numerous villages, and several monasteries and convents. All that is left of it at the present day is a church and five or six houses, built on high mounds of earth, but protected by dams so slight that they are in imminent danger from the sea.

The bailiwick of Emden has an area of about 78 square miles, and contains 1 town, 1 market-village, Oldersum, on the Ems, with about 820 inhabitants, 4 villages, and 30 parishes. The population amounts to about 11,500.

EMERALD. [BERYL.]

EMERITA. (Zoology.) [HIPPA.]

EMERSON (Astronomy), the reappearance of one heavenly body from behind another after an eclipse or occultation.

EMERSON, WILLIAM, an eminent mathematician,

philosopher, and mechanist, was born at Hurworth, a village about three miles from Darlington, in June. 1701 he died May 20th, 1782, at his native place, aged nearly eighty-one years.

His father, Dudley Emerson, was a schoolmaster, and is said to have been a tolerable proficient in the mathematics of that time: this circumstance furnished his son with ample means of cultivating his taste for the same science, both by means of a good mathematical library which his father possessed, and the good mathematical tuition which he received in his earlier years. A young clergyman, then curate of Hurworth, also lodged in his father's house, and from him he received all requisite assistance in the study of the Greek and Roman classics, in which he became well versed.

After the death of his father, Emerson attempted to continue the school, which however he soon relinquished; but whether it arose from the impetuosity of his temper which rendered him unfit for such an occupation, or that a small competence left him by his father (he being an only child) rendered it a matter of indifference to him to increase his income, cannot be ascertained. He devoted his long life to writing a series of mathematical works, which, except those of Simpson, were, till a comparatively recent time, the very best in our language. He also contributed largely to the different mathematical periodicals of his time, though almost always under some fanciful name, as Merones, Philofluentimecanalgegeomastrolongo, &c.

Mr. Emerson was in person rather short, but strong and well-formed, with an open honest countenance and ruddy complexion. A portrait of him, by Sykes, was painted and engraved in the latter part of his life; but it is not often to be met with, as only a few copies of it were circulated. His health was generally excellent till near the latter part of his life, when he became a great sufferer from the stone.

Emerson was in many respects a very eccentric person, fancifully coarse in his dress, and uncourteous in his conversation. He was, nevertheless, when in his happier moods, a delightful companion, and his discourse full of instruction, deep thought, and startling originality of opinion.

All his books were published in London; and it was his invariable practice to walk to town and shut himself up in some obscure lodging to devote himself sedulously to the correction of the successive sheets of his works with a care never exceeded even by Hamilton or Cruden; and certainly, of all the mathematical works that have ever been published, those of Emerson are the freest from errata.

Emerson was married, but had no children. He amused himself with fishing, a diversion to which he was much attached, and would frequently stand up in his middle in the water for hours together when he found it gave him a better position for the use of his fly or his angle. He was an excellent practical mechanic, and of most of the machines described in his work on mechanics he had made very good models. The spinning-wheel delineated in that work was the one on which his wife employed her leisure hours. He had also a very profound knowledge of the musical scales, both antient and modern, although he was but a poor performer: still he was dextrous in the repair of musical instruments, and was generally employed to tune the harpsichords and clean the clocks throughout the district in which he resided.

The bold and frank manner in which Emerson spoke on all subjects has led some persons to affirm that he was a sceptic in religion. Of this however there is not the slightest evidence; but it appears to have arisen from the insinuations of his scientific opponents, who thus attempted to crush his reputation with the world, and thereby weaken his authority in matters connected with science—a course too often adopted in our own day by those who contend for victory rather than truth. Emerson was through a long life universally accounted a man of integrity; but his honesty often led to dogmatism, and his indignation at error to an expression of feeling that gave his controversial writings an air of ungracious severity.

A considerable number of Emerson's processes are marked with peculiar elegance and considerable powers of invention; still there is apparent in all of them a want of that power of generalisation which distinguishes the highest order of minds. His Method of Increments is the most original of his works; and his Doctrine of Fluxions is perhaps the most elegant. His Mechanics is the work by

which he is most generally known, a circumstance probably owing to its containing descriptions of so many of the more usual and useful machines: but it is a work singularly crude and ill-digested, and not less singularly incomplete in even the enunciation of the most important principles of mechanical science.

The following is a list of his works, all in 8vo., except his *Mechanics and Increments* in 4to., and his *Navigation* in 12mo.

1. Doctrine of Fluxions. 2. Projection of the Sphere, Orthographic, Stereographic, and Gnomonic. 3. The Elements of Trigonometry. 4. Principles of Mechanics. 5. A Treatise on Navigation. 6. A Treatise on Arithmetic. 7. A Treatise on Geometry. 8. A Treatise on Algebra. 9. The Method of Increments. 10. Arithmetic of Infinities, and the Conic Sections, with other curve lines. 11. Elements of Optics and Perspective. 12. Astronomy. 13. Mechanics, with Centripetal and Centrifugal Forces. 14. Mathematical Principles of Geography, Navigation, and Dialling. 15. Commentary on the Principia, with a Defence of Newton. 16. Miscellanies.

EMERY. [CORUNDUM.]

E'MESA. [SYRIA.]

E'META, a vegetable alkali obtained from *ipecacuanha* root, in which the powers of that medicine reside. In order to prepare it, the root is reduced to powder, and then treated with sulphuric ether to separate a fatty substance, and afterwards with boiling alcohol. The alcoholic solutions, when evaporated, leave a bitter brown extract, which contains emeta combined with gallic acid. This is to be redissolved in water, and boiled with an excess of magnesia, which decomposes the gallate of emeta; the magnesian precipitate is to be washed with a little cold water, and then boiled in alcohol. The emeta dissolved in the alcohol is separated by evaporation; but as it is coloured, it is recombined with an acid, and after being decoloured by animal charcoal, it is to be again precipitated by magnesia.

Emeta, when pure, is white, pulverulent, and uncrystallizable; its taste is rather bitter, and it melts at 104° Fahrenheit, and afterwards decomposes at a temperature below 212°. It suffers no change by exposure to the air; it is slightly soluble in cold water, but readily dissolved by alcohol; the solution restores the blue colour of litmus paper which has been reddened; it is precipitated by tincture of galls; acids are but imperfectly saturated by it, and it yields with them uncrystallizable salts, which have been but little examined.

In the dose of half a grain it is stated to act as a powerful emetic, and in larger doses its effects are extremely violent.

It is composed of—

99.59

EMETICS (*ἰμετικά, emética*) are substances which influence the stomach in a peculiar manner, so as to invert its action and cause vomiting; and this effect is produced without reference to the quantity of matter introduced into that organ or into the circulation. This definition is intended to exclude, on the one hand, the mere inversion of the stomach by the introduction of food or drink, either in inordinate quantity, or of too stimulating a quality; and, on the other, to comprise those means of causing vomiting by their direct introduction into the circulation by injection into a vein. The action of emetics must be viewed in two stages, the primary and secondary. The primary effects of emetics are limited to the emptying of the stomach, compressing, during the act of vomiting, the gall-bladder and pancreas, and exciting to contraction the muscular parietes of the abdomen and thorax, as the machinery by which the process of vomiting is chiefly accomplished. We shall here briefly trace the obvious phenomena of this process, without attempting to account for their occurrence.

Soon after a quantity of an emetic substance or solution (such as *ipecacuanha* or emetic tartar) has been received into the stomach, a feeling of anxiety is experienced in the epigastrium, a general uneasiness termed nausea is felt, which progressively becomes greater, till it ends in the forcible expulsion of the contents of the stomach. This gives a succussion to the whole frame, every part of which experiences more or less of a vibratory motion. The con-

dition of the system is considerably different prior to and during the act of vomiting. In the preliminary stage, the countenance is pale and collapsed; the pulse is small, contracted, irregular, but quick more generally than slow; chilliness is felt, and a cold perspiration may ooze from the surface, all which symptoms disappear when the expulsive movement takes place. Then the face appears flushed; the pulse becomes quicker, fuller, and stronger, and rarely subsides till some time after all vomiting has ceased. If, after a brief interval, the expulsive action be not renewed, a state of languor succeeds, with tendency to sleep, and generally a considerable flow of warm perspiration.

Such are the effects of an emetic, when given in a dose sufficient to produce vomiting; but, if given in a smaller quantity, and repeated at intervals, it will merely create a state of nausea, during which the appetite is lowered, and arterial action is much diminished, while the function of absorption is roused to great activity.

The secondary effects of emetics depend upon the succussion of the frame, the equalization of the circulation, the increased secretion from the mucous membrane of the stomach, and also of the duodenum as well as the liver and pancreas, and frequently from the skin.

The secondary effects of nauseating doses are diminished arterial action and augmented absorption.

We shall now state a few of the morbid conditions to which these agents are suited, and a few of those for which they are unfit.

In fever. Whatever opinions may be entertained respecting the nature and origin of fever, there can be no question but that the sanguiferous system powerfully feels and shows disturbance, and in no point more conspicuously than in the capillaries. These become the seat of those morbid actions, to counteract which is the chief aim of the early treatment. By these vessels, too, are executed the functions of secretion, deposition of the nutrient material, exhalation, and, in some degree, the evolution of animal heat. The consequences of deranged action of the capillaries are—diminished or vitiated secretion, suspended nutrition, altered exhalation, and the animal heat augmented or diminished, or unequally diffused. But while the diseased impression is confined to the general circulation, which it always is for some time (varying in different cases and constitutions), the series of morbid actions may be arrested by venesection, purgatives, or more certainly by an emetic. This should be administered at as early a period of the disease as possible; but even should it fail in cutting short the febrile movement, still it clears the stomach, and fits it to retain whatever may subsequently be had recourse to in order to moderate or regulate the future condition of the system. Emetics invariably render the disease milder, owing to the greater freedom of the secretions which follows their use; and they may be advantageously repeated even in the more advanced stage, frequently inducing sleep and a moist state of the skin. They may be employed in epidemic, typhus, common fever, and exanthematous fevers, especially measles, scarlet fever, and small-pox. For the slight febrile affections of children, generally caused by something offending the stomach, nothing is so well suited or so efficacious as a gentle emetic. In bilious fevers emetics are required, especially at the beginning. In intermittent fevers, if given before the paroxysm, they early bring on the sweating stage, thus concentrating the fit into a short period. Their tendency to produce perspiration often renders them useful in rheumatic fevers. In common inflammation of the throat, and still more so in croup, emetics are of decided utility. In common catarrh they frequently shorten the disease; and in the suffocative catarrh and catarrh of old age, emetics mechanically unload the lungs, and render the respiration freer. Dr. James Clark and Dr. Carswell even think that they can dislodge tubercular matter from the lungs in the early stages of consumption. (See *Clark on Consumption*.)

Few agents are more useful in whooping-cough than emetics; and in many cases of indigestion, especially if accompanied with sick headache or hypochondriasis, emetics give effectual relief.

Emetics are very improper where there is a disposition to apoplexy, or tendency of blood to the head, or where the patient is liable to hæmorrhage from any organ, or is subject to hernia. They are also to be avoided during pregnancy.

EMIGRATION, may be defined to be a man's leaving his native country with all his property to settle perma-

nently in another. Emigration is therefore necessarily implied in the word colonization, and it is by the terms of our definition easily distinguished from a man's temporary absence from his native country and from the kind of absence specially called absenteeism.

Though a man may be properly called an emigrant who leaves Great Britain or Ireland, for instance, and settles in France or Germany or elsewhere in Europe, the term has in modern times come to have a more restricted and particular sense. By the term emigrant we generally understand one who leaves an old and thickly peopled country to settle in a country where there is abundance of land that has never been cultivated before, and where the native population is thinly scattered, and the foreign settlers are yet either few compared with the surface, or none at all. The countries to which emigration is mainly directed at present are the British possessions in North America, the United States of North America, and the great island of Australia with Van Diemen's Land.

An emigrant to any of these remote countries must be either a capitalist or a labourer, or he may combine in himself both conditions; but even a mere labourer cannot emigrate without some capital, though the amount may be only enough to convey him to the spot where his labour and skill will be in demand. It was long a prevalent notion among nations, or perhaps we may rather say with those possessed of power at the head of nations (who have generally been slower in learning any great practical truth than the mass of the people, whose understanding is sharpened by a nearer view of their own interest), that emigration should be discouraged or prevented, as tending to weaken a nation. The objection, we believe, was generally founded rather on a notion that the nation lost by its diminished population, than that it suffered from the abstraction of capital. As to the matter of population, however, some observers even then could not fail to remark, that emigration did not seem to diminish the population, but that on the contrary it seemed to be soon followed by an increase. This was observed with respect to Portugal at the time when she was extending her conquests and colonies, and is a fact confirmed by more recent experience, the explanation of which presents no difficulty. The abstraction of capital, skill, and industry might seem, and indeed is primarily, so much good taken from the mother country; but inasmuch as the emigrants retain in their new settlements, through the medium of commercial exchange which is daily becoming more rapid and easy, a connexion with the parent state, it may be and often is the fact, that they ultimately contribute more to the wealth of the mother country when in the new settlements than they could have done at home. Many of those, for example, who settle in the western States of America or in Canada with no capital beyond their hands, by their industry become the possessors of a well-cultivated piece of land, and ultimately consume more of the products of British industry, for which they must give something in exchange, than if they had remained in their native country. And as, in order that emigration to new countries may be a successful undertaking to those who emigrate, and ultimately advantageous to the mother country, there must be an emigration both of capitalists and labourers, it would seem to follow that a state, if it consult the happiness of its citizens, should place no impediments to the emigration either of capitalists of all kinds or of labourers or artisans of any kind, but should on the contrary give reasonable facilities. The objections that have been made and the legislative obstacles that once existed to the exportation of numerous articles from this country, and still exist with reference to some descriptions of machinery (for instance), are founded on a total misconception of the state and condition of newly settled countries, as to their capabilities for manufactures, and on an absurd notion that the exportation of anything can be prevented whenever the demand for it is sufficiently great to cover the risk of evading an absurd enactment.

[CONTRABAND.]

If a state then should be wise enough not to discourage emigration, it may be asked, should it aid and direct it? So far as a state should aid and direct emigration, there must be two distinct objects kept in view by the state; one must be to benefit the parent country, the other to benefit those who emigrate. On the contrary, as to the individual who emigrates, whether he emigrates under the protection and direction of the government or not, his sole object is of course to better his own condition.

One cannot well conceive why a state, or any section or part of a nation, should make any contribution or raise any fund for the purpose of aiding emigration, except it be with the view of bettering the condition of some who cannot find employment at home, and at the same time adopting some systematic plan for improving the condition of those who are left behind. Yet any system of emigration thus conducted by government, or by societies, or by the inhabitants of particular districts, would fail in its primary object, relief to the emigrants, unless a corresponding amount of capital should be taken out of the country by other emigrants who might settle in the same place to which the emigrant labourers were sent. To effect such an adjustment between capital and labour, not only should both these elements of wealth in due proportion be transported to the new country, but such proportion should, for some time at least, be maintained by the body which superintends such system of emigration; an arrangement which seems impracticable, except by some such provisions as are hereinafter mentioned.

It is further to be observed that, as no persons can ever succeed as emigrants who are not sober, intelligent, and industrious, and as such alone are consequently fit people to go to a new country, such alone should be sent out by a state or a society, if it interferes in the matter of emigration. But if a large number of the most industrious labourers should emigrate from a given district, and leave behind them the worthless and idle, though the emigrants might better their condition and improve the settlement of which they go to form a part, the mother country would be no gainer by this change. We are not inclined to consider that any advantage, at all commensurate to the expense, would result from any emigration, however extensive, from districts where there is a superabundant and pauperized, or a pauperized and not superabundant population. If the idle, the ignorant, and the vicious, were exported wholesale, they would only die a few years sooner in the land of their new settlement, without conferring any benefit on it, and those of the same kind who were left behind would hardly be more susceptible of improvement for the absence of any part of their numbers which did not amount to pretty nearly the whole number; while the industrious and the intelligent, who, by the supposition, remain at home and are willing to labour whenever it is in their power, would hardly derive any benefit by this removal of the bad from among them, at all commensurate to the amount of capital which must be expended on such wholesale exportations. Besides, as already observed, unless a proper supply of emigrant capitalists can be secured, all general plans for the emigration of labourers can only lead to disappointment and starvation. Any plan therefore which shall have for its object the amelioration of a population sunk in ignorance or debased by pauperism, must be one of an internal character, one which must gradually and on certain fixed principles aim at removing the evils which exist in the social system. Emigration must be left to the free choice of individuals, and must be recommended to the young, the sober, and industrious solely on the grounds of offering to them a reasonable prospect of bettering their condition in a new country.

The disadvantages of emigration however, when there is no plan, no controlling or directing power, are obvious. Emigrants often go to a new country without any definite or clear notion of what they are going to. Dissatisfied or unhappy at home, imagination pictures to them a remote and unknown country as an asylum from all the evils of life; or if they have any distinct idea of the new kind of existence which they are going to adopt, they often underrate the difficulties of the undertaking, or form a false estimate of their own capabilities to meet them. It is no wonder then that so many, on landing in the New World, are startled at the obstacles which then stare them in the face, and shut their eyes to the real advantages, such as they are, which a fertile unoccupied soil presents to a hardworking industrious man.

We have stated that any system of emigration for labourers without a corresponding emigration of capitalists would be fruitless; it is also obvious that if capitalists only were to emigrate without being able to secure a supply of labour, the result would be equally unfortunate. And further, it is clear that any system of emigration of labourers to Canada or the United States could produce no good effect, because voluntary emigration of labourers is still going on,

and cannot be checked, and the emigration of capitalists to the same countries is now equally beyond control or direction.

It seems that considerations like these have recently led to the formation of a scheme of emigration which is original in its design. We allude to the South Australian Colony, the first Annual Report of the Commissioners for which was ordered to be printed by the House of Commons, 28th July, 1836. To adopt the language of this Report, 'the distinguishing and cardinal principles of the colony of South Australia are, that all public lands shall be sold, and that the proceeds of the sale shall be employed in conveying labourers to the colony.' Further: 'it is essential to the prosperity of a new colony in which there are neither slaves nor convicts, that there should be a constant supply of free labourers willing to be employed for wages. No productive industry worthy of the name can be undertaken, unless several hands can be put on the same work at the same time; and if there be not, in a colony in which the compulsory services of slaves or convicts cannot be obtained, a constant supply of labour for hire, no extensive farm can be cultivated, no large and continuous work can be carried on, and the capital imported must perish for want of hands to render it reproductive.'

It is also the object of the Commissioners to prevent the labourers, for some time after their arrival in the colony, from purchasing land. It is proposed to effect this by fixing the price of land sufficiently high to prevent the labourer from being tempted too soon to exchange that condition which is for the time the most profitable both to himself and the body of emigrants for the apparently higher character of a land-owner.

It is justly remarked in the Report that the result of such premature purchases 'would be alike disastrous to the capitalist and to the labourer; as the supply of labour for hire being thus diminished, improvements requiring the co-operation of many hands would be suspended, and capital would waste and perish for want of means to use it; and the labouring population becoming separated upon small patches of land, each family would be obliged to perform every species of work for themselves; and the absence of all division of employment and combination of labour would so reduce the efficacy of their industry, that instead of advancing in wealth and civilization, they would fall back to a semi-barbarous state.' Such a result has already been witnessed in numerous new settlements, and such a result must inevitably follow the dispersion of small capitalists and labourers who aspire to be land-holders over a large uncultivated surface, however rich it may naturally be. The practical problem which the Commissioners have undertaken to solve is not without its difficulties, and time alone can show how far they will succeed. In the mean time we recommend to the reader the perusal of the First Report, together with the other publications that have appeared on this interesting subject.

We know no recent publication which is better adapted to give a correct notion of the kind of difficulties which an emigrant has to meet, even under circumstances not the most unfavourable, than a little work entitled the 'Backwoods of Canada,' published under the superintendence of the Society for the Diffusion of Useful Knowledge.

The number of persons who, according to the Custom House accounts, have emigrated from the United Kingdom to the British colonies in North America, the United States, the Cape of Good Hope, and the British settlements in Australia, in each year from 1820 to 1836, has been as follows:—

| Years. | British North American Colonies. | United States of America. | Cape of Good Hope. | Australian Settlements. | Total. |
|--------|----------------------------------|---------------------------|--------------------|-------------------------|---------|
| 1820 | 17,921 | | 1063 | .. | 18,984 |
| 1821 | 13,470 | | 404 | 220 | 13,194 |
| 1822 | 11,982 | | 192 | 875 | 13,349 |
| 1823 | 8,133 | | 184 | 543 | 8,860 |
| 1824 | 7,311 | | 119 | 780 | 8,210 |
| 1825 | 8,741 | | 114 | 485 | 9,340 |
| 1826 | 12,818 | | 116 | 903 | 13,837 |
| 1827 | 12,648 | | 114 | 715 | 13,477 |
| 1828 | 12,084 | | 135 | 1056 | 13,275 |
| 1829 | 13,607 | | 197 | 2016 | 15,820 |
| 1830 | 30,574 | | 264 | 1242 | 32,080 |
| 1831 | 49,383 | | 58 | 423 | 49,864 |
| 1832 | 66,389 | 32,960 | 903 | 3792 | 103,313 |
| 1833 | 28,808 | 29,225 | 517 | 4134 | 62,684 |
| 1834 | 40,060 | 33,074 | 288 | 2800 | 76,222 |
| 1835 | 18,572 | 26,730 | 325 | 1864 | 44,478 |
| 1836 | 24,226 | 37,774 | 293 | 3124 | 75,417 |

The above statement is almost necessarily defective, because many persons proceed from the United Kingdom as emigrants on board vessels which are not wholly devoted to the conveyance of passengers, and of whom no record is kept at the Custom House. The following statement, giving the number of emigrants who landed at Quebec and Montreal, at New York, and in New South Wales, in each year from 1829 to 1835, is compiled from returns made by the government agents, and is probably correct as regards those particular places, which are the principal points to which the tide of emigration from this country is continually tending:—

| | Quebec and Montreal. | New York. | New South Wales. |
|------|----------------------|-----------|------------------|
| 1829 | 15,945 | 11,501 | 554 |
| 1830 | 28,000 | 21,433 | 999 |
| 1831 | 25,254 | 22,697 | 457 |
| 1832 | 51,746 | 28,283 | 2,006 |
| 1833 | 21,752 | 16,100 | 3,685 |
| 1834 | 30,935 | 26,540 | 1,564 |
| 1835 | 12,537 | 16,749 | 1,428 |
| 1836 | 27,722 | 59,075 | — |

The countries from which the emigrants have proceeded who landed at Quebec and Montreal, as stated above, were—

| | 1829. | 1830. | 1831. | 1832. | 1833. | 1834. | 1835. | 1836. |
|---|--------|--------|--------|--------|--------|--------|--------|--------|
| Eng. and Wales | 3,565 | 6,799 | 10,343 | 17,481 | 5,198 | 6,799 | 3,067 | 12,188 |
| Ireland | 9,614 | 18,300 | 34,135 | 28,204 | 15,013 | 19,296 | 7,108 | 12,594 |
| Scotland | 2,643 | 2,450 | 5,354 | 5,500 | 4,196 | 4,591 | 3,127 | 2,224 |
| Hamburg and Gibraltar | .. | .. | .. | 15 | .. | .. | .. | .. |
| Nova Scotia, Newfoundland, West Ind., &c. | 123 | 451 | 424 | 546 | 345 | 339 | 226 | 236 |
| Havre de Grace (Swiss and Bavarians) | .. | .. | .. | .. | .. | .. | .. | *486 |
| | 15,945 | 28,000 | 50,254 | 51,746 | 21,752 | 30,935 | 12,527 | 27,722 |

The arrivals at New York in the four years from 1829 to 1832, since which time this information has not been afforded, were—

| | 1829. | 1830. | 1831. | 1832. |
|--------------|--------|--------|--------|--------|
| From England | 8,110 | 10,250 | 13,808 | 18,947 |
| Ireland | 2,443 | 3,499 | 6,721 | 6,050 |
| Scotland | 943 | 1,594 | 2,078 | 3,286 |
| | 11,501 | 21,433 | 22,607 | 28,283 |

A large proportion of English emigrants who land at New York have no intention of remaining in the United States, but take that route in preference to the Saint Lawrence, the navigation of which is tedious and dangerous, and proceed to Upper Canada: it is not possible however to state precisely their ultimate destination. The distribution of those emigrants who landed at Quebec and Montreal during the last three years is given by the agent for emigration in Canada as follows:—

| | 1834. | 1835. | 1836. |
|--|--------|--------|--------|
| LOWER CANADA. | | | |
| City and District of Quebec | 1,500 | 825 | 1,000 |
| District of Three Rivers | 350 | 132 | 200 |
| District of St. Francis and Eastern Townships | 640 | 900 | 6,000 |
| City and District of Montreal | 1,200 | 790 | 1,500 |
| Ottawa District | 400 | 350 | 900 |
| | 4,090 | 2,297 | 9,600 |
| UPPER CANADA. | | | |
| Ottawa, Bathurst, Midland, and Eastern Districts to Kingston included | 1,000 | 2,000 | 3,600 |
| District of Newcastle and Townships in the vicinity of the Bay of Quinte | 2,650 | 900 | 1,500 |
| Toronto and Home District, and Settlements round Lake Simco | 8,000 | 2,500 | 3,000 |
| Hamilton, Guelph, and Huron Tract | 2,660 | 1,300 | 1,400 |
| Niagara Frontier and District, and round the head of Lake Ontario to Hamilton | 3,300 | 1,300 | 1,500 |
| Settlements bordering on Lake Erie, including the London District, Adelaide Settlement, and on to Lake St. Clair | 4,600 | 1,800 | 2,000 |
| | 22,210 | 9,800 | 12,000 |
| Died at Grosse Ile | .. | 10 | 58 |
| " at Marine Hospital, Quebec | .. | 3 | 30 |
| Returned to United Kingdom | 350 | 117 | .. |
| " to Pictou | .. | .. | 67 |
| Gone to United States | 3,483 | 300 | 4,973 |
| Died of Cholera | 800 | .. | .. |
| | 4,633 | 430 | 5,123 |
| Total | 30,933 | 12,527 | 27,722 |

The emigrants who arrived at Quebec and Montreal in each of the years 1835 and 1836 were divided, as regards sex, &c., as follows:—

| | 1835. | 1836. |
|---|--------|--------|
| Males | 5,597 | 14,447 |
| Females | 3,866 | 7,898 |
| Children under 14 years of age | 3,064 | 5,448 |
| | 12,527 | 27,793 |
| Of these there were sent out by parochial aid | 1,043 | 4,640 |
| Went at their own expense | 11,484 | 23,098 |
| | 12,527 | 27,793 |

The parochial emigrants in 1836 were sent from Hampshire, Wiltshire, Norfolk, and Kent.

The following list of Reports may be useful.—

Report from Select Committee on Emigration from the United Kingdom, 1826. Three Reports from same Committee, 1826-27. Report to Colonial Department by Col. Cockburn, on the subject of Emigration, January, 1827. Reports from Commissioners for Emigration to the Colonial Secretary, 1832. Annual Reports from the Agent for Emigration in Canada, 1833 to 1836.

EMIR-AL-OMRAH, or more correctly *emîr-al-omarâ*, i. e. 'the prince of princes,' or 'chief of chiefs,' is the designation of an office under the caliphate, endowed with almost unlimited authority, which was created in the year of the Hegira 324 (A.D. 935), became hereditary in the year 333 (A.D. 944), and continued till near the middle of the following century. The disturbed state of the empire, in which the governors of the provinces frequently broke their allegiance to the sovereign, induced the caliph Al-Radhi, who had ascended the throne in the year 322 of the Hegira (A.D. 934), to seek for stronger aid in the management of public affairs than the previously existing office of a vizier, or prime minister, was able to afford; and with this view he sent for one of the refractory vassals, Mohammed ben Râyek, the governor of Waset, invited him to come to Bagdad, appointed him commander-in-chief of the army, and entrusted to him the superintendence of all his dominions, conferring upon him at the same time the title of *emîr-al-omarâ*, and directing his name to be inserted in the public prayers in the mosques throughout the empire, next to that of the caliph himself. The vizier Ebn Moklah, known as the reputed inventor of the Neskhî character, or Arabic current hand, was dismissed, and severely punished for an attempt to recover his station. Mohammed ben Râyek himself appointed a vizier in the person of Fadhl ben Jaafar, the governor of Egypt and Syria. Not two years elapsed after the elevation of Mohammed ben Râyek, before he was obliged to yield his place to the Turk Yahkam (called by Abulfeda, Bahkam), a freed slave, who had raised himself into power, and had been appointed governor of Ahwâz by Mohammed ben Râyek. This post he had been obliged to relinquish on account of the rising power of the Buides (Bawaihides) in Persia: he had in consequence taken possession of Waset, and now marched to Bagdad, and forced the caliph to submit to his dictation. Mohammed ben Râyek quitted the capital, but soon returned with an army, when a contest followed, which terminated in his being appointed governor of Harran, Roha (Edessa), Kinnesrin, and Awâsim, and subsequently of nearly the whole of Syria. Bahkam remained *emîr-al-omarâ* till his death, which took place shortly after the accession of Mottaki billah to the caliphate (A. Heg. 330, A.D. 941): he was, according to some, killed by the Kurds on a hunting excursion; according to others, he was assassinated by order of Mottaki, whom his arrogant behaviour had exasperated against him. Abdallah al-Baridi, governor of Basra, made an unsuccessful attempt to possess himself of the office of *emîr-al-omarâ*. Kurtekin, another Turkish chief, who succeeded him, held the office during eighty days, at the expiration of which Mohammed ben Râyek returned from Syria to Bagdad, took Kurtekin prisoner, and was re-appointed *emîr-al-omarâ* by the caliph. But after a very short time Mohammed was assassinated by the order of Naser-ed-daulah, the governor of Mosul, who succeeded him during a period of three months. In A. Heg. 331 (A.D. 942), Mottaki appointed Tûzûn *emîr-al-omarâ*. In the ensuing year the caliph quitted Bagdad, and fled towards Mosul in consequence of a disagreement with Tûzûn; the latter followed him, as the caliph had offered terms for a reconciliation; but when they had met, Tûzûn ordered both the eyes of the caliph to be put out,

led him back to Bagdad, and compelled him to resign the throne in favour of Mostakfi billah. In A. Heg. 334 (A.D. 945) Tûzûn died, and the Turkish guards at Bagdad chose Zairat, son of Shîrâd, as his successor, in which capacity he was confirmed by the caliph Mostakfi. But before the end of the year Moëzz-ed-daulah, the Buide (Bawaihides) prince of Ahwaz, entered Bagdad at the head of an army; Zairak and the Turkish guards fled to Mosul, and the caliph created Moëzz-ed-daulah his *emîr-al-omarâ*. Of this appointment he had soon reason to repent; for Moëzz-ed-daulah dethroned him, and made Al-Moti-lillah caliph in his stead. 'The caliphate,' observes Abulfeda, 'which was conferred upon Moti-lillah, was divested of nearly every prerogative of sovereignty: the officers of Moëzz-ed-daulah ruled throughout Irak, and to the caliph nothing was left but what Moëzz-ed-daulah out of his own free will conceded to him.' The authority of Moëzz-ed-daulah was for a time contested by Naser-ed-daulah of Mosul; but in A. Heg. 337 (A.D. 948) Moëzz-ed-daulah took Mosul, and his opponent fled to Nisibis. Moëzz-ed-daulah now continued undisturbed in the possession of his high authority till his death, which took place A. Heg. 356 (A.D. 966). How great his power was cannot perhaps be better shown than by mentioning the fact, that he was the first Mohammedan prince who sold an appointment of judge (for 200,000 dirhems), and that in a Sunnite country he, a Shiite, directed a public mourning in memory of the death of the caliph Hossain [ALI BEN ABI TALEB]. He was succeeded by his son Bakhtiar Azz-ed-daulah, an indolent and voluptuous prince, between whom and the chiefs of the Turkish body-guard, Sebuktekin and Aftekin, frequent dissensions and at last open hostilities took place. Bakhtiar was obliged to quit Bagdad, and to apply for assistance to his cousin Adad-ed-daulah. The latter conducted him back to the capital, but induced him to resign his office, which he himself assumed, till compelled by his father Rokn-ed-daulah to restore it to Bakhtiar. At the suggestion of Sebuktekin, Mosti-lillah had, in A. Heg. 363 (A.D. 973), abdicated the caliphate in favor of Tayi-lillah his son. In A. Heg. 366 (A.D. 976), Rokn-ed-daulah died, and Adad-ed-daulah, who succeeded him as sovereign of Persia Proper, Arjan and Kerman, now for the second time prevailed on Bakhtiar to surrender to him his post as *emîr-al-omarâ*: a war followed, in which Bakhtiar was taken prisoner and executed. Bardas, a rebel governor under the Greek empire, applied to Adad-ed-daulah for support; to prevent which Nicephorus was sent twice as ambassador from the court of Constantinople to that of the emir. Adad-ed-daulah remained *emîr-al-omarâ* till his death, A. Heg. 372 (A.D. 982). He encouraged literature and science, and was himself an accomplished poet. He restored and embellished the principal towns of the empire, which had been damaged during the civil wars: at Bagdad he erected an hospital; and in Persia Proper he inclosed the river Cyrus [BEND EMIR] with extensive dykes. After his death, his son Samsam-ed-daulah was chosen emir; but in A. Heg. 376 (A.D. 986) his brother Sharf-ed-daulah forced the caliph to confer that dignity upon him, and Samsam-ed-daulah was blinded. Sharf-ed-daulah died A. Heg. 379 (A.D. 989-990), and was succeeded by his brother Behâ-ed-daulah, who remained *emîr-al-omarâ* till his death; but was obliged to make concessions to the Turkish body-guards, and thereby diminished his power. He induced the caliph Tayi-lillah to resign in favor of Kader-billah, A. Heg. 381 (A.D. 991). Behâ-ed-daulah was, in A. Heg. 403 (A.D. 1012) followed by his son Soltan-ed-daulah, who was compelled by a military insurrection, in A. Heg. 411 (A.D. 1020), to appoint his brother Mushrif-ed-daulah commander-in-chief of the army, by whom he was subsequently deprived of his office. Soltan-ed-daulah died in A. Heg. 415 (A.D. 1024); Mushrif-ed-daulah in the following year. After an interval of two years, during which Bagdad seems to have suffered much from the insolence of the Turkish guards, Jelâl-ed-daulah, another son of Behâ-ed-daulah, was invited by the army to come from Basra to the capital; and the caliph confirmed his election as *emîr-al-omarâ*. During his administration the caliph Kader-billah died, A. Heg. 422 (A.D. 1031), after a nominal reign of forty-one lunar years, and was followed by his son Kâyim-bi-amrallah. The latter, instead of seeking an intimate union with Jelâl-ed-daulah, whom he considered to be of little influence, made a treaty with another Buide prince, Firûz Abû-Kâlenjâr of Shiraz. Insurrections at Bagdad, and predatory incursions of bands

of wandering Arabs became more and more frequent; and the authority of both the caliph and the emir-al-omarâ, who were moreover often of different opinions, seemed to be at an end. When Jeld-ed-daulah died, A. Heg. 435 (A.D. 1043), Fîrûz Abû-Kâlenjâr was elected emir-al-omarâ. During his administration the power of the Arabian empire began to yield to the conquest of the Seljuks, who had taken possession of Jorjan, Tabaristan, Khovarezm, and the Persian Irak, and were advancing towards Bagdad. He died on an expedition into Kerman against Bahram, the governor of that province, who had broken his allegiance to the court of Bagdad. His son Malek-er-Rahîm succeeded in suppressing the revolt in Kerman; but in the mean time Togrul Bek, the sovereign of the Seljuks, had taken possession of Isfahan, and a disension which had broken out between the caliph and Basasiri, the governor of Irak, rendered the conquest of that province and of the capital itself a matter of little difficulty for the Seljuks. In A. Heg. 447 (A.D. 1055), Togrul Bek entered Bagdad. Malek-er-Rahîm abdicated his office, and remained as a prisoner in the hands of Togrul, who thus put an end to the dominions of the Buide emir-al-omarâs.

(Umbreit, *Commentatio exhibens historiam Emirorum al Omrah ex Alfubeda*, Göttingen, 1816, 4to.; Wilken, *Mirkhond's Geschichte der Sultane aus dem Geschlechte Bujeh*, Berlin, 1835, 4to.)

EMLY, a bishop's see in the ecclesiastical province of Cashel in Ireland. The chapter consists of dean, precentor, chancellor, archdeacon, and four prebendaries. This diocese lies in the counties of Tipperary and Limerick, and contains forty-two parishes, constituting seventeen benefices. Its extent is about forty-one English miles by fifteen. In 1792 there were in Emly diocese thirty-five churches of the establishment: in 1834 the numbers were, churches of the establishment, eleven; other places of worship in connexion therewith, four; Roman Catholic chapels, thirty-one. In the same year the total population was 98,363, of whom there were 1246 members of the established church; 97,115 members of the church of Rome; one Presbyterian; and one other Protestant dissenter; being in the proportion of rather more than ninety-eight Roman Catholics to one Protestant of whatever denomination. In the same year there were in this diocese seventy-four schools, educating 4835 young persons, being in the proportion of 4½ per cent. of the entire population under daily instruction; in which respect Emly stands last but one among the thirty-two dioceses of Ireland, being only superior in educational rank to the diocese of Ardferit and Aghadoe.

The see of Emly was founded by Saint Ailbe, who died in the year 527. It was united to the archiepiscopal see of Cashel in 1568, which union still subsists. [CASHEL.]

(Beaufort's *Memoir of a Map of Ireland; Parliamentary Returns, &c.*)

EMMANUEL COLLEGE, Cambridge, was founded in 1584, by Sir Walter Mildmay, on the site of the monastery of the Black Friars, which he had purchased of a Mr. Sherwood. The original foundation was only for a master, three fellows, and four scholars. There are now twelve, which are called foundation fellowships, besides one founded by Mr. Gillingham, the holder of which receives a dividend arising from a distinct estate, but is in most other respects on an equality with the foundation fellows. These fellowships are open to all counties, but there cannot be more than one fellow of the same county at the same time; and no one can be a candidate till he has taken the degree of M.A., or is at least B.A. of the third year. He must be twenty-one years of age, and have been six years a member of the university. The four senior fellows are obliged to take priests' orders. Sir Wolstan Dixie, some time lord mayor of London, a contemporary of the founder, gave lands for the support of two fellows, distinct from those of the foundation. These fellows have no vote in college affairs, nor have they any claim to college livings: candidates for these fellowships must have taken the degree of B.A., and must be related to the founder, or have received their education at Market-Bosworth School. There are likewise four scholarships of Sir Wolstan Dixie's foundation, subject to the same restrictions. The foundation scholarships of Emmanuel College are open to Englishmen of all counties, but there cannot be more than three scholars of the same county at the same time. The scholars receive upwards of 12l. per annum in addition to the weekly payment of 7s. 6d.

during residence. Besides these there are many scholarships and exhibitions, founded by various benefactors, to be given to the candidates most distinguished for learning and exemplary conduct. Among the principal are five by Dr. Thorpe of 24l. per annum, with a preference, *cæteris paribus*, to the sons of orthodox clergymen; one by Mr. Hubbard of 12l. per annum to the best of Dr. Thorpe's scholars; ten by Mr. Ash of 10l. per annum; four by Archdeacon Johnson of 24l. per annum, with a preference to candidates from Oakham and Uppingham schools; one by Dr. Smith of 16l. per annum, with a preference to Durham and Newcastle schools; two by Mr. Richards of 12l. per annum, with a preference to Christ's Hospital; one by Sir Busick Harwood of 10l. per annum, with a preference to a medical student; and two by Lady Romney of 12l. per annum each. Various annual prizes are given in this college: amongst them, plate to the amount of 12l. to the best proficient among the commencing bachelors of arts. The number of members of this society upon the college boards, according to the University Calendar of 1837, is 224. There are eighteen benefices in the patronage of the society. To one of these, the rectory of Twyford in Hants, the college nominates, and the heirs of Carew Mildmay, Esq., present: to two others, Wallington rectory in Herts, and Fressing'eld-cum-Withersdale vicarage in Suffolk, the master nominates, and the society presents: to two other livings a Dixie fellow is to be presented alternately with one on the foundation. A copy of the statutes of Emmanuel College is preserved among the Sloane Manuscripts in the British Museum, No. 1739. Among the eminent persons who have been members of Emmanuel College, were Bishop Hall, Matthew Poole, author of the 'Synopsis Criticorum,' Joshua Barnes, Dr. Wallis the mathematician, Sir William Temple, Anthony Blackwall, and Dr. Richard Farmer, the commentator upon Shakspeare, who was master of this college. (Lysons' *Magna Brit.—Cambridgeshire*, p. 128; *Cambridge University Calendar for 1837.*)

EMMERICH, or EMRICH, a town on the left bank of the Rhine, with a good harbour, in 51° 50' N. lat. and 6° 13' E. long. It lies in the circle of Rees, in the northern extremity of the county or administrative circle of Düsseldorf, in Rhenish Prussia, close to the frontiers of Holland. It was formerly in the Hanseatic league. There are 4 churches, 2 Roman Catholic and 2 Protestant, a Mennonite place of worship, a minor gymnasium, an ecclesiastical seminary, 2 orphan asylums. The town is surrounded by walls and ditches. In 1765 the population was 3491; in 1817, 4412; and in 1831, 5569. There are manufactures of woollens, stockings, hats, galloons, soap, oil, &c., besides tanneries, wax-bleaching grounds, and a public salt factory.

EMMIUS UBBO, was born at Gretha, in East Friesland, in the year 1547. His father was a clergyman of the Lutheran communion. Emmius studied at Bremen, Rostock, and lastly at Geneva, where he became intimate with Beza. He afterwards returned to his native country, and in 1589 was made rector of the school of Norden, in East Friesland. In 1594 he was appointed to the chair of history and the Greek language in the College of Groningen, and when the University of Groningen was instituted in 1614 Emmius was made rector of the same. He was deeply imbued with classical learning, and he excelled in the knowledge of history, antient and modern. Among his historical works, the most important is the 'Vetus Græcia illustrata,' 3 vols., Leyden, 1626. The first volume consists of a description of antient Greece, including the islands; the second contains a history of that country; and the third, which is the most elaborate and interesting, gives an account of the political institutions and social manners of the various Greek states; namely, of Athens, Sparta, Creta, Argos, Thebes, Corinth, Syracuse, Corcyra, Samos, Chios, Rhodes, Achaia, Atolia, Massilia in Gaul, Locri in Italy, and Lycia in Asia. The author has also introduced a brief sketch of the Carthaginian republic. The appendix contains an account of the decline and fall of three of the above states, Athens, Carthage, and Sparta. Emmius gives a long list of antient authors from whom he derived his information. The work is altogether useful, and was still more so at the time of its appearance, when good works on classical learning were more scarce than they are at present. The other works of Emmius are, 2. 'Opus Chronologicum,' or a General Chronology, fol., 1619; 3. 'Rerum Frisicarum Historia, à gentis origine usque ad ann. 1565,' Leyden, 1632.

It is a good history of Friesland, the author's native country, to which is added 'De Frisiorum Republica Commentarius,' published before separately at Embden, 1619. 4. 'De Agro Frisiae inter Amasum et Lavicum flumina;' 5. 'Historia nostri Temporis,' Groningen, 1732. Emmius Ubbo died in 1625, in his 78th year. At the time of his death he was busy writing a history of Philip of Macedonia, the father of Alexander the Great, which he intended as a warning to the republic of the United Provinces against the designs and intrigues of their enemies. He had written as far as the fifteenth year of Philip's reign. Emmius was acquainted with, and appreciated by, most of the learned men of his time, such as De Thou, Gruter, Gomar the theologian, Pezelius, and others. He was especially a favourite with William Louis, of Nassau, the governor of Friesland and Groningen. (*Biog. Ubbonis Emmii, Historiarum et Græcæ linguae in Academia Groningensi Professoris ejusque Rectoris primi*, Groningæ, 1628.)

EMPALEMENT, an obsolete name of the stamen of a flower.

EMPANNEL, the writing and entering the names of a jury on a parchment schedule or roll of paper by the sheriff, which he has summoned to appear for the performance of such public service as juries are employed in. [**PANEL**.]

EMPE'DOCLES, a native of Agrigentum in Sicily, who flourished about B.C. 450: he was distinguished not only as a philosopher, but also for his knowledge of natural history and medicine, and as a poet and statesman. It is generally believed that he perished in the crater of Mount Ætna. The story that he threw himself into it in order that by disappearing suddenly and without a trace, he might establish his claim to divinity, and the charge of arrogance founded upon that pretension, seems to have rested on a misconception of his doctrine that the human soul (and consequently his own) is divine and immortal.

His masters in philosophy are variously given. By some, like the Eleatæ generally, he is called a Pythagorean, in consequence of a resemblance of doctrine in a few unessential points. But the principles of his theory evidently show that he belongs to the Eleatic school, though the statement which makes him a disciple of Parmenides rests apparently upon no other foundation than a comparison of their systems; as, in like manner, the common employment of the mechanical physiology has led to an opinion that he was a hearer of his contemporary Anaxagoras.

He taught that originally All was one:—God, eternal and at rest: a sphere and a mixture (*σφαῖρα, μίγμα*)—without a vacuum—in which the elements of things were held together in undistinguishable confusion by love (*φιλία*)—the primal force which unites like to unlike. In a portion of this whole, however, or, as he expresses it, in the members of the Deity, strife (*εἰσός*)—the force which binds like to like—prevailed and gave to the elements a tendency to separate themselves, whereby they first became perceptible as such, although the separation was not so complete, but that each contained portions of the others. Hence arose the multiplicity of things: by the vivifying counteraction of love organic life was produced, not however so perfect and so full of design as it now appears; but at first single limbs, then irregular combinations, till ultimately they received their present adjustments and perfection. But as the forces of love and hate are constantly acting upon each other for production or destruction, the present condition of things cannot persist for ever, and the world which, properly, is not the All, but only the ordered part of it, will again be reduced to a chaotic unity, out of which a new system will be formed, and so on for ever.

There is no real destruction of anything, only a change of combinations. It must be remarked that the primal forces, love and hate, must not be supposed to be extrinsically impressed upon matter; on the contrary, while strife is inherent in the elements separately, love is in the mass of things—nay, more, is one with it—God. Of the elements (which he seems to have been the first to exhibit as four distinct species of matter), fire, as the rarest and most powerful, he held to be the chief, and consequently the soul of all sentient and intellectual beings which issue from the central fire, or soul of the world. The soul migrates through animal and vegetable bodies in atonement for some guilt committed in its unembodied state when it is a dæmon; of which he supposed that an infinite number existed. The seat of the dæmon when in a human body is the blood.

Closely connected with his view of the objects of knowledge was his theory of human knowledge. In the impure separation of the elements it is only the predominant one that the senses can apprehend, and consequently, although man can know all the elements of the whole singly, he is unable to see them in their perfect unity wherein consists their truth. Empedocles therefore rejects the testimony of the senses, and maintains that pure intellect alone can arrive at a knowledge of the truth. This is the attribute of the Deity, for man cannot overlook the work of love in all its extent; and the true unity is only open to itself. Hence he was led to distinguish between the world, as presented to our senses (*κόσμος αἰσθητός*), and its type the intellectual world (*κόσμος νοητός*).

His explanation of the cognitive faculty, which rested upon the assumption that 'like can only be known by like,' is drawn naturally enough from his physical view. Man is capable of knowing outward things, since he is, like them, composed of the four elements, and of the two forces love and hate; and it is especially by the presence of love within him that he is able to arrive at an intellectual knowledge of the whole, however imperfect and inferior to the divine.

The Fragments of Empedocles were published with a commentary by Fr. W. Sturz, Leipzig, 1805, 8vo.; see also Empedocles and Parmenides *Fragments, ex Cod. Taur. Bibl. restituta et illustrata*, ab A. Peyron, Lips. 1810, 8vo.

EMPEROR, from the Latin *Imperitor*. Among the early Romans the title of Imperator was bestowed by the acclamations of his soldiers in the camp and by a vote of the Roman senate, on a commander-in-chief who had signalized himself by killing a certain number of the enemy. (Tacit. *Annal.* iii. 74.) The term was gradually extended to signify a commander-in-chief sent on any important expedition. (Cic. *Pro Lege Manil.* c. 2.) But it still continued usual for the appellation to be bestowed as a special title of honour for some military service: thus we find that the small military exploits of Cicero conferred on him the title of Imperator. C. J. Cæsar assumed the name as a prænomen, (Imperator C. J. Cæsar), a practice which was followed by his successors, as we may observe on their coins. (Suetonius, *Cæsar*, 76.) As examples of this title see the coins of ANTONIUS, AURELIUS, &c. On the reverse of the coin of Aurelius we observe IMP. VIII., that is, Imperator octavum, or imperator the eighth time, which shows, as indeed can be proved from a variety of examples, that the Roman emperors often assumed the title on special occasions when they or their generals had obtained some signal victory. This term Imperator then, it will be observed, under the early emperors, cannot be considered as denoting any sovereign power. It was indeed given to private individuals on the occasion of great military success, certainly as late as the time of Hadrian, and perhaps later. (Appian, *Civil Wars*, lib. 2.)

After the time of the Antonines the term Imperator seems to have gradually grown into common use as one of the titles which expressed the sovereign of the Roman world, though the name Princeps was also long used as indicating the same rank and power. (See the Dedication of J. Capitoletinus to Constantine.) It may be difficult to state when this term Imperator became exclusively the designation of the Roman sovereign. In the introduction to the Digest (*De Conceptione Digestorum*), Justinian assumes the title of Imperator Cæsar Flavius Justinianus, &c., semper Augustus. [Augustus.] In the proemium to the Institutes, Justinian uses the terms Imperatoria majestas to express his sovereign power, and yet in the same paragraph he calls himself by the name of Princeps, a term which dates from the time of the so-called Republic, and expressed the precedence given to one particular member of the senate. The term Princeps was adopted by Augustus as the least invidious title of dignity, and was applied to his successors.

From the emperors of the West this title, in the year 800, devolved to Charlemagne, the founder of the second or German empire of the West. Upon the expiration of the German branch of the Carolingian family, the imperial crown became elective, and continued so until the last century. The title of emperor of Germany now no longer exists, Francis II. having laid it aside, and assumed the title of emperor of Austria. [Austria, p. 151.] The only other European potentate who uses the style of emperor is the autocrat of Russia, the monarchs of which country, about the year 1520, exchanged their former title

of duke or great duke of Russia, for that of Czar or Tzar. [CZAR.] In early times it was asserted by the civilians that the possession of the imperial crown gave to the emperors of Germany, as titular sovereigns of the world, a supremacy over all the kings of Europe, though such was never attempted to be exercised; and they denied the existence of any other empire: but in spite of this denial it is certain that several of the kings of France of the second race, after they had lost the empire of Germany, styled themselves Basileus and Imperator. Our own King Edgar, in a charter to Oswald bishop of Winchester, styled himself 'Anglorum Basileus omnium que regum insularum oceani que Britanniam circumjacentis cunctarum que nationum que infra eam includuntur Imperator et Dominus.' Alfonso VII. also, in the 12th century, styled himself emperor of Spain. It might be easily shown how the title and rank of king and emperor have been feudalized, as it were, in passing through the ordeal of the middle ages.

EMPETRA'CEÆ, a small natural order of polypetalous exogens, related to Euphorbiaceæ. They consist of unisexual heath-like plants with minute flowers, having a calyx with a few imbricated sepals that change into about three membranous petals, a small number of hypogynous stamens, and a superior ovary with from three to nine cells, in each of which there is a single ascending ovule. The fruit is fleshy and berried. They are small acrid plants, of no known use. *Empetrum nigrum*, the craneberry or crowberry, is wild on the mountainous heaths in the north of England. Its black fruit forms an article of food in the northern parts of the world, but is reported to be unwholesome, and to cause headach. A sort of wine has been prepared from it for many centuries in Iceland and Norway; whence the report of real wine which was used at the sacrament being made in those countries.

Empetrum rubrum.

1, A female flower, much magnified; 2, a pistil; 3, a transverse section of the same.

EM'PHASIS, in articulation, is the mode of drawing attention to one or more words in a sentence by pronouncing them with a greater volume and duration of sound, and in a higher or lower note, than the adjoining words. In written language there are several symbols by which emphasis is denoted. In manuscript the emphatic word is commonly underlined; in printing it is common to employ a different character, particularly the inclined character called the Italic. The German printers have introduced the mode of placing the letters of the emphatic word farther apart from one another. In modern languages the employment of some symbol for emphasis is more requisite than in the ancient languages. In the latter, where the arrangement of words was less fixed, it was generally practicable by the very position of a word in a sentence to denote its emphatic power. Thus, in the Latin language, the first word of a sentence, or even of a clause, is generally emphatic; so also is the last word; and even in the middle of a sentence the verb is often so placed as to give emphasis to the preceding word. Indeed so closely connected is the order of words in

a Latin sentence with the principle of emphasis, that the utter neglect of this principle in the schools of the present day may be set down as one of the chief obstacles in the acquirement of the Latin language.

EMPIRIC. This word is derived from the Greek (*ἐμπειρία*, *empelrikos*) and means a man who derives his knowledge from experience. A medical sect which arose in opposition to that of the dogmatics assumed the name of empirics. Serapion of Alexandria and Philinus of Cos are regarded as the founders of this school. Ever since the world has existed, the human mind, in striving to find out the principles of truth, has considered the matter in two opposite ways. According to one system, the human mind contains the seeds of knowledge; according to the other, the mind is nothing but a blank sheet of paper, on which experience writes that which man perceives through the senses. Aristotle and Plato are still the representatives of the two opposite systems.

The science of medicine has been of necessity under the influence of one of the two opposite opinions, and the doctrine of Serapion or Philinus is nothing but the application of the Aristotelian theory, that nothing can be known by the understanding which has not been previously known by the senses.

Accordingly they maintained that experience was the only true knowledge which was derived from the unerring testimony of the senses; that dogmatism was erroneous, because it derived its principles from mere imagination. They opposed to the theorists their contradictions, and sneered at their learning and acuteness of reasoning as inadequate means of curing diseases.

The empirics admitted three kinds of experience, the one acquired by chance, the second by experiments, the third by imitation; and these three they called the tripod of medical science. However, it is evident that their mode of experience is nothing but a disguised mode of reasoning by analogy. Epilogism, as they called it, is as theoretical as pure dogmatism; for, how can we judge by analogy, if we do not assume some general laws to which the particulars are subjected?

If the empirics had remained true to their principles their name would stand high among the medical profession. But having abandoned the study of nature, and with it all scientific pursuits, they sank into such disrepute, that their name became a stigma. And even in our days when the natural sciences have, by the impulse given by Lord Bacon to genuine experiment, risen to a high degree of perfection, and empiricism is the character of modern science and philosophy, the name of empiric is still bestowed as an opprobrious term upon all ignorant pretenders in the medical art. (Celsus, *De Medicina*; Curt Sprengel, *Geschichte der Medizin*.)

EMPYREUMA denotes the peculiar and disagreeable smell and taste resulting from the action of a considerable degree of heat upon vegetable or animal substances in close vessels, which prevent such an access of air as is required for perfect combustion: in this way destructive distillation goes on so as frequently to produce an oil which has a strong, burnt, or, as it is termed, empyreumatic smell and taste.

EMS, a river in the north-west of Germany, which has its source in 51° 50' N. lat., and 9° 11' E. long., on the Havelhof, at the foot of a hill called Stapelag, which is at the south-eastern end of the Teutoburg Forest, and to the north-west of the town of Paderborn in Westphalia. From this point the river pursues a sluggish westward course between low banks to Rietberg, then turns to the north until it approaches Harzewinkel, where it bends again to the west past Warendorf and Telgte, and thence flows north-westwards to Schüttdorf, in Hanover, below the town of Rheine, where it quits the Prussian territory. At Fuestrup, about five miles below Telgte, it is from four to five feet deep; and about five miles lower down it becomes navigable for small flat-bottomed vessels. It enters the Hanoverian dominions above Schüttdorf, and traverses them for about 70 miles. The general direction of this part of its course, in which it makes numerous bends, is due north, until it quits the landrostei or circle of Osnaburg, in passing through which it approaches within a short distance of the town of Lingen, and has that of Meppen on its right bank. The Ems in this part, though full of water in the rainy season, is so shallow in dry weather that a canal, called the Ems canal,

has been opened at a very heavy expense from *Haukens-fähe*, about eight miles above *Lingen*, which runs parallel with the river, has a depth of five feet, and rejoins the *Ems* at the confluence of the *Hase* at *Meppen*. From this town to *Papenburg* its bed has been deepened, so that in the shallowest spots it has a depth of three feet. Just above *Papenburg*, which lies on the borders of the circle of *Aurich*, or *East Friesland*, the river winds eastwards, and then inclining somewhat to the north-east, runs on to *Leer*, whence it pursues a northerly course till it has passed *Vornhasen*, and from this spot turns to the north-west, and ultimately enters the *Dollart*, a bay of the North Sea, in $53^{\circ} 18' N.$ lat. The *Oster* (East) and *Wester* (West) *Ems*, which are formed by the sand banks *Ransel* and *Borkum-rif*, are the channels by which the *Ems* discharges its waters into the North Sea. Between the *Ransel* and *Dollart* the *Ems* is wide, and separates *East Friesland* from the Dutch province of *Groningen*. The *Ems* below *Leer* widens to a breadth of 300 feet, and between the Dutch and *Hanoverian* territories its width varies from five to nine miles. The whole length of this river is estimated at about 210 miles, and it is navigable for vessels of 80 or 100 tons burden as high as *Papenburg*, where it ceases to be affected by the tides. There are bridges across it at *Telgte*, *Wiedenbrück*, *Wahrendorf*, *Schönflint*, *Greven*, *Hembergen*, and near *Rheine*, in *Westphalia*, and at *Meppen* in *Hanover*. Its principal tributaries on the right bank are the *Hase*, which, passing *Osnaburg*, falls into it at *Meppen*, after a course of about 125 miles; and the *Leda*, which enters *Hanover* from the duchy of *Oldenburg*, and joins the *Ems* near *Leer*, after a course of about 56 miles. On the left bank the *Ems* receives the *Aa* to the south-west of *Papenburg*. The basin of the *Ems* has an area of about 4914 square miles, the smallest area of any of the rivers which fall into the North Sea.

The *Ems* is mentioned by Roman writers under the Latinized form *Amisia*. (*Tacit. Annal. i.*, 60, 63, &c.)

EMU. [*STRUTHIONIDÆ*.]

EMULSION, a term applied to mixtures which generally have a milky appearance, and which, in some cases, are partial solutions, in others merely mechanical suspensions, of oily or resinous substances: thus the oil of the almond seed may be for a time diffused through water by trituration, but will ultimately separate and float on the surface. Many resins are formed into emulsions by means of the yolk of an egg or of gum-arabic; while gum-resins contain in themselves the means of forming emulsions with water. Frequently syrups and distilled waters are added to render the compound more palatable; but alcohol and acids should never be used. Emulsions should be used soon after being formed, as in a few hours the constituent parts separate or become acid.

EMYDOSAURIANS. [*CROCODILE*, vol. viii. p. 162.]

EMYS. [*TORTOISES*.]

ENALIOSAURIANS, a name for certain fossil marine lizards. [*ICHTHYOSAURUS*, &c.]

ENAMEL (of the Teeth). [*DENTITION*.]

ENAMELS are vitrifiable substances, or a peculiar preparation of glass, to which different colours are given, sometimes preserving, sometimes depriving it of its transparency. Authors distinguish three kinds of enamels; those which are used to imitate precious stones, those employed in enamel painting (painting on enamel), and those with which an infinite variety of small works are made. The preparation of enamels is very various. In general ten parts of lead and three parts of tin may be oxidized by continued heat and exposure to air. To the mixed oxides thus obtained must be added ten parts of powdered quartz or flint and two parts of common salt, and the whole must be properly melted in a crucible; thus we obtain a white enamel and the basis of coloured enamel, metallic oxides being added in the preparation at the very beginning to give the required colour. The addition of oxide of lead or antimony produces a yellow enamel; reds are obtained by a mixture of the oxides of gold and iron; that composed of gold is the most beautiful and durable. The oxides of copper, cobalt, and iron, give greens, violets, and blues; and a great variety of intermediate colours is produced by mixing them in different proportions. The oxides are sometimes mixed before they are united to the vitreous basis. These are the principal ingredients in the composition of enamels; but the proportions in which they are used, the degree and continuance of the heat required for their perfection, are secrets which

the manufacturers carefully keep to themselves as far as they are able.

ENAMELLING is of great antiquity, and was practised by the Egyptians, from whom it probably passed to the Greeks, and subsequently to the Romans, who are supposed to have introduced the art into Britain, because Roman antiquities have been dug up in different parts of our island in which parts of the ornaments consist of enamels. The art was in use also among the Britons, the Saxons, and the Normans successively, as is proved by various specimens still existing; and it would not be difficult to trace its progress down to our own times. It appears, however, that antiently enamels were principally applied to ornamental purposes, but since the invention of clocks and watches their usefulness has increased in an extraordinary degree there being probably no substance for dial-plates equal to enamel in durability and beauty. The various processes in the practice of enamelling have probably never been completely made known to the public; they require extraordinary care and attention, and artists who may have been so fortunate as to discover any improved mode of operation are commonly too jealous to make it known.

Enamels being commonly laid on a metal ground, the first business is to prepare the plates, technically called *coppers*, to receive the enamel. This preparation requires much care and nicety, and the process is extremely curious. The metals used to enamel upon are gold, silver, and copper. Of the other metals some are too fusible to bear the fire, and the others, as platinum, &c., are too strong, as it is termed for the enamel. The best substance to enamel upon is gold, the richness of the colour giving a beautiful tinge through the enamel; but, except for watch-cases and valuable articles of jewellery, copper is generally used on account of its cheapness. Both the gold and the copper should be of the finest kinds.

Enamelling is now divided into two branches, dial-plate enamelling and transparent enamelling; the former including the manufacture of clock and watch plates, with fluxed plates for enamel painting; the other the enamelling of watch-cases, brooches, and other trinkets. The former is divided also into hard and soft or glass enamelling; the hard requiring the most time, skill, and labour. The coppers being duly prepared, the next process is that of enamelling, properly so called.

The enamel as it comes from the maker is commonly in small cakes four, five, or six inches in diameter. In preparing it for use it is split, by means of a small hammer applied to the edge of the cakes, into thin flakes, which are put into an agate mortar and finely pulverized, and then washed with water. The moistened mass is then laid very smooth on the metal ground with a spatula, and when dried is melted, or, as it is called, fired, under a muffle, in a small furnace heated with coke and coal. The back of the coppers is first covered with enamel, and then the face, to which two coats are given, the operation of firing being applied to each. The plates are then carefully polished, so which various substances are used; and when this is complete, they are put for the third and last time into the fire before painting.

ENAMEL PAINTING, which should be called painting on enamel, is of modern date. It was indeed long believed that the encaustic painting of the antients was the same thing as our enamel painting. But though the antient possessed the art of colouring glass, which might have led to enamel painting, they do not seem to have acquired this latter art, the invention of which, as it is practised in our days, is ascribed to the French. In 1632, Jean Toutin, a goldsmith at Châteaudun, painted on enamel, and he and his disciple, Gulden, taught others. Jean Petitot, born at Geneva in 1607, an admirable painter in miniature, carried the art of painting on enamel to a degree of perfection never before attained. He resided long in England, and French writers affirm that he obtained the knowledge of the most beautiful and durable colours for enamel painting from Sir Theodore Mayence, at London, an eminent physician and chemist, who generously communicated his secrets to him, and recommended him to Charles I., after whose death he went to Paris, where he was highly favoured by Louis XIV., and gained a large fortune. After the revocation of the edict of Nantes he withdrew to Geneva. The difficulty of preparing the plates for enamel painting, and more especially the care and caution re-

quired in burning in the colours, with the very great risk attending the operation, had, till within our own memory, restricted the ordinary size of fluxed plates, and consequently of enamel paintings, to five or six inches; and French writers think it would be little short of madness to attempt such works on a larger scale. But English artists have of late years so far exceeded these limits, that it would be absurd to hazard any dogmatic opinion respecting the possible extent to which they may go. The late Mr. Horace Hone was, we believe, the first who ventured much to exceed the usual size. We have seen a beautiful whole length portrait of a lady, which, if we remember rightly, was about twelve inches high, and broad in proportion; but this has been far exceeded by Mr. H. P. Bone, whose copy from the famous picture of Bacchus and Ariadne by Titian, in the National Gallery, measures 18 inches by 16½. The same artist had also in the exhibition of the Royal Academy, this year, 1837, a copy of the Virgin and Child, by Vandyke, of even larger dimensions.

When we contemplate such works finished in the most exquisite manner, we cannot but admire the courage of the artist in undertaking them. The brilliancy and permanency of the colours are indeed a great temptation and an ample reward for success. But chances of failure are great, and increase, as we understand, with the size of the work, which is not safe till it has undergone the operation of being exposed to the fire for the last time. Indeed the whole process from the very outset requires in every stage the utmost care and attention, and a degree of skill in the management which only long practice can give. No fault in the design can be corrected; it must be traced in the first instance with perfect accuracy: the fire may destroy the work, but what it fixes, whether good or bad, is unalterable.

ENCAMPMENT is the lodgment or station of an army, with its artillery, baggage, and stores, when it has taken the field for the purpose of a review, or of acting against an enemy.

Under the word **CAMP (ROMAN)** there has been given an account of the ancient castrametation, and, till the employment of fire-arms in war, it is probable that the manner of occupying ground for military purposes which had been adopted by the Romans continued to be used by the nations formed on the ruins of their empire, such alterations only being made in the internal arrangements of the camp as were rendered necessary by differences in the numerical strength of the principal divisions of the troops.

The camps of the ancient Britons, and those of the Anglo-Saxons and Danes in this country, seem to have been intrenched by breast-works made of felled trees, or of earth and stones rudely heaped together. Concerning the disposition of the troops within the inclosure, we only know that the Saxons drew up their cavalry in one dense body surrounding the standard, and that they placed the foot soldiers with their heavy battle-axes in front. In a description of the camp formed by Edward II. during his expedition to Scotland in 1301 is contained the first hint we have of any regularity in the distribution of an English army while in the field; this amounts however to little more than that the ground was marked out, and that to every one his proportion of the space was assigned. Within the spaces tents of white or coloured linen were set up, and huts were constructed, the latter probably for the private soldiers. (*Grose, Mil. Antiq.*, vol. ii., p. 205.)

Antiently, both the English and French commanders of armies appear to have fortified their encampments when they undertook the siege of any place, particularly if it appeared likely to be of long duration; and P. Daniel states, that when cannon was used, it was placed for the protection of the army in large redoubts of wood or earth, called *Bastilles*, constructed at intervals along the circumvallation. The same author relates that the English, while they made war in France, went by parties into the country, carrying with them strong palisades to form an intrenchment, behind which they were protected while using their cross-bows. (*Hist. de la Milice Française*, liv. vii., ch. 2.)

In the modern system of war, from the necessity of avoiding as much as possible the destructive effects of the enemy's artillery, and the desire of affording all possible development to the fire of their own infantry, commanders of armies have been compelled to abandon the square form of the antient encampments, and to adopt that of long and narrow lines. But with this arrangement it seldom hap-

pens that the ground will permit a perfect regularity in the dispositions of the several battalions and squadrons; and the occurrence of streams or other accidents of the country may break the continuity of the line, or may render it necessary to give it a bent or waving direction. When however an army is encamped under tents, it may be regarded as a general rule that the line should correspond to that in which the troops are to be drawn up to engage the enemy; also that the tents of each battalion should not occupy a greater space in front than the battalion itself would cover when in order of battle,—a practice which is said to have originated with Gustavus Adolphus.

The length of the front of a battalion of 750 men, two deep, allowing 21 inches to each file, will be 219 yards; and this would be the extent of the line of tents, were it not that the line is regulated by the probable number of effectives, instead of the numerical strength of the establishment. The depth of the encampment for a battalion is of less importance; but, when the ground will permit, it may be regulated by the following disposition, which is considered as affording sufficient convenience.

The tents of the privates may be ranged in two lines parallel to the front, with an interval of about 12 feet as a street between every two companies in each line, and those of the captains and subalterns may be in one line in the rear of these; the field-officers and the commanding officer may occupy a fourth line; the staff a fifth; and the line of kitchens may be in the rear of all. By this arrangement the depth, including a space for the sutler's tent, the batmen and horses, will be about 90 yards; but an interval of 16 yards should separate the front of the men's tents from the line of parade, which is parallel to that front. Opposite the centre of the battalion, and about 60 yards in front of the line of parade, are the tents of the party which forms what is called the quarter-guard; and at about 15 yards in rear of the kitchens the party forming the rear-guard is situated. Including all these intervals, the depth of the encampment for infantry will be 183 yards.

The length of front for a complete regiment of cavalry, consisting of eight troops, when formed two deep, is about 320 yards; and this may be considered as the extent occupied by the regiment in the line of the encampment. The seven tents of each troop are ranged in a line perpendicular to the front, and the horses are attached to pickets in lines parallel to those of the tents; the remainder of the space, reckoned parallel to the front, being occupied by the breadths of the streets. In rear of the men's tents and parallel to the front are arranged the subalterns' horses in one line; the tents of the captains and subalterns in another; those of the field-officers and commanding officer in a third, and the kitchens in the rear of all. The standards are placed parallel to the front at 10 yards before the tents of the privates; and the distance from thence to the line of parade is 30 yards: with these dispositions the whole depth of a regiment of cavalry will be 216 yards.

A large army is encamped in two lines which, if the ground will permit it, are parallel to, and at the distance of about 300 yards from each other; and a reserve, generally consisting of the best troops, is formed in rear of the second. The stations of the cavalry are on the flanks of each line. The artillery attached to an army is formed into brigades, and is posted either on the flanks of the camp or with the reserve in the rear; the extent of front, for a heavy brigade, is 69 yards, and the depth, including the line of guns, of limbers, and three lines of waggons, is 82 yards.

The circular tents at present in use are 13 feet 3 inches diameter within the walls (the canvas which hangs vertically between the conical part of the tent and the ground). Of the cavalry 12 men, and of the infantry 15 men, are appointed to each tent.

From a document which is supposed to be of the time of Elizabeth it appears that then an English camp was divided into six portions, of which three were assigned to the cavalry and three to the foot soldiers; and that between every division was a street 80 feet wide. There was also a space allotted for the market, and within this was the park of artillery, surrounded by carriages. It was regulated that no man should pitch his tent within 140 feet of the ring, or periphery of the camp.

The soldiers' huts or tents were placed 25 deep; each was eight feet square, and contained two men; the depth of the encampment, including the dépôts, the officers' tents, and the cross streets, was 300 feet; and, including the streets, the

whole extent in front of a regiment consisting of 13 companies, each of 150 men, was 712 feet. Originally, it seems, the officers' tents were placed in front of those occupied by the men; but Sir James Turner states that Henry of Nassau changed that custom, and caused them to be placed in the rear, as they are at present, in order that the soldiers might be enabled to have more easy access to the parade in front of the line. (Grose, ii., pp. 213, 214.)

The great extent of the space which, for the reasons before mentioned, is unavoidably occupied by an army in the field, renders it, in most cases, impossible to fortify the site of the encampment by a continuous line of parapet like that with which the Roman armies surrounded themselves on taking up a defensive position; and the security of a modern army against surprises is now obtained principally by the situation being difficult of access, from streams, marshes, or inequalities of the ground, and by keeping numerous advanced posts to watch all the approaches by which an enemy might arrive at the camp.

There are, however, some circumstances which render it indispensable that an encampment should be strengthened by fortifications; as when the troops are inexperienced or the army is deficient in cavalry; but chiefly when a position is occupied which it is of the utmost importance to hold, because the possession of it would be advantageous to the enemy. The latter may then be reduced to the alternative of attacking the encampment at a disadvantage, or of suffering a loss of valuable time in making the movements necessary to turn it. In these cases, every resource of the engineer in the construction of works and in obstructing the approaches should be put in practice for the purpose of augmenting the resistance which the army may be capable of making.

A continuous line of works may therefore be admissible for an army inferior to that of the enemy, provided the extent of the line be not so great as to prevent the intrenchments from being sufficiently manned in every part; but a camp so fortified would possess no advantages for an army which is strong enough to assume the offensive on a favourable occasion presenting itself; and it is evident that, in this case, it would be sufficient to construct merely a few redoubts in situations from whence a fire of artillery might be directed for the purpose of defending the approaches, while the disposable force of the army might be kept in masses ready, at a proper time, to make a movement to the front through the intervals between the works.

This principle does not, till lately, appear to have been well understood; and the cautious spirit with which a campaign was conducted during the eighteenth century contrasts strongly with the bold measures generally pursued in the late war. Marshal Daun, though always superior in number to the Prussians, intrenched himself with the utmost anxiety; and in 1759, when he took up a position near Dresden, though the king of Prussia had lost the battle of Kunersdorf, and the Austrian army was encamped upon steep rocks, covered by a stream difficult to pass, yet the marshal surrounded himself with works so numerous, that even the smallest paths were protected by them, and so strong, that twenty years afterwards they were in existence. But one of the most celebrated of these intrenched camps was that which, in 1761, the king of Prussia took up at Buntzelwitz in order to cover Breslau. This camp was formed within a chain of hills protected on three sides by streams: six salient points on the contour were fortified by bastions, the fires from which would have flanked the intermediate parts of the line, and these were further protected by *flèches* constituting a sort of broken curtain between every two redoubts. Nearly 180 pieces of artillery were planted to defend the avenues, and the camp was surrounded by abatis and other obstacles by which the approach of an enemy might be impeded. (Jomini, *Traité des Grandes Opérations Militaires*, tom. iv.) Such intrenchments however avail nothing when the army is not commanded by a man of great military genius. The French camp at Malpaquet, in 1709, is stated to have been fortified with a triple line, consisting of breast-works, hedges, and felled trees; it was forced however, though with great loss, by the allies under the duke of Marlborough.

It is remarkable that, during the war in Spain, which in general was distinguished by inattention to the means of strengthening the positions occupied by the troops, one of the finest examples of an intrenched camp was afforded in

that which the British army occupied before Lisbon in 1810. This consisted of a double line of detached redoubts constructed on all the commanding points of ground, for the purpose of defending the four great roads and the accessible passes by which the enemy could approach to that city. The first line began at the mouth of the Zizandra on the Atlantic; it crowned the heights above Torres Vedras, and following the chain of Monte Graça, extended to the Tagus at Alhandra, its whole length being about 29 miles. The second was about six miles in rear of the first; it began at the mouth of the S. Lorenzo, on the ocean, passed over the heights at Mafra, Montechique, and Bucellas, and reached the Tagus at Quintella, its whole extent, in length, being about 24 miles. The weakest part seems to have been the valley of Calhandria, near the Tagus, on the exterior line; but this part was afterwards strengthened by a double row of abatis, besides breast-works of earth and thick stone walls. When the lines were completed, they consisted of 152 redoubts, armed, in all, with 534 pieces of ordnance, and required above 34,000 men for their garrisons. The disbursements for their construction amounted to nearly 100,000*l.* (Colonel Jones, *Memoranda on the Lines about Lisbon*, p. 107.) [LINES OF INTRENCHMENT, MILITARY POSITIONS.]

ENCAUSTIC PAINTING (*ἐγκαυστική*, encaustike) is a kind of painting in which by heating or burning in (as the Greek term implies), the colours were rendered permanent in all their original splendour. It was not however enamelling, as some have imagined, but a mode of painting with heated or burnt wax, which was practised by the ancients, various specimens of which have been preserved in the East, and which, according to some historical statements, was in use at Venice even to the time of Titian. Pliny, in his 'Natural History' (xxxv. 11), gives a short account of the invention and nature of this art. He says, 'Ceri pingere ac picturam inurere, quis primus excogitavit non constat.' But though he expressly says wax, some persons have imagined that by *ceris* he here means some composition different from wax, and capable of bearing the fire, and that *inurere* means to enamel. In the same chapter he says that there were antiently two modes of encaustic painting, 'cera et in ebore, cestro, i.e., viriculo. Hoc tertium accessit, resolutis igni ceris, penicillo utendi.' The Marchese Haus, in accordance with Pliny, assumes three kinds of encaustic painting, distinguishing as an essential point, whether the cestrum (a style, or a graving tool) or the pencil was employed in the execution. In the first mode, the wax was melted, mixed with as much earth colour finely powdered, as it could imbibe, and then this mass spread on wood, or on a wall with a hot spatula. When it became cold, it was the ground, in which the designer cut the lines with a cold pointed tool (style, cestrum), and thus, properly speaking, it was not the painting but the wax ground that was burnt in, and the name encaustic was improperly given to the painting. With regard to the second kind, encaustic painting on ivory, the most erroneous notions were long entertained. Professor Grund, of Florence, who has devoted much attention to encaustic painting, seems to be nearest to the truth. When the practice of drawing on hard wax had been brought to some degree of perfection, they proceeded to apply it on a small scale to ivory, which was at that time in the highest estimation. Ivory tablets were therefore covered with red or black wax, and the design cut in it with the style, the object being to use the clear and smooth surface of the ivory for the lines, that they might look the more beautiful. This therefore was nothing more than applying to ivory what had previously been done on wood, or walls. The third kind is the applying the colours with the pencil. With respect to the manner in which this was executed, opinions differ. The most correct notion seems to be that the wax was dissolved, the colours mixed with it, and laid on with the pencil, and the painting then finished by careful approximation to the fire, whence this kind of painting became properly encaustic. For this purpose a hot iron (cauterium) was used. When painting had been greatly improved by the invention of the pencil, a new method of encaustic was attempted. Encaustic wax painting had hitherto been designing on a coloured ground: it now became painting with wax colours burnt in. When the artist had laid on the wax ground, and traced the outlines with the style, he proceeded to the colouring. From the wax mixed with the colours he separated with the hot style

as much as he wanted to cover a certain space, and spread it over the ground, put a second, third, &c., colour next the first, so that he had local tint, half tint, and shade together, which he softened into each other with the hot style. After the whole art of encaustic painting had long been lost, the memory of it was recovered by Count Caylus, in France, who announced to the Academy of Painting the method of painting in wax in 1752: a Mr. Bachelier however had actually painted a picture in wax in 1749, and is the author of a treatise on the art and secret of wax painting; and he was the first who communicated to the public the method of performing the operation of inustion, which chiefly characterizes encaustic painting.* The count kept his method secret for a time, and in 1754 exhibited at the Louvre a head of Minerva painted in the manner of the antients. This was much admired, and it was affirmed that in wax painting the colours were more permanent, purer, and brighter than in oil painting. Several other persons have made essays in this art, as Bien, Bertscher, Bar. Taube in Mannheim, W. Kalan, painter in Berlin, and Reifenstein. As neither Pliny, nor Vitruvius, nor any other ancient author, has left a clear account of the methods employed, it may be reasonably doubted whether any one among the various processes employed or recommended by the moderns is the same as those of the Greeks. J. G. Walter, in Berlin, and Professor J. Roux, in Heidelberg, have recently turned their attention to wax painting; the latter is said to have left many very successfully executed wax paintings; but he did not publish his secret, though he strongly recommended it to painters in his treatise on colours (*Die Farben*, Heidelberg, 1828). Since 1826 Mr. Peter Kraft, at Vienna, has painted several paintings on walls, in which however only the warmed ground was covered with wax, and the colours mixed with oil of turpentine laid on it. The process made known by Montabert in his '*Traité de la Peinture*,' vols. vii. and viii., has a greater resemblance to encaustic painting, properly so called. The laying on is nearly in the manner last mentioned, but a wax varnish is spread over the colours, and melted in by means of a kind of brasier. A series of paintings has been executed, according to his direction, on the walls of the royal palace at Munich, since 1831; but even here all the difficulties with respect to the durability of the ground and the colours have not been overcome.

ENCKE'S COMET, one of the periodic comets which have been ascertained to belong to the solar system, revolving round the sun in about 1200 days, within the orbit of Jupiter.

A full account of this body is contained in a memoir by Encke, published in numbers 210 and 211 of the *Astronomische Nachrichten*, and translated by Mr. Airy, under the title 'Encke's Dissertation,' &c., Cambridge, 1832. See also the 'Reports of the British Association,' vol. i. (1831-1832), and the tract of M. Arago '*Des Comètes en général*,' in the '*Annuaire*' of 1832.

This comet is now known to have been seen in 1786 by M'chain and Messier, in 1795 by Miss Herschel, and in 1805 by M. Pons of Marseilles, and others. But the train of investigation which established it as a *periodic* comet (all the preceding observations having been supposed to be of different bodies) dates from the observations of M. Pons in 1818-19. A comet having been then discovered by him, and its elements determined, Encke (from whom the comet has its name) immediately showed that it was the body which had been seen in 1805. Olbers detected it to be the comet of 1795; and Encke (*Berlin Ephemeris*, 1822 and 1823) having established the fact that its revolution was completed in about 1200 days, predicted approximately the part of the heavens in which it would reappear in 1822. The prediction was verified by the observations of M. Rumker at Paramatta, since which time it has regularly taken its place as one of the bodies of the solar system.

Upon the question which has been raised relative to the gradual approach of this comet to the sun, and the consequent presumption of the existence of a resisting medium, see COMET. The memoir of M. Encke (translated by Mr. Airy, as cited) enters fully into the discussion of this question.

The elements of this body, adopted by M. Encke for its reappearance in 1832, are as follows:—

Passage through perihelion, 1832, May 3.99.

Longitude of perihelion, $157^{\circ} 21'$

Longitude of ascending node, $334^{\circ} 32'$

Inclination, $13^{\circ} 22'$.

Angle of eccentricity, $57^{\circ} 43'$.

Mean daily sidereal motion, $1071''\cdot 1$.

Perihelion distance, $\cdot 3435$ Earth's mean distance from

Aphelion distance, $4\cdot 1015$ sun being unity.

Periodic time, 1210 days.

ENCRINITES, the name by which the petrified radiated animals commonly called *Stone Lilies* have been long known in Britain; it is frequently applied to the *Crinoidea* generally, both recent and fossil.

Lamarck arranged the genus *Encrinus* in his fifth order of *Polypes* (*Polypi natantes*), fixing its position between *Virgularia* and *Umbellularia*, and recording but two species, one recent, viz. *Encrinus Caput Medusæ* (*Isis Asteria Linn.*), from the seas of the Antilles, the other fossil, viz., *Encrinus liliiformis*, *Lilium lapideum* (Stone Lily) of Ellis and others.

Cuvier included the encrinites among his pedicellated echinoderms, considering that they should be placed near the *Comatulæ*; and, in the *Règne Animal*, they are, accordingly to be found between the great group of the *Starfishes* and that of the *Echinidans*.

De Blainville observes that the beautiful work of Guettard (*Acad. des Sc.* 1755) upon the living and fossil encrinites showed long ago the great relationship which there is between these and the stellerideans, now known under the name of *Comatulæ*; and he remarks upon the arrangement of Lamarck, who followed Linnæus and his adherents in placing them among the zoophytes, notwithstanding Guettard's exposition and Ellis's confirmation. After alluding to Miller's work on the family, and to Mr. Thompson's description of the living specimen found on the coast of Ireland. De Blainville takes as the basis of his terminology the parts which exist in *Comatula*, and adopting the views of Rosinus, rejects that proposed by Miller in his interesting memoir, objecting to the terms *pelvis*, *costal*, *intercostal scapula*, *hand*, *fingers*, &c., as derived from animals of an entirely different type of form and inapplicable to the radiated structure.

We find, then, that the *pelvis* of Miller is the *centro-dorsal joint* (*l'article centro-dorsal*) of De Blainville. The *costal* is the first *basilary joint* of each ray. The *intercostal* is the second *basilary joint*. The *scapula* is the third, or that on which the radii are supported. The *hand* is the part of the ray which is divided but not separated. The *fingers* are the *digitations* or divisions of the rays. Finally, the *pinnules* are the lateral divisions of the digitations; and De Blainville, like Miller, divides the *rays* into *principal rays* and *accessory or auxiliary rays*.*

Habits, &c. Dr. Buckland (*Bridgewater Treatise*), who uses the phraseology of Miller, speaks of these animals as destined to find their nourishment by spreading their nets and moving their bodies through a limited space, from a fixed position at the bottom of the sea; or by employing the same instruments, either when floating singly through the water, or attached like *Pentelasmis* (*CIRRIPEDA*) to floating pieces of wood. He refers to Miller for several instances of their power of repairing casual injuries, and figures a recent *Pentacrinus*, one of whose arms is under the process of being reproduced, as crabs and lobsters reproduce their lost claws and legs, and many lizards their tails and feet, observing that the arms of starfishes also, when broken off, are in the same manner reproduced. The same author remarks, that although the representatives of the crinoideans in our modern seas are of rare occurrence, this family was of vast numerical importance among the earliest inhabitants of the antient deep. 'We may judge,' say Dr. Buckland, 'of the degree to which the individuals of these species multiplied among the first inhabitants of the sea, from the countless myriads of their petrified remains which fill so many limestone-beds of the transition formations, and compose vast strata of entrochal marble, extending over large tracts of country in Northern Europe and North America. The substance of this marble is often almost as entirely made up of the petrified bones of encrinites as a corn-rick is composed of straws. Man applies it to

* It is necessary to put the student on his guard against the confusion and error manifest in this part of M. de Blainville's useful work. This was not a little puzzling when considered as coming from a pen of such high reputation as his; till the arrival of the '*Nouvelles additions et corrections*' brought the information that 'par une transposition singulière du manuscrit, il y a eu une sorte de mélange entre les paragraphes qui appartiennent aux genres *Encrinus* et *Pentacrinus*.' In short, among other mistakes, the titles *Encrinus* and *Pentacrinus*, together with whole paragraphs, have been misplaced.

construct his palace and adorn his sepulchre, but there are few who know, and fewer still who duly appreciate, the surprising fact, that much of this marble is composed of the skeletons of millions of organized beings, once endowed with life, and susceptible of enjoyment, which, after performing the part that was for a while assigned to them in living nature, have contributed their remains towards the composition of the mountain masses of the earth. Of more than thirty species of crinoideans that prevailed to such enormous extent in the transition period, nearly all became extinct before the deposition of the lias, and only one presents the angular column of the pentacrinite: with this one exception, pentangular columns first began to abound among the crinoideans at the commencement of the lias, and have from thence extended onwards into our present seas. Their several species and even genera are also limited in their extent; e. g. the great lily encrinite (*E. moniliformis*) is peculiar to the muschel-kalk, and the pear encrinite to the middle region of the oolitic formation.'

The same author, speaking of the joints which composed the stem, says, 'the name of Entrochi, or wheelstones, has with much propriety been applied to these insulated vertebrae. The perforations in the centre of these joints affording a facility for stringing them as beads, has caused them in ancient times to be used as rosaries. In the northern parts of England they still retain the appellation of St. Cuthbert's beads.'

On a rock by Lindisfarne
Saint Cuthbert sits, and toils to frame
The sea-born beads that bear his name.

'Each of these presents a similar series of articulations, varying as we ascend upwards through the body of the animal, every joint being exactly adjusted to give the requisite amount of flexibility and strength. From one extremity of the vertebral column to the other, and throughout the hands and fingers, the surface of each bone articulates with that adjacent to it, with the most perfect regularity and nicety of adjustment. So exact and methodical is this arrangement, even to the extremity of its minutest tentacula, that it is just as improbable that the metals which compose the wheels of a chronometer should for themselves have calculated and arranged the form and number of the teeth of each respective wheel, and that these wheels should have placed themselves in the precise position fitted to attain the end resulting from the combined action of them all, as for the successive hundreds and thousands of little bones that compose an Encrinite to have arranged themselves in a position subordinate to the end produced by the combined effect of their united mechanism, each acting its peculiar part in harmonious subordination to the rest; and all conjointly producing a result which no single series of them acting separately could possibly have effected.'

(*Bridgewater Treatise*.)

De Blainville characterizes his Fixed Asterencrinideans (*Asterencrinides fixés*) as having a body more or less bursiform, supported upon a long articulated stem, and fixed by a radiciform part.

Genera. Apiocrinites.

Miller, who established this genus, characterizes it as an animal with a column gradually enlarging at the apex, composed of numerous joints, of which the superior is marked by five diverging ridges, dividing the surface into as many equal portions, sustaining the pelvis, formed of five sub-cuneiform joints, supporting others of a figure nearly similar, from which proceed the arms and tentaculated fingers formed of simple joints having the figure of a horse-shoe.

De Blainville thus defines it. *Body* regular, circular, for the rest unknown, contained in a sort of cupule or conical test (têt), composed of three superposed rows, each consisting of five scaphoid plates, united or joined throughout, the upper one supporting on a radiated surface the rays which are formed by a simple series of non-pinnated (?) articulations. *Stem* round, at first as large as the body, attenuating by degrees down to the root; articulations circular, little elevated, pierced by a round hole, and radiated at their surface. *Auxiliary rays* scattered.

Geological Distribution.—The genus has occurred hitherto in a fossil state only, and has only been found in strata posterior to the lias. Example, *Apiocrinites rotundus*. Round-columned, Pear-like, Lily-shaped animal (Miller).

Description.—This appears to be the *Astropoda elegans* (stem) of DeFrance. It is the *Bradford Pear Encrinite* of Parkinson, and is described by Miller as a *Crinoidal animal*, with a *round column*, composed of joints adhering by radiating surfaces, of which from ten to fourteen gradually enlarge at its apex, sustaining the pelvis, costæ, and scapula, from which the arms and tentaculated fingers proceed. *Base* formed by exuding calcareous matter, which indurates in laminæ, and permanently attaches the animal to extraneous bodies.

Locality.—(Oolite, middle region.) Bradford in Wiltshire, Abbotsbury, near Weymouth, Dorsetshire, Soissons, Rochelle, &c

Apiocrinites rotundus restored and reduced: 1, expanded; 2, closed; 3, the remedial effect of calcareous secretions in repairing an injury of the joints of the stem; 4, pear-shaped body of *Apiocrinites rotundus*, showing at its upper extremity the internal disposition of the bones surrounding the cavity of the stomach; 5, vertical section of the body, showing the cavity of the stomach, and a series of lower cavities, or hollow lenticular spaces, between the central portions of the enlarged joints of the upper portion of the vertebral column. These spaces are considered by Miller as enlargements of the alimentary canal, which descends through the axis of the entire column. The surfaces of the joints of the vertebral column are striated with rays on the adjacent plates, and allow of flexure without risk of dislocation. (Dr. Buckland, *Bridgewater Treatise*.)

It will be observed, that De Blainville speaks of the rays as being formed of a simple series of articulations without pinnæ: he adds, it is true, a note of interrogation. Miller in his restoration has made the rays pinnated; and Dr. Buckland, from whose work the cuts above given are by permission taken, has continued Miller's restoration: nor do we see any reason for objecting to the views of the last-named authors. The absence of pinnæ on the rays would make the apparatus a very imperfect organ of capture; but the presence of those appendages produces at once the net-like structure observable in many others of the family, so admirably adapted for taking and securing the prey which might come within the sphere of the Encrinite's action.*

Miller describes and figures a second species, *Apiocrinites ellipticus* (*Bottle Encrinite*, *Strait Encrinite*, and *Stag-Horn Encrinite* of Parkinson; Goldfuss refers to it as *A. elongatus*), and gives the chalk-pits of Wiltshire and Kent as its localities. The bodies, &c., of this species are the *Chalk Bottles* of the quarrymen.

M. Goldfuss, in his great work, records four additional species, viz. *A. rosaceus*, *A. mespiliformis*, and *A. Milleri* (Schlotheim), and *A. flexuosus*, and *A. obconicus* (Goldfuss), retaining Miller's *A. ellipticus*, and referring to Miller's description of that species for *A. elongatus* also.

Encrinus. (Encrinites, True Lily-shaped animal of Miller.)

Miller characterizes his genus *Encrinites* as a crinoidal animal, with a column formed of numerous round depressed joints, adhering by a radiating grooved surface, and becoming subpentangular near the pelvis, which is composed of five pieces, giving a lateral insertion to the first series of costal plates, to which the second series and scapulæ succeed, whence the tentaculated arms or fingers proceed, formed by double series of joints. He observes, that the animals of this genus have not hitherto been found in a living state, nor does he believe that their remains have been discovered in England. Only one species known, viz. *Encrinites liliiformis* of Lamarck.

Description, &c.—This is the *Encrinites moniliformis*, *Bead-columned*, *True Lily-shaped animal* of Miller, who describes the species as a crinoidal animal, with a column formed of numerous round joints, alternately, as they approach the pelvis, larger and smaller, becoming subpentangular when nearly in contact with it. On the pelvis, formed of five pieces, adhere laterally the first series of costæ, on which the second series of costæ is placed, succeeded by the scapulæ, from which the ten tentaculated arms or fingers proceed. Animal permanently affixed by exuded indurated matter.

We consider his *Encrinites moniliformis* as the *Encrinus liliiformis* of Lamarck, the *Encrine*, and *Lys de Mer*, of the French, the *Lilium lapideum* of some of the older writers, and the *Stone Lily* of the English. Locality, (Muschel-kalk) Hildesheim, Rakenberg, near Goslar, Obern-scheden and Azenhausen, not far from Gemenden, in Lower Saxony; Scwerven in Juliers, in Westphalia; the village of Erkerode, in Brunswick, about two miles from the town bearing this name, near a wood called the Elm, &c. In this last-named locality the quarry is on the declivity of a hill overgrown with wood, on which account the inhabitants oppose the digging after them. The stratum containing them is hardly fifteen to eighteen inches in thickness. Under the surface of the earth is a friable, porous, argillaceous limestone, containing millions of columns and columnar joints; but many hours' digging is necessary before a good specimen of the superior part, or stone-lily, can be procured, since the moisture in the stone contributes to their rapid destruction, and their occurring on large pieces of stone makes them liable to separation, which accounts for the many mended specimens. Another and harder stratum under the above contains numerous crinoidal remains; but, according to the quarrymen, no stone lilies. (Miller.) The author last quoted adds that there is good reason to believe that the formation in which the remains are found near Brunswick corresponds with the white lias of England, as it appears to repose on the newer red sandstone, containing salt and gypsum.

Fine specimens of this fossil have always been and still are sought for with great eagerness by collectors. In the 'Beytraege zur Naturgeschichte,' Altenburg, 1774, it is

* Since the above was written, we find that M. de Blainville has corrected himself: for, in the 'Nouvelles Additions et Corrections,' he says, speaking of *Apiocrinites*, 'in the characteristic, instead of three, read four,' and add, 'rays vided to the base, and composed of simply pinnated articulations.'

stated that the emperor of Germany offered one hundred dollars for a stone lily free from the matrix, and attached to its column.

'The peculiarly fine lily encrinite,' writes Miller, 'figured by Knorr. tab. 11. a, was, it is said, purchased (Naturforscher, Stück 3) from the labourers at the limestone quarry at Schrapland, near Halle, by Inspector Wilkens, for thirty-two groschen, and given to Professor Lange, who sold it to baron Niegart. However in the same publication (Stück 6), it is stated that it was not bought by Wilkens, but by Mr. Vitigo, at Farrenstadt, near Quersfurt, for two dollars, and given to Lange, who sold it for three louis d'or. If my memory does not misgive me, I think I saw the specimen about twenty years ago in the collection of the Naturforschenden Gesellschaft, at Danzig. Where is it now?'

Encrinus liliiformis.

Pentacrinus. (Pentacrinites vel Pentacrinus, Five-angled Lily-shaped Animal. Miller. Pentagonites Rafinesque.

The following is Miller's *Generic character*. An animal with a column formed of numerous pentangular joints, articulating by surfaces with pentapetalous semistriated markings. Superior columnar joint supporting a pelvis of five joints, on which five first costals rest, succeeded by five second costals and five scapulæ, from which ten arms pro-

ceed, having each two hands, composed of several tentaculated fingers. *Column* long, having numerous auxiliary side-arms. *Base* not ascertained.

Recent species.

Pentacrinus Caput Medusæ. Description. A crinoidal animal having a column formed of numerous pentagonal joints, articulating by surfaces with pentapetalous, ovate, striated markings; five auxiliary side-arms formed of round joints proceeding from the column at intervals. Superior columnar joints supporting a pelvis of five plates, to which the first costals, second costals, and scapulæ, succeed, from which ten arms proceed, each supporting two hands, subdividing into three fingers. Lower extremity, or base, unknown. (Miller.)

This is the *Encrinus Caput Medusæ* of Lamarck, *Isis Asteria* of Linnæus. Locality, the seas of the Antilles. Near the island of Barbadoes (Dr. Hunter's specimen)—that of Nevis (specimen formerly belonging to James Tobin, Esq., now in the British Museum)—and Martinique (specimen in the Paris Museum). There is also a specimen in the Museum of the Royal College of Surgeons in London, and one in that of the Geological Society of London.

Pentacrinus Caput Medusæ. In the front of the figure two of the arms are much smaller than the others, showing that the animal had suffered mutilation, and had employed its power of reproducing the lost parts. *a*. The auxiliary side-arms, articulating at distant intervals with the vertebral column, capable also of being reproduced. (Miller and Buckland.)

Mr. Miller, in speaking of Mr. Tobin's specimen, says, 'In the drawing it up from the bottom of the sea, the animal has clearly been broken off, leaving its posterior portion behind; thus we have lost the chance of ascertaining the fact, whether it adhered by a fixed base, or had a locomotive power. The same accident has befallen the other recent individuals that have been mentioned when speaking of the locality of this species. However, judging from its analogy to the *Encrinus moniliformis*, from its long column, numerous auxiliary side-arms, and the associated manner in which groups of the following species are sometimes found preserved on the surface of a single slab, with the columns all tending towards the same point, as if

issuing from a common base, I conceive that this species also adhered by a base to extraneous matter. This idea gains some further ground, from all the recent specimens hitherto found having broken abruptly off in the endeavour to remove them, as not being able to free themselves from the points of adhesion, which certainly would have been the case had the animal possessed a locomotive power.' This inference acquires additional confirmation from the observations made by the late J. Tobin, Esq., on another specimen, viz.—'Some years ago I was in possession of a larger *Pentacrinite*, which was brought to me so fresh out of the sea that at the bottom (where it plainly appeared to have been broken off from the rock to which it was fixed) the blood was actually oozing from the vertebræ. This specimen I endeavoured to preserve, but it was totally destroyed by the ants, who ate every cartilage, so that it fell to pieces.' Miller observes upon this, that the 'blood' was the fluid in the alimentary canal, and refusing to admit the assertion of Walch, that the *Pentacrinite* is an animal crawling along the bottom of the sea, conceives it to have generally stood more or less erect in the sea, yielding to the fury of the storm in bending down, and adhering for additional security with its side-arms to extraneous matter, or closing them to the column, and thus offering the least surface possible to the element. The latter, he thinks, is the most probable idea, since he had frequently met with specimens in that state, but had never seen any side-arms clasping round extraneous matter. The author elsewhere states that he has in vain endeavoured to trace apertures at the terminating points of the fingers and tentacula, although Guettard alleges that here orifices existed serving as mouths to the animal in taking its food.

Miller observes that columnar fragments, smaller and rather neater than those of this species, occur in the oolite at Dundry, the forest marble at Chippenham, and the chalk near Lyme, but that it remains to be ascertained, by the acquisition of perfect specimens, whether these belong to a variety of *P. Caput Medusæ*, or possess peculiar characters sufficient to distinguish them as a new species.

FOSSIL SPECIES.

We select, as an example, the Briarean *Pentacrinite*, *Pentacrinus Briareus*, thus characterized by Miller. 'A crinoidal animal, having a large column formed of numerous pentagonal joints, alternately larger and smaller, articulating by surfaces with pentapetalous compressed semistriated markings; five auxiliary arms, formed of much compressed suboval joints, proceeding at intervals from the column; five joints of the pelvis, supporting five first and five second costal joints, on which the scapulæ affix, from which ten arms proceed, each having two hands, formed of numerous fingers, sometimes amounting to sixteen.'

Dr. Buckland observes that the root of the Briarean *Pentacrinite* was probably slight, and capable of being withdrawn from its attachment. The absence of any large solid secretions like those of the Pear *Encrinite*, by which this *Pentacrinite* could have been fixed permanently at the bottom, and the further fact of its being frequently found in contact with masses of drifted wood converted into jet, leads him to infer that the Briarean *Pentacrinite* was a locomotive animal, having the power of attaching itself temporarily either to extraneous floating bodies or to rocks at the bottom of the sea, either by its side-arms or by a moveable articulated small root. We confess that we cannot entirely concur with the professor on this point. That in early youth the animal may have floated till it found a substance fit for it to adhere to, we do not deny; but we think that after it was once established and had attained a good size, it was fixed for ever. The great length of the stem and the numerous side-arms must have secured for it a field of action beyond that of the Pear *Encrinite* and the Lily *Encrinite*, both of which we know had permanent roots; and if we are to judge by analogy, there is pregnant evidence that the specimens of the living species, more especially the larger one mentioned by Mr. Tobin, who saw it quite fresh out of the sea, and to whose expressions above given we refer the reader, suffered their stems to be torn asunder without quitting their moorings.

Locality.—Lower strata of the oolite formation, especially the Lias: Lyme, Watchet, Keynsham, &c.

Mr. Miller gives three other fossil species, viz., *P. subangularis*, *P. basaltiformis*, and *P. tuberculatus*. Goldfuss

has recorded the following additional species, viz., *P. scolaris* (Goldfuss), *P. cingulatus* (Münster), *P. pentagonalis* (Goldfuss), *P. moniliformis* (Münster), *P. subulcatus* (Münster), *P. subteres* (Münster), *P. dubius* (Goldfuss), and *P. prius* (Goldfuss), and, with a note of interrogation, *Pentacrinus? paradoxus*.

a, *Pentacrinus Briareus* reduced (Lyme); b, rare and beautiful specimen of Briarean Pentacrinite (nat. size), from the lias at Lyme Regis, in the collection of Mr. Johnson, of Bristol, showing the plated integument of the abdominal cavity, terminated upwards by a flexible proboscis, and surrounded by the commencement of the arms and fingers. (Figures and description from Dr. Buckland's 'Bridgewater Treatise'.)

Phytocrinus.

(De Blainville;—*Hibernula*, Fleming; *Pentacrinus*, Thompson.)

Generic Character.—Body regular, circular, covered and surrounded above by a sort of solid cupule, composed of a centro-dorsal undivided piece, round which are articulated, first, a single row of accessory unguiculated rays, then another row of great didymous and pinnated rays on the other side of three basilar joints, of which the first only partially touch each other. Stem articulated, round, and without accessory rays. Mouth central in the midst of five scales, which are foliaceous and bordered by a row of tentacular cirrhi; a large tubular orifice a little behind the mouth. Example, *Phytocrinus Europæus*, *Pentacrinus Europæus*, Thompson.

Pentacrinus Europæus of Thompson.

a, Several individuals in different stages of development adhering by the base of an articulated column to the stem of a coralline; b, one of the individuals expanded and magnified.

M. de Blainville states that he has thus characterized this genus, which he had not seen, from the excellent description and figure of Mr. Thompson; and that it seems to M. de Blainville that there are sufficient differences to warrant the generic distinction of the animal. He observes that in

Phytocrinus the stem is round, perhaps even inarticulate and flexible; that there are no accessory rays except at the summit; and, besides, that the great rays are all otherwise conformed in their basilar as well as in their pinnated part. It may be supposed, he adds, that the membranous part of the body differs equally both in the disposition of the mouth and in that of the visceral pouch; but of this there is no assurance, that part not being known in the great living *Pentacrinite*. He remarks that Dr. Fleming, admitting the doubt of Mr. Gray as to the existence of the visceral pouch in this last, has also characterized the European *Pentacrinus* under the name of *Hybermula*, a name which he allows may be adopted, though he gives the preference to his own as being more analogous to those invented by Mr. Miller for the Crinoideans. M. de Blainville goes on to declare that he has already had occasion to say that Mr. Thompson's memoir has destroyed all doubt as to the place of the living and fossil *Encrinites*, and has clearly demonstrated the justice of the views of Rosinus, adopted by Guettard, Ellis, Parkinson, and Cuvier, in opposition to that of Linnæus followed by Lamarck. 'An *Encrinus*, so to speak,' says M. de Blainville, 'is no more than a *Comatula* reversed, (even supposing that this position is not equally natural to it, which I am strongly inclined to think,) and which, instead of hooking on by means of accessory rays, is fixed by a prolongation of the centro-dorsal part.'

However more appropriate the name proposed by M. de Blainville may be, that of Dr. Fleming would have the right of priority according to the law of nomenclature; but if Mr. Thompson be right we are spared all consideration on this point; for in the 'Proceedings of the Royal Society of London' (June, 1835), he has expressed his opinion that his *Pentacrinus Europæus*, discovered in the Cove of Cork, and on other parts of the coast of Ireland, is fixed by its stem to other bodies in early life only; that it is produced from the ovum of *Comatula*, becomes afterwards detached, and forms a perfect *Comatula*, capable of moving freely in the ocean, crawling sometimes among submarine plants, and at others floating or swimming like the *Medusæ*.

Poteriocrinites.

Generic Character.—A crinoidal animal, with a round column, composed of numerous thin joints, having in their centre a round alimentary canal, and articulating by surfaces striated in radii. Round auxiliary side-arms proceeding at irregular distances from the column. Pelvis formed of five pentagonal plate-like joints, supporting five hexagonal intercostal plate-like joints, and five plate-like scapulæ, having on one of the intercostals an interscapular plate interposed. An arm proceeding from each of the scapulæ. Base probably fascicular, and permanently adhering. (Miller.)

The author of this generic character says, 'It is with considerable hesitation that I describe these five plates as belonging to the pelvis; the analogy of their lower articulating surfaces seems perhaps rather to indicate their belonging to the first costal series. I have never yet had an opportunity of seeing the connection of these plates with the first column or joint fairly developed, and it seems possible that the true pelvis may be small and almost concealed. This doubt will be done away by the acquisition of more instructive specimens, and my thus stating the case must be considered as resulting from an anxious desire to check errors. It is not unlikely that the real joints forming the pelvis are so much abbreviated as not to be visible externally. Every one acquainted with fossils must be aware how difficult it is to trace always organic details in them correctly, and how many specimens are sometimes necessary to ascertain a single fact.'

M. de Blainville observes that this genus does not appear to differ from *Apiocrinites*, excepting inasmuch as that the stem is not enlarged at its superior part, and that the basilar pieces of the rays are less approximated, and without doubt less immoveable. The details given by Mr. Miller point out a form differing strongly from that of *Apiocrinites*, and, if his data be admitted, there can be little doubt of the generic difference which he records.

Example. *Poteriocrinites tenuis*. Thin, vase-like, lily-shaped animal.

Description.—A crinoidal animal, with a column formed of numerous round thin joints, surface of articulation radiating and striated. The plate-like joints forming the cup-

like body, articulating by minute strise. One arm proceeding from each scapula, supporting two fingers. Locality, the mountain-limestone of the Mendip Hills, and in the Black Rock (the fourteenth bed of Dr. Bright's series (*Geol. Trans.*, vol. iv. p. 193), near the river Avon, Bristol, belonging to the same formation. (Miller.)

The other species recorded by Miller is *Poteriocrinites crassus*, from the mountain-lime in Yorkshire, and the mountain-lime at Bristol, near the river Avon, Bed 1. and 14. of Dr. Bright's paper in *Trans. of Geol. Soc.*, vol. iv., p. 193, and in the magnesian beds of the mountain-limestone, Clevedon Bay, Somersetshire. Miller further states that the specimen mentioned in Dr. Woodward's catalogue of foreign fossils (page 19, 8. 1.) as coming from Syria, is of this species, and that he (Miller) is indebted to the Rev. A. Sedgwick, Woodwardian Professor, Cambridge, for ascertaining this fact, he having kindly furnished Mr. Miller with a drawing made from the original, now in Dr. Woodward's collection, and under his care.

Platycrinites.

Generic Character.—A crinoidal animal, with an elliptic or (in one species) pentagonal column, formed of numerous joints, having a few side-arms at irregular distances. Pelvis saucer-shaped, formed of three unequal pieces, from which five large plate-like scapulæ proceed. Base provided with numerous fibres for attachment. Miller, who thus characterizes the genus, observes that the want of costæ supplied by the large plate-like scapulæ gives the superior part of these animals a pentagonal appearance, and furnishes so conspicuous a character, that they are readily distinguished from all other genera.

Example. *Platycrinites levis*, smooth, broad-plated, lily-shaped animal.

Description.—A crinoidal animal, with a column formed of very muscular elliptical joints adhering by a transverse ridge. Round side-arms occasionally proceeding from the column, whose joints adhere by radiated surfaces. Pelvis saucer-shaped, with the five scapulæ adhering to it, from each of which an arm proceeds supporting two hands, having each two fingers. Pelvis and scapulæ smooth. Locality, in the mountain-limestone of the Mendip Hills, the Black Rock (14th bed of Dr. Bright's series, in *Geol. Trans.*, vol. iv.) near Bristol; Dublin; Cork. (Miller.)

Miller remarks that he has noticed in the collection of Richard Bright, Esq., of Ham Green, near Bristol, numerous joints, probably appertaining to an animal forming a variety, or a distinct species. They came, he states, from Muir-kirk, in Dumfriesshire; and he adds that the scapulæ are shorter in proportion than those of the former species, and that the columnar joints are finely tuberculated.

The same author records the following species:—*P. rugosus*, from the mountain-limestone at Caldy Island, on the south coast of Wales; and at the Mendip Hills; *P. tuberculatus*, from the mountain-lime strata; *P. granulatus*, from the mountain-limestone of the Mendip Hills; *P. striatus*, from the Black Rock (14th bed of Dr. Bright's series); and *P. pentangularis*, from the mountain-lime of the Mendip Hills, at Weston-super-mare, Black Rock near Bristol, and at Mitchel-Dean; also occasionally in transition limestone of Dinevawr Park, and Dudley.

Goldfuss names and describes two additional species, viz. *P. depressus* and *P. ventricosus*.

Cyathocrinites.

Generic Character.—A crinoidal animal, with a round or pentagonal column, formed of numerous joints, having side-arms proceeding irregularly from it. On the summit adheres a saucer-shaped pelvis of five pieces, on which are placed in successive series five costal plates, five scapulæ, and an intervening plate. From each scapula proceeds one arm, having two hands. Locality, transition and mountain-limestone strata. (Miller.)

Example. *Cyathocrinites planus*.

Description.—A crinoidal animal, with a round column formed of numerous depressed joints, articulating by radiating surfaces, and perforated by an alimentary canal, pentagonal near the pelvis, which becomes round further from it. From each of the scapulæ, which rest on the summit of the cup formed by the pelvis and costæ, proceeds an arm supporting two hands, each being provided with two series of fingers. Locality, Clevedon, in the magnesian

beds of the mountain-limestone; at Wood-spring, Black Rock (14th bed of Dr. Bright's series), near Bristol. (Miller.)

Miller observes, that a specimen had occurred to him where the columnar joints were alternately smaller and larger, but that he was not aware whether it possessed sufficient character to be considered a variety of the former species. The same author records three other species, and Goldfuss has added three more, viz. *C. pinnatus*, *C. geometricus*, and *C. pentagonus*.

Actinocrinites.

Generic Character.—A crinoidal animal, with a round column composed of numerous joints, perforated by a round alimentary canal. At the summit of the column is placed a pelvis formed of three plates, on which five first costals and one irregular costal adhere, which are succeeded by the second costals and intercostals and the scapulæ, from whence five arms proceed, forming two hands with several tentaculated fingers. Round side-arms proceed at irregular distances from the column, which terminates at the base in a fascicular bundle or root of fibres.

Example. *Actinocrinites Triacontadactylus*. Thirty-

a. *Actinocrinites Triacontadactylus* (reduced); b. Body of the same (nat. size). (Miller and Buckland.)

fingered, radiated, lily-shaped animal. (Miller.) *Rock Plant* (Beaumont), *Nave Encrinure* (Parkinson).

Description.—A crinoidal animal, with a round column formed of many joints, on whose summit is placed a pelvis of three plates supporting five hexagonal and one pentagonal costal plate, on which the second costals, intercostals, and scapulae, in series adhere, the latter sending off five arms, having each two hands provided with three fingers. Column sending off at irregular distances auxiliary side-arms, and terminating at the base in a bundle of fibrous elongations resembling roots. Locality, mountain limestone at the villages Broughton and Stokes, in Craven, Yorkshire (Lister, 1874), mountain lime formation of the Mendip Hills (Beaumont), and the Black Rock near Bristol (Miller).

Miller describes another species, *A. polydactylus*, from the mountain limestone of the Mendip Hills and Cady Island. De Blainville observes that among the five (seven) new species which Goldfuss refers to this genus, viz. *A. granulatus*, *A. tesseracontadactylus*, *A. cingulatus*, *A. muricatus*, *A. nodulosus*, *A. moniliferus*, and *A. tesseraatus*, *A. tesseracontadactylus* appears to De Blainville to offer a new combination of the pieces of the test, and even, perhaps, of the ten rays of the root, each division being dichotomous.

Melocrinites. (Goldfuss.)

Generic Character.—Column smooth, perforated by a smooth or quinquelobate canal. *Auxiliary arms*. . . . *Pelvis* composed of four articulations or pieces. *Primary and secondary costals* five, hexagonal, alternately placed (sibi invicem impositi). *Intercostals* five, hexagonal. *Scapulae* five, hexagonal, placed upon the costals. *Interscapulars* four, in the region of the mouth five. *Arms* five. *Mouth* at the side of the vertex.

Example. *Melocrinites hieroglyphicus*. (Goldfuss.)

Description.—*Melocrinites* with the articulations or pieces of the cup or calyx nodulous. Locality, mountain lime, calcareum montanum Eitlæ. Goldfuss records a second species, viz. *Melocrinites laevis*.

Rhodocrinites. (Miller.)

Generic Character.—A crinoidal animal, with a round and sometimes slightly pentagonal column, formed of numerous joints perforated by a pentapetalous alimentary canal. The pelvis formed of three pieces supporting five square plates, in the spaces of whose lateral bevelled angles five heptagonal first costals are inserted. From the scapulae proceeds an arm supporting two hands. (Miller.)

Example. *Rhodocrinites verus*, true rose-like lily-shaped animal. Locality, upper bed, No. 1, and one of the lower beds, No. 15, of Dr. Bright's series, distinguishing the mountain limestone formation along the river Avon near Bristol, the Mendip Hills, Mitchel-Dean, the transition limestone at Dudley. (Miller.)

Goldfuss adds four species, viz. *R. gyratus*, *R. quinquepartitus*, *R. canaliculatus*, and *R. echinatus*, the last being *Encrinus echinatus* of Schlotheim.

Eugeniocrinites. (Miller.)

Generic Character.—Superior columnar joint subpentangular, enlarging above, having the five plates of the pelvis adhering to it by a solid ankylosis. Base, column, joints resting on the pelvis, and fingers unknown. (Miller.)

Example. *Eugeniocrinites quinqueangularis* (Miller). *Clove Encrinite* of Parkinson, *Caryophyllus lapideus*, *Caryophyllite* of Knorr. Locality, Switzerland, at Mount Randen (Knorr); also in the canton Zurich and Schaffhausen. (Miller.) Goldfuss records the following additional species, viz. *Eu. caryophyllatus*, *Eu. nutans*, *Eu. compressus*, *Eu. pyriformis*, *Eu. moniliformis*, and *Eu. Hoferi*. (Münster.)

Solanocrinites. (Goldfuss.)

Generic Character.—Column very short, pentagonal, perforated by a pentagonal canal, radiato-rugose at the base, depressed or hollowed out at the sides by the glenoid cavities of the auxiliary arms, articulated with the pelvis by slightly prominent rays which are trochitic and coadunate. Pelvis with five articulations. Scapulae, arms? Auxiliary arms of the column thick and close-set. (Goldfuss.)

Example. *Solanocrinites costatus*. (Goldfuss.)

Description.—S. with a turbinated column, 10 or 15-ribbed longitudinally; articulations of the pelvis linear. Silicified. Locality, Württemberg Jurassic limestone. (Goldfuss.)

P. C., No. 580.

M. Goldfuss describes two other species, *S. scrobiculatus* (Münster), and *S. Jaegeri* (calcareous) (Goldfuss), from the Jurassic limestone, Baireuth.

Caryocrinites. (Say.)

Generic Character.—*Pelvis* of four plates. *Costal plates* six. *Column* not dilated. Alimentary canal round. Articulating surface of the columnar joints radiated. *Auxiliary side-arms* cylindrical and placed irregularly.

Example. *Caryocrinites ornatus*.

Description.—*Costals*, four pentagonal and two hexagonal. *Column* inserted into a cavity at the base of the pelvis: *pelvis* rather large; two of the plates quadrangular, attenuated to the base, where they are truncated and a little recurved at the junction with the column: disks, particularly towards the base, granulated, with a distinct elevated interrupted line; two remaining plates pentagonal, attenuated to the base where they are truncated and a little recurved at the junction with the column; disk with elevated granules, and with two elevated interrupted lines extending to the terminal angles: *costals*, four pentagonal and two hexagonal, all with elevated interrupted lines, radiating from the centre to the angles, with a series of truncated granules on each side and a few granules in the intervening spaces; interscapulars, two hexagonal, situated immediately above the hexagonal costals; *scapulars* six pentagonal, the upper sides of which are more or less irregular by projecting a little between the scapulae, all with prominent lines granulated, similar to those of the preceding: *arms* six: *capital plates* with a heptagonal one in the middle, surrounded by five heptagonal plates and two irregular ones at the mouth: mouth not prominent, situated on one side of the middle, a little within the line of the arms, closed by small valvular pieces, its inferior side resting on the superior angle of one of the scapulars. Longitudinal diameter from three quarters to one inch and a half; transverse diameter from seven tenths to one inch and two fifths. Mr. Say, who gives this description, records and describes another species wit one of the costals hexagonal, viz. *C. loricatus*. Locality Found by Dr. Bigsby loose n brown clay at the foot of the ravine at Lockport, in which the New York canal mounts the parallel ridge of Lake Ontario.

Marsupites (Mantell), **Marsupiocrinites** (De Blainville).

Generic Character.—*Body* regular, oval, bursiform, rounded at the dorsal extremity, truncated and flattened at the other, enveloped in a sort of shell or test composed of great polygonal plates, articulated to each other, one centrodorsal, and three rows superposed, of which the terminal one supports ten simple rays. *Mouth* in the midst of four squamiform pieces. *Stem* none. This is De Blainville's character; the following is Miller's:—An unattached animal with a subglobose body containing the viscera protected by calcareous plates, of which that in the centre at the base is angular, having a series of costal plates resting on it, admitting intercostals at their superior angles, these giving insertion to the scapulae from which the arms proceed. Space between the scapulae covered by an integument, protected by numerous small plates.

Example. *Marsupites ornatus*, ornamented purse-like animal (Miller), *Tortoise Encrinite* (Parkinson).

Description.—A purse-like* animal, having the central plate at the base of its subglobose body containing the viscera; pentagonal, supporting at its edge five similar costals, which admit at their superior angles five hexagonal intercostals, into the angles of which five scapulae are inserted sending off the arms. All the plates ornamented by ridges proceeding from the centre, and forming angular markings near the corners. Locality, Offham Chalk-pits near Lewes; Clayton Chalk-pits, Hurstpoint, Sussex; Preston Chalk-pits, near Brighton (Mantell); Chalk-pits of Kent, and Chalk-pits, near Warminster. (Miller.)

Mr. Miller does not admit *Marsupites* among the *Crinoidae*, but considers it as the immediate link between that family and *Euryale*.

Pentremites. (Say.)

Generic Character.—*Column* cylindrical, perforated; segments articulating by radiated surfaces, with cylindrical side-arms at irregular intervals; *pelvis* of three unequal pieces, two pentagonal and one tetragonal; scapulae large, very profoundly emarginate for the reception of the lips of

* Miller's expression is 'a Marsupial animal,' this is objectionable when considered in reference to the Vertebrated Marsupialia.

the radiating ambulacræ, obliquely truncated at the extremities on each side, for the reception of one side of a sub-rhomboidal plate or interscapular; ambulacræ five, radiating from the summit, and terminating at the tips of the emarginations of the scapulae: each with a longitudinal, indented line, and numerous transverse striæ which terminate in a marginal series of pores; for the transmission of respiratory tubes; *summit* with five rounded openings (ovaries) and an angulated central one (mouth and anus). (Say.)

'This singular genus,' observes Mr. Say, 'is so remotely allied to any hitherto discovered, that I do not think it can, with propriety, be referred to any family yet instituted. By its columnar support it is related to the family *Crinoidea*; but the total absence of arms and hands excludes it from that very natural group. The superior termination, in which the ambulacræ, the rounded openings, and the central angulated one, are situated, has some affinity to the family *Echinidea* (Echinidæ), but the columnar support shows that it cannot be arranged there. Having thus on its inferior portion a resemblance to the *Crinoidea*, and on its superior surface a decided analogy to the *Echinidea*, I think it may with propriety form an intermediate family under the following name and characters: Family, *Blastoidea*. Column composed of numerous articulating segments, supporting at its summit a number of plates, so united as to form a calyciform body containing the viscera; arms none; branchiæ arranged in ambulacræ. In a natural series their bodies constitute the link between the *Crinoidea* and the *Echinidea*, on the one hand; whilst, on the other, the former is unquestionably, but not more obviously connected with the *Stelleridea* (Stellirideans) by the unequivocal intervention of *Comatula* and *Marsupites*. Of all the genera of *Crinoidea*, it is to *Platycrinites* that *Pentremite* seems most closely related.'

Mr. Say describes three species, viz. *P. globosa*, brought from England, and said to have been found in the vicinity of Bath; and *P. pyriformis* and *P. florealis*, from Kentucky. He gives, as the synonyms of the latter, *Kentucky Asterial Fossil* (Parkinson), and *Encrinites florealis* (Schlotheim), as quoted by Miller, and thus proceeds: 'This is extremely abundant in many parts of Kentucky, and on the margins of the Mississippi in a few places. Near Huntsville they are very numerous; and on the surface of a fragment of rock, three inches long by two and a quarter wide, sent to the Academy by Mr. Hazard of that place, I have enumerated eighteen specimens of this species more or less entire, and two specimens of the preceding species (*P. pyriformis*). On another still smaller piece of rock are twenty-one specimens, all in *alto relievo*, two of which are of the preceding species. On a third fragment of rock thirty may be counted, and on a fourth upwards of fifty. That these animals were pedunculated and fixed, there cannot be any doubt. We see at the base of the pelvis a small rounded surface, perforated in the centre for the passage of the alimentary canal, and on the outer margin are very short but distinct radii of elevated lines, evidently intended for articulation with the first joint of the column. The column itself is always found in fragments accompanying the body of the animal, but never attached to it. I think it highly probable that the branchial apparatus communicated with the surrounding fluid through the pores of the ambulacræ by means of filamentous processes: these may also have performed the office of tentacula in conveying the food to the mouth, which was perhaps provided with an exsertile proboscis; or may we not rather suppose that the animal fed on the minute beings that abounded in the sea water, and that it obtained them in the manner of *Ascidia*, by taking them in with the water. The residuum of digestion appears to have been rejected through the mouth.'

Mr. G. B. Sowerby, in a 'Note on the foregoing paper, together with a description of a new species of *Pentremites*,' observes, that all the specimens received in this country from Kentucky were changed into a sort of calcedony or chert, a circumstance which has perhaps not only prevented British naturalists from forming a correct judgment of their natural affinities as a family, but appears also to have had the effect of preventing them from recognising the generic resemblance to the species that occur here, which, bearing so much greater a similarity to some of the *Echinidæ*, has caused some of our naturalists to class them together: for it is observable, he remarks, that of perhaps twenty specimens of the Kentucky Asterial Fossil that he had examined, only one individual showed the sutures that

separate what Say calls the 'pelvic scapular and interscapular plates or pieces.' The examination of the new species however suggested to Mr. Sowerby the probability that part of the three unequal pieces which Say calls the pelvis, may in fact prove to be *costals*, thus evidencing one more relation to the *Crinoidea*. Mr. Sowerby records and describes two species, premising that the circumstance of Say's first species, *P. Globosa*, having been brought from England, led Mr. Sowerby at first to suppose that Say might refer to one of those species that had come into Mr. Sowerby's hands. Say's description however in Mr. Sowerby's opinion is so incomplete, and the terms he has used are so vague, that Mr. Sowerby had not been able to ascertain the fact, but thinks, nevertheless, that '*Pelvis* deep saucer-shaped convex' may serve to distinguish it from both. Mr. Sowerby's two species are *Pentremites Derbyensis* from Derbyshire (limestone) and *Pentremites elliptica* from near Preston in Lancashire.

In a second paper (*Zool. Journ.*, vol. iv.) Mr. Sowerby changes the name to *Pentatrematites*, and records three more species, viz. *P. angulata*, *P. inflata*, and *P. oblonga*; all from the calamine mines belonging to the duke of Buccleuch, on the Lancashire side of the Hodder; and in the last volume of the '*Zoological Journal*,' he describes three in addition, viz. *P. orbicularis*, *P. acuta*, and *P. pentangularis*; the last he considers to be the *Platycrinites pentangularis* of Miller, the arms being imaginary in his figure. Goldfuss describes a species from the transition limestone near Dusseldorf.

M. de Blainville places this genus at the end of the *Crinoideans*. It appears to be the connecting link between the *Crinoidea* and the *Echinidæ*, but to have a much stronger relationship to the former than to the latter. *Marsupites* we consider with Miller, Say, and others, to be the connexion between the true *Crinoideans* and the *Comatulæ*.

N.B. Goldfuss's *Glenotremites paradoxus* appears to approximate somewhat to *Pentremites*.

ENCYCLOPÆDIA. [DICTIONARY.]

ENCYCLOPÆDIE is the name of several general dictionaries of the arts and sciences in the French language. [DICTIONARY.] The first work published under this name was edited by Diderot and D'Alembert, is written in alphabetical order, and is styled 'Encyclopédie, ou Dictionnaire raisonné des Sciences, des Arts, et des Métiers,' 17 vols. fol. and 11 vols. plates, Paris, 1751-72, to which are added a Supplement in 4 vols. fol. of text and 1 vol. plates, Paris, 1776-77, and a Table des Matières, or General Index, 2 vols. fol., Paris, 1780, in all 35 vols. folio. For a brief sketch of the history of this work and the judgment which the editor himself passed upon it, see DIDEROT; and for its plan and arrangement, see the preface to the work itself, written by Diderot and D'Alembert. The *Encyclopédie* exercised a considerable influence on the political as well as religious opinions of the French reading public of the last century. But the incorrectness of many of its articles, and the rashness and dogmatism of many of its propositions becoming notorious, a new *Cyclopædia* was planned by a society of men of letters, upon a scale of greater magnitude, and on a different arrangement, every branch of learning being treated separately, and the whole being written in general with considerable impartiality, and being more free than the former *Encyclopédie* from party purposes and prejudices: the title of it is '*Encyclopédie Méthodique, ou par ordre de Matières*.' It is the largest work of the kind ever published, consisting of 201 volumes 4to., including 47 volumes of copper-plates. It began to appear in 1782, and was completed only in 1832, the publication having thus lasted half a century. Each science makes a dictionary of itself in two, three, or more volumes, arranged in alphabetical order, and the whole work is therefore a collection of dictionaries. The principal sciences contained in it are: geography ancient and modern, physical geography, mathematics, logic and metaphysics, philosophy history, theology, jurisprudence, political economy and diplomacy, grammar and literature, commercial science, naval art, military art, antiquities, financial science, chemistry, pharmacy, and metallurgy, natural history, ornithology, history of mammalia, anatomy, physics, botany, medicine, surgery, agriculture, fine arts, architecture, music, &c. Other but inferior works have appeared since in France under the name of *Encyclopédie*, but the *Encyclopédie Méthodique* remains the standard work of its kind in the French language.

ENDEAVOUR STRAIT. [TORRES STRAIT.]

ENDE'CAGON, a figure of eleven sides.

ENDECA'NDRIA, the ninth class of the Linnæan system of botany, distinguished by having nine stamens separate from each other.

ENDEMIC (*ἐνδημος*, *endémus*, from *ἐν*, in or among; and *δῆμος*, people, that which is among a people). By this word are expressed those peculiar forms of disease which arise spontaneously, as it is termed, in a country or in particular localities, and which are ordinarily produced by the peculiar climate, soil, air, water, &c. Thus, ague is the endemic disease of marshy countries or localities; the swelled throat or bronchocele is endemic in the Alps, and the plica in Poland. The word bears pretty much the same signification in relation to the diseases of a country that the term indigenous does to its plants. It is used in contradistinction to *epidemic*. [EPIDEMIC.]

ENDIVE, or CICHORIUM ENDIVIA, the parent of all the varieties of garden endive, was introduced to Britain about the beginning of the seventeenth century from the northern provinces of China. It is a species belonging to the narcotic lactescent division of Compositæ, to which it gives the name Cichoraceæ.

There are now many varieties in cultivation, which are divided, by those who have classed them, into two principal groups, Batavian and Curled-leaved; arranging under the former all those with broad ragged leaves, and under the latter those in which the leaves are narrower and curled. The French call the first of these *Scaroles* and the last *Chicorées*.

As it is the leaves of this plant, and not its flowers or seed, which are used in culinary operations, it is necessary to be particular as to the time of sowing; for if sown early in spring, it will, instead of forming fine leaves, produce flowers and seed, and so frustrate the object of the cultivator. A little seed may be sown in the beginning of May for early use; but for a general crop, throughout the months of June, July, to the middle of August, will be found to be the proper time for sowing. The soil upon which the endive is sown or planted should be light and rich. After the plants are strong enough to be removed from the seed-bed and planted out where they are intended to remain, various methods are practised in order to blanch the leaves. Some gardeners plant in drills two or three inches deep, and earth up the plants as they grow; others, after they are fully grown, cover them with flower-pots or something of that description, and so exclude the light; while others again simply tie the leaves close together with a piece of matting, when the same result is obtained. The effect of thus blanching the plants is not merely to render the endive colourless when employed as salad, but to diminish its natural bitterness, which in its concentrated state would render it unfit for food.

Endive-plants are impatient of wet in cold weather, being apt to rot in open situations. Care, therefore, should be taken to protect them by mats or boards upon the approach of winter.

In this country the cut-leaved or 'curled' endive is preferred for table; but the dwarf white Batavian endive is much more delicate and agreeable to the palate.

ENDOGENS. One of the large primary classes into which the vegetable kingdom is divided bears this name in consequence of its new woody matter being constantly developed in the first instance towards the interior of the trunk, only curving outwards in its subsequent course downwards. That palm-trees grow in this way was known so long since as the time of Theophrastus, who distinctly speaks of the differences between endogenous and exogenous wood.

But that this peculiarity is also extended to a considerable part of the vegetable kingdom is a modern fact, the discovery of which we owe to the French naturalists Daubenton and Desfontaines. The path being thus opened, the inquiry has subsequently, and more particularly of late years, been much extended, especially by Professor Mohl, in an elaborate essay upon the anatomy of palms. In the following observations we shall be found to differ in some respects from all the previous writers upon this subject, but at the same time a considerable part of our statements will necessarily be in accordance with those of one observer or another. We do not think it advisable, except here and there, to interrupt the thread of our argument by any references to these discrepancies; the reader learned in

such matters will be able to separate the views that are new from such as have previously been promulgated others would be little interested in the matter.

Mohl is of opinion that the first year's wood of an exogen is analogous in arrangement to that of an endogen, the woody bundles of each leaf curving upwards and outwards to the base of the leaf, and downwards and outwards towards the bark, crossing through those which have been previously developed.

For convenience we will take the phenomena of growth in a palm-tree as typical of the endogenous structure. In the beginning the embryo of a palm consists of a cellular basis, in which a certain number of cords of ligneous fibre are arranged circularly (fig. A, p. 396), down the radicle, deriving their origin from the plumule. Immediately subsequent to germination, and as soon as the rudimentary leaves of the plumule begin to lengthen, spiral vessels appear in their tissue in connection with the ligneous cords; the latter increase in quantity as the plant advances in growth, shooting downwards through the cellular tissue, and keeping parallel with the outside of the root. At the same time the cellular tissue increases in diameter to make room for the descending ligneous cords (or woody bundles, as they are also called). At last a young leaf is developed with a considerable number of such cords proceeding from its base downwards, and, as its base passes all round the plumule, consequently passing downwards, alike on all sides of the centre that it surrounds. Within this a second leaf gradually unfolds, the cellular tissue increasing horizontally at the same time; the ligneous cords, however, soon cease to maintain any thing like a parallel direction, but curve outwards as they pass downwards, losing their extremities in the roots, or in the cellular integument on the outside of the first circle of cords (fig. A); at the same time the second leaf pushes the first leaf a little from the centre towards the circumference of the plane or cone of growth; the consequence of which is that the ligneous cords next the base of the first leaf are drawn a little outwards, and form descending axes which henceforward are found at first to curve inwards towards the centre of the young stem, and afterwards outwards towards its circumference. In this manner leaf after leaf is developed, the horizontal cellular system enlarging all the time, and every successive leaf, as it forms at the growing point, emitting more woody bundles curving downwards and outwards, and consequently intersecting the older arcs at some place or other; the result of this is that the first formed leaf will have the upper end of the arcs which belong to it longest and much stretched outwardly, while the youngest will have the arcs the straightest; and the appearance produced in the stem will be that of a confused entanglement of woody bundles in the midst of a quantity of cellular tissue. As the stem extends its cellular tissue longitudinally while this is going on, the woody arcs are consequently in proportion long, and in fact usually appear to the eye as if almost parallel, excepting here and there, where two arcs abruptly intersect each other. As in all cases the greater number of arcs curve outwards as they descend, and eventually break up their ends into a multitude of fine divisions next the circumference, where they form a cortical integument, it will follow that the greater part of the woody matter of the stem will be collected near the circumference, while the centre is kept comparatively open, and will consist chiefly of cellular tissue; and when, as in many palms, the stem has a limited circumference, beyond which it is its specific nature not to distend, the density of the circumference must, it is obvious, be proportionably augmented. It is however a mistake to suppose that the great hardness of the circumference of old palm wood is owing merely to the presence of augmenting matter upon a fixed circumference; this will account but little for the phenomena. We find that the woody bundles next the circumference are larger and harder than they originally were, and consequently we must suppose that they have the power of increasing their own diameter subsequent to their first formation, and that they also act as reservoirs of secretions of a hard and solid nature, after the manner of the heartwood of exogens.

When the growth of the stem of an endogen goes on in this regular manner, with no power of extending horizontally beyond a specifically limited diameter, a stem is formed, the transverse section of which presents the appearance shown in the following cut.

There is a number of curved spots crowded together in a

confused way, most thick and numerous at the circumference, comparatively small and thinly placed at the centre; and the only regular structure that is observable with the naked eye is that the curves always present their convexity to the circumference.

When there is no limited circumference assigned by nature to an endogen, then the curved spots, which are sections of the woody arcs, are much more equally arranged, and are less crowded at the circumference. Never is there any distinct column of pith, or medullary rays, or concentric arrangement of the woody arcs; nor does the cortical integument of the surface of endogenous stems assume the character of bark, separating from the wood below it; on the contrary, as the cortical integument consists very much of the finely divided extremities of the woody arcs, they necessarily hold it fast to the wood of which they are themselves prolongations, and the cortical integument can only be stripped off by tearing it away from the whole surface of the wood, from which it does not separate without leaving myriads of little broken threads behind.

We therefore do not understand Professor Mohl when he asserts that the young wood of an exogen is the same as that of an endogen, and that they principally differ in exogens forming new wood between the old wood and liber, while endogens produce separate cords of woody tissue. On the contrary, exogens are, from the beginning of their growth, extremely different, collecting their woody cords in a parallel manner between those horizontal prolongations of the cellular system called medullary rays; there are no arcs developed; the cortical integument is altogether separate from the woody system, without any breaking off of the woody tubes; and, finally, there is a distinct column of cellular medulla, around which the wood itself is more or less concentrically disposed. We know very well that the disposition to form woody arcs in the pith, in addition to the concentric wood, which is so very conspicuous in *Zamia*, is also found elsewhere, as in *Piper*; and that something like it, although far from being correctly understood by Schultz, occurs in the pith of certain nyctaginaceous plants, as well as in elder, where it has been noticed by Henslow; but these cases are far from showing anything like identity between endogens and exogens, as will be more particularly explained in another place. [EXOGENS.]

While however we object to Mohl's identification of exogens and endogens, as most forced and unnatural, and essentially at variance with observation, we are far from adopting the language of Link, who calls a palm stem a *cauloma*, as if it were not a stem at all. That there is in the stem of an endogen and an exogen the same elementary matter, that the woody bundles of the former are analogous to the woody plates of the latter, that the function of their stems, although not made out with much precision, is nevertheless essentially similar, are facts about which we cannot anticipate any dispute, and therefore the new term *cauloma*, as distinguished from *caulis*, is just as superfluous as the old name of frond as distinguished from leaf.

In many of the larger kinds of endogens the stem increases principally by the development of a single terminal bud, a circumstance unknown in exogens, properly so called. In many however, as all grasses, the ordinary growth takes place by the full development of axillary buds in abundance.

In general there is so great a uniformity in the structure of an endogenous stem that the common cane or asparagus illustrate its peculiarities sufficiently. There are however anomalous states that require explanation.

Grasses are endogens with hollow stems strengthened by transverse plates at the nodes. This is seen in the bamboo,

whose joints are used as cases to hold rolls, or in any of our indigenous species. In this case the deviation from habitual structure is owing to the circumference growing faster than the centre, the consequence of which is the tearing the latter into a fistular passage, except at the nodes, where the arcs of ligneous tissue originating in the leaves cross over from one side of the stem to the other, and by their entanglement and extensibility prevent the possibility of any rupture taking place. That this is so is proved by the fact that the stems of all grasses are solid, or nearly so, as long as they grow slowly; and that it is when the rapidity of their development is much accelerated that they assume their habitual fistular character. Independently of that circumstance their organization is quite normal.

Xanthorrhæa hastilis has been shown by De Candolle to have an anomalous aspect. When cut through transversely, the section exhibits an appearance of medullary rays proceeding with considerable regularity from near the centre to the very circumference. (*Organographie Végétale*, t. 7.) But such horizontal rays are not constructed of muriform cellular tissue like real medullary processes, but are composed of ligneous cords lying across the other woody tissue; they are in fact the upper ends of the woody arcs pulled from a vertical into a horizontal direction by the growth of the stem and the thrusting of the leaves to which they belong from the centre to the circumference. Such a case throws great light upon the real nature of the more regular forms of endogenous wood.

Other appearances are owing to imperfect development, as in some of the aquatic species of this class. *Lemna*, for example, has its stem and leaves fused together into a small lenticular cavernous body; and in *Zannichellia* and others, a few tubes of lengthened cellular tissue constitute almost all the axis; but the examination of such cases is comparatively unimportant, and would lead too much into details of subordinate interest.

By far the most striking kind of anomaly in the stem of endogens is that which occurs in *Barbacenia*, and which has been already slightly noticed by the writer of this sketch. (*Nat. Syst. of Botany*, p. 334.) It is so very important that we shall describe it more particularly on this occasion. In an unpublished species of *Barbacenia* from

Rio Janeiro, allied to *B. purpurea*, the stems appear externally like those of any other rough-barked plant, only that their surface is unusually fibrous and ragged when old,

and closely coated by the remains of sheathing leaves when young. Upon examining a transverse section of it, the stem is found to consist of a small firm pale central circle having the ordinary endogenous organization, and of a large number of smaller and very irregular oval spaces pressed closely together but having no organic connection; between these are traces of a chaffy ragged kind of tissue which seems as if principally absorbed and destroyed. (See fig. A.)

A vertical section of the thickest part of this stem exhibits, in addition to a pale central endogenous column, woody bundles crossing each other or lying parallel, after the manner of the ordinary ligneous tissue of a palm stem (fig. B), only the bundles do not adhere to each other, and are not embodied as usual in a cellular substance. These bundles may be readily traced to the central column, particularly in the younger branches (fig. C), and are plainly the roots of the stem, of exactly the same nature as those aerial roots which serve to stay the stem of a screw pine (*Pandanus*). When they reach the earth the woody bundles become more apparently roots, dividing at their points into fine segments, and entirely resembling on a small scale the roots of a palm-tree. The central column is much smaller at the base of the stem than near the upper extremity.

Nothing can well show more distinctly than this, that the woody bundles of an endogenous stem are a sort of root emitted by the leaves, plunging down through their whole length into the cellular substance of the stem in ordinary cases; but in *barbacenia* soon quitting the stem and continuing their course downwards on the outside. The observation of Du Petit Thouars, that when *dracenas* push forth branches, each of the latter produces from its base a quantity

of fibres, which are interposed between the cortical integument and the body of the wood, forming a sort of plaster analogous to what is found in the graft of an exogen; and that of the fibres just mentioned the lowermost have a tendency to descend, while those originating on the upper side of the branch turn downwards and finally descend also—that observation had already rendered the above-mentioned conclusion probable. The case of *barbacenia* can scarcely leave a doubt upon the subject, and leads to the important conclusion that the theory of the wood of exogens being also a state of roots belonging to the leaves of the stem, is well founded also.

The age of endogenous trees has been little studied. When the circumference of their stem is limited specifically, it is obvious that their lives will be limited also; and hence we find the longevity of palms inconsiderable when compared with that of exogenous trees. Two or three hundred years are estimated to form the extreme extent of life in a date palm and in many others. But where, as in *Dracæna*, the degree to which the stem will grow in diameter is indefinite, the age seems, as in exogens, to be indefinite also—thus a famous dragon tree, *Dracæna Draco*, of Oratava in Teneriffe, was an object of great antiquity so long ago as A. D. 1402, and is still alive.

Important as the character furnished by the internal manner of growth of an endogen obviously is, it is much enhanced in value by its being found very generally accompanied by peculiarities of organization in other parts. The leaves have in almost all cases the veins placed in parallel lines, merely connected by transverse single or nearly single bars. Straight-veined foliage is therefore an external symptom of an endogenous mode of growth. When such an appearance is found in exogens it is always fallacious,

ENDOGENOUS VEGETATION.

Scene, consisting of *Coccothraustes* (a); *Manisuris saccifera* (b); *Iriarten ventricosa* (f). *Pandanus*, represented by *Pandanus odoratissimus* (e); *Musa*, by *Musa sapientum* (d); *Dracæna*, by *Rambusia arundinacea* (g); and arborescent *Amaryllidaceæ*, by *Agave Americana* (g). The fore and back ground are composed of small palms, grasses, rushes, and filiceous plants.

and is found to be owing to the excessive size and peculiar direction of a few of the larger veins, and not to hereditary character of all the venous system; as is sufficiently obvious in *Plantago lanceolata*, *Gentiana lutea*, and many more.

The flowers too of endogens have in most cases their sepals, petals, and stamens corresponding with the number three, or clearly referrible to that type; and the pistil usually participates in the same peculiarity. Where such a proportion exists in exogens, it is usually confined to the sepals and petals by themselves, or to the pistil by itself, not extending to the other organs. In endogens it is almost universal in all the whorls of the flower, although sometimes obscured by the abortion, dislocation, or cohesion of particular parts, as happens in the whole of the extensive natural order of grasses.

The effect of the manner of growth in endogens is to give them a very peculiar appearance. Their trunks frequently resemble columns rising majestically with a plume of leaves upon their summit; and the leaves, often very large—the fan-shaped leaves of some palms are from 20 to 30 feet wide—have most commonly a lengthened form, resembling a sword blade if stiff, or a strap if weak and broad. A landscape consisting entirely of endogens would have such an appearance as is presented by the cut in the preceding page.

These peculiarities are connected with others belonging to endogenous vegetation in its most rudimentary condition. The embryo of an endogen is, in its commonest state, a small undivided cylinder, which protrudes from within its substance a radicle from one end and a plumule from a little above the radicle; in other cases its embryo has a slit on one side, in the cavity of which the plumule reposes, or, finally, the embryo is a flat plate as in grasses, with the plumule and radicle attached to its face near the base. In the latter case the flat plate is a solitary cotyledon, which, in the second instance, is folded together so as to give the embryo the appearance of being slit, and which in the first, or most habitual, condition is not only folded up, but united at its edges into a case entirely burying the plumule and cotyledon. Hence the embryo of an endogen is called monocotyledonous; a name that is really unexceptionable, notwithstanding the occasional appearance of a second rudimentary cotyledon, as occurs in common wheat.

It has already been stated that the radicle is protruded in germination from within the substance of the embryo; the base of the radicle is consequently surrounded by a minute collar formed of the edges of the aperture produced by the radicle upon its egress. For this reason exogens are called *endorhizal*.

Hence the great natural class of plants forming the subject of these remarks has five most important physiological peculiarities, by all which combined, or usually by each of which separately, the class may be characterized.

1. The wood is endogenous.
2. The leaves are straight-veined.
3. The organs of fructification are ternary
4. The embryo is monocotyledonous.
5. The germination is endorhizal.

This explains why Endogens are also called *Monocotyledons* and *Endorhizæ*; they have moreover been called *Cryptocotyledonæ* by Agardh, *Acroblastæ* by Reichenbach, and *Caulophytæ* by the school of Oken; but these names have been given upon mere hypothetical grounds, and are not of sufficient importance to deserve explanation in this place.

It may however be readily supposed that, viewed as a large class of plants, Endogens are essentially characterized only by the combination of these five peculiarities, and that occasional deviations may occur from every one of them. Thus in *Nais*, *Caulinia*, *Zannichellia*, and others which constitute a part of what Professor Schultz names *Homorganous floriferous* plants, the whole organization of the stem is so imperfect that the endogenous character is lost; but their true nature is nevertheless sufficiently indicated by their straight veins, monocotyledonous embryo, &c. Again, in *Smilax*, the common reticulated leaves of exogens are found; but the endogenous stem, the ternary organs of fructification, the embryo and germination of that order, are all good evidence of its real nature; and so with other cases. Such occurrences are instances of endogenous development tending towards the exogenous, and are usually looked upon as cases of transition from one form to the other—perhaps not very correctly. Of this nature are the resemblances between the columnar Cycadaceous Gymnosperms and Palms, between the livid, fœtid, one-sided calyx of *Aris-*

tolochia and the equally livid, fœtid, one-sided spathe of araceous endogens, or, in another point of view, between such lenticular plants as *lemna* in endogens, with the leaves and stems fused, as it were, together, and similar forms of stem and leaf among marchantiaceous exogens.

With regard to really intermediate forms of vegetation connecting endogens with other classes, they are extremely uncommon. One of the most striking is that which occurs between *Ranunculacææ* and *Nymphæacææ* on the part of exogens, and *Alismacææ* and *Hydrocharacææ* on that of endogens; if *Ranunculus lingua*, or better *R. parnassifolius*, is contrasted with *Alisma plantago*, or *Damasonium*, leaving out of consideration subordinate differences, it will be found that there is little of a positive nature to distinguish them except the albuminous dicotyledonous seeds of the former as compared with the exalbuminous monocotyledonous seeds of the latter; and the resemblances between *Hydropeltis* and *Hydrocharis* in the other case, are so very great that Schultz and others actually refer them to the same class.

Endogens probably contain more plants contributing to the food of man, and fewer poisonous species in proportion to their whole number, than exogens. Grasses, with their floury albumen, form a large portion of this class, to which have to be added Palms yielding fruit, wine, sugar, sago, *Aracææ*, *Marantacææ*, some *Amaryllidacææ*, &c., producing arrow-root, the nutritious fruit of the plantains, the aromatic secretions of *Zingiberacææ*, *Orchidacææ* forming salep, and *Dioscoreacææ*, the mothers of yams. Among the deleterious species we have little worth notice beyond the poisonous mucilage in the bulbs of certain *Amaryllidacææ*, and the acrid secretions of *Aracææ*.

What proportion endogens bear to the whole vegetable kingdom is unknown. De Candolle computes the proportions of the three great classes into which plants used to be divided, thus:

| | |
|-----------------------------|-----|
| Exogens, or Dicotyledons | 636 |
| Endogens, or Monocotyledons | 144 |
| Acrogens, or Acotyledons | 220 |

1000

But these numbers can only be regarded as loose approximations to the truth.

In these, as in all other large groups, we find the extremes of development so exceedingly far apart, that one would be almost tempted to doubt the possibility of their being mere forms of each other, were it not certain that numerous traces exist in the vegetable kingdom of a frequent tendency to produce the typical structure of a natural association of whatever kind in both an *exaggerated* and *degraded* state, if such figurative terms may be employed in science. For instance, the genus *Ficus* contains some species creeping on the ground like diminutive herbaceous plants, and others rising into the air to the height of 150 feet, overspreading with the arms of their colossal trunks a sufficient space of ground to protect a multitude of men; the type of organization in the willow is in like manner represented on the one hand by the tiny *Salix herbacea*, which can hardly raise its head above the dwarf moss and saxifrages that surround it; and on the other by *Salix alba*, a tree sixty feet high. Then among natural orders we have the Rosaceous structure, exaggerated, on the one hand, into the arborescent *Pomææ*, and degraded, on the other, into the apetalous imperfect *Sanguisorbææ*; the *Onagraceææ* type, highly developed in *Fuchsia*, and almost obliterated in *Haloragææ*; the *Urticaceææ*, in excess in *Artocarpus*, and most imperfect in *Ceratophyllum*; grasses, presenting the most striking differences of perfection between the moss-like *Knappia*, and Bamboos a hundred feet high; and the *Liliacææ* occurs in equally different states of development, when asparagus is compared with the Dragon-tree, or an autumnal squill with an arborescent *Yucca*. So, in like manner, we find at one extreme of the organization of the class of Endogens, palms, plantains, and arborescent liliaceous plants, and at the other, such submerged plants as *Potamogeton*, *Zannichellia*, and duckweed, the latter of which has not even the distinction of leaf and stem, and bears its flowers, reduced to one carpel and two stamens, without either calyx or corolla—therefore at the minimum of reduction, if to remain flowers at all—in little chinks in its edges.

The classification of endogens is not a subject upon which there is any very great diversity of opinion among botanists: if the natural orders are sometimes not distinctly limited, they are, upon the whole, grouped much better than those of exogens; and although it may be expected, whenever

more positive rules for classification than are yet known shall have been discovered, that great changes will be introduced into this part of systematic botany, yet we do not contemplate the probability of disturbing the limits of the natural orders themselves to any considerable extent.

According to the views of the writer of this article (*Nat. Syst. of Botany*, ed. 2, p. 320, &c.), there are six principal groups into which endogens may be divided. Of these, four have the organization of the flowers *perfect*, there being in all cases a distinct calyx and corolla, and a regular consolidated cotyledon; and two are *imperfect*, the calyx and corolla being either altogether absent or in an incomplete condition, as in *Araceæ*, where scale-like bodies are all that represent the floral envelopes, or grasses, in which for calyx and corolla are substituted imbricated scales, and the cotyledon is very commonly rolled up without consolidation or actually flat.

The perfect groups consist, firstly, of plants whose leaves are those of exogens, having reticulated veins, a taper foot-stalk disarticulating from the stem, and the habit of *Menispermaceæ* or *Aristolochiaceæ*: these form the *Retrose* group; secondly, of straight-veined plants, some of which have a superior and others an inferior ovary: all those with a superior ovary form the *Hypogynous* group. Those with an inferior ovary separate into two series, of which one has a distinct style and stamens (*Epigynous*), and the other those parts consolidated into a central column (*Gynandrosæ*).

The two groups of imperfect endogens are the *Spadicose*, in which a coloured spathe is usually present, and the flowers either altogether naked or provided only with rudimentary scales: in these plants the cotyledon is rolled up, but its edges are not united, so that it appears to have a slit on one side; and the *Glumose*, where the flowers have imbricated scales representing the calyx, and frequently minute scales in lieu of a corolla; in these the cotyledon is very usually flat, with the double cone, formed by the plumule and the radicle, adhering to its face at the lower end.

The following table presents this arrangement in one view, and shows under which of the groups the different natural orders are stationed. Of all the more important of the latter, some account will be found in this *Cyclopædia* at the proper places.

ENDOGENS.

* Perfect. *Flowers complete.* (Cotyledon usually rolled up and consolidated over the plumule and radicle.)

Group 1. *EPIGYNOUS.* Zingiberaceæ, Marantaceæ, Musaceæ, Amaryllidaceæ, Hæmodoraceæ, Burmanniaceæ, Taccaceæ, Iridaceæ, Bromeliaceæ, Hydrocharaceæ.

Group 2. *GYNANDROUS.* Orchidaceæ, Vanillaceæ, Apostasiaceæ.

Group 3. *HYPOGYNOUS.* Palmaceæ, Pontederaceæ, Melanthaceæ, Gilliesiaceæ, Liliaceæ, Commelinaceæ, Butomaceæ, Alismaceæ, Juncaceæ, Philydraceæ.

Group 4. *RETROSE.* Smilacaceæ, Dioscoreaceæ, Roxburghiaceæ.

** Imperfect. *Flowers incomplete.* (Cotyledon not consolidated, frequently quite flat and open.)

Group 5. *SPADICOSE.* Pandanaceæ, Cyclanthaceæ, Araceæ, Acoraceæ, Typhaceæ, Naiadaceæ, Juncaginaceæ, Pistiaceæ.

Group 6. *GLUMOSE.* Graminaceæ, Cyperaceæ, Desvauxiaceæ, Restiaceæ (Eriocaulaceæ), Xyridaceæ.

ENDORHIZÆ. [ENDOGENS.]

ENDORSEMENT. [BILL OF EXCHANGE.]

ENDOSMOSE is the attraction through an animal or vegetable membrane of thin fluid by a denser fluid. Mons. Dutrochet found that if he filled the swimming bladder of a carp with thin mucilage and placed it in water, the bladder gained weight by attracting water through its sides: to this phenomenon he gave the name of *Endosmose*. He also found that if he filled the same bladder with water and placed it in thin mucilage, it lost weight, its contents being partially attracted through its sides into the surrounding mucilage; this counter phenomenon he named *Exosmose*. The same circumstances were seen to occur in the transmission of fluids through the tissue of plants; it was found possible to gorge parts of vegetables with fluid by merely placing them in water, and to empty them again by rendering the fluid in which they were placed more dense than that which they contained. It was also ascertained that this phenomenon took place with considerable force: Dutrochet says that water thickened with sugar in the pro-

portion of 1 sugar to 2 water, was productive of a power of endosmose capable of sustaining a column of mercury of 127 inches, or the weight of $4\frac{1}{2}$ atmospheres.

This phenomenon is by its discoverer considered sufficient to explain many of the movements of the fluids both of plants and animals; his first book upon the subject is entitled *L'Agent immédiat du Mouvement Vital, dévoilé dans sa nature et dans son mode d'action chez les Végétaux et chez les Animaux*, Paris, 1826, and in his numerous more recent writings he sustains the same opinion. To the effects of endosmose he refers the motion of sap; the sleep of leaves; the various directions taken by plants under the influence of external agents, such as turning to the light or away from it; many kinds of irritability; the attraction of fluids to particular points, and the like. That Mons. Dutrochet's arguments are extremely ingenious, and his observations highly curious, no one will deny; but we quite agree with De Candolle, that, supposing this celebrated physiologist's views to be correct, we must still have recourse to vital force as the great and inexplicable cause of all such phenomena. When organic tissue dies, it does not lose its mere hygrometrical powers, nor do its tubes cease their capillarity, but no more vital movement of fluids takes place; yet mere endosmose will take effect through dead membranes, as is proved by the instrument called an endosmometer. We can only then allow endosmose to be one of the powers which, in combination with vital force, assists in producing some of the phenomena of life.

Dutrochet considers endosmose to be owing to what he calls intercapillary electricity, grounding his opinion partly upon the experiment of Porret, who found that when two liquids of different levels are separated by a membrane, they may be brought to a level by establishing an electrical current between the two, thus rendering the membrane permeable; and partly upon experiments of his own. But M. Poisson, on the contrary, has demonstrated that endosmose may be the result of capillary attraction joined to differences in the affinity of heterogeneous substances. (*Ann. de Chim.*, 1827, v. 35, p. 98.)

ENEMATA. [CLYSTERS.]

ENFROFFMENT. [FROFFMENT.]

ENFIELD, WILLIAM, was born at Sudbury, in Suffolk, on March 29, 1741, of humble but truly respectable parents. The disadvantages of his early education, arising from the condition of life in which he was born, were made amends for, in a great degree, by a fondness for reading and incessant labour towards improving his mind. This disposition to literary application introduced him to the notice of Mr. Hextall, the dissenting minister of the place, who kindly and judiciously directed him in his studies. Mr. Hextall's encouragement and advice led to his devoting himself to the Christian ministry. In his seventeenth year he was admitted to the Academy or Dissenting College at Daventry, then conducted by the Rev. Dr. Ashworth. Here he passed through the usual course of study of five years, and was distinguished for his habitual diligence and for an unusual facility and elegance of composition. It was here also that he, with some others of his fellow-students, were among the first of the dissenting ministry who formed the design of making Christian morality the principal object of their discourses, rather than points of faith or the dogmas of sectarianism.

Immediately on leaving the Academy, he was invited to the office of minister to the congregation of Benn's Garden, in Liverpool. In 1767 he married Mary, the only daughter of Mr. Holland, draper in Liverpool; a connexion which constituted his principal happiness for the rest of his life. In 1768 and 1770 he published two volumes of sermons, which were very favourably received. One of these volumes, now scarce, is rather remarkable for being embellished with vignette sketches illustrative of the subject of each discourse, from the pencil of Fuseli.

He took his leave of Liverpool on being invited to the office of tutor in the belles lettres and resident conductor of the discipline at the academy of Warrington. These offices he accepted in conjunction with that of minister to the dissenting congregation of Warrington. Of Dr. Enfield's qualifications for the office of tutor in the belles lettres there could be no doubt; but if, as was supposed, his mild disposition and amiable manners disqualified him for a disciplinarian, it must in justice be acknowledged that sterner deportment and stricter discipline have also failed in preserving dissenting academical institutions from the

fate that has so frequently attended them. The degree of doctor of laws was obtained from Edinburgh for him and others of the tutors by the trustees of the academy.

Of Dr. Enfield's industry some idea may be formed from the following list of the works which he published during his residence at Warrington and in the midst of his other various and important occupations—

'The Preacher's Directory,' 4to., 1771. 'The English Preacher; a Collection of Sermons abridged and selected from various Authors,' 9 vols. 12mo., 1773. 'An Essay towards the History of Liverpool, principally from the Papers of Mr. George Perry,' fol., 1774. 'Observations on Literary Property,' 4to., 1774. 'The Speaker; or Miscellaneous Pieces selected from the best English Writers, for the purposes of Reading and Speaking,' 8vo. 1774. 'Biographical Sermons on the Principal Characters of the Old and New Testament,' 12mo., 1777. 'Exercises in Elocution, being a Sequel to the Speaker,' 8vo., 1781. 'A Translation of Rosignol's Elements of Geometry,' 8vo. 'Institutes of Natural Philosophy, Theoretical and Experimental,' 4to., 1783. And besides these, various occasional sermons.

'Several of the above,' as Dr. Aikin observes, 'belong to the humble but useful class of compilations; yet in them he found occasion to display the elegance of his taste and the soundness of his judgment.' The 'Speaker' was one of the first, and is still, perhaps, one of the best selections from our English classical writers.

After the dissolution of the academy, Dr. Enfield remained two years at Warrington, occupied in the education of private pupils, and in his duties as minister of the congregation. In 1785 he accepted an invitation from the Octagon dissenting congregation at Norwich. He first settled at the village of Thorpe, where he received private pupils, and afterwards removed to Norwich, where, at length, he devoted his whole time to literary occupations and his official duties. It was during his residence at Norwich, that besides being engaged as a writer in the Monthly and Analytical Reviews, he undertook an abridgment of Brucker's 'History of Philosophy,' in 2 vols., 4to. In this task he was kindly encouraged by Dr. Bagot, at that time bishop of Norwich, and accommodated by him with books from Cambridge and from his own library.

Dr. Enfield published also while at Warrington another small volume of sermons on the principal characters of the Old and New Testament; and Dr. Aikin says, that while there he drew up a series of discourses on the principal incidents and moral precepts of the gospel, in which he displayed both his talents as a commentator and his skill in expanding into general lessons of conduct those hints and particular observations which occur in the sacred narratives. This work was not published, but a selection of twenty sermons from it forms the last of three volumes of discourses which were published after his decease by subscription for the benefit of his widow: and these productions of his maturer years will be found much superior to those sermons which were given to the world at an early period of his life. The series of discourses on the gospels was written chiefly, if not altogether, at Norwich.

Dr. Enfield was also a frequent contributor to the Monthly Magazine at its commencement, in which the papers under the title of the 'Enquirer' are mostly from his pen. His last literary undertaking was that of a General Biographical Dictionary, in conjunction with one of his oldest and most valued friends, Dr. John Aikin. He resided at Norwich till his death, which, after a short but painful illness, took place on November 3rd, 1797, in the fifty-seventh year of his age.

As a sermon-writer, Dr. Enfield obtained so great a reputation as not only to be applied to for assistance by his less industrious dissenting brethren, but also, through the agency of a London bookseller, by several of the clergy of the Establishment, for sermons on particular occasions, for which he was liberally remunerated.

As a preacher, his manner of delivery was, as Dr. Aikin characterizes it, grave and impressive, affecting rather a uniform dignity than a variety of expression. It was entirely free from what is called tone, and though not highly animated, was by no means dull, and never careless or indifferent.

As a companion, he was universally esteemed in every situation, and at every period of his life. That influential intercourse with a congregation, formerly considered a more essential part of the duty of a dissenting minister than it now is, in the case of Dr. Enfield, who never assumed the

priest, had uniformly a beneficial tendency. He was one whose entrance into any society of those who knew him instantly diffused pleasure. In small parties he frequently exhibited the rare talent of good reading, and with equal effect in the humorous and the pathetic. Both at Warrington and at Norwich he was instrumental in forming societies for the free discussion of the most interesting topics, without limitation or exclusion. He thus did much towards delighting, elevating, and refining the circle in which he moved; and the mildness and amiability of his disposition and manners aided the gentle and unobtrusive influence of his benevolent heart.

ENFIELD. [MIDDLESEX.]

ENFILADE is the denomination applied to a fire of artillery or musketry when made in the direction of an enemy's line of troops, or to that which is made from any battery to the interior of an enemy's rampart or trench, and in the direction of its length. When an artillery fire is so employed by the besiegers of a fortress, the intention is to dismount the guns of the defenders; and this end it accomplishes with more certainty than if the fire were directed from the front towards the mouths of the embrasures, both because the side of a gun-carriage presents a larger surface than the muzzle of the piece to the action of the shot, and because the same shot may take effect against two or more guns placed upon the same line of rampart. An enfilading fire of artillery is also used by the besiegers to destroy the palisades or other obstacles behind a glacis, and to prevent the defenders from remaining at their parapets. When employed by the defenders of a fortress, it is intended to sweep any of the besiegers' trenches which may from necessity, or through the fault of the engineer, lie in a direction tending towards some part of the ramparts of the fortress.

The destructive effects of an enfilading fire, when directed against the guns on a rampart, are diminished by constructing traverses across the rampart at intervals, or by placing the guns in blindages. And, to avoid such fire in the trenches of the besiegers, the practice is to form those trenches in zig-zag directions, tending alternately to the right and left of the general line of the approaches, so that, if produced, they may fall on the exterior of all the ramparts from whence a fire might be directed towards the approaches: when this is not possible it becomes necessary to raise traverses in such trenches as are thus exposed to the fire.

In Sir John T. Jones's Journals of the Sieges in Spain, there is given an account of the ingenious attempt made by a French corporal to cause one of the trenches of the besiegers before Badajos to be enfiladed by the guns of the fortress: the man contrived secretly in the evening to displace on the ground the tracing cord which the British engineer had stretched in order to indicate the intended direction of the trench; and the attempt only failed because the officer who came on duty for the night accidentally discovered, before darkness came on, the error in the position of the line. [RICOCHET.]

ENFRANCHISEMENT. [COPYHOLD.]

ENGADIN, the valley of the Upper Inn in the canton of the Grisons, in Eastern Switzerland, runs from southwest to north-east, from the sources of the Inn at the foot of Mount Maloya to the defile of Finstermünz, where the Inn enters the Tyrol, a length of about 50 miles. It is the largest valley in Switzerland next to the Valais, and one of the finest; it lies between two massive and lofty ridges of the Rhætian Alps, both of which branch off from Mount Maloya. The northern ridge, which contains the summits known by the names of Julier (6800 feet), Albula (7200), Scaletta (8000), Flüela, Piz Linnard, Selvetta, &c., divides the waters of the Inn from those of the Albula, the Lanquart, and the Iller, which flow into the Rhine. The southern range consists of the Monte dell' Oro (8000 feet), the Bernina (6200), the Casanna, the Fraele, the Piz Pisogg, Sursas, Pizlat, &c., and divides the valley of the Inn from that of the Adda, called also Valtelina, and from the valley of the Upper Etsch or Adige in the Tyrol. More than twenty transverse valleys open into the longitudinal valley of Engadin. The width of the plain which forms the bottom of the valley of Engadin is from one to two miles in its widest parts, but it is much narrower in many places.

The slopes of the mountains are covered with forests or pastures. The cultivated grounds produce some barley, rye, and oats, potatoes, turnips, peas, and other vegetables. The Upper Engadin being more elevated than the lower part of the valley, has a keener air and sharper winters,

yet Kasthofer (*Voyage dans les petits Cantons et dans les Alpes Rhétiennes*) saw at Celerina, about 5300 feet above the sea, barley and oats, and at St. Moriz, which is about the same elevation, he saw cabbages, peas, carrots, turnips, and lettuce. Potatoes sometimes succeed in certain localities, but the barley harvest is uncertain. The Lower Engadin enjoys a milder climate; at Zernetz, 4400 feet above the sea, barley, rye, peas, potatoes, and hemp succeed; lower down the valley, flax is cultivated with success. The cherry and other fruit trees are also met with. But the chief wealth of Engadin and especially of the upper part, consists in its cattle; its cheese equals that of Gruyère, and is largely exported. Many of the men emigrate to foreign countries, especially to Lombardy and the Venetian States, where they follow the trade of pastry cooks and confectioners. Some of them make money, with which they return home, and build fine houses, which are conspicuous objects in most of the villages. Their fields are therefore either left to the care of the women or let, and such is the scarcity of native labourers, that about 1500 hay makers from the neighbouring countries repair to Engadin for the hay harvest, and are paid at the rate of 1½ to 2 florins a-day, besides a plentiful allowance of victuals. Masons, carpenters, and smiths are mostly foreigners. Leather is imported, while a quantity of raw hides are exported. Most of the pastures on the high Alps are let to herdsmen from Bergamo and other parts of Lombardy, who migrate thither with their cattle in the summer months. These herdsmen take along with them very fierce mastiffs, which are dangerous to stray pedestrians or hunters.

The villages of Engadin are chiefly along the road which follows the course of the Inn for the whole length of the valley, and then leads into Tyrol by St. Martinsbruck, and joins the high road coming from Italy by the Stilfser Joch to Innspruck. [BORMIO.] Several paths lead from Engadin into the other valleys of the Grisons; the principal one is over the Julier leading into the valley of the Albula, and thence to Chur or Coira. Another path over the Maloja leads into the Val Bregaglia, which belongs likewise to the Grisons, and thence to the Chiavenna. Other paths lead over the southern ridge into Valtelina; the most frequented is that over the Bernina into the valley of Poschiavo, also belonging to the Grisons, and from thence to Tirano and Sondrio on the Adda. A road leads from Zernetz in Lower Engadin by the Val del Forno, and over the Buffalora mountain, 6000 feet high, into the Munster Thal, also a Grison district, bordering upon Tyrol, and which opens into the valley of the Etsch.

Upper Engadin has eleven communes or parishes, and reckons about 800 men fit to bear arms, and Lower Engadin has ten communes and 1300 men fit for military service. The whole population is estimated at about 8000, of which Lower Engadin contains 5000. Upper Engadin returns three members and Lower Engadin four to the great council or legislature of the canton. Every commune elects its municipal magistrates, and each of the two divisions of the valley has its landamman and its court of justice, the members of which are renewed every two years.

The people of Engadin are Protestants of the reformed Swiss church, with the exception of the commune of Tarasp, which is Catholic, and which belonged to the house of Austria till 1801. They speak the Ladin, a dialect of the Romane or Romance language, which has much resemblance to the Italian. There are books printed in Ladin.

Schools, in Lower Engadin, is the largest village in the whole valley; it contains nearly 200 dwelling-houses, and a handsome parish church. Zernetz, also in Lower Engadin, has about 450 inhabitants. Samaden, which is the principal village of the Upper Engadin, has about 500 inhabitants, some fine houses, and three churches. The families of Salis and Planta, which had once very extensive feudal powers in these parts, and whose rivalry occasioned much bloodshed, are originally from Engadin, the history of which is connected with that of the Grisons' country. [GRISONS.] (Leresche, *Dictionnaire Géographique de la Suisse*, 1836; Dandolo, *Lettere sulla Svizzera, Cantone dei Grigioni*.)

ENGHIEN, LOUIS ANTOINE HENRI DE BOURBON, DUKE OF, was born at Chantilly, August, 1772. He was the son of the duke of Bourbon and grandson of the prince of Condé, being a lateral branch of the then reigning family of France. After the French revolution broke out, young d'Enghien served under his grandfather in the corps of the French emigrants who fought on the

Rhine. At the peace of Lunéville with Austria, in 1801, the corps was disbanded, and Enghien fixed his residence at Ettenheim, a château on the German side of the Rhine, a few miles from that river, and in the territories of the margrave of Baden. An attachment between him and the princess Charlotte of Rohan, who resided at Ettenheim with her relative the Cardinal de Rohan, induced the duke to remain there. After the war had broken out again between England and France, in 1803, the English government took the French emigrants again into its pay, and they were directed to go to the German side of the Rhine to act when required. The duke of Enghien was looked upon as their head. Meantime the conspiracy of Georges and Pichegru against the person of the first consul, Bonaparte, was discovered at Paris. It has never been proved that the Duke of Enghien was privy to that conspiracy, but it is evident that he was led to expect an insurrectionary movement in France in favour of the Bourbons, of which he intended to avail himself by entering France at the head of the emigrants. This he did not deny. Bonaparte, alarmed at the conspiracy and at the avowed intention of Georges to assassinate him, seems to have persuaded himself that the Duke of Enghien was connected with the Paris conspirators, and that the whole was a plan directed by the Bourbons in England and by the English government. That all the above parties desired his overthrow is undoubted, and is no more than might be expected, as they were his declared enemies, but considerable difference may have existed as to the means which they intended to employ. Georges and his Chouan friends preferred assassination as the shortest and most congenial to their habits, but there is no evidence that they had instructions to that effect, or were countenanced in it by any of the higher parties, who really seem to have expected an insurrectionary movement in Paris, in which Moreau, Pichegru, and other influential persons would have participated. The insurrection, however, if successful, would, in all probability, have occasioned the death of Bonaparte, if not by assassination, at least in the scramble and fight which must have taken place. How far the persons engaged in or countenancing such a plot were justifiable, is a question which cannot be resolved by any code of political justice yet in existence. Bonaparte, on his part, determined upon getting rid of his enemies by summary means similar to those which they employed against him. He dispatched a party of gens d'armes, who crossed the Rhine, entered without ceremony the neutral territory of Baden, surrounded the château of Ettenheim, and took the duke of Enghien prisoner, the 15th of March, 1804. [For the following part of the transaction, see BONAPARTE.] The duke was tried before a secret court, which was evidently influenced in its decision by fear of the first consul, and whose sentence was carried into execution with a most indecent haste. The duke was found guilty of all the charges preferred against him, some of which were never proved. Even the recommendation of the court for a respite to the prisoner was overruled by Savary, who was present at the sitting as a sort of extra-judicial authority to watch over the proceedings. It was altogether a dark affair worthy of the worst times of the old monarchy. Bonaparte at the time openly avowed to the Council of State his firm purpose of making an example of the duke in order to deter the other Bourbon princes and their partisans from plotting against him in future. (Thibaudeau *Le Consulat et l'Empire*, vol. iii. ch. 41.) And again, at St. Helena, almost at his dying hour, he took upon himself alone the whole responsibility of that deed. (*Testament de Napoléon*.) After the Restoration, Hulin, president of the court, Savary, Caulincourt, and others who had a share in the arrest, trial, and execution of the duke, wrote each in justification or extenuation of their respective conduct. The fate of the duke of Enghien excited interest and commiseration throughout Europe; he was young, brave, amiable, and one of the most promising of the Bourbon princes.

ENGHIEN. [HAINAULT.]

ENGINEERING (from the French word *engin*) is properly the art of constructing and using engines or machines; but the term is also applied to that of executing such works as are the objects of civil and military architecture, in which machinery is in general extensively employed.

A distinction has long been made between the civil and military engineer; and since every thing relating to the service of artillery is now confided to a particular corps, the duty of the military engineer may be said to comprehend the

construction of fortifications, both permanent and temporary, including the trenches and batteries required in besieging places; also of barracks, magazines, and other works connected with warlike affairs.

The profession of the civil engineer comprehends the design and execution of every great work by which commerce and the practice of the useful arts may be facilitated. Thus, in creating or improving the communications of a country, he would be called upon to form a road through hills or over valleys or rivers, or to excavate a canal in connection with the waters by which it may be supplied, and to build the locks for retaining the surface at different levels, in different places, when the inequalities of the ground are considerable. He raises embankments to resist the encroachments of the sea or to reclaim the land which it may have covered, and dams to break the force of its waves at the mouths of natural harbours. He renders rivers navigable when their course is obstructed by rocks or banks; he forms docks or artificial harbours where ships may remain in security; and he is required to penetrate by mines to vast depths for the purpose of seeking the mineral treasures contained within the bosom of the earth. Such are the occupations of this important class of men; and it is necessary to observe that they frequently, in addition, practise the avocation of the machinist in executing the presses, mills, looms, and other great machines employed in the arts and manufactures; particularly in constructing steam-engines and the apparatus by which they are rendered available for giving motion to ships, carriages, or machinery.

In France the title of engineer is extended to persons who are employed for the public service in trigonometrical surveying in the interior of a country or on the coasts, and in the practice of naval architecture. The French have thus a corps of *ingénieurs géographes*, of *ingénieurs d'hydrographie*, and of *ingénieurs de marine*.

Engineering must have originated with the first application of a lever for the purpose of moving a mass of any material which exerted a resistance exceeding the unassisted strength of man: by observing the effects produced in operations of that nature, the laws of the action of bodies on one another were gradually discovered, and mechanics, the science of the engineer, arose.

Archimedes, in addition to the title of geometer, may with justice claim that of mechanician; and in fact he is the first person who is known to have applied himself to the cultivation of the mixed mathematical sciences. Besides demonstrating the fundamental property of the lever, he determined the centre of gravity in bodies of certain forms, and the positions in which bodies remain in equilibrio in a fluid; and from the celebrity he acquired among the ancients by the mechanical contrivances which, according to Polybius, he put in practice for the defence of Syracuse, we may conclude that if those contrivances were not his own inventions, they must have contained improvements upon such as had been in use before his time.

Vitruvius wrote his treatise on architecture during the reign, as it is generally believed, of Vespasian. In that treatise he describes the manner of building the walls and towers for fortifying towns, the construction of temples, basilicas, theatres, and private dwellings; he describes the principal military engines which were then in use; he also gives some account of machines for drawing and raising weights, of engines for raising water, and of mills turned by water for grinding corn. The work may therefore be considered as comprehending every important object connected with engineering at the time in which he lived. Now he states, in the preface to the first book, that he had been appointed by the emperor to have the charge of the warlike engines; and in another place, that he had designed and executed a basilica at Fanum; it is evident therefore that he united in his person the character of engineer and architect; and among the ancients the profession of the former seems to have been always included in that of the latter. The 'machinarius' was probably the artificer who executed the civil and military machines, or the petty officer who, at the siege of a fortress, superintended the service of the engines.

Of the national works executed by the ancients, and which are to be considered as properly falling within the province of the engineer, one of the first of which we have any intimation is the canal uniting the Red Sea and the Nile, which, according to Pliny, was begun by Sesostrius, or, according to Herodotus, by Neco, the son of Psammeti-

chus, and finished by Darius the First. The canal of Xerxes across the isthmus of the peninsula of Athos is another example of works of this kind. The introduction of arches in works of magnitude may be said to have constituted an epoch in the profession of the architectural engineer, as the idea of giving to blocks of stone a form which would enable them to sustain themselves in balanced rest by their mutual pressures, the discovery of the means of arranging them on a curve surface, and the determination of the magnitudes of the piers or abutments so that the lateral pressure of the vault might be adequately resisted, imply a higher degree of intellectual power than is exhibited in covering a space with a horizontal roof. The Cloaca Maxima [CLOACÆ] at Rome is probably the most ancient example in Europe of this scientific construction; the dome of the Pantheon, and the various arches of the Thermæ and of other public buildings both at Rome and in the provinces, such as aqueducts and bridges, attest the grandeur of the design, combined with purposes of public utility, which characterized the architects who lived under the early emperors.

Vitruvius enumerates several Greeks who had written on machinery; but from his time to that in which Italy rose again to importance after the fall of the empire, little is known concerning the state of engineering in Europe. Subsequently to the last-mentioned epoch, Cardan, Guido Ubaldi, Valerius, and Galileo, in that country, and Stevinus, Huygens, and Descartes, in the north, are distinguished as cultivators of theoretical mechanics. Galileo particularly deserves to be named for his discovery of the laws of motion, his application of the pendulum to the measurement of time, and for his theory of projectiles. From his day to the present almost every distinguished mathematician, both on the continent and in this country, has contributed to the advancement of the mechanical sciences.

Previously to the commencement of the eighteenth century the most celebrated practical engineers were Brunelleschi, who built the dome of St. Mary at Florence; Peruzzi, San Gallo, and Michel Angelo, who executed that of St. Peter at Rome; San Michæli, the supposed inventor of the bastion system of fortification; and to these may be added Sir Christopher Wren, the architect of St. Paul's Cathedral in London.

In Holland and in the north of Italy the necessity of securing the low grounds against the inundations of the seas and rivers, and of obtaining an inland navigation for the purposes of commerce, gave rise to the cultivation of that branch of engineering which relates to hydraulic constructions; and the invention of the lock for canals is believed to have taken place in the former country about the middle of the thirteenth century. Indeed we find the profession practised in those countries on an extensive scale when there was not a man in England capable of undertaking the formation of a canal to drain the ground. Before the reign of Charles I. it appears to have been the practice to send to Holland for an engineer when any work of that nature was to be undertaken.

But the extension of the manufactures of this country soon after that period, and the consequent augmentation both of its internal and foreign commerce, called forth all the energies of the people, who, at length, in the works performed for facilitating the means of communicating between one place and another, and in the practice of the useful arts, rose to an eminence which other nations have not been able to attain. Among the former may be mentioned the numerous canals and railways which intersect the country; the majestic bridges executed in stone over the Thames; in cast-iron over the Avon, the Thames, &c.; and those on the suspension principle at the Menai and at Hammersmith. And among the men to whose useful talents in this branch of engineering the nation is indebted may be named Brindley, Smeaton, Jessop, Telford, the Rennies, and Brunel.

The invention of the steam-engine, or rather its improvement in 1769, opened a new field for the talent of the engineer in the numerous uses to which the machine became applicable. Before the time of Watt it had been employed only as a pump to raise water; but this mechanician, by converting the reciprocating motion of the beam into a rotatory motion, rendered it capable, not only of replacing, with greatly augmented energy, the power of wind, water, or horses, in giving motion to machinery for the purposes required in the arts, but also of serving as a first mover for

propelling vessels through water, or for drawing carriages over land.

The course of education by which a student may qualify himself to become an engineer, whether civil or military, must necessarily comprehend a greater extent both of the pure and physical sciences than would be required for a person who is to follow any other profession. It will be, perhaps for ever, a matter of opinion how much mathematics should enter into a school course of engineering; and there are, no doubt, some persons who contend that no more is required than would serve to compute the cost of materials and the wages of labour; this, and the observation of existing examples, being supposed sufficient to enable a man to enter upon the practice of the profession. It is not however with such knowledge only that an engineer is qualified to design an important work which it may be required to conduct under new and difficult circumstances. Mere science certainly cannot make a man an engineer; for analytical formulæ relating to mechanical equilibrium or operations, being necessarily founded on the erroneous assumption that materials are perfectly hard, perfectly smooth, &c., and that the actions of bodies on one another are subject to invariable laws, have no practical utility unless corrected by observation and experiment. On the other hand, mere diligence in observing the results of practical operations will never raise a man to proficiency in art unless he is gifted with very extraordinary powers. A judicious combination of theory and practice is indispensable, and such a combination can only be made by a man in whom great natural talent is blended with all the aids that the sciences can afford.

Of the military engineer it may be said that a greater knowledge of the more minute details of construction is required than would suffice in the civil practitioner; because it may happen that the former is called upon to exercise his profession in some colony where workmen adequately skilled in the mechanical operations may be wanting. The accomplishment of the work may then become impossible, should the officer not be qualified to give the necessary instructions to those who are placed under his direction.

It is to be regretted that in the schools of this country there prevails an almost exclusive attention to the studies which may be comprehended under the general term 'literature'; and that, notwithstanding the vast importance of the sciences and arts in promoting the prosperity of the nation, there is not, if we except the military schools at Woolwich, Sandhurst, and Addiscombe, any place of education where young men are instructed in the *science of the engineer*. In a discourse delivered by M. Bureaux de Puy, which was printed in 1790, it is stated that the pupils, on entering the Ecole de Génie at Mézières, were required to undergo an examination in arithmetic, algebra, geometry, the infinitesimal calculus, mechanics, hydraulics, and drawing. And these branches of science are said to be but the key to those taught at the institution itself, which are stereotomy (the art of representing the sections of solids), the principles of carpentry, civil and military architecture, perspective, the theory of shadows, and surveying; and with these are said to have been combined the science of military tactics and a course of chemistry. If the above branches of study were considered requisite for the Ecole de Génie, much more, omitting only that which relates to tactics, would they be proper for the civil engineer, who is called upon to design and carry into execution works of far greater complexity than those which appertain to the science of war.

It is easy to conceive that the knowledge which a boy, at the age of entering a public school, can have of the infinitesimal calculus and mechanics must be very superficial; and it would perhaps suffice if he then possessed a competent knowledge of plane geometry, trigonometry, mensuration, and common algebra. But it is correct to say that, before a youth is placed in the office of a practical engineer, his education should have comprehended most of the subjects above enumerated, particularly the principal propositions in mechanics, hydrostatics, and pneumatics; since it is scarcely probable that the means of instruction will afterwards be within his reach, even were he led by inclination to seek them.

The institution of civil engineers which was formed at London in 1828 cannot fail, by the publication of its transactions, to be the means of greatly assisting such persons as may hereafter enter the profession; and, through them, of rendering service to society itself. Even established prac-

tioners may occasionally derive benefit from the theoretical investigations and the practical details of construction which are the subjects of the papers read at the meetings of the members.

The professions of an architect and of an engineer, as they are practised at present, may be said to coincide with one another to a certain extent. The members of both must be able to form a judgment of the quality of the ground in which the foundations of their buildings are to be laid; they must be acquainted with the capacities of different materials, wood, stone, and iron, for resisting the strains to which such materials may be exposed, so that sufficient strength may be obtained with a due attention to economy; and they must equally attend to the principles of equilibrium in their roofs, arches, and domes, arranging the beams, bars, or voussours so that they may remain at rest with as little strain as possible upon the connecting ties by which the joints are strengthened. But here the two professions diverge from one another: while the engineer has to determine, by a process of levelling, the profile of the ground on perhaps an extensive line of country, for a road or a canal; or has to determine the forms and dimensions of his retaining walls so that they may resist the pressure of earth or water against them; or, finally, to devise methods of rendering the action of his moving powers uniform, and of transmitting them through a train of machinery to the place where the effect is to be produced,—the architect is engaged in designing the external forms and internal arrangements of edifices, in which, whether intended as palaces or private dwellings, or as buildings consecrated to the service of religion or of the state, architectural beauty must be combined with fitness for the purposes for which they are intended.

ENGLAND, originally *Engla-land*, *Engle-land*, and *Engle-lond*, means the land of the Angles, Aengles, or Engles. The vowel in the first syllable appears to have preserved its proper sound most completely in the French *Angleterre*. In the languages of the Teutonic family it has generally slid into the thinner sound of *E* or *Æ*, which is nearly, but not quite, the same with our English *a* in such a word as *made*. Thus the Dutch say *Engeland*, and the Germans *England*, spelling the word exactly as we do. It is to be observed, however, that in this country we have receded still farther from the original form of the word in our pronunciation than in our spelling; for both in *England* and *English*, the first syllable is pronounced as if the vowel were not *e*, but *i*. This last fact connects itself, in some way or other, with the manner in which the nations of the south of Europe both pronounce and write the word; the Italians saying *Inghilterra*, the Spaniards *Inglaterra*, and the Portuguese *Inglaterra*. But these forms may have been adopted either from an imitation of the English pronunciation, or from some tendency peculiar to the languages of the Latin family (in which case it is possible that our present pronunciation of the word may be an innovation derived, probably not longer ago than the latter part of the sixteenth century, from Spain or Italy); or the Italian, Spanish, and Portuguese forms on the one hand, and the English mode of pronouncing the word on the other, may be so many independent exemplifications of a tendency to farther and farther attenuation natural to the vowel sound in this position, the reduction from *e* to *i* being only a continuation of the process by which the broad *a* had been previously converted into *e* or *æ*.

There can be no doubt, at all events, that the meaning of the word is, as we have just explained it, the land or country of the Angles. It is usual to speak of the people who occupied the south of Britain before the Norman Conquest by the names of the Saxons or the Anglo-Saxons; but each of these appellations is apt to lead to some misapprehension. To begin with the latter: by the Anglo-Saxon people and language seem commonly to be understood the nation and language of the English Saxons, as distinguished from the Saxons of Germany; indeed the Anglo-Saxons are often called the English Saxons (for instance, in Gibson's translation of Camden's *Britannia*, pp. 154-168). In this sense, however, we believe, the word is altogether a modern formation. Our ancestors before the Norman Conquest did not call themselves Anglo-Saxons, as meaning the English Saxons or the Saxons of England. Asser indeed designates Alfred as Angul-Saxonum Rex; but the meaning intended to be conveyed by this awkward compound term appears to have been, not the English Saxons, but the Angles or English and the Saxons. When the Saxon part of the population

alone was spoken of, they were never called the Anglo-Saxons or English Saxons, but simply the Saxons, or, as the case might be, the West or East or South Saxons. Then, secondly, with regard to the term Saxons: that name, we believe, was never used among our ancestors themselves, in the times before the Norman conquest; as applicable to the general population of South Britain: they confined it to that particular portion of the population which was of Saxon lineage, and which did not occupy half the country. It is true that foreigners did not always strictly observe this distinction, but often spoke of the whole people as Saxons, naturally misled both by the greater celebrity of that name for some ages before the settlement of the Saxons and the other kindred tribes in Britain, and by the circumstance that the first of those invaders that arrived in the country appear to have been Jutes and Saxons. We easily account in this way for the application of the term Saxons to the entire body of the new population by the Welsh writer Gildas, and for its having apparently been generally used in the same comprehensive sense both by the Welsh and the Scots of North Britain from the earliest times. The *Sassenagh* is still the name given to the English by the Scottish Highlanders and by the Welsh; and antiently the southern part of the present Scotland, which was chiefly occupied by a population of English descent, was known in the more northern parts by the name of Saxonia or Saxony. The prevalence, again, of the term Saxon in modern times, as applied to the entire population of England before the Norman Conquest, and to the language then spoken in the country, is to be attributed principally to the appropriation of the term English in another sense, namely, to the inhabitants and the language of the country since the Conquest, and also perhaps in part to the circumstance of the state which eventually obtained the general sovereignty in the times previous to the Conquest having been a Saxon state. But the name by which the entire population was commonly described in those times by natives of the country was certainly not the Saxons, but the Angles or the English; and that from the earliest date to which our evidence on the subject extends. It is commonly said that the use of the term English as the common national appellation is probably to be traced to the circumstance of Bede, himself an Angle, having entitled his history '*Historia Ecclesiastica Gentis Anglorum*,' and having, in conformity with that title, applied the name Angli throughout the work as the general designation of his countrymen. But the use of the name in that comprehensive sense appears to be considerably older than the time of Bede, who died in A.D. 735. We find the Kentish king Ethelbert, considerably more than a century before this, subscribing himself to a charter '*Ego Ethelbertus, Rex Anglorum*,' in virtue apparently of his dignity as Bretwalda or supreme monarch, which he held from about the year 589 till his death in 616. Taking this fact along with the other, which is unquestionable, that the kings of Wessex, after they acquired the sovereignty of the whole country, although their own state was Saxon, yet called themselves, not kings of the Saxons, but kings of the Angles and of England, we may safely conclude that the latter had all along been the names by which the whole people and country were commonly known, and that Bede in employing them as he did only followed antecedent usage. We believe the country to have been called England, and the people and their language English, from the time of the introduction of Christianity.

To the circumstances of that introduction we would trace this use of the names. The captives from Britain exposed for sale in the market-place of Rome, who first drew upon their country the attention of Gregory, afterwards pope, were Angles, as the well-known pun, 'They would be not Angles, but angels, if they were but Christians,' which the name of their nation and their fair appearance suggested to Gregory, may remind us. It was the Angles, therefore, that Gregory formed the desire of converting; and it was to the inhabitants of Britain considered as Angles that Augustine and his companions were some years afterwards sent as missionaries. These circumstances were enough to fix the name as the proper Christian appellation of the nation. It was that by which the people had been known to the missionaries before their arrival among them, and which the anecdote of Gregory would doubtless endeavor to these holy men and to their disciples. Hence its assumption by their royal convert Ethelbert, taking, in his quality of supreme monarch, the title of *Rex Anglorum*, as already noticed. It

was of course also the most appropriate appellation which Bede, writing the history of the church thus planted, could employ. And although we cannot suppose that he was the first who so applied it, the constant use of it in his great work may be reasonably supposed to have had much effect in establishing its acceptance in the sense in which it had been there employed. In this way the terms England and English very soon came into universal use as the proper names of the country, the people, and the language, just as they are at this day.

According to the statement of Bede, which, repeated in the Saxon Chronicle, is the only distinct account we possess of the invaders from the Continent who effected the conquest of South Britain in the fifth and sixth centuries, they consisted principally of three nations or tribes, the Jutes, the Saxons, and the Angles. (*Hist. Eccles.* i. 15.) In another place, however (v. 10), he mentions Frisians as being mixed with these; and there are other antient testimonies to the same effect, especially a remarkable passage in Procopius (*Bell. Goth.* iv. 20), where, in his account of the island under the name of Brittia, he describes it as inhabited by three nations, the Angles, the Frisones, and those of the same name with the island, the Britons ('*Ἀγγλοὶ τε καὶ Φρίσωνες καὶ οἱ τῆ νήσου ὀνόματι Βριττονες*'), each of which nations had a king. Sir Francis Palgrave (*Rise and Progress of the Eng. Com.* pp. 41, 42) considers the name Frisians in this passage to include both the Jutes and the Angles, as well as the Frisians proper, all these apparently being alike Belgic tribes. 'By the Frisians,' he adds, 'Hengist is deemed to be a Frisian king; and the legend of Rowena, or, as they term her, Ronix, is incorporated in their history. A better proof of affinity is to be found in the resemblance of the Frisic and Anglo-Saxon languages, which in many instances amounts to an absolute identity. But the most conclusive argument of the unity of the nations is deduced from the judgments dictated by Wulemar, and incorporated in their respective laws of the Frisians and Angles, showing thereby that they obeyed the dictates of a common legislator.' It is to be recollected, that antiently the Frisians appear to have been spread, in detached settlements, along the whole line of the coast from the Schelde to the North Sea. Down to the eighth century, what was called the Greater Friesland (or Frisia Major), then forming part of the empire of Charlemagne, extended all the way from the Schelde to the Weser. But the Frisians who passed over into Britain with the Saxons, Angles, and Jutes, were most probably the Strandfrisii, or inhabitants of the small district called the Lesser Friesland (Frisia Minor), lying opposite to the isle of Northstrand, on the western coast of Schleswig. (See further upon this subject Usher, *Antiq. Eccles. Brit.*, p. 397; and Turner, *Hist. Ang. Sax.* i. 306.)

We may here observe that, although it has been commonly assumed that our present Teutonic speech was brought over by these Saxons, Angles, and other kindred tribes in the fifth and sixth centuries, there are not wanting some writers who contend that it has been known in the island from a much earlier date. Sir John Clerk of Penicuik was, as far as we are aware, the first who advanced the opinion that the Belgic tribes who, according to Cæsar, occupied the whole or the greater part of the southern coast before the arrival of the Romans, spoke, not a Celtic, but a Teutonic dialect; in other words, a language radically the same with that brought over many ages afterwards by the Angles and Saxons. His '*Dissertation on the Antient Language of Britain*,' although written forty years before, was not published till 1782, when it appeared in the first volume of the '*Bibliotheca Topographica Britannica*,' 4to., London. Pinkerton, in his '*Inquiry into the History of Scotland*' (first published in 1789), claims the credit of having made the same discovery two years before he saw Sir J. Clerk's Dissertation. 'It is one,' he observes, 'which in the history of no other country would have been reserved for this century, and which I will venture to say is more important to English history than any yet made, or that can be made. For it not only adds seven centuries to the history of Englishmen, as such, but will, if duly attended to, put the whole history of law, manners, antiquities, &c., in England, upon quite a new and far more interesting footing.' Sir Francis Palgrave, in his work quoted above, also inclines to the presumption that 'a dialect closely allied to the Anglo-Saxon was spoken in Britain long before the arrival of the last invaders' (p. 27). This supposition certainly would enable us to explain some difficulties not otherwise to be easily got over, especially the remarkable fact,

that, while the old inhabitants cannot be believed to have been wholly swept from the soil by their invaders and conquerors, but were most probably retained in great numbers as slaves, both domestic and predial, no hint or indication is to be found of any distinction of language having existed between the two races that were thus associated.

The first of the Germanic invaders that arrived after the departure of the Romans are described as having been a body of Jutes, under two leaders named Hengist and Horsa. They arrived A.D. 449 at Ebbsfleet, now an inland spot, but then on the coast of the Isle of Thanet, and near the mouth of the Wansum, now a mere rivulet, which divides Thanet from the rest of Kent. The name of the Jutes is variously written Jutae, Juitae, Jotuni, Giotae, Gutae, Jetae, &c. It is probably the same name with Getae, and that again is probably identical with Gothi, Scythae, and Scoti. (See upon this subject Pinkerton's *Dissertation on the Scythians or Goths*, chap. i.) The Jutes who came to Britain with Hengist and Horsa, however, appear to have come immediately from what was formerly called South Jutland, and is now the duchy of Schleswig. They were probably, therefore, in part at least, from the district called the Lesser Friesland, which, as already mentioned, was situated on the coast of South Jutland. The Jutes, according to Bede, were the ancestors of the people of Kent, and also of the inhabitants of the Isle of Wight, and of the part of the coast of Hampshire opposite to it: that is to say, the Jutes settled in those parts, mixing most probably with the former inhabitants.

The Jutes under Hengist and Horsa were followed in A.D. 477 by a body of Saxons under Ella, who made their descent on the coast of Sussex. The next leader that arrived was Cerdic, with another colony of Saxons, in A.D. 495. He probably landed somewhere on the south coast, perhaps at Southampton, although one account makes Yarmouth (in Norfolk) to have been the place. The general history of the Saxons, of which their connection with Britain forms only a very small portion, will be treated of in another article. At this period the name, in its most comprehensive acceptation, appears to have been used as that, not of one nation, but of a great confederacy of nations, the territories occupied by which extended from the Baltic far into the interior of Germany. We are inclined however to derive the Saxon invaders of Britain from the immediate vicinity of the Baltic, most probably from the country now forming the duchy of Holstein, with perhaps part of the north of Hanover, or the west of Mecklenburg. Thus situated, they would be the next neighbours of the Jutes and the Angles. And this appears to be the district which their English descendants recognized as the country of their ancestors, or the land, as they called it, of the Old Saxons, as we may learn from the account of Germany which Alfred has inserted in his translation of the Geography of Orosius. The 'Eald Seaxan' are here described as lying to the north of the Thyringas (or Thuringians); to the south-east of the Frisians (this must mean the Strandfrisians); to the east of the mouth of the Aelfe (the Elbe) and Frysland; and to the south-east of Angle and Sillende (Zealand), and part of Dena (Denmark). Bede expressly brings the English Saxons from 'the land now called the country of the Old Saxons.' They appear to have eventually occupied Sussex, Essex, Middlesex, the south part of Hertford, Surrey, Hampshire (with the exception of the coast opposite to the Isle of Wight), Berks, Wilts, Dorset, Somerset, Devon, and part of Cornwall.

It was not till the year 527 that the first Angles arrived. From that time they made a succession of descents under various petty chiefs, whose names have not been preserved, upon the coasts of Suffolk and Norfolk. In 547, however, a much more numerous body of them than had yet appeared landed under the conduct of Ida on the coast between the Tweed and the Forth, and eventually established themselves in the country to the north of the Humber. Tacitus, who in his 'Germany' has mentioned neither the Saxons nor the Jutes, merely notices the Angli along with several other tribes as lying beyond the Longobardi, and surrounded by the natural protection of their rivers and woods. As far however as anything can be made of his vague account, he appears to place them somewhere in the peninsula of Jutland. This is the situation which is assigned to them both by Bede and other ancient English writers. 'From the Angles,' says Bede, 'that is to say, from the country called Anglia, and which from that time till now is said to have remained waste, between the provinces

of the Jutes and the old Saxons, descended the East Angles, the Mercians, the race of the Northumbrians, and all the rest of the nations of England.' Alfred, in his 'Orosius,' also places the Angles in the Danish countries on the Baltic. And Ettheiwerd, a writer of the eleventh century, describes Old Anglia as situated between the Saxons and the Jutes, and as having the city of Schleswig for its capital. This account is adopted by Camden: 'Seeing,' he observes, 'that between Jutland and Holsatia or Holstein (the antient seat of the Saxons) there is a small province in the kingdom of Denmark, and under the city of Flensburg, called at this day Angel, which Lindebergius in his Epistles terms Little England, I am pretty well assured that I have found the antient seat of our forefathers, and that from this very place the Angles came into our island.' (*Brit. Introd.*) This district of Angel, or Angeln, is thus described by Dr. Edward Clarke in his 'Travels,' part iii. 4to., Lon. 1819:—'It is called Angeln,' he says, 'but this word is pronounced exactly as we pronounce England, or Engelande. (This is not very intelligible). 'We were surprised at the number of English faces we met; and resemblance is not confined to features. Many articles of dress, and many customs, are common to the two countries. The method of cultivating and dividing the land is the same in both; the meadows bounded by quickset hedges, or by fences made of intertwisted boughs, reminded us of Kent, Surrey, and Sussex. The natural appearance of the country is also like the south of England, being diversified by numerous hills and valleys, adorned with flourishing woods and fertile fields.' Angeln, however, is not, as Dr. Clarke calls it, 'the part of the duchy of Sleswick which a traveller must pass in his route from Flensburg to Apenrade.' It lies all to the south of Flensburg. [ANGELN.] The Angles obtained possession of the whole of what is now called England, with the exception of the parts already mentioned as occupied by the Jutes and Saxons; in other words, of all England to the north of the Bristol Avon and the Thames, except the present counties of Essex, Middlesex, and part of Hertford. They also extended their settlements over a great part of the south of Scotland.

The following were the kingdoms founded by the several invading bands, the dates being those assigned in the valuable summaries of Anglo-Saxon history, given by Sir F. Palgrave in his Appendix of *Proofs and Illustrations* to his *Rise and Progress of the English Commonwealth*, p. cccxix—cccxi:—

1. Kent, consisting of the present county of that name, founded by Hengist and Horsa, whose followers were Jutes, A.D. 457. From Æsc or Eric, the son and successor of Hengist, the kings of Kent acquired the name of Æscingas. Kent subsisted as an independent state till its conquest by Cenwulf, king of Mercia, in 796. In 823 it was finally annexed to Wessex by Egbert; but for at least a century after that date it is still mentioned as a separate though subordinate kingdom.

2. Sussex, consisting of the present county of that name, founded by Ella, whose followers were Saxons, A.D. 491. In A.D. 686 it was conquered by Ceadwalla, king of Wessex, and appears to have remained ever after in subjection either to that state or to Mercia. In 828 it finally submitted to Egbert; and 'from this period,' says Sir F. Palgrave, 'Sussex and Surrey appear to have been considered as integral portions of the empire of Wessex, but as annexed to the kingdom of Kent and passing with it.'

3. Wessex, including (in its greatest extent) Surrey, Hants with the Isle of Wight, Berks, Wilts, Dorset, Somerset, Devon, and part of Cornwall, founded by Cerdic and his son Cynric, whose followers were Saxons, A.D. 519. The Jutes of the Isle of Wight were conquered by Cerdic and Cynric, A.D. 530; but in 661 the island was wrested from Wessex by Wulfere, king of Mercia; some time after which it appears to have asserted its independence, which it maintained under kings of its own till the beginning of the 10th century, when it submitted to Edward the Elder. In the reign of Egbert (A.D. 800—836) the kingdom of Wessex attained a supremacy over the other states, which it never lost afterwards. [EGBERT.]

4. Essex, including the present counties of Essex and Middlesex, and the southern part of Hertfordshire, supposed to have been founded by Æscwine, or Ercenwine, whose followers were Saxons, A.D. 527. 'It is doubtful,' says Sir F. Palgrave, 'whether this monarchy ever enjoyed independence.' It certainly became subject to Mercia in

the course of the seventh century, and in 823 it finally submitted to Egbert of Wessex.

5. Northumbria, consisting of the sometimes separate but commonly united states of Bernicia and Deira; the former (from the native name Bryneich) including the county of Northumberland, and the south-eastern counties of Scotland as far as the Forth, founded by Ida, whose followers were Angles, A.D. 547; the latter (from the native name Deifyr) including the counties of Cumberland, Durham, Westmoreland, York, and Lancaster, founded by Ella, whose followers were also Angles, A.D. 560. These two states appear to have coalesced before the beginning of the seventh century; and after the year 655 they were never separated, so long as they retained their independence. The limits of the kingdom of Northumbria to the north varied greatly from time to time according to the fortunes of the almost constant warfare which it carried on with the Scots, the Picts, and the kingdom of Strathclyde. From the middle of the eighth century the history of Northumbria consists of little else than a detail of civil dissensions, confusion, and bloodshed, arising from the claims of rival competitors for the throne. The Northumbrians made a formal submission to Egbert of Wessex in 829. In 867 the country was conquered by the Danes; and from this time it may be considered to have remained independent under princes of Danish race till 924, when both the Danes and the English inhabitants acknowledged the supremacy of Edward the Elder. Northumbria, however, continued to be governed by princes of its own, who, although nominally subject to the English monarch, took the title of kings, till 952. After this its rulers were only designated earls; the district forming sometimes one earldom, sometimes two, under the names of Bernicia and Deira, or Northumbria and York. It was not till some time after the Norman conquest that the territories which had formed this Saxon state came to be considered as strictly included within the realm of England.

6. East Anglia, including Norfolk, Suffolk, Cambridge, and part of Bedfordshire, founded by Uffa, whose followers were Angles, and from whom the kings of this state took the name of Uffingas, A.D. 571. The East Angles placed themselves under the sovereignty of Egbert of Wessex about the year 823, but they continued for some time after this under the immediate government of their own kings. The country was conquered by the Danes in 883; and it was not completely brought back under subjection to the English crown till after the accession of Athelstane in 925. From this time it appears to have been governed by ealdermen or dukes.

7. Mercia, including the counties of Chester, Derby, Nottingham, Lincoln, Shropshire, Stafford, Leicester, Rutland, Northampton, Huntingdon, Hereford, Worcester, Warwick, Gloucester, Oxford, Buckingham, and parts of Hertford and Bedford, said to have been founded by Crida, whose followers were Angles, A.D. 585. The name Mercia has been derived, by Camden and others, from the word *mearc*, a limit; 'for the other kingdoms,' it is said, 'bordered upon it.' Lingard thinks that 'the people were called Mercians,' perhaps from the marshy district in which they first settled. The most probable explanation, however, appears to be that given by Macpherson, in his 'Annals of Commerce,' who observes that the Saxon name *Myrcna-ric* properly signifies the woodland kingdom, 'which,' he adds, 'agrees very closely with *Coitani*, the Latinized name of the old British inhabitants, signifying woodland-men, or foresters.' About the middle of the seventh century Mercia was conquered by Oswio, king of Northumbria; but after a few years it recovered its independence; and before the end of the next century it had reduced to subjection both the neighbouring states of East Anglia and Kent. It was eventually subjugated however about the year 825, by Egbert of Wessex, and although for some time considered as a separate kingdom, it continued ever after dependent upon that state, with the exception of a short period in the latter part of that century, during which it was overrun and taken possession of by the Danes.

This assemblage of states has been commonly called the Heptarchy, for which Mr. Turner has proposed to substitute the Octarchy, on the ground that Deira and Bernicia ought to be considered as two distinct kingdoms. But in truth it may be doubted if there ever was a time when so many as seven of the states co-existed separately and independently. Various small districts also appear to have for longer or

shorter periods preserved an all but nominal independence in the midst of the larger states, to some one or other of which they were severally considered as annexed. Such were the Isle of Wight; the Suthrige, or Southern Kingdom, now Surrey; the district of Hwiccas, or Magesettam, which was contemporaneous with the ancient bishopric of Worcester; and others, of which the annals have been for the first time collected by Sir Francis Palgrave. But above all it would be difficult to show that either term is perfectly admissible, if it be intended to imply (as in strict propriety both heptarchy and octarchy would seem to do) that the several states were all connected together into any sort of union or confederacy; that they formed, in fact, any political system entitled to be designated by one word at all. We know that they were constantly at war with one another, and of the existence of any general controlling authority, except such as one king was occasionally enabled to maintain over the rest by his sword, their history affords no trace. To certain of the kings however by whom this temporary supremacy appears to have been asserted in the most marked manner, Bede, and after him, the Saxon Chronicle, have attributed the title of Bretwalda, that is, as it has been interpreted, Wielder or Emperor of Britain; and it is probable that a species of superior honour and dignity, such as this title would imply, may have been claimed by the princes in question, and accorded to them by those of their neighbours whom they had brought under subjection, or who, although unsubdued, preferred not to provoke their enmity. The following is the succession of the Bretwaldas as given by Bede:—1. Ella, or Aelli, who was king of Sussex from 491 to 518; 2. Coelin, or Ceawlin, who reigned in Wessex from 560 to 591, and is supposed to have held the place of Bretwalda from 568 to 589; 3. Ethilbert, or Aedilbert, who was king of Kent before 568, and is supposed to have been acknowledged as Bretwalda from 589 till his death in 616; 4. Redwald, king of East Anglia, from 616 to 624; 5. Edwin, of Northumbria, from 624 to 633; 6. Oswald, of Northumbria, from 635 to 642; 7. Oswio, of Northumbria, from 642 to 670. Egbert of Wessex is reckoned the eighth Bretwalda, and is considered to have attained the dignity in the year 827. This account, it will be observed, makes the country to have been without any general sovereign for about one half of the whole period that elapsed between the death of Ella and the accession of Egbert. The enumeration also omits some kings, such as Ina of Wessex, and Offa of Mercia, who were certainly possessed of as much power as any of those, excepting Egbert, upon whom the title of Bretwalda is bestowed.

Upon the whole, the title of Bretwalda cannot well be regarded as any thing more than an ostentatious and empty assumption of some of the Saxon kings, or an epithet of distinction bestowed upon them by the flattery of the chroniclers. It certainly carried with it no real or legal authority. In the same manner we may dismiss the vaunting claims put forward by or for the Saxon Bretwaldas to the sovereignty of the Scots, the Picts, the Irish, and all the nations of other lineage inhabiting the British islands, founded as they are on little else than the interpretation put upon this title.

Lists of the kings of the several states of the heptarchy do not exist in a complete form. The most perfect that have been compiled are those published by Sir Francis Palgrave, which are stated to have been examined and verified by Mr. Allen. The more remarkable names are noticed in this Cyclopædia in separate articles.

Egbert of Wessex, although not strictly entitled to be called the first king of all England, certainly laid the foundation of what afterwards became the English monarchy. The royal house of Wessex never lost the ascendancy which he acquired for it so long as the Anglo-Saxons remained masters of England. It will be convenient therefore to begin from him the chronological table of the kings of the country, which is all that we shall now add, an account of the events of each reign from this period being given in separate articles.

Kings of Wessex, with which Kent, Essex, and Sussex were sometimes incorporated, sometimes connected as vassal states, and to which also East Anglia, Mercia, and Northumbria acknowledged a more qualified subordination:—A.D. 800. Egbert, acknowledged as Bretwalda from A.D. 827.

836. Ethelwulf;—with Athelstane till 852, and then Ethelbert, in Kent, Essex, and Sussex.

A.D. 855. **Ethelbald**;—with **Ethelwulf** (the preceding king) as supreme till 856, and **Ethelbert** as subordinate, in Kent, Essex, and Sussex.

860. **Ethelbert**.

866. **Ethered**, or **Ethelred I.**

871. **Alfred the Great**.

901. **Edward the Elder**.

Kings of all England, of the House of Wessex:—

925. **Athelstane**. 958. **Edgar**.

941. **Edmund I.** 975. **Edward the Martyr**.

946. **Edred**. 978. **Ethelred the Unready**

955. **Edwy**. 1016. **Edmund Ironside**.

Danish Kings of England:—

1017. **Canute the Great**.

1035. **Hardacnute**, or **Hardicanute**, with **Harold Harefoot** in **Mercia** and **Northumbria**

1037. **Harold Harefoot**.

1040. **Hardacnute restored**.

House of Wessex restored:—

1042. **Edward the Confessor**.

Line of the Earls of Kent, &c.:—

1366. **Harold II.**

Norman Line:—

1066. **William the Conqueror**. 1100. **Henry I.**

1037. **William Rufus**. 1135. **Stephen**.

Line of Plantagenet:—

1154. **Henry II.** 1272. **Edward I.**

1189. **Richard I.** 1307. **Edward II.**

1199. **John**. 1327. **Edward III.**

1216. **Henry III.** 1377. **Richard II.**

House of Lancaster:—

1399. **Henry IV.** 1422. **Henry VI.**

1413. **Henry V.**

House of York:—

1461. **Edward IV.** 1483. **Richard III.**

1483. **Edward V.**

House of Tudor:—

1485. **Henry VII.** 1553. **Jane Grey**.

1509. **Henry VIII.** 1553. **Mary**.

1547. **Edward VI.** 1558. **Elizabeth**.

House of Stewart:—

1603. **James I.** 1625. **Charles I.**

Commonwealth, from the execution of Charles I. in 1649:—

1653. **Oliver Cromwell, Protector**.

1660. **Richard Cromwell, do.**

House of Stewart restored:—

1660. **Charles II.** 1685. **James II.**

House of Orange:—

1689. **William III., with Mary II. till 1695.**

House of Stewart restored:—

1702. **Anne**.

House of Hanover:—

1714. **George I.** 1820. **George IV.**

1727. **George II.** 1830. **William IV.**

1760. **George III.** 1837. **Victoria**.

ENGLAND. The general description of this part of the island is under the head of **GREAT BRITAIN**; and that of Roman Britain under the head of **BRITANNIA**.

ENGLAND, NEW, is a name which, in the seventeenth and eighteenth centuries, was applied to the English settlements on the eastern coast of North America, north of 41° N. lat. But as, in the progress of colonization, the British population increased, the country was divided into several provinces, which, at the time when these countries acquired their independence, were formed into so many states. The provinces formerly comprehended under the name of New England were the present states of New Hampshire, Massachusetts, Rhode Island, and Connecticut; but the states of Maine and Vermont, which, before the revolution, did not form provinces, were also considered as portions of New England, though some later writers think that the state of Vermont never belonged to it. At present the term New England is rarely used.

ENGLISH ARCHITECTURE. [**GOthic ARCHITECTURE.**]

ENGLISH CHANNEL, called by the French *La Manche*, is that narrow sea which separates the southern shores of England from the northern shores of France. On the west it opens into the Atlantic Ocean by a wide mouth, between the Land's End and the French island of Ushant (Ouessant), where it is about 100 English miles across. On the east it is united to the North Sea by the Straits of Dover (Pas de Calais of the French.) This strait, which must be considered as a part of the channel, is formed on the English side by the shore between the South Foreland and Folkstone, and on the French side by that between the harbour of Calais and Cape Grisnez, and at its narrowest point between Folkstone and Cape Grisnez is only about 20 English miles across, and at other points very little more. West of the strait of Dover, the channel rapidly increases in width; between Brighton and Havre is more than 90 English miles across. Farther west however it is narrowed by the peninsula of Cotentin, which projects from the French coast into the channel, and terminates in Cape de la Hogue, its most north-western point. Between St. Catherine's Point on the Isle of Wight and Cape Bardeur, the eastern termination of the peninsula of Cotentin, the shores of both countries are hardly 70 miles from one another. West of the peninsula is the widest part of the channel, which between St. Alban's Head in Dorsetshire and the harbour of St. Malo is nearly 140 English miles across. The remainder of the channel to its junction with the Atlantic is between 100 and 110 miles wide.

Though there is no perceptible current in any part of the channel, it can hardly be questioned that a current generally, if not constantly, is running up it from the west. This is evident from the eastern tides being stronger than the western or ebb tides, and their running longer in stormy weather from the west. It is also observed, that at the same time the surface of the channel is raised two feet or more above that of the North Sea, and consequently discharges a great quantity of water into that sea. The ports of the channel are some feet deeper in strong westerly winds than at ordinary times. It is worthy of remark, that the French ports along the channel are shallow, and that none of them are deep enough to admit men-of-war, while England has some of its finest harbours on the coast-line of the channel. As this circumstance secures to England a great advantage over France in time of war, the French government at different times have been at great expense in attempting to deepen the harbour of Cherbourg, but hitherto they have not succeeded, the works being in a short period again filled up with sand. It is not improbable that this is owing to the current, as the coast of France does not lie parallel to it, like the shores of England, but meets it in an oblique line. The channel is well stocked with fish, which gives constant occupation to a considerable number of fishermen on the coasts of England and France; the most important branch is the fishery of pilchards along the coast of Cornwall and Devonshire.

ENGLISH DRAMA. Under the head **DRAMA** the reader will find the history of the Greek and Roman, or what is commonly called the Antient Drama. Under the present title we have placed the History of the Modern Drama in Europe, distributed under the following heads:

1. Italian. 2. Spanish. 3. French. 4. German. 5. English.

ITALIAN DRAMA.

After the long sleep of the true dramatic and theatrical spirit in the middle ages, which began to dawn again in mysteries and moralities independent of classical models, the first endeavour to imitate the antients in their theatre, as in other departments of art and poetry, was made by the Italians. Nevertheless, apart from the religious plays, we find in the earliest dramatic attempts of modern Italy upon secular subjects a thorough independence of the classical rules. Among these first essays we find the *'Philodoxeos, o l'Amico della Gloria'* of Leon Battista Alberti; and others might be cited which, written first in Latin and afterwards in Italian, combined in like manner all the elements of tragedy, comedy, and pastoral. For although, for instance, *'L'Orfeo'* of Politian, performed at Mantua, and *'Il Cefalo, o L'Aurora'* of Niccolò da Correggio at Ferrara, were given under the name of pastorals, while, on the other hand, a certain Antonio da Pistoja gave that of tragedies to two dramas of his entitled *'Il Filostrato e Panfilo'* and *'Il Demetrio'*, yet these designations were determined merely by the predominance of particular

elements in the respective pieces, and not at all by adherence to or regard for the strictly classical system of keeping those elements as much as possible apart. In this respect, whatever their rudeness, these pieces were the native growth of their age and country, appearing among the numberless proofs that the marked separation between tragedy and comedy which existed in the ancient theatre had no foundation in the essence of human nature and human life, but resulted from the peculiar social and religious circumstances of the people amongst whom it arose, together with the distinction and opposition in spirit and qualifications which existed among their most powerful dramatic writers.

The first specimen of the Grecian or Greco-Roman comedy that was presented to the Italians in their own language was a translation, by Collenuccio, of the 'Amphitryo' of Plautus; and soon after, Bojardo brought upon the stage 'Il Timone Misanthropo.' This was about the commencement of the sixteenth century; and in 1529 was performed at Bologna, in the presence of the Emperor Charles V. and Pope Pius VII., 'The Three Tyrants' (I Tre Tiranni) of Agostino Ricchi, a piece which, though in itself original and ingenious, is now chiefly worthy of notice as marking the commencement of the long war between the *classic* and the *romantic* species. This author not only disregards the Aristotelic *unities* in the construction of his piece, but states his reasons for doing so, urging that, as the laws, customs, and manners of his own time were so different from those of antiquity, it was necessary for the moderns to pursue a different plan in the dramatic art; and to give the announcement of this principle the greater authority, he makes Mercury himself deliver it in the prologue. Sound and reasonable, however, as this doctrine is, it could not at first prevail against the countenance which the opposite system derived from the ablest writers of the period, inveterately prepossessed as they were by their sedulous study of the antique *forms* as well as spirit. Already the first example of a *regular* modern tragedy had been given in the 'Sophonisba' of Trissino, a piece not otherwise remarkable; and now Ariosto, Bibbiena, and Macchiavelli appeared as the first distinguished cultivators of the classic comedy. Of these, Ariosto was the closest imitator of the antients; while yet very young he wrote in prose, as a kind of exercise, 'La Casaria' and 'I Suppositi,' and, pleased with these first essays, he next wrote 'La Lena,' 'Il Negromante,' and 'La Scolastica,' in 'versi sdruccioli,' a kind of verse in which he satisfied himself so well that he re-wrote in it his two former pieces. These productions are full of that spirit at once keen and polished for which their author was so distinguished; and though under the necessity of respecting the prejudices of the petty court of Ferrara, to which he was attached, yet he spares neither the lawyers and magistrates of the country, nor those other characters, much more powerful in those days, the astrologers, the courtiers, and the ecclesiastics; he was the first who ventured to exhibit on the stage a Dominican friar in the character of an inquisitor, which he did in 'La Scolastica' abovementioned. Bernardo Divizio da Bibbiena, confidential secretary to Pope Leo X., and afterwards cardinal, showed a more decided originality in 'La Calandria,' though it was partly modelled after the 'Menæchmi' of Plautus. This piece, indeed, may be considered as the most faithful mirror of the court of Rome at that remarkable period: amidst the extreme liberty of manners which prevailed in that court, for whose entertainment 'La Calandria' seems chiefly to have been written, we find frequent indications of a certain philosophic spirit which it would be vain to seek there in later times. Bibbiena seems to have aimed at nothing beyond amusement; but Macchiavelli, whose historical and political writings exhibit so forcibly the characteristic Florentine acuteness, betrays, in his 'Mandragola,' a deeper intention. In the person of Fra Timoteo, in this piece, who most conscientiously panders to the vicious appetites of an individual to promote the interests of his convent, the author has given a most humorous and piquant exhibition of the *fratrimo*, or monkish domination, which degraded the society of his time: it was nevertheless acted with applause before the indulgent eyes of Leo X. and his cardinals.

The comedies of these three distinguished writers all appearing near the commencement of the sixteenth century, while no other nation had anything of equal merit to oppose to them, made such an impression that all the best writers zealously strove to follow their dramatic system. Although, in the political

becoming predominant, the Spanish plays, composed on the opposite system, had not yet exhibited that strength and fire of genius which afterwards gave the Spanish theatre so powerful an influence upon the dramatic literature of Europe; so that the Italians still adhered closely to the antique models. In this kind of secondhand imitation of the antients, the Florentines most distinguished themselves by a certain subtle grace of dialogue derived from the richness of their idiom and their proverbial expressions. Among the comic writers of Florence, Aretino is certainly not to be cited for elegance and correctness, but he surpassed all the others in licentiousness and causticity. These qualities he displays yet more strikingly in his comedies than in his prose writings; and in that respect approaches perhaps, of all the moderns, the nearest to Aristophanes, attacking all ranks and all institutions. The school of Aretino had many disciples; countenanced by the example of the court of Leo, it established itself more especially in Venice, where liberty was rapidly being corrupted into licentiousness. Lodovico Dolce, indeed, the most distinguished follower of Aretino, strove to justify this unbounded license on the ground, certainly not altogether fallacious, that there was no other possible way of delineating the manners of the time. Some, however, there were, who, scandalized at the excessive liberty of the comic poets, strove to reclaim them by example to a more moderate and decent course; but these efforts, wanting comic power, only served to raise a belief that the true comic spirit was inconsistent with any moral restraint, and so confirmed the evil instead of removing it.

Among the successful comic poets of this period, the most distinguished was Giambattista de la Porta, who flourished at the close of the sixteenth century and the beginning of the seventeenth. He was a Neapolitan gentleman with a truly encyclopædic genius, who from the deepest scientific studies could pass to the lightest amusements of literature. After forming among his countrymen the first academy of experimental philosophy, he pleased himself with instructing a company of amateur performers in the comic art, and producing a number of comedies for exhibition at his own house. Though he drew both the subjects and the form from the same source as his predecessors, yet he displayed so much happy invention in the contrivance and conduct of his pieces as to give them an air of considerable originality. Though most of his comedies were of the familiar species, and some of them even bordered on farce, yet a few rose to the noble and pathetic tone: of the latter kind are 'La Furiosa,' 'La Cintia,' 'Le Due Fratelli Rivali,' 'La Sorella,' and 'Il Moro.'

But the Italian public were satiated by such an accumulation of these regular productions. The Spanish theatre was now approaching the meridian of its glory; and the political influence of Spain on the Italian territory, being now at its height, greatly favoured the introduction of the Spanish taste in dramatic composition. These circumstances gave birth to such pieces as 'La Donna Costante,' and 'L'Amante Furioso' of Raffaele Borghini, 'L'Eroflomachia,' 'La Prigione d'Amore,' and 'I Morti Vivi' of Sforza d'Oddi, the very titles of which indicate the school to which they belong; and in which the imaginations of the zealous followers of the classic school were horrified by such incidents as that of a young lady suffering herself to be buried alive as her only means of avoiding a hateful marriage, and that of an unfortunate lover letting himself be carried like a thief to the gallows, having no other way to preserve his mistress's honour. It does, indeed, appear that the first endeavours at this period to introduce the Spanish taste went directly over from the one extreme to the other, proceeding, not so much according to higher and freer views of dramatic art itself than had hitherto prevailed on the Italian stage, as on the erroneous principle which has been too often acted on in similar cases, that what was farthest from the old system in every respect must be the best. It was probably the first extravagances of this dramatic innovation that induced Tasso, in his latter days, to compose, as a burlesque of the new romantic taste, a play entitled 'Love Intrigues' (GI' Intrichi d'Amore), which was acted in 1598 and printed in 1604. The matter of this piece well corresponds with its title; for so prodigious a number of wonderful intrigues are accumulated in it that it is not so much a comedy as a whole bundle of comedies all rolled up into five acts. Some years after, a yet more open attack was made upon the romanticists by Scipione Erriico of Messina;

in a comedy which he entitled 'The Revolt of Parnassus,' (*Le Rivolte di Parnaso*), wherein, with little comic force, he not only introduces Trissino, Ariosto, and Tasso as rival suitors of Marini to the muse Calliope, but also, to little purpose, arrays Trajano Boccalini, Cesare Caporali, Petrarch, Boccaccio, Dante, and Homer himself, in his classic phalanx.

We find a curious evidence of the transitional state of the public taste at this time in the productions of a poet of high name who thought fit to try his powers in each of the rival species. This was Michel Angelo Buonarroti the younger, nephew of the great Michel Angelo, who composed two comedies of totally different characters, entitled 'La Tancia' and 'La Fiera.' In the former he adhered closely to the classic rules. It is one of the class of pieces much in vogue at that time, and denominated *rustiche*, wherein the characters were made to speak in the dialect peculiar to that part of Italy to which they belonged; and sometimes in the same piece persons were introduced from different provinces, talking a diversity of dialects, as the Venetian, the Paduan, the Bergamask, the Milanese, &c. The most distinguished productions in this species were, this 'La Tancia' of Buonarroti, and the 'Rosa' of Cesare Cortese, a Neapolitan; the latter displaying the characteristic diction of the Neapolitan people, as the former did that of the Florentines. The other production of Buonarroti, 'The Fair' (*La Fiera*), is a remarkable work, the very conception of which implies a total departure from the classical restrictions. The author, passionately fond of his native language, was desirous of exhibiting a full development of its resources as applicable to all ranks and professions. He therefore chose for his subject a fair, wherein most of the conditions, transactions, and occurrences of human life could be conveniently exhibited. Here, each class of society appears in succession, and the author has ample opportunity to display the riches of his mother tongue in assigning to each one its peculiar diction. To execute such a design, it was necessary not only to multiply incident, action, and character, but also to vary the scene, and extend the time beyond the narrow space of a single day. No unity, in short, was here admissible, beyond that of the one magistrate who superintends all the transactions of the fair. The whole composition forms a connected series of five plays, of five acts each, which were actually performed at Florence on five successive nights. Indeed the scale was now decidedly turned against the predominance of the classic system; and another circumstance contributed at this time to prevent the return of that predominance for a very considerable period.

This was the invention, by Ottavio Rinuccini, of the *melodrama*, which more commonly took the name of *opera per musica*, and which we now briefly term the opera. The magic power of this union of music with the romantic drama completed the triumph of the latter among the Italians of the seventeenth century; for not only was this musical melo-drama thenceforward their prime theatrical favourite, but the ordinary drama itself was no longer tolerated except under the romantic garb. To the despair of the few who still adhered to the classic school, the very names of *tragedy* and *comedy* were for a while laid aside; and the public would hear of nothing but those *azioni*, which went by the various names of *reali*, *reali-comiche*, *tragi-comiche*, *tragi-satiro-comiche*, &c., and seem to have been all translations or imitations of Spanish pieces.

At the same time the public continued their favour to a species of comedy, or rather comic recitation, which in Italy seems to have been in all times peculiarly national. This was called the *commedia a soggetto* or *commedia dell'arte*. It consisted of the mere outline of a dramatic composition, wherein the parts very slightly sketched were assigned to the several performers, who were to fill them up extemporarily. These sketches were called *scenarij*, from their containing merely the argument of each scene: those of the comedian Flaminio Scala were particularly celebrated. Some of these *improvisatori*, especially those who appeared in the standing masks of Arlecchino, Pantalone, Puncinella, &c., displayed a liveliness of humour which, in spite of the great mass of empty buffoonery by which they were accompanied, made this kind of performance long continue to be well received by the Italians, until the more general cultivation given to the higher dramatic departments, and the general advance of social refinement, caused the improvisatory masks to be finally abandoned to the populace.

At the commencement of the eighteenth century, no P. C. No 582.

great original genius had yet arisen in Italy, as in Spain and England, to establish the romantic drama on an unshaken foundation. The political preponderance of Spain, too, had now given place to that of France; and hence it is not surprising that the French taste now began to invade the Italian theatre as it subdued the Spanish. Girolamo Gigli, of Sienna, an ingenious critic and an elegant writer, gave, in his 'Litiganti,' a free translation of the 'Plaideurs' of Racine; recast Molière's 'Tartuffe' in his 'Don Pilone'; and endeavoured to bring upon the stage 'La Sorella di Don Pilone,' wherein, it is believed, were exhibited the caprices of the author's wife and the bigotry of her Jesuit confessor. This period is also remarkable for the production of a number of comedies expressly devoted to the service of the literary warfare of the time, in the mutual satire by the literati of each other's peculiar systems and opinions: these pieces, as may well be supposed, were much more academical and erudite than theatrical and entertaining.

In the *reform* or *purification* of the Italian stage, as the endeavours now making to follow the *classic* steps of the French were denominated, Maffei led the way in the tragic department. The first classical tragedy that had appeared in modern Italy, or indeed in modern Europe, the 'Sophonisba' of Trissino, already mentioned, was a dull work of diligence without any poetic spirit; wherein, however, it is singular that while all the antique forms, including the chorus, are scrupulously retained, the author has abandoned the field of mythology for that of Roman history. The pastoral dramas of Tasso and Guarini, which appeared about the middle of the sixteenth century, and in which the subject, though for the most part not tragical, is elevated and even ideal, though more important in the history of poetry than of the stage, were certainly intended for the theatre. Their choruses indeed float like lyrical voices in the air, and do not appear in person; but the pieces were exhibited with great splendour at Ferrara and Turin. With all their noble and exquisite poetic grace and beauty, they at the same time show us the infant state of the *dramatic* art in the languid progress of the action. After 'Sophonisba' and a few other pieces of the same period, which Calsabigi, an Italian critic wholly devoted to the French system, calls the first tragic lispings of Italy, a number of similar works of the sixteenth and seventeenth centuries might be cited, but not one of them has preserved any considerable reputation. Though all these writers laboured, as they thought, according to the rules of Aristotle, we have the following description of their tragical abortions from Calsabigi himself:—'Distorted, complicated, improbable plots, misconception of scenic regulations, useless personages, double actions, inconsistency of character, gigantic or childish thoughts, feeble verses, affected phrases, total absence of harmonious and natural poetry; all this decked out with ill-timed descriptions and similes, or idle political and philosophical disquisitions; in every scene some silly amour, with all the trite insipidity of commonplace gallantry; but of tragic strength, of the conflict of passions, of overpowering dramatic catastrophes, not the smallest trace.' Maffei, however, to whom we must now return, printed a selection of the best of these tragic attempts, and produced a tragedy of his own, entitled 'Merope,' which had great success in Italy on its first publication, and obtained a high reputation in other countries from its competition with Voltaire's tragedy on the same subject. Both writers attempted to restore in some sense a lost piece of Euripides, highly estimated by the ancients from the account given of its contents by Hyginus. Maffei's work, however, is rather the production of a learned antiquary than of a mind naturally adapted for and practised in the dramatic art; it is not therefore unfair to attribute its great reputation in Italy to the previous low state of Italian tragedy.

The task of classicizing the musical drama was undertaken first by Apostolo Zeno, and afterwards, with more success, by the Abate Metastasio. The marks of the French taste in Metastasio, as pointed out by Schlegel, are, the total absence of the romantic spirit, a certain faultless insipidity of composition, his manner of handling mythological and historical materials, which is not properly either historical or mythological, and the endeavour to produce a certain tragic purity which degenerates into monotony. The unity of place, however, it was impossible for him to observe, as a change of scene was required of the opera poet: in his rich intrigues too he followed Spanish models.

and borrowed especially a great deal from Calderon. 'The merits,' says the German critic, 'which have gained him the reputation of a classic among the Italians of the present day, and have made him in some degree for them what Racine is for the French, are, the most perfect purity, clearness, elegance, and sweetness of language in general, and in particular the softest melody and the greatest loveliness in the songs. Perhaps no poet ever possessed in a greater degree the talent of comprehending in a few lines the essential features of a pathetic situation: the songs with which the characters make their exit are almost always the purest musical extract of their state of mind that can possibly be given.' On the other hand, he has lines which, for dignity and vigorous conciseness, are perfectly suited to tragedy; yet on the whole, it is evident that a certain melting effeminacy in feeling and expression rendered Metastasio the delight of his countrymen and of courtly society throughout Europe. Only a few of his operas have still possession of the stage, as the change of taste in music demands a different arrangement of the text. Metastasio seldom has choruses, and nearly all his airs are for a single voice. 'We now,' says Schlegel, 'require more frequent duos and trios, and a crashing finale. In fact, the most difficult problem for the opera poet is, the mixing the complicated voices of conflicting passions in one common harmony without injuring their essence; a problem, however, which is generally solved by both poet and musical composer in a very arbitrary manner.'

The first endeavour to restore what the classicists denominated the *true comedy* was made by Luigi Riccoboni, a theatrical manager, who attempted, on the Venetian stage, to revive the 'Scolastica' of Ariosto. The result was remarkably curious: the audience, idolizing in Ariosto the painter of the romantic loves of Orlando and Angelica, and eagerly expecting to see something of a kindred spirit in this long neglected dramatic production from such a pen, showed such indignation at the disappointment they received from this *regular comedy*, that Riccoboni hastily quitted Venice, and repaired to Paris, where, of all places in Europe, classicism was in greatest honour and glory. Venice, however, was destined shortly after to be the scene of a successful struggle on the part of the same comic school to re-establish itself in the public estimation. A native of that city, Carlo Goldoni, nursed, both as a comedian and a poet, in the study of Macchiavelli and Molière, and, it should seem, admirably qualified by nature for developing all the resources that can enter into that comparatively narrow dramatic circumscription, sedulously applied himself, in a series of original compositions, to the task in which Riccoboni had made so unlucky an experiment. He displayed such abundant nature and fertility in painting the manners and the follies of his own age and country, that at length he brought the comedy of *character* into vogue, to the discredit both of the improvisatory farce and the melodrama. His first successes, however, received a severe check. The injury sustained by the masked and improvisatory comedy, for which the company of Sacchi in Venice had the highest talents, was one of the causes that led to the production, at this period, of the fantastic dramas of Gozzi. These are fairy tales in a dramatic form, in which, however, along with the wonderful, versified, and serious part, this author introduced the whole of the masks, and allowed them the most unrestrained development. When his imagination was in some degree wearied with oriental tales, he applied himself to the re-modelling of Spanish plays, especially those of Calderon; and although the ethereal poetry of the Spaniard lost much of its delicacy under this kind of handling, yet the extravagant caricature of the Italian masks formed an admirable contrast to the wild wonders of the fairy tale. This bold and original flight in the romantic region so fascinated the Venetians, that Goldoni was fairly driven from the field, and retired to Paris, as Riccoboni had done before him. There, by his production of 'Le Bourru Bienfaisant,' &c., he had the satisfaction of exhibiting himself to the French as the ablest follower that had yet appeared in the track of Molière, and of being honoured and applauded accordingly.

It is a remarkable instance, too, of the sway which French criticism at that day exercised over the European continent, that Goldoni's Parisian success mainly contributed to his speedy reinstatement in Italian favour, and to the proscription of the wildly romantic pieces of Gozzi. From the pen of Goldoni we have about a hundred and fifty pieces, of

which no enumeration can here be attempted. Among the comic dramatists of his own country he still occupies the highest place; and though some very respectable writers in the same department have succeeded him, they have done little either to extend or to enrich the dramatic field. We shall therefore, in enumerating the principal of these, dismiss them with all possible brevity.

Francesco Albergati Capacelli, a Bolognese gentleman of a distinguished family, and on that account more familiar than Goldoni with the tone of good society, displays in his comedies a purer style, more dignified manners, and occasionally more elevation in his characters, but wants the nature and vivacity of his predecessor. Camillo Federici, a Piedmontese, who had originally entered the order of Jesuits, afterwards became a comedian and a prolific writer of comedies: taking his characters chiefly from history, romance, or allegory, he inclined much to the romantic school; but, though he was very popular in his time, and though his countrymen the Piedmontese strove to rank him as high in comedy as Alfieri in tragedy, yet he did not exhibit powers at all capable of permanently establishing the romantic drama in public favour. Gherardo de Rossi, of Rome, was a tamely correct follower of Goldoni; and the Conte Giraud, also a Roman, full of natural wit and liveliness, is the most spirited successor of the latter that has yet appeared, and has succeeded accordingly. We find Vittorio Alfieri himself devoting, in his latter years, his austere pen to comedy. He translated some pieces from the ancients; and in his original comedies he appears to have made Aristophanes his principal model, mixing up the historical and the actual with the fictitious and the allegorical. Four of these bearing the quaint but significant titles of 'The One' ('L'Uno'); 'The Few' ('I Pochi'); 'The Too Many' ('I Troppi'); and 'The Antidote' ('L'Antidoto'), are thoroughly political, being designed to exhibit, under the veil of antique names and manners, the several effects of despotism, of oligarchy, of simple democracy, and of rational liberty. The small pieces of the Neapolitan Giulio Genoino, written for the exercise and instruction of youth, are worthy of mention as being among the best in that peculiar and rather difficult line of theatrical composition. These comedies, ten in number, first appeared not many years ago, under the title of 'Dramatic Ethics' ('Etica Drammatica'), five of them being designed for boys, and five for girls. In none of them is there the slightest trace of the passion of love, or any injudicious exhibition of high-flown heroism. The quiet sentiments and duties they are designed to inculcate are sufficiently indicated in their titles—'Religion'; 'Love of our Neighbour'; 'Gratitude'; 'Modesty'; 'Friendship'; 'Prudence'; 'Filial Piety'; 'Conscience'; 'Generosity'; 'Beneficence'; and the author has succeeded in giving to these juvenile plays a greater warmth of interest than might be expected from the very circumscribed nature of his plan. Alberto Nota, born of a good family at Turin in 1775, and bred to the law, but early addicted as a recreation to dramatic writing, is the most celebrated and productive among the living comic writers of the school of Goldoni: with stricter moral views than the latter, his most characteristic excellence with respect to art is the great correctness and purity of his Italian style, in which the best critics of his country have declared him to be unsurpassed.

In the latter period of the last century, Alfieri opened a new era of Italian tragedy. He adhered indeed to the established classic school, took his subjects chiefly from ancient story, and was a strict observer of the unities. But, indignant at the voluptuous degeneracy of his countrymen, his muse too uniformly appears with a stoical severity and simplicity which, how well soever they might be suited to the purposes of the moral and political reformer, are unfavourable to the primary objects of dramatic art; and hence the productions of Alfieri have ever been found to give more satisfaction in the closet than on the stage. As a dramatist, he has been the most successful in painting, as in his 'Virginia,' the public life of the Roman republic; and in his tragedy of 'Saul' we find, with a certain Oriental splendour, great lyrical sublimity of expression. Since Alfieri, that nobler and more masculine-spirited Italian tragedy, of which he is justly regarded as the founder, has been cultivated by several distinguished writers with a less rigid adherence to antique subjects and to classic forms. Among the most estimable of these recent productions we may particularize the 'Aristodemo,' the 'Cajo Gracco,' and the 'Galeotta Manfredi.'

of Vincenzo Monti; 'Il Conte di Carmagnola,' and 'L' Adelfi,' of Alessandro Manzoni, better known in England as an historical romance-writer, and the 'Antonio Foscari,' the 'Giovanni da Procida,' the 'Ludovico Il Moro,' and the 'Nabucco' of Giovan Battista Niccolini, who in this latter piece has ably exhibited, under fictitious names, Napoleon and some of his contemporaries, and of whose future efforts his countrymen have the highest expectations.

In the musical drama, though, for a long time past, the poetry has been cultivated as little more than a mere vocal accessory to the musical composition, there have been some very meritorious exceptions to this, as in the case of the recent productions, by the Conte Pepoli, 'I Puritani,' and 'Malek Adel,' which last is founded on Madame Cottin's well known romance of the time of the crusades, and was first performed at Paris in 1836.

SPANISH DRAMA.

In Spain, as elsewhere, it was the church that gave birth to the modern drama; but this remarkable circumstance is peculiar to Spain, that while in the other great nations of Europe the mature development of the drama detached it wholly from the service of religion, in the peninsula, on the contrary, the greatest dramatic geniuses constantly devoted a large portion of their efforts to religious compositions for ecclesiastical purposes; and the most perfect of all the Spanish theatrical poets made such compositions his favourite occupation. Owing to this very striking peculiarity of the Spanish stage, the source of which also will be indicated below, we defer some further notice of the spiritual plays of the Spaniards until we come to particularize the several species of their dramatic productions as exhibited in the most advanced period of their theatre.

The earliest performance that can strictly be called theatrical of which we find any mention in the Spanish annals, is that exhibited in 1414 at the coronation festival of Ferdinand and the Good, king of Arragon. It was from the pen of the marquis De Villena, a man who possessing intellectual acquirements prodigious for the time in which he lived, marched boldly, as a writer, in advance of his age and generation—so boldly, indeed, that all his writings were burned after his death, and this piece among them, so that its very title has perished. We only learn that it was an allegorical play, wherein figured the personages of Justice, Peace, Truth, and Clemency; so that it seems to have belonged to the class of *moralities* in vogue for a while in the infancy of the Spanish drama, and which Cervantes afterwards revived. Shortly after this attempt of Villena, his friend, the marquis de Santillana, a man of equally extensive knowledge, and of equal freedom both of thought and pen, dramatized, under the title of 'Comediate de Ponza,' the incidents of a naval action which took place in 1435, near the island of Ponza, between the Genoese and the Arragonese, and in which the latter were defeated. This piece was never acted, nor was it printed among the author's works; its title, quoted in his letters, was all that was known of it until Sr. Martinez de la Rosa (lately prime minister of Spain) recently discovered it among the manuscripts in the Royal Library at Paris. This interesting relic of the earliest efforts of the dramatic genius of Spain exhibits remarkable skill in the handling of an historical occurrence, as well as great beauty of plot, dialogue, and versification.

It was near the close of the fifteenth century that a sort of theatre was first established in Castile. The earliest dramatic attempt in this division of the peninsula was made by Juan de la Encina, who excelled in light poetry, and whose numerous works form a *cancionero* of themselves. After extending the field of religious representations by composing for exhibition on festival days a number of autos, wherein we find, not mere paraphrases of Scripture, but conceptions of the poet's own, together with a certain dignity of action and language, he formed the project of carrying the stage beyond the walls of the church. With this view he composed some small pastoral pieces, which he denominated eclogues. These pieces, in which he himself enacted the principal parts, were first exhibited at the houses of the Admiral of Castile and the Duchess del Infantado. As their name indicates, they consisted of nothing more than a dialogue between two or more shepherds. The author, imitating Virgil, used this expedient in the first instance to celebrate, by means of allusion, some particular event, such as the conclusion of a peace, or the return of a prince;

and next, he invented some short and simple action wherein he brought into play the passions of his interlocutors themselves. These little pieces, interrupted by dances and ending with songs (*villancicos*), usually contained also some farcical scene; so that they may be said to have comprised at once the elements of the comedy, the ballet, and the vaudeville. These premature efforts have in them much grace and wit, as well as nature and liveliness. The first performance of these pastoral comedies took place in the year 1492, so memorable in the Spanish annals as being that of the conquest of Granada and the discovery of the New World.

About the same time appeared the famous 'Celestina,' begun by Rodrigo Cota and finished by Fernando Rojas de Montalvan. Though entitled a 'tragi-comedy,' it was never performed, nor was it capable of being so, as it was in reality but a tale told in dialogue. Yet the singular merit of this truly primitive composition, which went through several editions, and was translated into almost every European language, contributed much to the advancement of the stage by furnishing a genuine model of dramatic diction.

It was in the beginning of the sixteenth century that to these various attempts succeeded the first regular Spanish dramas, but, through a singular concurrence of circumstances, they appeared out of Spain. One Bartolome de Torres-Naharro, long a captive in the hands of the Moors, and residing at Rome after his redemption, there composed some comedies in his native language, and got them performed at the tasteful and voluptuous court of Leo X. at the same time that, as we have already seen, the 'Mandragola' of Machiavelli and the productions of Aretino were being exhibited there. In the compositions of Torres-Naharro, though little known, and unjustly depreciated by Signorelli in his 'Historia Critica del Teatri,' there is much happiness of invention, well-drawn character, and spirited dialogue; they have also the licentious tone of the Italian comedies of that period, and contain some strokes of a malicious boldness peculiar to the author, who, though a priest, and living at the pontifical court, composed satires against the church such as Luther himself might have dictated. On printing his comedies at Naples in 1517, under the title of 'Propaladia,' he published along with them some 'Precepts on the Dramatic Art,' the first that made their appearance in the Castilian tongue. He there draws a very distinct line between tragedy and comedy; he divides the latter into historical comedy (*comedias a noticia*), and comedy of invention (*comedias a fantasia*). He too it was that invented the *introito*, or prologue, and gave to the acts the name which they have ever since borne, of *jornadas*, that is, journeys or stages, alluding to the pauses or resting-places for the actor and the spectator, which seem to constitute the chief utility of such division.

No sooner did Naharro's pieces find their way to Spain (about 1520) than they were proscribed by the Inquisition, so watchful to extirpate every trace of Protestantism. The like sentence fell upon those written shortly after in Germany by the author of the 'Satire on Women,' Cristoval de Castillejo, secretary to the emperors Maximilian and Ferdinand. These latter pieces, which it was not deemed prudent to publish among the author's works when the prohibition was taken off in 1573, but which are known to have been of the satirical and licentious class, are entirely lost. So that the Spanish stage presents the singular phenomenon of having really had two infancies. The first attempts in regular dramatic composition being suppressed by the formidable authority above-mentioned, found no imitators, and even seem to have been completely forgotten, for it was a play of Ariosto's that was exhibited at the marriage of an infanta in 1548. Some few classical scholars, indeed, as Villalobos, Fernan Perez de Oliva, and Simon de Abril, strove to bring forward the antients as dramatic models, by translating Plautus, Terence, and Aristophanes; but their works were still less adapted to take possession of the national mind. So that while, of those dramatic productions which Spain already possessed, one part lay hidden in the libraries of a few of the learned, and the other buried in the archives of the Inquisition, the people were abandoned to the gross merriment of the jugglers and buffoons. Hence it is that Schlegel, Bouterweck, Sismondi, and almost every other foreign critic, apparently ignorant even of the names of the first dramatic writers of Spain, make no mention of them, but fix the middle of the sixteenth

century as the period of the earliest origin of the Spanish drama.

The founder of the truly national and popular theatre of Spain was Lope de Rueda, of Seville, who quitted his trade of a goldbeater to join a company of strollers, of whom he shortly became the chief, or, according to the Spanish expression, the *autor*. This title, derived, not from the Latin *autor*, but from *auto*, an act or performance, was at that time given to one who composed and recited pieces, and is still retained to signify the manager of a company of comedians. He was also called *maestro de hacer comedias*. Lope de Rueda united the two kinds of talent necessary to an *autor* of that period; had prodigious success; was unanimously declared to be both a great poet and a great performer; and so entirely forgotten were the dramatic attempts which had preceded him, that he had the credit of being the inventor of the division into *jornadas* or acts, and of the prologue, called at first *introito*, and afterwards *loa*. For a number of years Lope perambulated from town to town; but his great reputation at length made him in request at court; and the grandees of the time crowded to the diversion which his exhibitions afforded them from the gloomy gravity of the palace of Philip II. The few of his plays, pastoral dialogues, &c., that remain, are distinguished for natural grace and liveliness; and though these are all in prose, he wrote with equal facility in verse. We find a curious fact, illustrative of the indulgence which the Spanish ecclesiastics of that day extended even to the profane drama, recorded by Diego de Colmenares, the contemporary historian of Segovia,—that on occasion of the grand festival held on the opening of the new cathedral there in 1558, Lope's company, on a stage erected within the church, exhibited, after 'solemn vespers,' a 'pleasant play' (*una gustosa comedia*). And Lope himself, on his death at Cordova in 1567, was interred there with great honour in the choir of the great cathedral church.

'In the time of this celebrated Spanish actor,' says Cervantes in the Preface to his own published plays, 'the whole wardrobe of an *autor* could be thrust into a bag: there were three or four close vests of white skin trimmed with gilt leather, and the like number of beards, wigs, and trunk hose. The plays were colloquies in the manner of eclogues, between two or three shepherds and some shepherdess, and were eked out with two or three interludes (*entremeses*), exhibiting sometimes the character of a negress, sometimes of a bravo, sometimes of a simpleton, sometimes of a Biscayan; for these characters and many others Lope represented with the greatest truth and perfection imaginable. At that time there were neither machinery, nor decorations, nor combats between Moor and Christian, on foot or on horseback: there were no figures made to issue through the boards of the stage as from the centre of the earth; still less were any angels or souls let down from heaven upon clouds. The stage consisted of four planks, laid in a square form across four benches, which raised them four hands from the ground. The whole decoration consisted of an old coverlet, which was drawn from one end to the other by two cords, to make what was called the *vestiario*, or dressing-room, and behind which were the musicians, who sang, without the guitar, some antient romance.'

At the same period (1561), the Spanish court, which had hitherto migrated from one provincial capital to another, fixed itself permanently at Madrid, a circumstance favourable to the dramatic art, as it established a permanent theatre. Authentic documents attest, that a year after the death of Lope de Rueda, there were play-houses (*corrales de comedias*) at Madrid. There were then, in the capital as well as in the provinces, various troops of actors, distinguished one from another by whimsical and ludicrous names, and sufficiently numerous to be classified by a Spanish writer of that day under eight different species. Shortly after, Juan de Malara, a celebrated professor of the *humanities*, caused a versified drama of his, entitled 'Locusta,' which he had written at first in Latin, to be acted at Salamanca. Then came an actor of Toledo, named Navarro, who, Cervantes tells us, converted the manager's clothes'-bag into the more important-looking form of trunks and portmanteaus; brought forth the music from behind the hanging; took the false beards from the chins of those whose parts did not require them; invented machinery, clouds, thunder and lightning, duels and battles. Moral development, too, accompanied this material progress: the pieces now began to display something like a plot, and some

of the animation which arises from conflicting interests and passions. The titles of a few of these may afford some notion of this transitional, or, more properly, adolescent period of the Spanish theatre: there were, for instance, 'Dido and Æneas, or the Pious Trojan,' 'The Grand Prior of Castile,' 'Loyalty against one's King,' 'The Sun at Midnight and the Stars at Noon,' 'The Taking of Seville by St. Ferdinand,' and 'The Cortes of Death'; the costume of which latter piece is so humorously described in a passage of the second part of Don Quixote.

About 1580 were established at Madrid the two theatres *de la Cruz* and *del Príncipe*, which are still existing; and now some superior minds turned their efforts to dramatic composition, which had hitherto been left entirely to the managers of strolling companies. Cervantes, just returned from his eventful Algerine captivity, was one of the earliest adventurers in this career. 'I was the first,' he tells us, 'that exhibited the imaginings and hidden thoughts of the soul, by bringing forward moral characters on the stage, which I did with warm and general applause from the public. I wrote at that period some twenty or thirty plays, which were all acted unsaluted by cucumbers or any other matters convenient for pelting with; they ran their course free from hissing, shouting, or clamour.' Cervantes, indeed, advanced the Spanish drama most importantly, both as to dramatic invention and moral dignity. His 'Numancia,' in particular, one of the only two of these his earlier dramatic productions that have found their way to the press, is very remarkable in the dramatic history of Europe. 'It stands altogether,' observes Schlegel, 'on the elevation of the tragical cothurnus; and, from the unconscious and unsought-for approximation to antique grandeur and purity, forms a remarkable phenomenon in the history of modern poetry. The idea of destiny prevails in it throughout; the allegorical figures which enter between the acts supply, though in another way, nearly the place of the chorus in the Greek tragedies; they guide our consideration and propitiate our feeling. A great deed of heroic determination is completed; the extremity of suffering is endured with constancy, but it is the deed and suffering of a whole nation, whose individual members may almost be said to appear only as examples, while the Roman heroes seem merely the instruments of fate. There is a sort of Spartan pathos in this piece; every separate consideration is swallowed up in the feeling for country; and by a reference to the modern warlike fame of his nation, the poet has contrived to connect the antient history with the circumstances immediately before him.' On the whole, however, it appears that the mind of Cervantes was more inclined to the *epic*, taking the word in its more extensive signification for the narrative form of composition in general; and that the soft and unassuming manner in which he chiefly delights to excite the feelings is not the best suited to the rapid compression required on the stage.

Cervantes wrote at Madrid; and at the same time Juan de la Cueva produced some dramas on the stage of Seville, reducing to four the number of *jornadas*, or acts, which had hitherto been five or six. The day's performance then consisted, besides the principal piece, of three *entremeses*, or interludes, played between the acts, and a little ballet. Valencia, too, which had always, in arts and letters, its rival school to that of Seville, made some advances in the dramatic career. It was a Valencian poet, Cristobal de Virues, who further reduced the number of acts from four to three, which latter number was thenceforward adhered to by all Spanish writers. 'Until then,' according to the ludicrous conceit of Lope de Vega, 'the Spanish drama had gone on all fours, like a child, because it was yet in its infancy.'

The scenic pomp of the Spanish theatre had already made great progress. The same writer, Rojas, who said that in the days of Lope de Rueda an *autor* and his company might have deposited their bundle of *properties* upon a spider's back, relates, that in the time of Cueva and Virues, women played their parts in dresses of silk and velvet, with chains of gold and pearls; that, in the interludes, airs were executed by three or four voices; and that even horses were introduced in the warlike plays to complete the illusion.

It is well worthy of remark that already, in the sixteenth century we find, in Spain the contest fully and warmly engaged between the claims of the dramatic writers to an absolute independence of the classic rules, and the critics demanding a rigid adherence to the precepts of Aristotle. Thus, while the rhetorician Pinciano was zealously conjuring the thea-

trical writers to respect the unities, for which they showed little regard, one of them, Juan de la Cueva, openly undertook, in his 'Exemplar Poetico,' the defence of the dramatic liberties. He claimed them as the offspring of that succession of ages which had abolished all antique laws,—as more favourable to the boldest flights of imagination,—and, in fine, as better adapted to please the public. But, while delivering this judicious opinion, he lays down such maxims for the regulation of this dramatic freedom as good sense and good taste must ever dictate, though his countrymen, in their fiery impatience of any such restriction, have not paid them sufficient attention.

This uncontrollable fervour of imagination was however but a necessary result of the very peculiar circumstances which for a long course of ages had operated to form and to confirm the Spanish national character. 'The Spaniards,' to use the words of Schlegel, 'act a glorious part in the history of the middle ages, a part too much forgotten by the envious ingratitude of modern times. They were then the forlorn outpost of Europe; they lay on their Pyrenean peninsula as in a camp, exposed to the incessant irruptions of the Arabians, and always ready for renewed conflicts without foreign aid. The re-establishment of their Christian kingdom, for centuries from the time when the descendants of the Goths who had been driven back into the northern mountains rushed forth again from those places of refuge, down to the complete expulsion of the Moors from Spain, was one single and long-continued adventure; nay, the preservation of Christianity in that land against such a preponderating power seemed even to be the wondrous work of more than mortal guidance. Ever accustomed to fight at one and the same time for his liberty and his religion, the Spaniard clung to the latter with a fiery zeal, as to an acquisition dearly purchased by the noblest blood. Every consolation of divine worship was a reward of heroic exertion; every church might be considered by him as a trophy of his ancestors.' In later times, 'the Spaniard never presumed to examine into the conduct of his spiritual and worldly superiors, but carried on their wars of aggression and ambition with the same fidelity and bravery which he had formerly displayed in his own wars of defence. Personal fame and a supposed zeal for religion blinded him as to the justice of his cause. Unexampled enterprises were successfully executed; a newly discovered world beyond the ocean had been subjugated by a handful of bold adventurers; individual instances of cruelty and rapine had stained the splendour of the most determined heroisms, but the mass of the nation remained unaffected by this degeneracy. The spirit of chivalry nowhere survived its political existence so long as in Spain: long after the internal prosperity of the nation, together with its foreign influence, had experienced a deep decline in consequence of the ruinous errors of Philip II., that spirit propagated itself down to the flourishing period of their literature, and imprinted its stamp upon it in a manner which cannot be mistaken. The fancy of the Spaniards was bold, like their active powers; no mental adventure seemed too dangerous for it. The predilection of the people for the extravagantly wonderful had already been shown in the chivalry romances. They wished to see the wonderful once more on the stage; and when their poets, standing on a high eminence of cultivation in art and social life, gave it the requisite form, breathed into it a musical soul, and purified it from corporeal grossness to colour and fragrance, there arises from the contrast between the subject and the form an irresistible fascination. Their spectators imagined they perceived a refulgence of the world-conquering greatness of their nation, then half lost, when all the harmony of the most varied metre, all the elegance of fanciful allusion, all that splendour of imagery and comparison which their language alone could afford, were poured out into inventions always new, and almost always pre-eminently ingenious. The treasures of the most distant times were procured in fancy, as in reality, for the gratification of the mother country; and we may say that in the dominions of this poetry, as in those of Charles V., the sun never set.'

Such was the public mind upon which Lope de Vega now arose to exercise his marvellous fertility of dramatic invention and facility of metrical composition. He had the first great requisite for success in this career, a most thorough knowledge of the tastes and passions of the people for whom he wrote; but that farther and nobler merit, an elevated view of his art and deep devotion to it for its own

sake, he never evinced. Success, in the more vulgar acceptance of the term, was not only his first object, as with every popular dramatist it ought to be—it seems to have been his only care—and that success he attained even to an unparalleled degree; affording, perhaps, the most conspicuous instance upon record of the sacrifice of high and permanent literary reputation for unbounded living popularity. We do not, indeed, as so many writers have done, make it any subject of reproach to him that, as he himself tells us in his 'New Art of Play-writing' ('Arte Nuevo de hacer Comedias'), whenever he was going to write a play he used to shut the door upon Terence and Plautus, that they might not cry to heaven against him; but in the interests of art it is impossible to admit the excuse which, in the same treatise, he broadly offers for his extravagancies, namely, 'I write pieces for the public; and as the public pay, it is but right that, to please them, I should talk to them the language of fools.' After reading such an admission as this from his own pen, we need not wonder at finding in the large portion that remains to us of his countless dramatic productions, that his exhaustless invention of incident, his varied skill in delineating characters and exhibiting the play of the passions, with all the spirit and subtlety of his dialogue—that all these brilliant qualities have, as it were, nearly stifled one another by their own unpruned luxuriance.

Neither in his own country, however, nor in Europe, had Lope any model to guide him or rival to excite his emulation. Italy had not yet got farther than the *Mundragola*, nor France beyond her first uncouth imitations of the ancients; Germany had not yet emerged from the *mysterien*; and England, except politically, was a terra incognita to the Spanish writers.

In 1621, twelve years before the death of Lope de Vega, happened that of the gloomily devout Philip III., who was succeeded by a young prince addicted to pleasure and passionately fond of the theatre. Philip IV. liked the conversation of literary men, received them at his court, and amused himself with enacting along with them that sort of improvisatory pieces which were then so much in vogue in Italy. He is even the reputed author of some dramatic works which were brought out under an anonymous designation; and such was his prepossession in favour of the national drama that he would not allow the introduction of the Italian opera, then in general favour at the continental courts. These circumstances added force to the impulse already given by Lope de Vega, and introduced the most brilliant period of the Spanish drama. During Lope's lifetime, a multitude of writers endeavoured to tread in his steps—as the Drs. Ramon and Mira de Mesca, the licentiate Mexia and Miguel Sanchez, the canon Tarraga, Don Guillen de Castro, Aguilar, Luis Velez de Guevara, Antonio de Galarza, Gaspar de Avila, Damian Salustrio del Poyo, and a great many others;—but all were merely his imitators, and fell far below him; it was not until near the close of his dramatic reign that the rival appeared who was destined to dethrone him.

This was Calderon de la Barca, who, with no less intimate a knowledge of his public than Lope himself, had all that high devotion to his art which was wanting to the latter. As the compositions of this great writer occupy the summit of the truly national drama of Spain—as they fully equal those of Lope in variety and more nearly approach them in number than those of any other of his countrymen—and as, consequently, they afford us the most perfect specimens of each of the several species of dramatic productions which are peculiarly Spanish—there is no way in which we can convey so clear an idea of the forms and spirit of the Spanish stage in its highest maturity as by characterizing briefly but distinctly the several classes of Calderon's dramatic pieces. The principal classification of their plays on profane subjects recognized by the Spaniards themselves was that which distinguished *comedias heroicas*, *comedias de capa y espada*, and *comedias de figuron*. The first of these classes, the *heroic* plays, occupied much the same place in dramatic literature as the tales of chivalry did in narrative fiction: driven from prose composition by the Don Quixote, they seem to have taken refuge on the stage, where they were long welcomed by the public. The second class, named, from the costume of the time in which they were acted, plays of the *cloak and sword*, exhibited the Spanish manners of the day; but owing to the strong tincture of romance which those manners still retained, the

were capable of being represented under an ideal aspect. 'This,' Schlegel remarks, 'could not have been possible had Calderon introduced us into the interior of domestic life, where want and habit generally reduce all things to every day narrowness. These pieces end, like the comedies of the ancients, with marriages; but how different what precedes! . . . Calderon represents to us his principal characters of both sexes in the first ebullitions of youth, it is true; but the aim after which they strive, and in the prosecution of which everything else kicks the beam, is never confounded in their minds with any other good. Honour, love, and jealousy are uniformly the motives; the plot arises out of their daring but noble collision, and is not purposely instigated by knavish deception. . . . The feeling for honour is equally powerful in the female characters; it rules over love, which is allowed a place beside it, but not above it. The honour of the women, according to the manner of thinking exhibited in the dramas of Calderon, consists in loving only one man of unspotted honour, and loving him with perfect purity. Love requires inviolable secrecy till a lawful union permits it to be publicly declared. This secrecy secures it from the poisonous intermixture of vanity, which would boast of pretensions or conceded favours; it gives it the appearance of a vow, which, from its mystery, is the more sacredly observed. In this morality, it is true, cunning and dissimulation are allowed for the sake of love, and so far honour may be said to be infringed on; but the most delicate regards are nevertheless observed in the collision with other duties—as, for example, with those of friendship. The power of jealousy, always alive, and often breaking out in a dreadful manner—not, like that of eastern countries, a jealousy of possession, but of the slightest emotions of the heart and its least perceptible demonstrations, serves to ennoble love, as this feeling, whenever it is not altogether exclusive, sinks beneath itself. The perplexity to which the collision of all these mental motives gives rise frequently ends in nothing, and then the catastrophe is truly comic: sometimes, however, it takes a tragic turn; and then honour becomes a hostile destiny for him who cannot satisfy it without either annihilating his own happiness, or even becoming a criminal.' These pieces have commonly no other burlesque part than that of a merry servant, called by the Spanish writers the *gracioso*, who chiefly serves to parody the ideal motives from which his master acts, which he is often made to do in the most elegant and witty manner. He is seldom used as an efficient instrument in complicating the intrigue, in which we seem to admire the ingenuity of accident rather than of contrivance. The *comedias de figuron*, or plays of *character*, are distinguished from the class last described, chiefly by this—that the interest of the action, instead of being distributed over the personages of a double or triple intrigue, is centred in some one individual, in whom some particular vice or absurdity is broadly personified.

Some of Calderon's plays, historical or mythological, cannot strictly be ranked in any of the three foregoing species. The earlier periods of Spanish history he has often seized with the utmost truth; but he seems to have had too vehement a predilection for his own clime and nation to enter easily into the peculiarities of another. Classical antiquity, as well as the north of Europe, were altogether foreign to his conception; and thus, as Schlegel observes, the Greek mythology usually became in his hands a delightful tale, and the Roman history a majestic hyperbole. 'Another class of his pieces are entitled by Calderon himself *fiestas* dramas (*fiestas*). These were designed for representation at court on solemn occasions: although they require the theatrical pomp of frequent change of decoration and visible wonders, and though music is often introduced into them, yet we may call them *poetical* operas, that is, dramas which, by the mere splendour of poetry, achieve what in the actual opera can be attained only by the machinery, the music, and the dancing. Here the poet gives himself wholly up to the boldest flights of his fancy, and his creations hardly touch the earth.'

But it is in the class of *autos sacramentales*, or religious dramas, of which we must now speak, that the genius and spirit of Calderon are most richly and fully developed. As the religious ceremonies of Paganism had given birth to the Grecian theatre, so did those of Christianity give birth to the modern. The original principle of the dramatic spectacles, introduced or sanctioned by the Romish ecclesiastics,

was that of exhibiting before the eyes of the faithful, on each of the great festivals of the church and commemoration days of the saints, a living representation of the passage of the New Testament or of legendary history to which the celebration in question referred. These performances, which, in all the rest of Europe went by the name of mysteries, were, in Spain, called from the beginning *divine plays* (*comedias divinas*) and *sacramental acts* (*autos sacramentales*). They were performed with great pomp, not only in the public squares and in processions, but also at the great theatres of the capital. This species of dramas, being performed on the most solemn festivals, under the patronage both of the ecclesiastical and the civil authorities, and in the presence of the whole people, were more profitable as well as more glorious to their authors than any other kind. Lope de Vega wrote some hundreds of these pieces; but Calderon, in this department as in others, so far excelled both his predecessors and his contemporaries, that letters patent were granted to him conferring the exclusive privilege of furnishing the *autos* for the use of the capital; a monopoly which he enjoyed for thirty-seven years. 'His mind,' to borrow the eloquent characterization of his able German translator, 'is most distinctly expressed in his treatment of religious subjects. He paints love with general features merely; he speaks its technical poetical language. But religion is his peculiar love, the heart of his heart. For religion alone he excites the most overpowering emotions, which penetrate into the innocent recesses of the soul. It would rather appear that he did not wish to enter with the same fervour into worldly events. However turbid they may be in themselves, yet, from the religious medium through which he views them, they appear to him perfectly bright. This fortunate man escaped from the wild labyrinth of doubt into the citadel of belief, from whence he viewed and portrayed the storms of the world with undisturbed tranquillity of soul: human life was to him no longer a dark riddle. Even his tears reflect the image of heaven, like dew-drops on a flower in the sun. His poetry, whatever its object may apparently be, is an incessant hymn of joy on the majesty of the creation: he celebrates the productions of nature and human art with an astonishment always joyful and always new, as if he saw them for the first time in an unworn festal splendour. It is the first awaking of Adam, combined with an eloquence and skill of expression, and a thorough acquaintance with the most mysterious relations of nature, such as high mental cultivation and mature contemplation can alone give. When he compares objects the most remote, the greatest and the smallest, stars and flowers, the sense of all his metaphors is the mutual attraction of created things to one another on account of their common origin; and, again, this delightful harmony and unity of the world is with him but a refulgence of the eternal love which embraces the universe.'

We have felt it the more necessary to endeavour to convey some just idea of the real spirit and execution of these dramas, because in recent times, in England especially, they have, through ignorance of the works themselves, and of the national spirit and circumstances out of which they arose, been confounded, under the designation of productions evincing much more zeal than taste, with the rude and barbarous compositions which the remains of the dramatic mysteries of the other European nations almost exclusively present to us. On the contrary, the more perfect spiritual plays of the old Spanish theatre will remain, through all changes of manners and opinions, highly valuable and interesting, as showing us how some of the noblest efforts of modern dramatic art were devoted in one country, as those of all the other arts have so generally been, to the service of the Christian faith.

It is remarkable, that during this most brilliant period of the Spanish stage, the council of Castile ventured to propose, as a condition of the re-opening of the theatres, which, on account of court mournings, had remained shut from 1644 to 1649, that the plays to be performed should be confined to subjects of good example taken from edifying lives and deaths, without any mixture of love; that consequently, nearly all those which had theretofore been acted should be prohibited, especially the works of Lope de Vega, which had been so prejudicial to good morals. But fortunately, the taste of the monarch, in accordance with that of the public, made him reject the proposal of his austere advisers.

In the course of Calderon's protracted career arose Moreto, who, with less of the national fire of invention and richness

of fancy, distinguished himself chiefly by giving a more perfect development to the 'comedias de figuron,' or plays of character. Such, for instance, are his pieces 'El Lindo Don Diego,' which might be called 'The Coxcomb,' and 'El Marques de Cigarral,' a Don Quixote of a certain sort, gone mad over the eternal repudiation of his family papers and reckoning up of his quarters of nobility. In this line Moreto may be regarded as one of the models of Molière, amongst whose pieces, indeed, there is one weak imitation of him. At the same period lived another dramatic poet whose living fame was not equal to his posthumous celebrity, yet who, by some extraordinary chance, has remained so unknown to other nations that the most eminent critics—Signorelli, Schlegel, Sismondi—have not so much as mentioned him: this was a monk of the order of Mercy, Fray Gabriel Tellez, who, under the assumed name of Tirso de Molina, gave to the stage a great number of pieces, which were afterwards collected and published by his nephew. Less ingenious than Calderon, and less delicate than Moreto, he does, however, excel every poet of his country in a certain mischievous gaiety. He pays little regard either to rule or probability, caring only to find room for the sallies of a laughing and caustic wit, a freedom of language which he carries even to licentiousness, and a boldness of thought which respects neither the powers of earth nor those of heaven. He spares nothing, but attacks whatever either offends or diverts him. There is but one writer to whom he can justly be compared, and to whom he bears a very striking resemblance, namely, the more recent French dramatist Beaumarchais. And as the latter writer was the original parent of Figaro, so it is a curious fact that Fray Gabriel was the first who brought upon the stage the famous story of 'Don Juan and the Statue,' availing himself of the legend invented by the Franciscan monks of Seville to account for the disappearance of the real 'Don Juan de Tenorio,' whom, in order to put a quiet end to his notorious excesses and impieties, the holy brethren had drawn into an ambush and slain.

The brilliant period of the Spanish theatre is comprised in the first half of the seventeenth century. The taste of the monarch, the court, and the nation, had thrown a multitude of literary men into that career, then the most honoured and the most lucrative. Thus, besides the eminent masters already mentioned, there were a host of dramatists of the second order, at the head of whom must be ranked Francisco de Rojas, who had all the qualifications of Moreto, but exceeded him in his defects. Then follow Guillen de Castro, Ruis de Alarcon, La Hoz, Diamante, Mendoza, Belmonte, the brothers Figueroas (who wrote conjointly, like the French vaudevillists of the present day), Cancer, Enciso, Salazar, and Bances Candamo, each of whom, though establishing no school, produced at least some important composition.

The disasters that befel the Spanish monarchy in the latter years of the reign of Philip IV., together with a succession of court mournings which closed the theatres for a considerable time, gave the first blow to the dramatic art in Spain. In 1665, the death of that prince, who had been its most zealous protector, gave the signal for its rapid and thorough decline. His successor, the imbecile Charles II., was yet in his infancy; and the queen-regent signalized the commencement of her administration by a decree, dictated no doubt by her spiritual director the jesuit Nitard, and certainly unique in dramatic history: she commanded 'that all plays do cease until the king my son shall be old enough to be entertained by them.' Although this strange order could not be rigorously executed, yet it is plain how great an effect it must have produced at a time when literature could only thrive under the patronage of the great, and when the theatre could maintain itself against the reiterated attacks of the council of Castile only by the special protection of the monarch. But of the effect in question we find the most striking evidence in contrasting two remarkable facts. A memorial addressed to Philip IV. in 1632 by the comedian Cristoval Santiago Ortiz shows us that there were then in Spain upwards of forty companies of comedians (although the council would license no more than six); that these companies comprised about a thousand individuals; and that so many playhouses had been erected that there were very few cities, or even considerable towns, that had not at least one actually engaged. And yet, in 1679, at the marriage of Charles II. with a niece of Louis XIV., wherein all possible magnificence was dis-

played, no more than three companies could be got together to perform at court.

At this period of decay and neglect one writer alone endeavoured to support the tottering stage: Solis, the eloquent historian of the conquest of Mexico, likewise devoted to the service of the theatre his brilliant imagination, polished wit, and glowing style. He has left us several plays well worthy of the dramatic period which he survived, one of which especially, entitled 'Love à la Mode' (El Amor al Uso), has peculiar excellence.

With Solis may be said to have expired the Spanish theatre properly so called. The elevation of Philip V. to the throne of Spain having given prevalence to the French taste, and introduced, at court at least, the habits and manners of the court of Louis XIV., the Spaniards, after having been, as we shall shortly show, the dramatic precursors and teachers of the French, were content to become their humble translators and copyists. In the course of the eighteenth century, it is true, some attempts to re-erect a national drama were made successively by Zamora, Luzan, Canizares, and Jovellanos; but these honourable endeavours had but a transitory success; and to arrive at a work of originality—after, however, noticing as such the *sainetes* (small satirical pieces) of Ramon de la Cruz—we must come down to the commencement of the present century, to Moratin, the witty and elegant author of 'The Coffee-house,' 'The Baron,' 'The Maiden's Yes,' &c., and next, to Martinez de la Rosa, who wrote 'The Mother at the Ball and the Daughter at Home.'

The description which we have already given of the several kinds of dramatic composition in the days of Calderon may sufficiently show that in the old Spanish drama the classic tragedy, even less than the classic comedy, could find a broad and effective place. Yet, misled, it should seem, in a great degree by the word *comedia*, which in Spanish has always had as comprehensive a signification as the English term *play*, many of the most eminent continental critics, especially among the French, have alleged a total absence of tragedy in the Spanish theatre, and spoken of it as a singular and unaccountable phenomenon. So obstinately have such critics been prepossessed by the *classical* distinctions in which they have been trained up, that they can gravely make this astounding assertion, even while admitting that 'the tragic element predominates in a great number of the most celebrated pieces of the Spanish stage, and that the most popular subjects appear in general, to use the antique phrase, more appropriate to the buskin of Melpomene than to the sock of Thalia.' This very predominance of either element, as we have shown in the opening of this article, is the only ground for distinction between tragedy and comedy that exists in the essence of human nature and of dramatic art, or even that admits of any precise definition. According to this more rational mode of classification, the old Spanish theatre, by the very admission of the critics in question, is abundantly rich in tragedy. We must notice very briefly the few scattered specimens of dramatic writing under the name of tragedy that appear in the early Spanish literature.

Boscan, who first introduced into Spain the Italian style of versification, is said to have made a translation from one of the tragedies of Euripides, which has not been preserved; and in like manner, almost immediately after, about the year 1520, the learned Fernan Peres de Oliva, returning from the court of Leo X., where he had witnessed the performance of Trissino's 'Sophonisba,' wrote two other imitations of the Greek theatre, the 'Venganza de Agamemnon,' taken from the 'Electra' of Sophocles, and the 'Hecuba,' translated from Euripides. These tragedies, written in elegant prose, remained unknown beyond the universities: nor have we reason to suppose that they were acted even there. About 1570, however, Juan de Malara gave to the theatre of Seville several tragedies on scriptural subjects, as 'Absalom,' 'Saul,' &c.; and at Madrid, then recently chosen to be the capital of the kingdom, a monk named Geronimo Bermudez produced, under the name of Antonio de Silva, two tragedies which deserve particular mention. They are founded on the remarkable history of Inez de Castro. The first of the two, entitled 'Nise Lastimosa,' and relating to the death of Inez, is imitated from a Portuguese play on the same subject by Antonio Ferrera: the second, entitled 'Nise Laureada,' exhibiting the revenge which the infante, become king, took upon the murderers of his wife, and the coronation of the corpse of Inez,

it more original than the first, but inferior to it in plot and development. These two pieces, divided each into five acts, with intervening choral odes, may be regarded as the first *regular* tragedies that were written in Castilian *verse*. About the same time also, at Valencia, where the first theatre, built in 1526, was the property of an hospital, were played various dramas, still more remarkable, composed by Cristoval de Virues, whom we have already had occasion to mention, and by Andres Rey de Artieda. Virues, a military officer, was one of the leaders in that day of the great Spanish school which had gloried from the first in spurning the Aristotelian restrictions. His first production was 'La Gran Semiramis,' a subject handled at the same time in Italy by Muzio Manfredi. Virues however, instead of the five acts of the Greeks, divided his play into three *jornadas*, which, together, contain the whole life of Semiramis, the first act being laid at Bactria, the second at Nineveh, and the third at Babylon. He afterwards produced successively, and with the same disregard to the unities, the tragedies of 'Cruel Cassandra,' 'Atila Furioso,' 'Infeliz Marcela,' &c. That entitled 'Elisa Dido,' which he himself announced as written 'conforme al arte antiguo,' is in fact the only one wherein 'the rules' are at all respected. So little however does its plot resemble the famous episode of the *Æneid*, which Ludovico Dolce had lately brought upon the tragic stage of Italy, that he makes his heroine remain faithful to her first husband Sichæus, and kill herself that she may not marry Iarbas. The associate of Virues in this old war against the classic rules, Juan de la Cueva, after imitating the 'Ajax' of Sophocles, brought out at Seville two original tragedies; one, 'Las Siete Infantes de Lara,' founded on a popular tradition; the other taken from Roman history, and combining two tragic subjects, the death of Virginia and that of Appius Claudius. Cueva was the first who dramatised this subject, which, since then, has been so repeatedly brought upon the stage. Meanwhile, at the Madrid theatre, the tragedies of the friar Bermudes were succeeded by those of Lupericio de Argensola, to which Cervantes, ever more prompt to applaud his contemporaries than to criticise them, gives much higher praise than they can now be admitted to deserve. Of the noble pathos of his own 'Numancia' we have already spoken.

It is plain how much the romantic spirit predominates over the classical, even in these productions *professedly* tragic of the old Spanish stage. When, however, the accession of Philip V. had brought the Spanish theatre within the influence of Parisian taste, not only were the French tragic poets translated into the language of Spain, but some attempts were also made by the Spanish poets to imitate them. Of this number were the 'Virginia' and the 'Ataulfo' of Montiano.

Subsequently, under the enlightened ministry of the marquis of Aranda, this endeavour was resumed by Fernandez de Moratin, Cadalso, and Garcia de la Huerta; the first of whom produced 'Hormesinda,' the second 'Don Sancho Garcia,' and the third 'Raquel;' but these works, though valuable, especially the last, were not striking enough to naturalize a species of drama so novel in Spain. At the commencement of the present century, the like effort was made with better success by Don Nicasio Alvarez de Cienfuegos, ably supported by the talent of the celebrated actor Isidoro Mayquez, in some sort a pupil of Talma, not unworthy of his master, besides that he approached nearer to the wonderful versatility of Garrick, for he succeeded not only in the tragic department, but in every other, even down to simple buffoonery. After Cienfuegos, who left an 'Idomeneo,' a 'Pitaco,' and a 'Zoraida,' appeared two other tragic poets who are yet living. One of these, Quintana, is the author of a tragedy entitled 'Pelayo,' and founded on the history of that old champion of the forlorn cause of Spanish independence against the triumphant Arabians. a truly noble and pathetic piece, of which the Spaniards of the present day, forced like their ancestors to repel a foreign domination, used to repeat the most energetic passages in marching to battle. The other is Martinez de la Rosa, lately prime minister, whose first production of this class was likewise a patriotic piece, 'The Widow of Padilla,' founded on the memorable struggle of the municipal cities of Spain against the tyrannical aggressions of Charles V. This tragedy, composed during the siege of Cadix by the French, was performed there on a stage erected for that express purpose. Its author has subsequently produced a 'Morayma,' somewhat after the

manner of the 'Mérope' of Voltaire, and an 'Œdipus,' played recently at Madrid, wherein, says one of the most intelligent critics of Spanish literature (M. Louis Viardot), he has contrived to be original on a subject already treated by Sophocles, Seneca, Corneille, Voltaire, La Motte, and Dryden.

As regards the present theatrical vogue of the elder Spanish dramatists in their own country, we may remark that while Lope de Vega is almost wholly banished to the libraries, and while Calderon and Moreto seldom occupy the stage, Tirso de Molina, whom we have already characterized, is to be seen there more frequently than any other of the old dramatic writers. The late king, Ferdinand VII., so renowned for his delicate testimonies of devotion to the Virgin, used to enjoy most royally the *rich* jokes of this free-witted friar; and this declared predilection imposed silence on the susceptibility of certain agents of authority, which the friar's bold attacks upon the great were calculated to arouse. His comedy, entitled 'Don Gil of the Green Breeches' (Don Gil de las Calzas Verdes) was Ferdinand's especial favourite; and accordingly the municipality of Madrid never failed to have this dainty served up to him on state occasions.

Although the performance of the *autos sacramentales* on the ordinary stage was suppressed in 1765, in the reign of Charles III., yet the seasons of Advent and Lent, and more especially the Holy Week, are still solemnized by the like representations in the great churches: a sort of stage, called *the monument*, is erected in the choir, upon which are played the acts of the Passion, wherein the numerous characters that successively figure in the piece still wear the costume of the middle ages as it must have been at the origin of these exhibitions,—san-benitos, black masks, high pointed caps, long skirts, belts, or rather breastplates, made of cords,—all the wardrobe, in short, of an *auto-da-fe* procession.

FRENCH DRAMA.

In France the *mysteries* appear to have had their immediate source in the pilgrimages so common in those days. Menestrier tells us (*Représentations en Musique Anciennes et Modernes*) that the pilgrims to the Holy Land, St. James of Galicia, Mont St. Michel in Normandy, and the various other places of pious resort in France and abroad, used to compose rude songs on their travels, wherein they introduced a recital of the life and death of Christ, or of the last judgment: in others they celebrated the miracles of saints, their martyrdom, and divers wonderful visions and apparitions. These pilgrims, going in companies, and taking their stand in the streets and public places, where they sang with their staves in their hands, and their hats and mantles covered with shells, and painted images of various colours, formed a kind of spectacle which pleased the public of that day, and at Paris excited the piety of some of the citizens to raise a fund for purchasing a proper place in which to erect a stage whereon these performances might be regularly exhibited on holidays, as well for the instruction of the people as for their entertainment. This appears to have been the origin of the society at Paris called the Brethren of the Passion. In 1402 Charles VI. authorised these exhibitions by letters patent: the Premonstratensian monks gave the use of a great hall of their convent, and a stage was constructed in it upon which the fraternity enacted scriptural pieces. The ecclesiastics crowded to these exhibitions; stages soon arose in every province; and the *mystères* were so much relished, that on holidays the hour of vespers was hastened, that the people might have more ample time to be present at the play. The brethren, to vary the attractions of the performance, added a sort of farcical interludes or after-pieces of a merely worldly character, the enacting of which however, careful of their own histrionic dignity, they delegated to a junior society called that of the *Enfants sans Soucis*. These latter pieces, in allusion to their burlesque and buffoon character, were denominated *sottises* or *oties*.

The stage upon which the mysteries were played consisted of several scaffoldings one above another: the most elevated of all represented heaven; that immediately beneath it, earth; a third, still lower, the palace of Herod, the house of Pilate, &c.; and hell, which was at the bottom and in front, was figured by the gaping mouth of a dragon, which opened and shut as the devils went in and out. On each side were seats rising in steps one above another, on

which the actors rested when they were not upon the stage, a contrivance not very favourable to scenic illusion; and at the back was a recess, with curtains drawn across it, for the exhibition of such matters as were supposed to take place in the interior of a house.

Among the French, as elsewhere, the Passion was the primary, the most constant, and most solemn subject of these representations, the parts of Christ on the cross, Judas hanging himself, &c., being all played by real persons, sometimes at the actual peril of their lives. It seems to have been owing chiefly to the efforts of the early reformers to diffuse a knowledge of the Scriptures among the people that the Romish ecclesiastics throughout Europe, as one means of securing the fidelity of their flocks, proceeded studiously to extend the field of the religious representations so as to embrace the whole series of Old and New Testament history, or as much of that history as they deemed it prudent to disclose to the multitude. This zealous exertion on the part of the Catholic clergy was supported by all the authority of the Catholic princes. Thus we find that in 1541, under Francis I., the performance of a grand mystery of the Acts of the Apostles was proclaimed with great solemnity under the royal authority, and acted at Paris in the course of many successive days, before the nobility, clergy, and a great concourse of the people, in the Hôtel de Flandres. These plays, written in French rhyme by the brothers Greban, were printed in 2 vols., folio, black letter, under patent of the king to one Guillaume Alabat, of Bourges. The dramatis personæ are, God the Father, the Son, and the Holy Ghost; the Virgin and Joseph; archangels, angels, apostles, and disciples; Jewish priests, emperors, philosophers, magicians, Lucifer, Satan, Beelzebub, Belial, Cerberus, and a multitude of other celestial, terrestrial, and infernal personages, amounting altogether to nearly five hundred. The subjects of these plays are chiefly scriptural; but many of them are from apocryphal New Testament subjects, and the whole forms a strange medley of sacred and profane history. This grand performance was executed, not by any standing company, but by actors selected from the people at large after trial of the merits of the respective candidates. In the present instance, the proclamation notified 'that all should be, on the feast of St. Stephen, the first holiday in Christmas following, in the hall of the Passion, the accustomed place for rehearsals and repetitions of the mysteries played in the said city of Paris, which place, being well furnished with rich tapestry, chairs, and forms, is for the reception of all persons of honest and virtuous report, and of all qualities therein assisting, as also a great number of citizens, merchants, and others, as well clergy as laity, in the presence of the commissioners and judicial officers appointed and deputed to hear the speeches of each personage; and these are to make report, according to the merit of each, as in such case required, as to which have a gracious reception; and from day to day, every day so to continue to do until the perfection of the said mystery.'

Among the numerous legendary pieces, one of the most curious extant is 'The Mystery of the Knight who gives his Wife to the Devil,' (*Le Mystère du Chevalier qui donne sa Femme au Diable*); but the most universally popular of them all seems to have been that of the miraculous host, or consecrated wafer, tortured by a Jew at Paris, commonly called '*Le Mystère de la Sainte Hostie*,' two several versions of which exist in black letter.

After the *mystères* and the *soities*, and during their continuance, came the *moralités* and the *farces*, of which the clerks of the Basoche were the inventors. These clerks were the young assistants of the procureurs, or solicitors, to whom Philippe le Bel granted the privilege of choosing from among themselves a chief, to be called their king, to have supreme jurisdiction over their body, and even to coin money for currency among the clerks. Francis I., in requital of the service rendered him by the king of the Basoche and 6000 of his clerks in marching against the revolvers of Guienne, presented them, in 1547, with an extensive promenade ground, bordering on the Seine, which thence took the name of *Pré aux Clercs*. As early as the commencement of the fifteenth century, the king of the Basoche used every year, in July, to make a review of his clerks, divided into twelve bands under as many commanders: after the review, they went and offered their salutations to those gentlemen at the head of the legal profession who composed the parliament of Paris; and then

P. C. No. 583.

they went and performed a morality or a farce. The brethren of the Passion having the exclusive privilege of acting mysteries, the clerks were driven to the invention of the moralities, which were purely allegorical pieces personifying the vices and virtues. The farces and the soities, on the other hand, took a satirical turn, the success of which soon carried the authors to licentious extremes. The public calamities and violent political dissensions of the reigns of Charles VI. and Charles VII. favoured this tendency: the two leading parties, the Armagnacs and the Burgundians, had each its poet, and insulted each other by turns upon the stage. When public order was restored, the royal authority availed itself of the fair pretext which these satirical excesses afforded to suppress this exclusively popular stage altogether: the clerks were forbidden to play either farce, soitie, or morality, on pain of flagellation and banishment. This suspension continued until the reign of a prince who was less afraid to hear the truth. 'The good king Louis XII.,' says the historian Bouchet, 'afflicted that in his time he could find nobody to tell him the truth, wherefore he could not know how his kingdom was governed, to the intent that the truth should find its way to him he gave liberty to the stage, and willed that upon it should be freely acted the abuses that were committed in his court and kingdom; thinking thereby to be acquainted with many things which it would otherwise be impossible for him to hear of.' He did indeed hear some things of a kind rather novel to royal ears, for the players represented him as mean and miserly. This good-natured king, it is true, only laughed at them; but his peculiar relish for homely truths was not likely to predominate among his successors; and accordingly we find that this renovated satirical liberty of the clerks brought on them numerous persecutions, which, however, they seem to have braved at first with something like the daring of an Aristophanes.

The society of the *Enfans sans Soucis*, too, already mentioned, had been established under Charles VI., had been authorized by patent, and had suffered political oppression. Louis XII. took them likewise under his protection; and their most celebrated soitie, entitled 'The Abuse of the World' (*L'Abus du Monde*) is attributed to the historian Bouchet above quoted. Their farces have been more celebrated, especially that of 'Pathelin,' whose name has ever since been proverbial in France. The best writers of the beginning of the sixteenth century speak of it as a work enjoying the highest reputation; and in recent times it has been revived in the shape of a modern adaptation, by Brueis and Palaprat. The characters are—Pathelin, a lawyer with little practice; Guillemet, his wife; Guillaume, a draper; Thibaut Aignelet, a shepherd; and the judge; and the humour of the plot consists chiefly in the droll expedient by which the lawyer, after using it to outwit his neighbour the draper, is outwitted by his client the shepherd. But the dialogue itself, written in octosyllabic rhyme, is full of humour; and from one passage it may be mentioned that Lafontaine has taken his charming fable, '*Le Renard et le Corbeau*.' This piece, with all its levity, is very interesting, as one of the most truly original and national productions of the early French stage, and therefore as one of those which gave promise of something like that spontaneous and vigorous dramatic growth which was springing in one or two neighbouring countries. But the three several kinds of theatre which we have particularized were fated soon to sink under the repeated blows aimed at them by the government. This strong tendency, however, of the infant stage of France to freedom of political animadversion, and the early jealousy and arbitrary repression of theatrical liberty on the part of the French crown, should be clearly and constantly borne in mind, in order to understand and appreciate that very peculiar course which dramatic composition took in that country, and which the predominance of French taste made for so long a period ascendant in Europe. To this determined stifling by the government of the first germs of a truly national drama we ought to attribute the immediate and general success of the earliest French imitations of the antient theatre that were actually brought upon the stage. The national taste, the romantic tendencies of which had decidedly manifested themselves, was not suffered to develop itself freely. Theatrical enjoyment, since they first tasted it, has ever appeared a more imperious want of the French, and of the Parisians in particular, than of any other people, excepting perhaps the antient Athenians; and when, at the period in

VOL. IX.—3 H

question, their rulers had violently crushed every other species of dramatic production, they eagerly welcomed those only forms of it which those rulers would vouchsafe to let them have.

Some French translations from Sophocles and Euripides already existed, but nobody had yet thought of adapting them to the stage; indeed they were little to the purpose either of the brethren of the Passion or the performers of the Basoche. A young gentleman, Etienne Jodelle, seigneur of Limodin, who had studied the antient dramatists both in their original works and in the Italian imitations of them, was the first to avail himself of the opportunity thus afforded, by bringing forward his 'Cléopâtre Captive', a tragedy in five acts, with choruses after the manner of the Greeks. His friends got a stage erected in the Hôtel de Reims at Paris; two poets of note in that day, Remi Belleau and Jean de la Péruse, undertook the principal male parts; and Jodelle himself, trusting to his youth, his personal beauty, and histrionic talent, personated Cleopatra. Henry II. and his court, seeing plainly that while this dramatic innovation would gratify in some degree the craving appetite of the Parisian public for theatrical exhibitions, there was little danger of its contributing to develop those truly national feelings which it was now the confirmed policy of French administrations to discourage, warmly patronized this performance; and all Paris, delighted to have once more a theatre of some sort, followed the court's example. This piece is remarkable only as being the first of its class, and so commencing a new era of French dramatic history. Jodelle was more successful in his comedy entitled 'L'Abbé Eugène,' wherein, still emulating the Italian imitations of the antients, though in the manners of his own age and country, he exhibits a libertine ecclesiastic intriguing with the wife of a simple man, and his chaplain acting the honourable part of go-between in the affair. There is much comic power and sprightliness in this play, to which succeeded his second tragedy of 'Didon,' the fate of which is not known.

From Jodelle down to Corneille, French dramatic art made little progress; but dramatic productions, in the same line of classic imitation, abounded, especially in tragedy, the heroes of which were constantly taken from Greek or Roman history, or at most from that of the Turks, who were first introduced upon the stage by Gabriel Bonnin. At this early period, indeed, of the French theatre, that singular dramatic prejudice seems to have firmly established itself, that the pomp of tragic style could not be well supported on the stage, except both costume and character were either Greek, Roman, or Mussulman. The Alexandrine verse, too, was almost invariably used; though once, and but once, was acted a prose tragedy of 'Sophonisba,' by St. Gelais. The versified comedies of the same period have nothing remarkable; but in 1562, the two brothers De la Taille began to accustom the French public to comedies in prose. Nicolas Filleul attempted unsuccessfully to naturalize pastoral poetry on the stage. All these writers had still to contend against the privileged possessors of the stage. There was not in all France a single company regularly trained for the new class of performances. Under Henry IV., the brethren of the Passion had obtained almost a revocation of the edict of 1548, which prohibited them from enacting religious subjects; but the public had now little relish for these rude exhibitions, so that the fraternity found themselves obliged to let their theatre to a more modern class of performers. The other dramatic societies endeavoured to adopt their antiquated pieces in some degree to the modern taste; and thus out of their old moralities they contrived to make pastoral pieces wherein the Church was a bride, and Christ the bridegroom. Robert Garnier rose in tragedy some little above his predecessors in elegance and dignity, and was so much celebrated in his own day as to have the pre-eminence of his tragic powers commemorated in one of the best sonnets of Ronsard. Though he usually drew abundantly from Sophocles, Euripides, and Seneca, he showed in some of his pieces more original vigour, as for instance in 'Les Juives,' taken from Jewish history. The prose comedy of intrigue (for the comedy of character had not yet appeared) continued to be cultivated with vigour and success by Pierre de l'Arivey, contemporary with Garnier. The Jesuit father Fronton attempted a tragedy on the grand national subject of 'Jeanne d'Arc,' but without success. At length, in 1600, two permanent theatres were

erected at Paris, one of which was occupied by a company which took the title of *Troupe de la Comédie Française*; the other company established itself in the quarter of Paris called the Marais, with the consent of the brethren of the Passion, and thus the old stage of the middle ages was finally extinguished in the French metropolis. Still, however, as before, the theatre took its tone from the exclusive taste of the court; and from the commencement of the sixteenth century till the appearance of Corneille, scarcely anything was brought forward but either tragedy or that very harmless description of farce which, it was thought, might without much danger be conceded to the popular taste: this is the grand era of the popularity of the well-known burlesque personages *Gros Guillaume*, *Tabarin*, and *Turlupin*, whose merry reign was protracted even into the age of Louis XIV.

Most of the tragedies of this period flowed from the exhaustless pen of Alexandre Hardy, a poet employed by the company which had succeeded to the privilege of the brethren of the Passion, and who wrote more than eight hundred dramatic pieces, of which forty remain. Possessed of very extensive reading, Hardy made some efforts to deviate from the beaten track of his predecessors: he ventured in some instances to compose what he called tragi-comedies, one of which is founded on a tale of Cervantes; but his genius was not equal to his boldness and facility. The dramatists who immediately preceded Corneille and Molière were Mairret and Tristan, the former of whom, like so many before and after him, tried and failed in the eternal subject of *Sophonisba*; while the latter failed yet more signally in the Jewish subject of *Mariamme*.

We come now to the age of Louis XIV., of which Cardinal Richelieu was the real creator in literature, as well as in politics. This great artificer of despotism, whose genius raised the French crown to a height and a solidity of irresponsible power, for the abuse of which it has dearly paid in later times, had the sagacity, which many powerful ministers have wanted, to perceive that, in order to consolidate his favourite political fabric the more, it was worth while to permanently organize the literary talent of the country in the service of the court. 'Leave us at least the republic of letters,' said Napoleon once to a poet who was showing him too much of the courtier; but Richelieu understood the matter differently; and arranged it so that his literary senate should ever remain as subservient as Napoleon's own political senate was under his imperial reign. The court, it is true, did not directly dictate to the cardinal's chosen forty in what quarters they should bestow their praise or censure; but things were so ordered that the men to whom the protectorship of letters was officially entrusted should always share more or less the tastes and opinions of the government: by the court it was that they were paid; under the eyes of the court they held their sittings; it was by court intrigue that a vacant chair was to be obtained; and every writer was ambitious of that honour.

Such was the predominant influence under which Corneille began his dramatic career. To enter the academy, he must please the court; and to please the court, he must defer to the literary dictation of the academy. Now, in dramatic composition, the academy not merely recommended adherence to the so-called rules of Aristotle, but prescribed their observance with the greatest rigidity. These same Aristotelian maxims were, indeed, in the present instance, little more than a pretext; but the far-sighted cardinal was well aware how admirably they were adapted to facilitate that strictness of surveillance, and that repression of everything like popular enthusiasm, to which his views required that this grand focus of public sympathies, the drama, should be subjected. There was, however, one serious obstacle to the complete establishment of his dramatic system, viz. the general estimation of the Spanish literature and the Spanish drama in particular, then as ascendant in Europe as those of France have been since. Familiarly cultivated and highly relished as the language and literature of Spain then were at Paris, any young dramatic writer of vigorous talents must have found himself, with all his anxiety to please the court, rather disagreeably circumstanced, between the academy and its classic code on the one hand, and the successful example of the most popular European dramatists on the other. Corneille produced six comedies and one tragedy after the antique models, before he ventured on any bolder attempt. Their great superiority in

elegance and dignity of style over those of all his French predecessors, who in this respect had remained so far behind the Italians and the Spaniards, would alone have been sufficient to ensure their success. He next produced a comedy in the Spanish taste; and shortly after ventured to give a yet more striking evidence of his romantic tendencies in his tragedy of *Le Cid*.

This vigorous experiment brought the academic code and the public taste fairly into collision; the latter decided loudly for the author, and under any other political system might have effectually supported and encouraged him in his independent views of art. But the league of the academy with the court was too strong even for his masculine resolution; and in two of his best pieces, which next followed, '*The Horatii*,' and '*Cinna*,' he returned to the Roman tragedy. In comedy, however, Corneille still borrowed avowedly from the Spanish stage. In his tragedy of '*The Cid*,' he had imitated two Spanish dramatists, Guillen de Castro and Diamante, who had both successively treated the same subject; and now, in his comedy of '*The Liar*' (*Le menteur*), he frankly and warmly acknowledged his obligations to a Spanish original, '*The Doubtful Truth*' (*La Verdad Sospechosa*), of Don Juan Ruiz de Alarcon, which was long attributed by some to Lope de Vega, by others to Francisco de Rojas, and of which Corneille himself did not know the real author. When he afterwards produced the '*Sequel to the Liar*' (*La Suite du menteur*), he owned that he drew it also from a Spanish source; we find his original in Lope de Vega's '*Loving without knowing whom*' (*Amar sin saber á quien*). Fontenelle himself, so careful of his uncle's fame, tells us, in speaking of another of his pieces, that it is taken almost entirely from the Spanish; 'for,' says he, 'at that time nearly all the plots were taken from the Spaniards, on account of their great superiority in those matters.' But Corneille's deep study of and sympathy with the Spanish dramatists appear also in the compositions more peculiarly his own; those chivalric manners, those lofty sentiments and swelling images, with which he was so familiarized, are discoverable throughout; his very Romans belong rather to the middle ages than to the old republic; and, indeed, are perhaps hardly so much Roman as they are Spanish. However, he kept himself in a feverish and constrained submission to the academy, for which he was at last appropriately rewarded with a seat among its members.

The rise of the French comedy of character, of which Molière is the great representative, is yet more clearly deducible from the Spanish source than that of their classic tragedy. The marked separation between tragedy and comedy was a fundamental article of the academic code. To that most numerous order of writers who are fitted to deal only with one of the two great classes of dramatic elements, the comic and the serious, such an injunction operates indeed rather as an encouragement than as a shackle or a clog; but when this prohibition of the mixed or truly romantic species falls upon a genius so bold and comprehensive as that of Corneille, it cripples the noblest of his powers, and shuts out from him the richest of his resources. A writer, however, having this depth and compass of genius, with that constant tendency to seriousness of purpose which ever attends them, finds it a less painful effort to abstain from the comic intermixture in tragedy than to exclude the passionate and the pathetic from comedy; and will thus, like Corneille, devote himself less to the latter than to the former. But Molière was born for the comic only, and could therefore indulge his dramatic tastes and propensities with comparatively little restraint. In his first piece, written for a strolling company, he imitated the lively trickery and buffoonery of the Italian farces, a species of composition for which, throughout his career, he showed a strong inclination. Next, in '*L'Etourdi*' and '*Le Dépit Amoureux*' he imitated the Spanish comedy of intrigue. And how he was led, by Corneille's adaptation from the Spanish, to the comedy of character, wherein he was destined to establish his fame so solidly and so durably, he himself tells us in a letter to Boileau, recently quoted by Martinez de la Rosa. 'I am much indebted,' he says, 'to "*Le menteur*." When it was first performed, I had already a wish to write, but was in doubt as to what it should be. My ideas were still confused, but this piece determined them. In short, but for the appearance of "*Le menteur*," though I should no doubt have written comedies of intrigue, as "*L'Etourdi*" or "*Le Dépit Amoureux*," I

should perhaps never have written "*Le Misanthrope*." Nor was it alone through the medium of Corneille that Molière, in his maturer compositions, received the influence of the Spanish stage: in various instances he borrowed directly from it, especially in his secondary pieces.

It is remarked by Schlegel, that when Molière in his farcical pieces did not lean on foreign invention, he still appropriated to himself the comic manner of other countries, especially that of the Italian buffoonery. 'He wished to introduce a sort of masked characters without masks, who should recur with the same name. They have never however been able to become properly domiciliated in France; because the flexible national character of the French, which imitates every mode that is prevalent for the time, is incompatible with that odd originality of exterior to which humorous and singular individuals give themselves carelessly up in other nations, where all are not modelled by the social tone after the same manner. As the Sganarelles, Mascarilles, Scapins, and Crispins have been allowed to retain their uniform that everything like consistency may not be lost, they are now completely obsolete on the stage. The French taste is, generally speaking, very little inclined to the self-conscious, drolly exaggerating, and arbitrary comic; because these descriptions of the comic speak more to the fancy than to the understanding. We do not mean to censure this, nor to quarrel about the respective merits of the different species. The low estimation in which the former are held may perhaps contribute the more to the success of the comic of observation; and in fact the French comic writers have here displayed a great deal of refinement and ingenuity: herein consists the great merit of Molière, and it is certainly very distinguished.' The highest refinement and delicacy of the comic of observation, however, consists in this, that the characters disclose themselves unconsciously by traits which involuntarily escape from them; whereas long argumentative disquisitions between the several personages are frequent in all the most admired pieces of Molière, and nowhere more so than in '*Le Misanthrope*,' which has always been cited by the French critics of the old school as the great model of French comedy; close by which they rank the '*Tartuffe*,' '*Les Femmes Savantes*,' and '*L'Ecole des Femmes*' of the same author. Molière's greater comedies, in short, are too didactic, too expressly instructive; whereas the auditor should only be instructed covertly and incidentally. It should be observed that '*The Miser*' of Molière ('*L'Avare*'), some scenes of which are taken from Plautus, is the earliest instance of a five-act French comedy written in prose.

The restrictions which cramped the genius of Corneille comfortably fitted that of Racine, and contributed to render him in every sense the favourite tragic poet of the court of Louis XIV. He seemed born to carry to the highest possible perfection what we must call, for want of a neater term that should be equally appropriate, the Frenchification of Greek tragedy. He managed with consummate art and most felicitous ease to flatter at once the dramatic taste and the moral temperament of the court. The very anomaly which his works presented, in giving to antique heroes the tone and the language of the French gallantry of his time, thus became one of their highest recommendations. Above all, his excellence in investing the expression of love, real or pretended, with conventional dignity and delicacy, was a merit invaluable in the eyes of Louis and his courtiers of both sexes. For tenderness and elegance of expression, Racine is indeed unrivalled among the French dramatists of the classic school. His high powers of this kind made him also one of the ablest appropriators and improvers of the eloquence of preceding writers in numberless scattered passages of his own productions. Among his pieces on Grecian subjects, '*Andromaque*' is that in which he displays the most originality: in this tragedy, says Schlegel, 'he expressed the inward struggles and inconsistencies of passion with a truth and energy which had never before been heard on the French stage.' And respecting '*Phèdre*,' the same critic, looking with no partial eye upon the masters of the French classic school, observes—'How much soever in this tragedy Racine may have borrowed from Euripides and Seneca, and how much soever he may have spoiled the former and not improved the latter, still it was a great step from the affected mannerism of his age to a more genuine tragic style. When we compare it with the '*Phèdre*' of Pradon, which was so well received by his contemporaries, for no other reason than because no trace what-

ever of the antients was discernible in it, but every thing reduced to the scale of a fashionable miniature-portrait for a toilette, we must entertain the higher admiration for the writer who had so strong a feeling for the antient poets, had the courage to connect himself with them, and dared to display so much purity and unaffected simplicity in an age of which the prevailing taste was every way vitiated and unnatural.' Racine's 'Britannicus' is one of those among French classic tragedies which have the highest claims to historical accuracy and delicate discrimination of character, in the persons of Nero, Agrippina, Narcissus, and Burrhus. 'In "Athalie,"' says his German critic, 'he exhibited himself for the last time, before taking leave of poetry and the world, in his whole strength. It is not only his most finished work, but I have no hesitation in declaring it, of all the French tragedies, to be the one which, free from all mannerism, approaches nearest to the grand style of the Greeks. The chorus is fully in the sense of the antients, though introduced in a different manner for the sake of suiting our music and the different arrangement of our theatre. The scene has all the majesty of a public action: expectation, wonder, and keen agitation, succeed each other, and constantly rise with the progress of the drama: with a severe abstinence from everything extraneous, there is a display of the richest variety, sometimes of sweetness, but more frequently of majesty and grandeur. The inspiration of the prophet elevates the fancy to flights of more than usual boldness. The signification is that which a religious drama ought to have; on earth, the struggle between good and evil; in heaven, the wakeful eye of Providence darting down rays of decision from unapproachable glory. All is animated by one breath, by the pious inspiration of the poet; of the genuineness of which neither his life nor this work will allow us to entertain a doubt. This is the very thing in which so many pretended works of art of the French are deficient: the authors have not been inspired by a fervent love for their subject, but by the desire of external effect; hence the vanity of the artist everywhere breaks forth, and casts a damp over our feelings.'

In the history of French tragedy, it is little gratifying to pass from Racine to Richelieu's favourite, the Abbé D'Aubignac, who revenged himself for the failure of his tragedy of 'Zénobie' by censuring bitterly the works of Corneille. Racine himself found a similar adversary in Nicolas Pradon, who wrote a rival tragedy of 'Phédre,' which Madame Deshoulières was not ashamed to extol above Racine's, and a 'Régulus,' which the praises of St. Evremond and Madame de Sévigné have not saved from oblivion. Lafosse profited somewhat better by Corneille's example in the dignity and intelligence which he threw into his otherwise feeble 'Manlius,' which Talma's acting recently made so popular. As for the tragedies of Dûché, Campistron, the abbé Pellegrin, the abbé Longepierre, and others, suffice it to say, that they brought little fame to their authors, and no advancement to the art. Thomas Corneille ventured to write tragedy after his brother, and wrote it very 'correctly.' Crébillon was by far the most successful tragic writer that arose in the interval between Racine and Voltaire; but his reputation, rapidly acquired, resting on an unsound basis, declined almost as rapidly; ever striving rather to horrify than to affect, the unnatural exaggeration both of situation and character into which he was constantly betrayed was a defect too serious to be redeemed even by the great force and mastery of style which he displays.

This species of composition occupied no small proportion of the wonderful versatility of Voltaire; and although he was irresistibly led to press the tragic muse into the service of the unceasing warfare which he waged against superstition, fanaticism, and hypocrisy, and might even owe some portion of his theatrical success to that circumstance, yet he has earned, in universal estimation, a place beside Corneille and Racine as a dramatic artist. The same independence of genius and spirit which made him rebel against other conventionalisms of graver import, prompted him to break through some of the more irksome part of the restrictions imposed by the established dramatic system. He insisted on treating subjects with more historical truth, and raised once more to the dignity of the tragic stage the chivalrous and Christian characters of modern Europe, which, ever since 'The Cid' of Corneille, had been altogether excluded from it. Thus his Lusignan and Nerestan, in 'Zaire,' are among his most true, affecting, and noble creations; and the plot of his 'Tancred' is founded on as pure

motives of honour and love without any ignoble internixture, as entirely consecrated to the exhibition of chivalrous sentiments, as that of 'Le Cid' itself. In 'Alzire,' Voltaire went still farther, treating a subject in modern history never before touched by his countrymen; and as in the pieces already mentioned he had contrasted the chivalric ideas and motives with the Saracenic, so here, with great historical truth and noble pathos, he has ventured to exhibit the old Spaniards in opposition to the Peruvians. 'It is singular enough,' remarks Schlegel, 'that Voltaire, in his restless search after tragical materials, has actually completed the circumnavigation of the globe; for, as in 'Alzire' he exhibits the American tribes of the other hemisphere, in his 'Dschingis Kan,' he brings Chinese upon the stage from the farthest extremity of ours, who, from the faithful observance of their costume, have the appearance of comic or grotesque figures.' 'As the French,' observes our German critic in another place, 'are in general better acquainted with the Romans than with the Greeks, we might expect the Roman pieces of Voltaire to be more consistent, in a political point of view, with historical truth, than his Greek pieces are with the symbolical nature of mythology. This, however, is the case only in 'Brutus,' the earliest of them, and the only one which can be said to be sensibly planned. Voltaire sketched this tragedy in England; he had learned from "Julius Cæsar" the effect which the publicity of republican transactions is capable of producing on the stage, and so endeavoured to hold in some degree a middle course between Corneille and Shakspeare;' of the latter of whom, we may add, he acquired, or at least evinced, very little in the way of due appreciation. On the whole, however, though Corneille is deemed to have expressed heroic sentiments with greater sublimity, and Racine the natural emotions with greater sweetness, it is admitted that Voltaire introduced moral motives into the drama with greater effect, and displays a more intimate acquaintance with the original relations of the mind.

Only the first and the last of these three great masters of the French tragic stage may be said to have been fruitful in this class of productions. Racine, however, has this advantage, that, excepting his first youthful attempts, the whole of his pieces have kept possession of the stage and of the public favour, while many of Corneille's and Voltaire's which pleased at first are not now even so much as read, so that it has become common to publish selections from their dramatic works under the title of *Chefs-d'œuvre*.

Voltaire seems to have come too late, even with his moderate attempts at reformation of the dramatic system. The prejudice which gave such disproportionate importance to the observance of external rules and proprieties was already immovably established; nor was it until after the great political change which took place towards the close of the last century that any considerable effort was again made to break through the academic limitations. We shall therefore pass briefly over the half century of French dramatic history which immediately followed the age of Louis XIV., notwithstanding that, during that period, upwards of fifty authors, of more or less celebrity, wrote for the higher departments of the stage, of whose pieces the greater part were actually performed, many of them with high temporary and some few with permanent success. In tragedy we shall mention nothing more than the names, for the most part now obscure, of Lagrange, Chancel, Lamotte, Piron, Lanoue, Guimond de Latouche, Châteaubrun, Saurin, and Debelloy.

La Harpe, whose critical labours had so extensively injurious an influence throughout Europe in enforcing the classic system in all its rigidity, contributed nothing to recommend it by his own tragic compositions, which, while they are among the most correct in style, are among the most frigid in sentiment and effect, although, indeed, he has the merit of having presented, in his 'Philoctète,' the most exact imitation of a Greek tragedy that France has produced. On the other hand, Marie Joseph Chénier, who, flourishing in the early days of the Revolution, wrote, like the tragic poets of Greece, in the midst of free men, and with like ardour stimulated them to the love of liberty, made nearer approaches than any of his predecessors to the tragic strength and fervid diction of Voltaire. His 'Charles the Ninth, or the School for Kings' (*École des Rois*), from which the people, too, might draw an important lesson, was that among his pieces which produced the greatest excitement in the public mind. So far, however, from stu-

diously blackening the character of the young king, he casts chiefly upon his mother-in-law and the cardinal of Lorraine the odium of the St. Bartholomew massacre, the horrors of which he depicts with unsparing energy. In his 'Tibère' he no less forcibly exhibits the interior of a hypocritical tyrant, as he does that of a fanatical one in his 'Philippe II.,' in some parts of which he has happily, but not servilely, imitated Schiller. It was in his 'Fénélon,' too, wherein he paints the miseries of the cloister, and shows Fénélon's angelic piety in admirable contrast with the fanatical passions which possess the other characters, that the young Talma, whose histrionic powers Chénier had already divined, began to make himself known to the public. Ducis, possessing brilliant powers of poetic execution, portrayed the Arabian manners, in his tragedy of 'Albucar,' with great warmth of imagination and originality of style; but his highest claim to dramatic celebrity rests upon the endeavour, which he made with considerable success, to bring his countrymen acquainted with the masterpieces of Shakspeare. Having high qualifications for this task, it is to be regretted that he felt himself bound to cramp and maim his adaptations by reducing them within the French dramatic limitations, when, by copying his English original more closely, he might have made himself a creator in French literature: still his work was most praiseworthy and important, as the first able and cordial attempt to give the French public some remote idea at least of the real merits of that transcendent genius whom Voltaire, though he made some efforts to appreciate, had remained so far from understanding as to call him deliberately 'a drunken savage.' The name of M. Arnault appears already in the dramatic annals of that period. His first tragedies, 'Marius à Miirturnes,' 'Lucrèce,' and 'Cincinnatus,' with their energetic simplicity, are in spirit and design truly antique. Gabriel Legouvé's 'Death of Abel' (Mort d'Abel) was a hazardous but successful attempt to make an antediluvian subject acceptable on a modern stage, to which he had been encouraged by the popularity which Gessner and his poetry then enjoyed. The same author ventured to exhibit, not unsuccessfully, in 'Epicharis et Néron,' the latter days of Nero, the opening of whose career is shown in one of the masterpieces of Racine. 'Les Templiers' of M. Raynouard, founded on the destruction of the order of Knights Templars in the reign of Philippe le Bel, is much more remarkable for art and correctness of structure and execution than for poetic vitality; but these merits, added to the powerful interest of its national subject, made it highly successful.

Some of the comedies of Boursault, a younger contemporary of Molière, have kept possession of the stage: they are all of the secondary description which the French call *pièces à tiroir*, of which Molière himself, in his 'Fâcheux,' gave the first example. This kind, in the accidental nature of the scenes, which are strung together on one common occasion, bear a resemblance to the *mimi* of the antients: they are particularly favourable for the display of the mimetic art in the more limited signification of the term, as it is one and the same player that re-appears throughout in a fresh character and a different disguise. The want of dramatic movement however in such productions requires they should be short, whereas Boursault's pieces, though otherwise possessing considerable merit, are drawn out to the wearisome length of five acts.

After Molière's death, a considerable time elapsed before the appearance of Regnard, to whom the second place among the French comic writers has usually been assigned. He divided his labours between the Italian theatre, which still flourished under Gherardi, and for which he sketched the French scenes, and the composition of regular comedy in verse. His earliest play, 'The Gambler' (Le Joueur), is the most esteemed: it is a picture after nature, drawn strongly, but without exaggeration, from his intimate acquaintance with the subject resulting from his personal experience. His 'Absent Man' (Le Distant), running exclusively upon the exhibition of that characteristic defect, is necessarily tedious: the author has here done little more than dramatize a series of anecdotes which La Bruyère had assembled under the name of a particular character. His 'Légataire Universel,' though exhibiting more comic power, fails through a deficiency of moral feeling. La Harpe however declares it to be a masterpiece of comic pleasantry; whereupon Schlegel remarks: 'It is in fact such a subject for pleasantry as would move a stone to pity; as enlivening as

the grin of a death's head. What a subject for mirth!—a feeble old man in the jaws of death, who is teased by young profligates for his property, and has a false will imposed on him while lying insensible, as is believed, on his death-bed.'

A contemporary of Regnard, the actor Legrand, was one of the first comic poets of his nation who acquired celebrity in versified afterpieces, a kind in which the French have since produced many elegant trifles. His posthumous fame however has been far inferior to that of Regnard; although there is one piece of his, 'Le Roi de Cocagne,' a sprightly farce in the wonderful style, overflowing with a quality then rarely found in the French drama, a native and fanciful wit, animated by the liveliest mirth, which sports about all sorts of subjects in the most frolicsome yet harmless manner. But the French critics of the old school have generally been indifferent or unjust towards any impulse of genuine fancy; confounding, it should seem, the levity of jocularly with that of mere shallowness, which has been so much complained of in their countrymen.

The eighteenth century produced a number of comic writers in France of the second and third rank, but no genius capable of advancing that department of the dramatic art a step farther, and thus the belief in the unapproachable excellence of Molière became yet more firmly fixed. 'Want of easy progress,' observes Schlegel, 'and the use of lengthened disquisitions in stationary dialogue, have characterized more or less every writer since the time of Molière, on whose regular pieces the conventional rules applied to tragedy have had an indisputable influence. French comedy in verse has its tirades as well as tragedy; which circumstance contributed to introduce into it a certain degree of stiff etiquette. The comedy of other nations has generally descended, from motives which we can be at no loss to understand, into the circle of the inferior classes: but the range of the French comedy is nearly confined to the upper classes of society. Here also we trace the influence of the court as the central point of the whole national vanity. Those spectators who in reality had no access to the great world, were flattered by having marquises and chevaliers brought before them on the stage; and the poet himself, while satirising the fashionable follies, endeavoured to snatch something of that privileged tone which was esteemed so enviable. Society rubs off the salient angles of character; its peculiar entertainment consists in detecting the ridiculous; and hence we acquire the faculty of being on our guard against the observations of others. Thus it is that the natural, cordial, and jovial comic of the inferior classes is laid aside, and another description, the fruit of polished society, and characterized by the insipidity of such an aimless way of living, comes to be substituted in its place. The object of these comedies is no longer life, but society; that perpetual negotiation between conflicting vanities which never ends in a sincere treaty of peace: the embroidered dress, the hat under the arm, and the sword by the side, essentially belong to them; and the whole of the characterization is limited to the folly of the men and the coquetry of the women. The insipid uniformity of these pictures was unfortunately too often seasoned by the corruption of moral principles which, especially after the age of Louis XIV. till the middle of the century, under the Regency and Louis XV., it became the fashion openly to avow. In this period the favourite of the women, the *homme à bonnes fortunes*, who in a tone of satiety boasts of the multitude of his conquests, too easily achieved, was not a character invented by the comic writers, but an accurate portrait from real life, as is proved by many memoirs of the last century, even down to those of a Besenval. We are disgusted at the unrivalled sensuality of the love intrigues of the Grecian comedy; but the Greeks would have thought the intrigues with married women in the French comedy, entered into merely from giddy vanity, much more disgusting. Limits have been fixed by nature herself to sensual excess; but where vanity assumes the part of a sensuality already deadened and enervated, it gives birth to the most hollow corruption. If, in the constant ridicule of marriage by the *petit-maitres*, and in their moral scepticism, especially with regard to women, the poets merely intended to censure a prevailing depravity, the picture is not therefore the less dangerous. The great or fashionable world, which in point of numbers is the small, but which considers itself as alone of any importance, can hardly be improved by it; and the example is but too seductive for the other classes, from the brilliancy with which the characters are sur-

rounded. But in so far as comedy is concerned, this deadening corruption is by no means entertaining; and in many pieces in which fools of quality give the tone, as in the 'Chevalier à la Mode' of Dancourt for instance, the picture of complete moral dissoluteness, which, though true, is both unpoetical and unnatural, is not only wearisome in the extreme, but most decidedly disgusting.

From the number of writers to whom this charge principally attaches, Destouches and Marivaux, fertile, or at least diligent, comic poets, the former in verse, the latter in prose, deserve to be excepted. They acquired considerable distinction among their contemporaries in the first half of the eighteenth century, but few of their works survived either of them on the stage.

Two other separate works are named as masterpieces in regular comedy in verse, belonging to two writers who perhaps have here taken more pains, but in other poetical departments have given freer scope to their natural talent—the 'Métromanie' of Piron, and the 'Méchant' of Gresset. The 'Métromanie' is not without humorous inspiration: in the young man possessed by a rage for versifying, Piron meant in some degree to portray himself; but as we always go tenderly to work in ridiculing ourselves, so, together with the amiable weakness in question, he exhibits in his hero talents, magnanimity, and good-heartedness: but this same tender regard is not peculiarly conducive to comic strength. The 'Méchant' is one of those gloomy comedies which might be rapturously hailed by a Timon as serving to confirm him in his aversion to human society, but on social and cheerful minds can only be productive of the most painful effects. Yet, according to the decision of the French critics, these three comedies, 'The Vainglorious Man' (Le Glorieux) of Destouches, 'La Métromanie' of Piron, and 'Le Méchant' of Gresset, are all that the eighteenth century has to oppose to Molière. To Diderot's attempts at dramatic innovation, as they were founded on false views of the objects and conditions of art in general, we shall do no more than allude. And of Beaumarchais, the celebrated of 'Le Barbier de Seville' and 'Les Noces de Figaro,' it may be said, that, under the last days of the monarchy, he assailed the corrupt society of his time with a wit no less caustic, sportive, and subtle, in his dramatic pieces, than Voltaire had employed against it in his lighter tales and essays.

In the overthrow of the *ancien régime* in politics fell the main support of the old dramatic code; yet it is remarkable, though perhaps not wonderful, that many of the warmest and firmest opponents of the former, both then and since, have clung with extreme tenacity to the latter; so strong and so binding is the force of habit, especially of literary habit, so long as the analytic powers have not been brought to bear directly and expressly upon the subject in question. Hence the revolution in French art and literature has followed but tardily the political revolution; and its first promoters have had to contend against the most formidable obstacles. However, they presented themselves early in the field. The stormy days of the Convention, and the saturnalian period of the Directory which followed them, did indeed afford little leisure or encouragement for the cultivation of the liberal arts; but no sooner were the danger and the fear of anarchy removed by the firm and vigorous administration of the Consulate, than the new literary and dramatic ideas began to develop themselves, and, in consequence, a violent war to be waged between the *classicistes* of the old school and the *romanticistes* of the new.

Among the earliest, ablest, and steadiest cultivators of the French romantic drama, the first place seems due to M. Népomucène Lemercier. In his tragedy of 'Agamemnon,' the most perfect work of the kind that had yet appeared since Racine and Voltaire, he strove, with signal success, to combine with felicity of plot and purity of style, more original and striking attractions. He penetrated far beneath the costume and the forms of antiquity, to its inmost soul and spirit: to the numerous personages, so different in their characters and their interests, whom he grouped with admirable skill, he lent their respective habits, manners, and language, with such clear and just discrimination, as to create a class of dramatic beauties, which, at that day, took the French public by surprise, while the consummate art with which they were introduced won their admiration for that which otherwise they would have regarded merely as an audacious innovation. When the first shocks of the Revolution had subsided, and, as we have already observed, literature and art once more found room to breathe, M.

Lemercier made a yet bolder step in his devoted cultivation of the *drame*, as the new species was distinctively denominated by its advocates, who characterized it as a simple adherence to the higher spirit of art, while its opponents stigmatized it as a forced and incongruous mixture of tragedy and comedy. In his drama of 'Pinto,' he ventured to unfold at once the whole romantic system; it exhibits the freest intermixture of humorous scenes with grave situations, in a most lively and varied picture of the popular emotions and the protracted anxiety of a band of conspirators, with all the vacillations, the inquietudes, the reverses, and the bursts of enthusiasm, attendant on similar attempts at political change.

We cannot better convey a notion of the course of French dramatic art from that time down to the years which immediately preceded the revolution of 1830, and of the manner in which that course was affected by the remarkable variations of political circumstances, than in the words of M. Lemercier himself, writing under the government of the Restoration, about the year 1825. (*Revue Européenne*, No. 5.) 'In former time,' says he, 'urged by that want in the public mind which made it seek to quit the *académie* routine, I strove to create, under the name of *Pinto*, a sort of *historic play*, wherein the reverse side of the court decorations should be presented to the audience; where the great and the people should speak, each in their genuine language, and show their respective absurdities in contrast. The art was gradually advancing, when its march was again embarrassed by the complication of public affairs. A fatally personal ambition erected the imperial government. Truth gave it umbrage, and therefore silence was to be imposed on her interpreters. All progress was stopped; all poetic reputation excited suspicion in a three fold police: we stood aside, and held our peace during the concerts of constrained applause. The muses are irreconcilable with tyranny: the forced silence of the former has always attested the presence of the latter; but their patience ever finds an opportunity to stigmatize this disgrace. After so many checks and vicissitudes, the obstacles accumulated by thirty years of civil discord are now united against the free progress of art, with shackles imposed by a mistaken prudence. The opposing parties, the coterie, proscribe the noblest recollections of antiquity through dread of the republican spirit: the church, whose history is so closely mingled in all modern annals, forbids the delineation even of her virtues, lest it should lead to that of her crimes. She proscribes her own sacerdotal costume, which Wolsey wears upon the English stage, and the grand-inquisitor of Madrid upon that of Vienna: she shrinks from beholding her sacred habit, not only on the cardinal of Lorraine, but even on the venerable Fénelon. Not more uncompromising was the rigidity with which Robespierre rejected the purple of royalty and the costume of count or marquis. A censorship, sprung up under the Empire, is now exercised through agents more numerous and more secretly inquisitorial: with such a censorship nothing can be portrayed, nothing can be thought; we must not even dare to remember anything. Such few sparks of the sacred fire as yet escape at rare intervals from a vessel so carefully covered up, so thoroughly smothered, go and die out in some party committee or some *bureau de surveillance*. Not that there is any reason to believe that dramatic literature is dead in France; but it is languishing, imprisoned, and has no refuge in most of the other countries of Europe, where the same causes oppose to it the same barriers as amongst ourselves. However, as the people must have spectacle, and as the appearance is to be given them when the reality is taken away, the idle are left in possession, not only of *academies* and censured journals, but of theatres—laborious manufactories wherein each individual associating himself with the mass, contributes the full amount of his most insignificant ideas, in order that the police may tolerate them, and so not prevent him from gaining his livelihood or enriching the theatrical storehouse. Hence all this painting of little vices, little oddities, little people, little commonplace minds; and all these nothings amuse, while they take its money, a nation flattered by the little compliments which form the customary burden of its theatrical *éphémérides*. And thus, by the voice of these *muselles*, singing with permission and according to orders, has it been consoled for the loss of its noblest pleasures, and diverted from its pursuit of glory and liberty by the distractions administered to its levity. Too long has the blindness of

parties converted our great theatres into so many fields for the trial of their political strength—so many arenas opened to the frantic impulses of allusion: the lapse of thirty years has not deadened this scandalous strife; and during all this time the censorship, vainly occupied in striving to defeat these malicious contrivances, has sometimes suppressed the most salutary productions, and sometimes inserted into them whole passages favourable to the reigning systems. but the public revenge themselves by rejecting the applications which self-interest has suggested, at the same time that they eagerly lay hold on those which punish this wretched exercise of a power that cannot wisely suppress anything but positive abuses. What, then, can any talent accomplish under chains at once so galling and so depressing? It is cheated of the substance, and has nothing left it but the superficial graces of versification.

The revolution of 1830 was a victory won for liberty in art as well as in politics. Since then, the higher departments of the French drama, both as to writing and acting, have been in full activity. Among the advocates and emulators of the Shakspearian *drame*, Victor Hugo has hitherto shown himself the foremost, the boldest, and the ablest. In tragedy in the more limited sense, though still of the romantic school, Alexandre Dumas and Alfred de Vigny are the most distinguished. It is the higher comedy that seems at present to be the least flourishing. Meanwhile, the classic reputation of Molière preserves his comedies on the stage, although in tone and manners they are altogether obsolete.

The serious or ideal French opera dates from the time of Louis XIV. Cardinal Mazarin, himself an Italian, had introduced into France the taste for the Italian opera. Louis too was desirous of rivalling or surpassing foreign nations in the external magnificence of the drama—in decoration, machinery, music, and dancing; these were to be used on festival occasions at court, and accordingly Molière was employed to write gay operas, and Quinault grave ones, for the music of Lulli. As Quinault is the only great poetical name in the history of the higher French opera, we refer to his article [QUINAULT] for what we have further to say of that particular species. The *opérette*, or comic opera, has been much more successfully cultivated by modern French writers, owing, in a great degree, to the substitution, in this kind, of ordinary dialogue in lieu of recitative, so unfavourable to dramatic animation. The *vaudeville*, in which the lighter dramatic writers of France have of late been so wonderfully prolific, and which so peculiarly harmonizes with the tone of good-natured gaiety in the more popular classes of that country, is but a variety of the comic opera; its essential distinction being, that it dispenses with musical composition, as the songs are set to well-known popular airs.

It is a fact worthy of attention, that the histrionic art, especially in tragedy and the higher comedy, has long been carried in France to very high perfection. Schlegel himself admits, that in external dignity, quickness, correctness of memory, and in a wonderful degree of propriety and elegance in the delivery of verse, the best French actors can hardly be surpassed.

On the whole, we must observe, there is no cause to apprehend any permanent decay of dramatic art in France. The most powerful and most salutary external stimulus that the artist can receive, more especially the dramatist, is not the merely material and pecuniary support of the public for whom he labours, but an enlightened interest and sympathy on the part of that public for his art itself; and the French people, with a livelier general susceptibility of this nature than some of their neighbours, have ever been peculiarly alive to the attractions of the stage. When, therefore, we consider the important advances which the liberated mind of France has already made in philosophy, in poetry, and especially in history; when, also, we consider that the French theatre has not been operated on by circumstances like those which in England, as we shall see, have so long created purely physical yet insurmountable obstacles to vigorous dramatic cultivation; we may fairly conclude, that the modern stage of France is destined to reach far higher and more varied excellence than even its noblest geniuses could attain under the despotic restrictions of the old dramatic system. Nor can we help remarking, that in the mean time the English critic is bound to show indulgence rather than severity to the very errors and extravagances of a rising school which so cordially and so explicitly sets up Shakspeare, if not as the god of its idolatry, yet

certainly as the object of its highest, most admiring, and most affectionate reverence, as well as its most zealous emulation.

GERMAN DRAMA.

The earliest mention of the performance of *Mysterien* in Germany appears in the 'Eulen-spiegel,' which professes to be the history of a celebrated buffoon of that name, who is stated to have lived about the middle of the fourteenth century, although the book itself is not older than the beginning of the fifteenth. We there find, amongst other elegant matters, 'How Eulen-spiegel made a play in the Easter fair, wherein the priest and his maid-servant fought with the boors.' The oldest extant German drama was written about the middle of the fifteenth century, by one Hans Rosenpluet, a native of Nuremberg. He was succeeded by two fertile writers born in the same imperial city, Hans Sachs and Ayser. Among the works of Hans Sachs we find a great number of tragedies, comedies, spiritual and temporal histories, where the prologue and epilogue are always spoken by the herald, besides merry carnival plays. All these pieces, it appears, were acted, not by players, but by respectable citizens, as an allowable relaxation, without any theatrical apparatus. The carnival plays are rather coarse, but often extremely droll, running indeed into the wildest farce, and overleaping all the bounds of reality. 'The composition,' says Schlegel, 'is respectable, and does not contain many circumlocutions: all the characters, from God the Father downwards, state at once in plain terms what they have at heart, and why they make their appearance; like those figures in old pictures, who have labels put in their mouths to assist the defective expression of the attitudes.' Allegorical personages frequently appear; and the form approaches most on the whole to what were elsewhere called Moralities.

In the first half of the seventeenth century, Opitz, regarded as the founder of the modern forms of German poetry, translated several tragedies from the antients into verse, and composed operatic pastorals after the Italian manner; but it is not known whether he wrote anything expressly for the stage. Next came Andreas Gryphius, considered as the first dramatic writer of Germany. Among his imitations and translations from various modern languages, are, a tragedy from the Flemish of Vondel, and a farce called 'Peter Squenz' (Peter Quince), which is an extension of the burlesque tragedy of Pyramus and Thisbe in Shakspeare's 'Midsummer Night's Dream.' The latter was then almost unknown beyond his own island: the learned Morhof, who wrote in the last half of the seventeenth century, confesses that he had never seen Shakspeare's works, though he was well acquainted with Ben Jonson. Even so late as the middle of last century, a German writer of some merit could institute a comparison between Gryphius and Shakspeare; though assuredly no further resemblance is traceable than this, that Gryphius, as well as Shakspeare, was fond of calling up the spirits of the departed. He seems rather to have had before his eyes the Flemish writer Vondel, whom his countrymen still call the great Vondel, while Gryphius himself has been consigned to oblivion. The plays of Gryphius are written after the French model in Alexandrines; the scene sometimes changes; and the interludes, partly musical, partly allegorical, somewhat resemble the old English masks; the author however shows little theatrical skill; nor is it even known that his pieces were actually performed. The tragedies of Lohenstein, who wrote at the same time, are of such immeasurable length as clearly to have set all representation at defiance.

'The pitiful condition of the theatre in Germany at the end of the seventeenth and during the first third part of the eighteenth century,' says Schlegel, 'wherever there was any other stage than that of puppet-shows and mountebanks, exactly corresponded to that of the other parts of our literature. We have a standard for this wretchedness when we consider that Gottsched could pass for the restorer of our literature—Gottsched, whose writings resemble a watery beverage, such as was then usually recommended to patients in a state of convalescence, from a notion that they could bear nothing stronger, by which means their stomachs become still more enfeebled. Gottsched, among his other labours, composed a great deal for the theatre. Connected with a certain Madame Neuber, who was at the head of a company of players in Leipzig, he discarded Punch (*Hanswurst*), and they buried him solemnly with great triumph. I am willing to believe that the parts of Punch,

of which we may even yet form a judgment from puppet-shows, were not always ingeniously filled up extemporarily; still Punch had undoubtedly more sense in his little finger than Gottsched had in his whole body. Punch, as an allegorical personage, is immortal; and however strong the belief of his burial may be, he still pops unexpectedly upon us, in some grave office-bearer or other, almost every day.

Gottsched and his school now inundated the German theatre, which was thenceforward to be regular by dint of insipid and diffuse translations from the French. Heads of a better description began to labour for the stage; but instead of producing really original works, they brought forth only wretched imitations; and the reputation of the French theatre was so great, that the most contemptible mannerism was as eagerly caught hold of as the fruits of a better taste. Thus, for instance, Gellert still composed pastoral plays after bad French models, wherein shepherds and shepherdesses, with rose-red and apple-green ribands, uttered all manner of insipid compliments to one another. Besides the French comedies, those translated from the Danish of Holberg were acted with great applause. This writer certainly has great merit. His pictures of manners possess great local truth; his exhibitions of depravity, folly, and stupidity, rest on an extremely good foundation; in strength of comic motives and situations he is not deficient; he is only not very inventive in his plots; the execution runs too much out into breadth. The Danes highly relish the delicacy of his jokes in their own language, but the vulgarity of his tone is revolting to our present taste; yet in the low sphere in which he moves, and in which there are incessant storms of cudgellings, it may be natural enough. Attempts have lately been made to revive him, but seldom with much success. As his chief merit consists in his characterization, which is certainly somewhat caricatured, he requires good comic actors to appear to any advantage. A few of the plays of that time, in the manners of our country, by Gellert and Elias Schlegel, are not without merit; only they have this error, that into their pictures of folly and stupidity the same wearisomeness has crept which accompanies them in real life. In tragedies, properly so called, after French models, the first who were in any degree successful were Elias Schlegel and afterwards Kronegk and Weisse. I know not whether their labours, if translated into good French verse, would appear as frigid to us as they do in German. It is insufferable to us to read verses of an ell long, in which the style seldom rises above watery prose; truly poetical expression was first created in Germany at a subsequent period. The Alexandrine, which in no language can be a good metre, is doubly stiff and heavy in ours. Thus, bad translations of French plays, with pieces from Holberg, and afterwards from Goldoni, and with some feeble German imitations devoid of any peculiar spirit, may be said to have constituted the repertory of the German stage, until Lessing appeared to commence the work of redeeming it from its long-continued mediocrity.

The sceptical and analytic spirit of Lessing was, however, more successful in reforming the theory than improving the practice of the German drama. His first original play, 'Miss Sara Sampson,' is a familiar tragedy of the lacrymose kind, in which he seems to have had before him as a model 'The London Merchant' of Lillo, better known in England under the name of 'George Barnwell.' But in 1767, his connexion with a company of comedians at Hamburg, and a periodical paper devoted to theatrical criticism which he conducted, gave him occasion to enter more deeply into the consideration of dramatic art. The boldness and acuteness with which, through this medium, he attacked the prevalent French taste in tragedy were so successful that in a short time not only the translations of French tragedies, but the German tragedies modelled after them, disappeared from the stage. He was the first who spoke warmly of Shakspeare, and paved the way for his appearance in Germany. But his faith in Aristotle, and the influence which Diderot's writings had exercised over him, produced a singular mixture in his theory of the drama. Unacquainted with the rights and the necessary conditions of poetical imitation, he desired to have in dialogue everything else a naked copy of nature. His attack on the Alexandrine measure was just; but the best critics of his country regret that he succeeded so far in his efforts to abolish all versification: hereby, say they, he opened greater facilities to that insipid affectation of nature in which so many of their later dramatic writers have indulged.

Owing to these prosaic views of art, Lessing, in the few dramatic works which he produced with great labour, and in which he proceeded for the most part on the classical principle of separating the comic and the tragic species, was much more effective in the former kind than in the latter. 'Minna von Barnhelm,' although it owed much of its extraordinary success to the allusions which it contained to the memorable circumstances of the seven years' war, is a genuine comedy of the more refined description, the whole social tone of which is peculiarly German, while its comic secondary characters are drawn with great humour. But in 'Emilia Galotti,' which exhibits the story of Virginia, transferred, by change of names and places, to modern Italy, the author has introduced the cool and prying observation of the comic writer into the province of tragedy, and the passions are acutely characterised rather than eloquently expressed. 'It is singular enough,' remarks Schlegel, 'that of all the dramatic works of Lessing, the last, "Nathan the Wise" (Nathan der Weise), which he wrote merely with a view,' as he says, 'to laugh at theologians, when his zeal for the improvement of the German theatre had pretty much cooled, should yet be the most conformable to the genuine principles of art. A remarkable tale of Boccaccio is wrought up with a number of inventions which are wonderful, yet not improbable, when we consider the circumstances of the times; the fictitious persons are grouped round a celebrated historical character, the great Saladin, who is drawn with historic truth; the crusades in the back ground, the scene at Jerusalem, the meeting of persons of various nations and religions on this oriental soil,—all this gives to the work a romantic air; while the thoughts, foreign to the age in question, which the poet has allowed himself to intersperse for the sake of his philosophical views, form a contrast somewhat hazardous indeed, but yet exceedingly attractive. The form is more free and comprehensive than in the other pieces of Lessing; it is nearly that of a drama of Shakspeare.' Here, too, the author returns to the use of versification; not, indeed, to the Alexandrine, but to the unrhymed iambic, answering to the English blank verse. 'That Lessing,' adds Schlegel, 'although possessing so independent a mind, still allowed himself in his dramatic practice to be in some measure overcome by the general inclination of his age, I infer from this, that the number of imitations of "Nathan" were very few in comparison with those of "Emilia Galotti."'

As the leading object of Goethe seems to have been to give his genius the fullest possible expression in his works, so he was indifferent as to the form, though generally preferring the dramatic. He was at the same time a warm friend to the theatre, and sometimes laboured to comply with its wants as determined by custom and the taste of the day; as, for instance, in 'Clavigo,' where he produced a familiar tragedy, in the manner of Lessing, and in 'Stella,' where he took nearly the same liberty with the old German story of Count Von Gleichen as Lessing did with that of Virginia. 'At an after period,' says Schlegel, 'he endeavoured to effect a reconciliation between his views of art and the common dramatic forms, even the subordinate, nearly all of which he ran through with single attempts. In his "Iphigenia" he expressed the spirit of the antique tragedy according to his conceptions of it, especially as to repose, perspicuity, and ideality. With the same simplicity, flexibility, and noble elegance, he composed his "Tasso," in which he applied an historical anecdote to mark the general signification of the contrast between a court life and a poetical one. His "Egmont," again, is a romantic and historic drama, the style of which steers a middle course between his first manner in "Götz von Berlichingen" and the form of Shakspeare. "Erwin und Elmire," and "Claudine von Villabella," may be called ideal operettes, breathed out so lightly and airily, that, with musical accompaniment and representation, they do but run the risk of becoming heavy and prosaic: in these pieces the noble and sustained style of the dialogue of his "Tasso" is varied by the tenderest songs. "Jery und Bätely" is a charming natural picture of Swiss manners, in the spirit and form of the best French operettes; while "Scherz List und Rache" is a true *opera buffa*, full of Italian *lazzi*. "Die Mitschuldigen" is a rhymed comedy, in the manner of common life, according to the French rules. "The Triumph of Sentimentality" ('Der Triumph der Empfindsamkeit') is a highly ingenious satire of Goethe's own imitators, inclining to the arbitrary comic

and the fancifully symbolical of Aristophanes, but a modest Aristophanes in good company and at court. At a much earlier period Goethe had, in some of his merry tales and carnival plays, completely appropriated to himself the manner of our honest Hans Sachs. Of the 'Faust,' which must be regarded as Goethe's peculiar creation, though forming so grand and remarkable a feature in the poetical literature of modern Europe, there is little to be said in immediate relation to the drama. It is well observed by Schlegel, that to exhibit that boundless and labyrinthian production on the stage, we should be possessed of Faustus's own magic staff and his formulæ of conjuration. Yet much is to be learned from it both as to plan and execution. In a prologue the poet declares why he could not accommodate himself to the demands of a mixed multitude of spectators, and so writes, as it were, a farewell epistle to the theatre.

Meanwhile, shortly after the first appearance of Goethe, a very vigorous effort had been made to bring Shakspeare upon the German stage; and Schlegel is of opinion that, in some of his most celebrated characters, tragic and comic, Schröder perhaps attained the same perfection which had been almost idolized in Garrick. The plays however had the disadvantage of appearing in cumbersome prose translations, and often in mere abstracts, with disfiguring alterations: the separate characters and situations had been to a certain degree hit, but by no means the sense of his composition.

Under these circumstances appeared Schiller, endowed with the qualities requisite for producing a strong effect on the multitude as well as on minds of higher cultivation. Though his genius was daring in the highest degree, yet in the works of his youth he was influenced by the models of Lessing, by the earlier productions of Goethe, and by Shakspeare, so far as he could understand him without an acquaintance with the original. 'The Robbers' ('Die Räuber'), wild and horrible as it is, had, as is well known, so powerful an effect as absolutely to turn the heads of some youthful enthusiasts. Notwithstanding the signal success of this and his other first attempts, Schiller became sensible of the discipline which his genius required, and threw himself, with all the natural vehemence of his character, into the task of self-cultivation. The first result was his 'Don Carlos,' wherein, with great depth of characterization and great pathetic power, the plot is so intricately complicated, and the characters philosophize so much, as to swell the work to a size incompatible with due theatrical representation. After the course of sound historical and philosophical study by which the poet next enriched his mind and enlightened his views of art, he applied himself wholly to historical tragedy, and endeavoured, by divesting himself of his individuality, to rise to purely *objective* exhibitions. In 'Wallenstein' he strove to adhere so conscientiously to historical truth, that his materials, though embracing no great didactic extent, swelled out into two plays and a rather didactic prologue: in the forms he closely followed Shakspeare, but endeavoured to confine the changes of place and time within narrower limits, and to maintain what he conceived to be a more sustained tragical dignity. 'Maria Stuart' is executed with more perfect artistical skill. In 'The Maid of Orleans' the plot is looser and less faithful to history; but its dazzling effect and rich ornaments of language gained it distinguished and deserved success upon the stage. 'The Bride of Messina' is an attempt, apparently neither judicious nor successful, to produce a tragedy romantic in substance, but antique in form. The last of Schiller's productions, 'Wilhelm Tell,' is considered by Schlegel as his best. 'Here he has wholly returned to the poetry of history: the manner in which he has handled his subject is true, and cordial, and, when we consider Schiller's ignorance of Swiss nature and manners, wonderful in point of local truth. It is true he had here a noble source to draw from, in the speaking pictures of the immortal John Müller. Within view of Tell's chapel, on the banks of the lake of Lucerne, in the open air, with the Alps for a background, this picture of heart-elevating old German manners, piety, and true heroism, might have merited performance as a solemnization of Swiss freedom five centuries after its foundation. How much farther Schiller might have carried the advancement of the German drama it is difficult to estimate, as he now devoted himself exclusively to the theatre, attained with every fresh work a higher mastery in his art, and was carried off by an untimely death in the full maturity of his mind.

The appearance of great original minds in Germany has
P C., No. 584.

always been followed by crowds of imitators. Thus an early production of Goethe's, 'Götz von Berlichingen,' wherein he exhibits, in a bold and vivid way, the manners of the latter part of the middle ages, produced a whole inundation of *chivalrous plays*, in which, says Schlegel, 'there was nothing historical but the names and other historical circumstances; nothing chivalrous but the helmets, bucklers, and swords, nor anything of old German honesty but the supposed rudeness: the sentiments were as modern as they were vulgar: from chivalry pieces they became real *cavalry* pieces, which certainly deserve to be acted by horses rather than by men.' The next place in the public favour has been held by the *family picture*, and the *affecting* or *sentimental drama*, two secondary species which Lessing, Goethe, and Schiller themselves cannot be acquitted of having encouraged, the former by precept, the two latter by the example of their earliest compositions. In these kinds (in the latter of which Kotzebue was so prolific, and for a while so popular), the essence of dramatic poetry being mistaken, a pretended moral aim is laid down; the morality appearing however in the one class of pieces under the confined shape of economy, in the other under that of sensibility; and the dramatic fruits have been correspondent to the unsoundness of such principles.

'The poetical as well as moral decline of the taste of the time,' observes Schlegel, in conclusion, 'has been attended by this consequence, that the writers who are the greatest favourites on the stage seek only for a momentary applause, regardless of the opinion of good judges and of true esteem; those, however, who, with higher aims, have both these objects before them, cannot prevail upon themselves to comply with the demands of the multitude, and when they do compose dramatically are wholly regardless of the stage: hence they remain deficient in the theatrical portion of the art, which can be attained in perfection only by practice and experience. The repository of our stage exhibits therefore in its miserable wealth a motley assemblage of chivalrous pieces, family pictures, and sentimental dramas, occasionally, though seldom, varied by works in a grander and more cultivated style, of Shakspeare and Schiller. In this state of things, translations and imitations of foreign novelties, especially of the French afterpieces and operettes, are indispensable. Owing to the worthlessness of the individual works, the fleeting charm of novelty is alone sought for in theatrical entertainment, to the great injury of the histrionic art, as a great number of insignificant parts must be got by rote in the most hurried manner, to be immediately forgotten.'

ENGLISH DRAMA.

The period in which we find the earliest traces of the general introduction of dramatic exhibitions by the clergy throughout the spiritual empire of Rome, being that in which, under the regime of the Norman conquest, the old French language and literature had full predominance in England, and a very large proportion of its clergy were of Gallic extraction, French was necessarily the original language of our religious drama; and the first pieces that it possessed were either borrowed directly from continental writers, or were composed by the Anglo-Norman clerks in the Gallic idiom. None of the dramatic manuscripts in that language, which must have been used in England for two or three centuries after the conquest, have descended to us; but in addition to the most sufficient historical evidence of the fact, some of the miracle plays that remain in English contain the plainest internal evidence of their having been closely translated from a French original. It was not until the 36th of Edward III. that the pleadings in any of the courts of law were allowed to be made in English. At the commencement of Edward's reign (as observed by Tyrwhitt in the essay on the language and versification of Chaucer, prefixed to his excellent edition of the 'Canterbury Tales') the French and English languages subsisted together throughout the kingdom; the higher orders, both clergy and laity, speaking almost universally French; while the lower retained the use of their native tongue, but also frequently added to it some knowledge of the other. Ralph Higden himself, the reputed author of the Chester miracle-plays as they now appear in English, bears a remarkable testimony (in his *Polyconicon*, B. I., c. lix.) to the manner in which the English language was impaired by the children in general being still obliged at school to construe their lessons, &c. in French, by the children of the gentry being taught to speak French from

then cradle, and by the anxiety of the commoners to talk French that they might be the more highly thought of.

We find religious dramas to have been regularly established performances in London as early as 1180. William Fitzstephen, in the introduction to his *Life of his friend and patron, archbishop Becket*, written between 1170 and 1182, tells us that London, in lieu of the theatrical spectacles and stage plays of the Romans, to which he has just before alluded, had then a holier description of plays, in the representations of the miracles worked by holy confessors, or of the sufferings wherein the martyrs had displayed their constancy.* However, from Mathew Paris (*Vita Abbatis*) and from Buloëus (*Historia Universitatis Parisiensis*) we learn that the miracle-play of 'St. Katherine' had been exhibited at Dunstable before the year 1119. According to the latter authority this play of 'St. Katherine' was not then by any means a novelty; and from a passage in the 'Annales Burtonenses,' or 'Annals of Burton Abbey,' we may infer that in the middle of the 13th century itinerant actors were well known in England.

The oldest extant specimen of a miracle-play in English is among the Harleian MSS. in the British Museum: it probably formed one of a series, and is certainly as ancient as the earlier part of the reign of Edward III.; it is founded on the 16th chapter of the apocryphal gospel of 'Nicodemus,' and relates to the descent of Christ into hell, to liberate from thence Adam, Eve, John the Baptist, and the prophets. Besides this and a few other single pieces, and a set of three plays founded on that part of the 'Acts of the Apostles' which relates to the conversion of St. Paul, there exist in this country three series of miracle-plays which go through the principal incidents of the Old and New Testaments. These are:—1. The Towneley collection, supposed to have belonged to Widkirk Abbey, the MS. of which appears to have been written about the reign of Henry VI. 2. A volume called the 'Ludus Coventrie,' consisting of plays said to have been represented at Coventry at the festival of Corpus Christi, the MS. of which is at least as old as the reign of Henry VII. 3. The Chester Whitsun plays, of which there are two MSS. in the British Museum, one dated in 1600, the other in 1607. Several specimens of Cornish miracle-plays are extant, which differ from the English in no material characteristic but that of language.

The best idea that we can give of the groundwork of these plays is by specifying the subjects of that one of the series above mentioned which is the most numerous. This is, the Coventry series, comprising 42 plays, viz.:—1. 'The Creation.' 2. 'The Fall of Man.' 3. 'The Death of Abel.' 4. 'Noah's Flood.' 5. 'Abraham's Sacrifice.' 6. 'Moses and the Two Tables.' 7. 'The Genealogy of Christ.' 8. 'Anna's Pregnancy.' 9. 'Mary in the Temple.' 10. 'Mary's Betrothment.' 11. 'The Salutation and Conception.' 12. 'Joseph's Return.' 13. 'The Visit to Elizabeth.' 14. 'The Trial of Joseph and Mary.' 15. 'The Birth of Christ.' 16. 'The Shepherds' Offering.' 17. (Wanting in the MS.) 18. 'Adoration of the Magi.' 19. 'The Purification.' 20. 'Slaughter of the Innocents.' 21. 'Christ disputing in the Temple.' 22. 'The Baptism of Christ.' 23. 'The Temptation.' 24. 'The Woman taken in Adultery.' 25. 'Lazarus.' 26. 'Council of the Jews.' 27. 'Mary Magdalen.' 28. 'Christ Betrayed.' 29. 'Herod.' 30. 'The Trial of Christ.' 31. 'Pilate's Wife's Dream.' 32. 'The Crucifixion.' 33. 'Christ's Descent into Hell.' 34. 'Sealing of the Tomb.' 35. 'The Resurrection.' 36. 'The Three Marys.' 37. 'Christ appearing to Mary Magdalen.' 38. 'The Pilgrim of Emaus.' 39. 'The Ascension.' 40. 'Descent of the Holy Ghost.' 41. 'The Assumption of the Virgin.' 42. 'Doomsday.'

There is abundant evidence that the Romish ecclesiastics, in their first introduction of this kind of representations, especially that part of them relating to the birth, passion, and resurrection of Christ, had the perfectly serious intention of strengthening the faith of the multitude in the fundamental doctrines of their church; and it seems the less extraordinary that they should have resorted to this expedient, when we reflect that before the invention of printing, books had no existence for the people at large. But it is no less certain that the repetition of these exhi-

bitions rapidly worked upon the popular mind an effect which, it is likely, the priestly dramatists themselves had not contemplated in the first instance: it developed the universally latent passion in the breast of social man for spectacle in general, and for dramatic spectacle especially, *for its own sake*. Here, again, was the strongest encouragement of all for the clergy to persevere in their dramatic efforts. Finding the lively pleasure which the people took in this mode of receiving religious instruction, they were attempted to add, according to their barbarous ability, embellishment after embellishment to the simple copies which they had originally presented of the most remarkable passages of Scripture story, until the profane exhibition itself, 'the miracle play,' and not the sacred subject of it, became the sole object of interest to the people who composed the audience at these representations, as, also, it certainly became the primary object of the greater part of the ecclesiastics who took part in getting them up. These two facts are shown with the utmost clearness by the collective testimony of all the contemporary writers who have thrown a general light upon the manners of the later middle ages.

These considerations will sufficiently account for one remarkable contrast, amongst others, which the early drama of modern Europe presents to the early Greek drama, though both flowed directly from a religious source; that while in the latter a groundwork drawn from human history was adorned and elevated by mythological intermixtures; in the middle-age drama, on the contrary, the basis or substratum was religious, but soon became so much overlaid with allusions to actual life, and with sketches of manners, and even of character, drawn from the actual society, as to leave scarcely a trace of that solemnity which must in the beginning have been intended to characterize the performance. The proclamation of the Chester plays, which was read over in various parts of the city on St. George's day, before the commencement of the performances, expressly excuses the introduction of 'some things not warranted by any writ,' on the ground that it was done 'to make sport' and to 'glad the hearers.'

The dialogue in these productions was, for the most part, extremely rude and inartificial; and as to plot, they cannot properly be said to have had any. It is not until the middle of the sixteenth century that we arrive at a scriptural play having anything approaching to a regularly constructed dramatic action. In this respect the series of plays which we have been considering should rather be described as a series of shows or pageants exhibited in succession, but without any artificial connection. Each of these detached divisions of the representation was indeed commonly called a 'pageant'; and each succeeding play or pageant of the series was supported by a new set of performers. Thus, to get up one of these extensive sets of plays, it was necessary to provide and to prepare a large number of actors; and here we see one manifest reason why this longer class of performances was almost wholly confined, in England as well as on the continent, to the larger cities.

The seasons for exhibiting the grand scriptural plays were chiefly the Christmas and the Whitsun holidays. The getting up and acting of these in the great cities early devolved upon the trading companies, each guild undertaking a portion of the performance and sustaining a share of the expense. The authentic information regarding the exhibition of the Corpus Christi plays at Coventry extends from the year 1416 to 1591, during the whole of which period there is no indication that the clergy in any way co-operated. The Chester records likewise establish that the whole management of these representations there was in the hands of laymen. From Stow's Chronicle we learn that in London this class of performances was undertaken by the parish clerks (who were incorporated by Henry III.) as early as 1409; and it is remarkable that no instance is to be found of the trading companies of London having been, at any date, so engaged. The pieces were acted on temporary erections of timber, called scaffolds or stages; and it appears that in some instances they were placed upon wheels, in order that they might be removed from one part to another of a large town, and so the plays might be repeated successively in various quarters. Some of the Chester pieces required the employment of two, and even of three scaffolds, besides other contrivances: the street also must have been used,

* The reader may like to see this very remarkable passage as it stands in the original text; the words are these: 'Lundonia pro spectaculis theatralibus, pro ludis scenicis, ludos habet sanctiores, representationes miraculorum que sancti confessorum operati sunt, seu representationes passionum quibus claruit constantia martyrum.'

as several of the characters enter and go out on horseback. The same remark is applicable both to the *Widdikirk* and the *Coventry* plays. In the latter indeed 'the place' and 'the mid place' are mentioned as the scene of part of the action; and it is evident from some of the stage directions, that two, three, and even four scaffolds, were erected round a centre, the performers proceeding, as occasion required, from one stage to another across 'the mid place.' It may be observed, too, that in one of the *Widdikirk* plays Cain is exhibited at plough with a team of horses; and that in another it is absolutely necessary that something like the interior of a cottage should be represented, with a peasant's wife in bed, who pretends to have been just delivered of a child, which lies beside her in a cradle.

These exhibitions however of long 'successions of Scripture pageants form a kind of exception to the general footing of the drama in those ages. The dramas which still most generally prevailed were those which proceeded originally from two distinct though kindred sources, which may be thus described. The first was the desire to impress the minds of the people in a vivid manner with those fundamental points of Scripture history which the greater festivals of the Christian church were established to celebrate, by exhibiting before them, especially during the seasons of Christmas and Easter, a living representation of the subject of celebration at that particular time. The second was the desire to strengthen and maintain the people's devotion to the patron saint of the church of their particular locality, by exhibiting on his feast-day a lively representation of his most remarkable actions or sufferings. To these two classes of performances the ecclesiastical establishments, not only of the cathedrals and monasteries, but of a great many parochial churches, were quite equal; and accordingly they continued to be generally prevalent in England until the commencement of the Reformation, and did not entirely cease until its complete establishment. From first to last, the clergy were not only the authors of the pieces exhibited within the churches, but were also, without any liability to ecclesiastical censure, the actors in or managers of the representations. But they did not long confine the exercise of their histrionic powers either to the consecrated subjects or within the consecrated walls. They soon partook of the dramatic passion which they had indirectly awakened, and came to like both plays and playing for their own sake. In Burnet's History of the Reformation we find that, so late as 1542, bishop Bonner had occasion to issue a proclamation to the clergy of his diocese, prohibiting 'all manner of common plays, games, or interludes, to be played, set forth, or delivered, within their churches and chapels.' And from the following passage of a tract printed in 1573 it appears that even then interludes were occasionally played in churches: the author is describing how the clergy neglect their duties: 'He againe posteth it (the service) over as fast as he can gallop; for either he hath two places to serve, or else there are some games to be played in the afternoon, as lying for the whetstone, heathonische dauncing for the ring, a beare or a bull to be bayted, or else jack-an-apes to ride on horseback, or an enterlude to be played; and if no place else can be gotten, it must be doone in the church.' In proof also, that in the early part of the same century ecclesiastics still exhibited themselves as common players, we see, among many other evidences, that in 1519 Cardinal Wolsey found it necessary to insert an express injunction against this practice in the regulations of the *Canons Regular of St. Austin*.*

Miracle plays were acted very constantly at Chester until 1577, at Coventry until 1591, at York until late in the sixteenth century, at Newcastle until 1598, at Lancaster, Preston, and last of all at Kendal, in the beginning of the reign of James I. Although, in the beginning, these plays only dramatised certain scriptural events by the characters historically concerned, yet abstract impersonations found their way into them by degrees. This was perhaps done to introduce some variety into the constant repetition of the same sets of *dramatis personæ*. Among the first innovations of this kind were the representatives of Truth, Justice, Peace, and Mercy, in the 'Parliament of Heaven,' which forms part of the eleventh play or pageant of the *Ludus Coventrie*. Death, in the same series, was a subsequent addition; and the Mother of Death, a still later enrichment; until at length such characters as 'Renfin' and

'Lyon' were employed, having more of individuality, but still personifying the passions supposed to have actuated the Jews against Christ. As such characters became more numerous, they interfered in a certain degree with the progress of the action; in some pieces the scriptural characters fell quite into the back-ground; and thus, in course of time, what seems to have been at first designed as a sort of poetical embellishment to an historical drama became a new species of drama unconnected with history. This was called a 'moral' or 'moral-play,' the object being to enforce and illustrate some ethical precept; for it must be observed, that the term 'morality,' as applied to a dramatic production, is, like 'mystery,' of comparatively recent introduction into our language. Some manuscript productions of this class have been lately discovered, which show that moral-plays were in a state of considerable advancement early in the reign of Henry VI. They seem to have reached their highest perfection under Henry VII., although they afterwards exhibited a greater degree of ingenious complication. In the reigns of Henry VII. and VIII., a company of actors usually consisted of only four or five individuals; but by doubling some of the parts, they were able to perform the greater number of the dramatic entertainments then in fashion.

Besides allegorical personages, there are two standing characters very prominent in moral-plays, the Devil and the Vice. The Devil was no doubt introduced into moral-plays from the old miracle-plays, where he had figured so amusingly that his presence was indispensable in the new species of drama; and accordingly we find him acting as leader of the Seven Deadly Sins in one of the most ancient moral-plays that have been preserved. He was made as hideous as possible by the mask and dress which he wore; and from various sources we learn that his exterior was shaggy and hairy, so that in one piece he is mistaken by one of the characters for 'a dancing bear.' His 'bottle nose' and 'evil face' are repeatedly mentioned; and that he was not without a tail is evident from the circumstance that in one place the Vice asks him for a piece of it to make a fly-flap. His ordinary exclamation on entering was 'Ho, ho, ho!' and on all occasions he was given to roaring and crying out, especially when, for the amusement of the audience, he was provoked to it by castigation at the hands of the Vice, by whom he was generally, though not invariably, accompanied. As for the Vice himself, his name appears to have been derived from the predominant nature of his character, as amidst all his varieties of form, he is constantly represented as most wicked in design. As the Devil now and then appeared without the Vice, so the Vice appeared sometimes without the Devil. Malone tells us, that 'the principal employment of the Vice was to belabour the Devil;' but, though frequently so engaged, he had also higher functions. He was never introduced into the miracle-plays until after the reign of Mary; but in 'The Life and Repentance of Mary Magdalen,' which appeared in 1567, we find him performing the part of her lover, before her conversion, under the name of Infidelity; in which character he assumes various disguises, and successfully recommends to her 'not to make two bells instead of one,' but to live merrily in this world, since she is sure to be damned in the next. In 'King Darius,' dated 1565, he likewise acted a prominent part, under the name of Iniquity, by his own mischievous impulses, without any prompting from the representative of the principle of evil. Such was the general style of the Vice; and as Iniquity we find him spoken of by Shakespeare and Ben Jonson. Sometimes, however, the Vice and Iniquity seem to have been two distinct personages; and the former was not unfrequently called by the name of some particular vice. In the moral-plays, as in the miracle-plays before them, the comic ingredients were made to predominate more and more over the serious; and the Vice became a standing vehicle of grosser and more thorough buffoonery than the Devil himself. Thus it was that he came to be so completely confounded with the character of the domestic fool, as to be very commonly dressed in the fool's parti-coloured habit, wearing his dagger of lath. It appears to have been a very common termination of the adventures of the Vice for him to be carried off to hell on the Devil's back. In 'King Darius,' he runs thither of his own accord, to escape from Constancy, Equity, and Charity. It seems, also, that he was in the habit of riding and beating the Devil at other times than when he was thus forcibly carried off to punishment.

* The original MS. is in the British Museum, Cotton MS. Vesp. F. ix. It is printed in Wilkins's *Concilia*, iii. 687.

The mechanical contrivances used for the representation of moral-plays differed in no material point from those employed in the religious exhibitions which they gradually superseded; except that, in general, there seems to have been only one scaffold or stage, which was erected either in a street or on a green adjoining a town or village, sometimes in the public hall of a city or borough, and sometimes in a great private mansion.

One of the most curious of the later moral-plays was written in defence of dramatic exhibitions in general, in answer to a tract against them by Stephen Gosson, called 'The School of Abuse,' and published in 1579. This piece, entitled 'The Play of Plays,' was acted at a theatre in Shoreditch about 1580. A considerable portion remains of a still more remarkable production of this class, which must here be noticed as being the only one that we can trace as having had an object openly and entirely political: it seems to have been designed to illustrate and enforce the right rules of government for the good of a nation at large, and there is reason to suppose that it was suppressed immediately after its first performance. The portion preserved, about one-third of the whole, is in the Duke of Devonshire's collection, and consists of twelve closely-printed quarto pages, apparently of the date of 1566. From this fragment we gather that among the characters of the play were the following:—Albion, personified as a knight; Justice; Injury, who seems to have been the Vice of the piece; Division, and his two ministers Double-Device and Old-Debate; Temporality and Spirituality; Principality and Commonalty; Sovereignty, Peace, and Plenty. In the commencement of it, Injury, under the assumed name of Manhood, ingratiates himself with Justice and Albion, and endeavours to persuade the latter, amongst other things, that salutary acts of parliament are not enforced as they ought to be, but allowed to sleep, because they touch the lords spiritual and temporal, so that, although passed to benefit merchants and the commonalty, the great declare them only 'fit to wipe a pan.' In like manner, Division sends his agents to sow dissension, on the one hand, between the lords spiritual and the lords temporal, on the other between Principality (personifying the sovereign authority) and the Commons. But, although there is every appearance that the author made his play terminate in the defeat of the scheme of Injury and Division, and the happy union of Albion and Plenty, yet it is manifest that the Vice of the play was here made use of to cover some serious strokes of satire and reprobation against the political abuses of the time, involving the most important principles of constitutional government, and rendering this unique and mutilated piece a very interesting feature of our old dramatic literature, and an illustration of the various uses to which the stage was turned while no periodical press yet existed.

The moral-plays now extant are classed by Mr. Payne Collier (*Annals of the Stage*, &c.) in the following divisions:—1. The curious manuscript specimens formerly in the collection of Dr. Cox Mâcro, and now in that of Hudson Gurney, Esq., which are much more ancient than any others yet discovered. 2. Printed moral-plays, the lesson enforced by which relates to the vices and regeneration of mankind at large. 3. Such as convey instructions for human conduct of a more varied character. 4. Pieces belonging to the class of moral-plays, but making approaches to the representation of real life and manners.

The performance of moral-plays was not wholly discontinued until the end of Elizabeth's reign; and one of the last dramatic representations that she witnessed was a piece of this kind, 'The Contention between Liberty and Prodigality,' played before her in the 43rd year of her reign. Attempts had however been very early made to invest even symbolical representatives with metaphysical as well as physical peculiarities, and attract for them a personal interest; and thus it was that even in the allegorical species, the nature of which would seem to have least admitted of such modification, advances more and more decided were successively made towards individuality of character, and consequently towards the representation of actual life. Hence nearly all the later moral-plays exhibit a strange mixture of individual characters with allegorical impersonations, which, however, with all its violent incongruity, was a necessary step in the progress towards the modern drama, the drama of human passions and manners.

The first English dramatic productions in which it was attempted to exhibit sketches from actual life without any

scriptural, saintly, or allegorical intermixture, belong to that class to which the denomination of *interludes*, though it has had a more general application, most properly and distinctively belongs. These pieces being, as their name imports, expressly designed for performance during the intervals of convivial entertainment, the first condition of their structure was that the limits should be brief and the characters few. The historical play of 'Sir Thomas More,' written towards the close of the reign of Elizabeth, and extant among the Harleian MSS., shows very exactly the time, form, and manner of such representations. Sir Thomas More there gives a splendid supper to the lord mayor of London, the aldermen, their wives, &c.; and four men players and a boy (the latter taking, no doubt, the female parts) having heard of the intended banquet, tender their services in order to vary the amusements. Sir Thomas declares that it 'will be excellent to have a play before the banquet,' and asks the actors what pieces they can perform. In answer, they run over the titles of six different pieces, out of which Sir Thomas chooses the one entitled 'The Marriage of Wit and Wisdom.' Its representation accordingly commences, as a play within a play, and is continued until there occurs an accidental interruption. The piece selected by Sir Thomas More on this occasion was evidently of the class of 'morals,' and so do all the pieces acted by way of interlude appear to have been until the reign of Henry VIII.; so much was this the case, that the very terms 'moral' and 'interlude' came to be generally confounded. John Heywood, a musician of Henry's household, set the first example of composing interludes quite independently of allegorical materials.

Among the pieces of Heywood's that have come down to us, the three which alone can strictly be termed *comic* are directed against the vices of the clergy, and more especially of the holy mendicants who swarmed over the land under the names of friars and pardoners. They have much of the genuine humour as well as broad satire of Chaucer's comic pictures wherein the same characters so prominently figure; and indeed it should here be borne in mind that, in the same spirit which favoured the production of these satirical interludes, Henry, when his thoughts had begun to tend towards ecclesiastical reform, patronized the first printed edition of 'The Canterbury Tales.' In the earliest of the pieces in question, 'A mery play betwene the pardoner and the frere, the curate and neybour Pratte,' Leo X., whose remarkable indulgence to similar compositions we have already had occasion to mention, is spoken of as still living. A pardoner and a friar have each obtained leave of the curate to use his church; the former to exhibit his relics (among which he shows 'the great toe of the Holy Trinity'), the latter to deliver a sermon, their common object being the raising of money. The friar arrives first, and is about to commence his discourse, when the pardoner comes in and disturbs him; each desires to be heard; and after many vain attempts by force of lungs, they proceed to kick and cuff each other unmercifully. The curate, called by the disturbance in his church, endeavours, without avail, to part the combatants; he therefore calls in neighbour Pratt to his aid; and while the curate seizes the friar, Pratt undertakes to deal with the pardoner, in order that they may set them in the stocks. Both friar and pardoner, however, prove too strong for their assailants, and the latter, after receiving a sound drubbing, are glad to allow the former quietly to depart. In the course of the piece, the friar, pardoner, and curate deal out the most furious oaths, and neighbour Pratt is the only decently-spoken man of the party. In 'The Four P's' (that is, the Palmer, the Pardoner, the Poticary, and the Pedlar), the question at issue among them is, which shall tell the greatest lie. And in the 'mery play between Johan the husbunde, Tyb his wife, and syr Johan the preest,' the nature of the plot will easily be divined, especially by such as are acquainted with Chaucer's comic tales. Heywood's play of 'The Weather' was written to illustrate a point of natural philosophy, and vindicate Providence in its distribution of the seasons. Perhaps, too, he should be regarded as the inventor of another species of composition, dramatic in so far as that it was conducted in dialogue and recited in public, but without plot, being merely a discussion in verse, between two or more characters, of some particular topic or opinion. This sort of production being little calculated for popularity, it is not surprising that but one specimen of it by him has descended to us, and that in manuscript. The point de-

bated in this colloquy, which would occupy about three quarters of an hour in the delivery, is whether a fool or a wise man be the happier; and though the conclusion eventually come to is in favour of the latter, it is remarkable that Will Somer, the fool of Henry VIII., is often mentioned in the course of the dialogue as illustrating the advantage of being without understanding and education.

The only extant English interlude from real life in which the tragic element predominates, was designed, its title tells us, to show 'as well the beauty and good properties of women, as their vices and evil conditions,' contrasting the character of the heroine Melibea with that of Celestina, a sort of compound of prociress and sorceress, who is hired by Melibea's lover to corrupt her, in which, after using extreme art, she succeeds; and the piece ends with exhibiting the bitter grief and repentance of the heroine. It is founded on the famous Spanish 'Celestina,' which we have already described as a long dramatic dialogue rather than a drama; but though the English piece has some vigour, it altogether wants those subtle graces which gave so wide a popularity to its foreign prototype.

It must here be observed, that in the literature of the later middle ages the term 'tragedy' was used to denote any serious narrative in verse. In his treatise *Della Volgare Eloquenza*, Dante speaks of it as denoting elevation of style ('per tragediam superiorem stilum induimus'); and he modestly names his own great poem *comedia*, while, in its 21st canto, he terms Virgil's *Æneid*, in his admiration, *una tragedia*. Bojardo, at a later date, calls his romantic poem a 'comedy,' comparing it with Homer's 'tragedy,' the *Iliad*. To the like effect is Chaucer's definition of tragedy in 'The Monke's Tale,' and consistently with it Lydgate calls his 'Fall of Princes' a series of 'tragedies.' Churchyard wrote several elegies which he terms tragedies; and Markham, so late as 1595, published 'the tragedy of Sir Richard Greenville,' an heroic poem in octave stanzas. Bishop Bale was the first to apply the denominations 'tragedy' and 'comedy' to dramatic productions in English: he calls 'God's Promises,' one of his own printed religious plays, a tragedy; and a series of plays from the life of Christ, one of which, 'The Temptation,' is also extant in print, he terms comedies. None of these however differs in any essential respect from the previous miracle-plays: they were all printed abroad in 1538; and it is to be remarked of them that they contain the first extant attempts to promote the Reformation by means of the stage. Besides religious plays of the beginning of Elizabeth's reign connected in subject and acted in succession, several dramas were written and printed at the same period upon separate stories and incidents in the Bible, complete in themselves, and apparently performed without reference to any other pieces that might precede or follow them. One of the most remarkable of these is 'The Life and Repentance of Mary Magdalen,' already mentioned, printed in 1567, and apparently written after the Reformation was completed.

'A newe, mery, and wittie comedie or enterlude, treating upon the historie of Jacob and Esau' (apparently written about 1557, but not printed till 1568), though its subject is scriptural, makes nearer advances to the structure and general character of a modern play than any piece that preceded it. In addition to the scriptural characters, it has, of the author's invention, Ragau, servant to Esau; Mido, a boy who leads blind Isaac; Hanon and Zethar, two of Isaac's neighbours; Abra, a girl who assists Rebecca; and Debora, an old nurse. Here indeed we have a five-act play, with a plot regularly constructed, characters discriminated and contrasted, and a versification, for that period, vigorous and flowing, while the comic portions of the piece have humour independent of coarseness.

The general tenor of the last-mentioned play is tragic, or at least decidedly serious. In the earliest piece of equal dimensions and regularity of structure that can properly be termed a comedy we have also the first avowed dramatic imitation, in English, of the antients. This is 'Ralph Roister Doister,' which was certainly in being as early as 1551, and probably written as early as the reign of Henry VIII. The former existence of such a piece had long been known, when in 1818 a printed copy was discovered, of which a limited reprint has been made. The author was Nicholas Udall, who died after 1564, having been master, first of Eton and afterwards of Westminster School. Warton (*Hist. Eng. Poet.* iii., 213) quotes from the antient Constatudinary of Eton School a passage importing that yearly,

about St. Andrew's day, November 30, the master was accustomed to select, according to his own discretion, such Latin plays as were best and fittest to be acted by the boys in the following Christmas holidays, with scenic decorations, before a public audience; and that sometimes also he ordered the performance of plays in English, provided that he found any with sufficient grace and wit. The author of the piece in question calls it, in his prologue of four seven-line stanzas, a 'comedie or enterlude;' the latter, as we have already intimated, being at that date the ordinary appellation for a dramatic production in general; so that, in employing also the less usual term 'comedy,' Udall seems to claim to have his play regarded as of more *regular* and *classical* construction, making at the same time express reference to the works of Plautus and Terence, as precedents which he had endeavoured to imitate. The scene of this comedy is laid in London; and it is in a great degree a representation of the manners and notions of the middle classes of the metropolis at that period. It is divided into acts and scenes, has nine male and four female characters, and the performance must have occupied two hours and a half, while few of the moral-plays would require more than an hour, for of those which were in two parts each part was exhibited on a separate day. The plot is amusing and well constructed, with an agreeable intermixture of serious and humorous dialogue, and a variety of character to which no other English play of a similar date can make any pretension. Another comedy, of the like dimensions and general structure, has lately been discovered in manuscript. It is entitled 'Misogonus,' and the author was apparently one Thomas Rychardes. The scene is laid in Italy, and the piece was probably founded on some Italian tale or play; it represents however the manners of England, and has many allusions to the circumstances of the day: although the plot is simple, there is much variety of situation and character; and it is worthy of remark that, under the name of *Cucurgus*, the qualities and functions of that important personage, the domestic fool, are more distinctly as well as amusingly exhibited than in almost any other of our old plays. This piece is ascertained to have been composed about 1560. It is certain that the former of these two comedies, and extremely probable that the latter, preceded the production of 'Gammer Gurton's Needle,' which all our literary and dramatic antiquaries before Mr. Collier have spoken of as the earliest English comedy, though, when it was acted at Christ's College, Cambridge, in 1566, its author, Still, afterwards bishop of Bath and Wells, was only in his twenty-third year. In merit it is far inferior to the pieces just mentioned; 'the writer,' as Warton observes, 'has a degree of jocularity which sometimes rises above buffoonery, but is often disgraced by lowness of incident.' The dialogue too is for the most part in the broadest provincial dialect, not in any respect exhibiting a specimen of the ordinary language of the time. This however appears to be the first existing English play that was acted at either university; and it is a singular coincidence that its author should have been the very same person who, many years after, when become vice-chancellor of Cambridge, was called upon to remonstrate with Queen Elizabeth's ministers against the having an English play performed before her at that university, as unbefitting its learning, dignity, and character.

The earliest extant piece in English that can now with any propriety be termed a tragedy, was written by Thomas Sackville (afterwards Lord Buckhurst and Earl of Dorset) and Thomas Norton, a barrister; and was acted before the queen at Whitehall, on the 18th of January, 1561. In the first and third printed editions it is called 'The Tragedy of Gorboduc,' from the name of a supposed antient British king; but in the second it is entitled, more correctly, 'The Tragedy of Ferrex and Porrex,' from those of his two sons, who contend for sole possession of his kingdom after he has divided it between them. A dumb show precedes each of the five acts, prefiguring what is to occur: the first four acts are closed by choruses in rhyme, and the fifth by a didactic speech of nearly two hundred lines. Sir Philip Sidney, who, in his 'Apology of Poetry' (written about 1583) maintains the fitness of observing the antique unities, though complaining that those of time and place are neglected in 'Ferrex

* It should be remarked that in our oldest tragedies these dumb shows were not always typical of the ensuing incidents: they sometimes served to introduce compendiously such circumstances as could not be conveniently included in the actual performance, and sometimes they supplied deficiencies, or covered the want of business on the scene.

and Porrex,' admits that it is 'full of stately speeches and well-sounding phrases, climbing to the height of Seneca his stile, and full of notable morality, which it doth most delightfully teach.' It is not indeed surprising that this first attempt to imitate or emulate the regular or classic tragedy should have been highly extolled at the time, especially by those who inculcated by formal precept a general imitation of the antique models; but certain it is, that, both as to incident and dialogue, the piece is laboriously heavy; the speeches are of most tedious length, and the thoughts and sentiments very trite and commonplace. It is however worthy of especial notice, that this was the first play in the English language the dialogue of which was written in blank verse. This, again, in all probability was owing to the earnest endeavour which the authors were making to follow the method of the antients. This tragedy was followed almost immediately by 'Julius Cæsar,' the earliest instance on record in which events from the Roman history were dramatised in English, although the precise nature of this performance, of which we have nothing but the mention in an old MS. chronicle, cannot be ascertained. It is doubtful, however, whether both these pieces were not preceded by a tragedy founded on Luigi da Porto's famous tale of 'Romeo and Juliet.' From about this date until shortly after 1570, the dramatic field seems to have been pretty equally divided between the later moral-plays and the earlier attempts in tragedy, comedy, and history. In some pieces of this date and a little later, as already shown, endeavours were made to reconcile or combine the two kinds of composition; but afterwards the morals generally gave way to the more popular and intelligible species of performance. We find precedence given to the latter in the license to James Burbage and others in 1574, in its mention of 'comedies, tragedies, interludes, and stage-plays'; and in the act of common council of the following year against theatrical performances in the city they are designated as 'interludes, tragedies, comedies, and shows.'

Still the terms tragedy and comedy, in general acceptance, remained far from the strictness of signification attached to them by the professed inculcators, by example or precept, of the imitation of the antients. It is observable, however, that comedy was from the beginning used in a more comprehensive sense than tragedy, being in fact very often employed as synonymous with the general designation of play. It is plain, even from the instances we have already cited, that, for a long period, any play might without impropriety be termed a comedy, though none but a serious piece was ever called a tragedy. Hence it was, that, as late as 1578, Thomas Lupton called his moral-play of 'All for Money' both a comedy and a tragedy; and hence it is, that Shakspeare makes Hamlet, after he has had the tragedy exhibited before the king and queen, exclaim,

'For if the king like not the comedy,' &c.

Not only, however, was the tragic element, as we here see, by no means excluded from what was at that time understood as comedy; but the comic, as we find, both from examining the productions of the time, and from the testimony of the contemporary critics, was employed without reserve in tragedy. Thus Sir Philip Sidney, the most distinguished at that day among the English champions of the classic school, in his 'Apology of Poetry,' written, as already mentioned, about 1583, after inveighing severely against the total disregard, by the English dramatists, of the unities of time and place, felt himself called upon to add:—'But besides these gross absurdities, how all their plays be neither right tragedies nor right comedies, mingling kings and clowns, not because the matter so carrieth it, but thrust in the clown by head and shoulders, to play a part in majestic matters with neither decency nor discretion; so as neither the admiration and commiseration, nor right sportfulness, is by their mongrel tragi-comedy obtained.'

Small as is the value now-a-days of this critical opinion of Sidney's, it affords an interesting and conclusive testimony as to the essentially romantic character of the rising drama, which we thus find it to have thoroughly, and, as the classic advocates deemed, incorrigibly, assumed at least ten years before Shakspeare, who by some has been supposed to have impressed that character upon it, became an original writer for the stage. The vast variety of matters embraced by the dramatists of that day, and of sources from which they drew, is perfectly expressed in the prologue to the 'Royal King and Loyal Subject,' one of the earlier pro-

ductions of Thomas Heywood, who became a writer for the stage some years before the death of Elizabeth.

Sidney says nothing of the performance of miracle plays in his time; but we know from many other authorities, that while the romantic drama was thus establishing itself, and moral-plays were still frequently exhibited, pieces founded on Scripture history continued to be represented. The latter, however, already confined chiefly to country places, soon ceased altogether; nor have we any specimen of what can strictly be termed a moral-play subsequent to the death of Elizabeth.

We have now traced the progress of the English stage from its ecclesiastical and religious origin until it became almost exclusively a mirror of actual life, and attained all those dramatic and theatrical forms which most prominently characterized the later and fuller maturity of our elder modern drama. It was in the same year, 1583, wherein Sidney wrote his 'Apology,' that Elizabeth first allowed a public company to act under her name and authority. As the dramatic writers who flourished in the brief interval between this period and that of the fullest development of Shakspeare's genius, with one exception, did nothing importantly to alter or improve dramatic art, it is needless to enlarge upon the various kinds and degrees of merit which made a number of them, as Kyd, Lodge, Greene, Lyly, Peele, Nash, Chettle, Munday, Wilson, &c., highly popular and celebrated in their own time. Immediate predecessors of Shakspeare, they have long been lost, necessarily and deservedly, 'in the near effulgence of his blaze.' The single exception that we are called upon to make is in favour of Christopher Marlow, of whom we must observe, not only that his works exhibit greater vigour both of conception and of language than belongs to any of his contemporaries, but also that he was the first who established the use of blank verse upon the public stage, in lieu of that exclusive rhyming which possessed it before he wrote.

The collection of Shakspeare's plays, as commonly printed, affords the grandest and most instructive study possible of the progress of the romantic drama from the crudeness of its early state to the blended richness of its full maturity. In this view, even those pieces in that collection in the composition of which Shakspeare is known to have had little or no concern, become extremely interesting. Such plays as the 'First Part of Henry VI.,' 'Pericles of Tyre,' and 'Titus Andronicus,' for instance, if not highly favourable, are not unfair specimens of the state of the art when Shakspeare was first introduced to its acquaintance: the 'Second' and 'Third Part of Henry VI.,' 'King John,' &c., show us in progressive gradation the rapid development of his wonderful power of infusing a spirit of life into a production which came into his hands a piece of cold, heavy, mechanical, and often incongruous composition. In the 'Two Gentlemen of Verona,' &c. we have the first free spontaneous flowings from his own peculiar and delightful spring of dramatic poesy, 'unmixed with baser matter;' and then, proceeding onward, still rising as we proceed, we pass through those greater historical compositions, whether from English or Roman history, which display so deep an insight into national as well as individual character, and into the personal springs of political transactions; then through those pieces founded on romantic story, as 'Romeo and Juliet,' 'Othello,' &c., fraught with all the depth, the wildness, and the richness of vehement passion; until we reach the grandest and most profound of his dramatic creations, where, in boundless diversity, the beauties and the deformities, the glory and the emptiness, of human existence, are unfolded in the tender light of a compassionate sympathy, as in 'The Tempest,' or disclosed with more awful depth and unsparing though beautiful rigour in 'Macbeth,' in 'Lear,' in 'Timon of Athens,' or in 'Hamlet.'

Indeed, as the compositions of Shakspeare form the most elevated region of dramatic poetry in that age, so the play of 'Hamlet' may, we think, be taken as the highest summit of that region. It seems to present the finest example of the depth, sublimity, refinement, and variety of which the romantic drama is capable; and it is the most abundantly marked with those peculiar characteristics which sprang from the union, in the person of its author, of such wonderful dramatic powers with such familiar and thorough experience of theatrical management. Thus, besides its exalted interest in a poetical view, it is singularly valuable as an historical study of dramatic and histrionic art. Here Shakspeare exhibits to us even the relation in which

the lord chamberlain stood to the players; and from the pedantic enumeration which Polonius's loquacity gives us of the various kinds of pieces which the actors whom Hamlet engages could perform, we gather what was then the established mode of classifying dramatic productions. 'The best actors in the world,' says Polonius, 'either for tragedy, comedy, history, pastoral, pastoral-comical, historical-pastoral, tragical-historical, tragical-comical, scene indivisible, or poem unlimited.' The latter part of this nomenclature, indeed, seems chiefly the offspring of the chamberlain's own pedantic and talkative affectation: it is to the three leading distinctions of tragedy, comedy, and history, that we should principally attend.

Of Shakspeare's younger contemporaries and competitors few have transmitted a living memorial of their works to posterity: the principal are Ben Jonson, Beaumont and Fletcher, and Massinger. Jonson demands our more particular notice as the chief advocate and practiser, among the old English dramatists, of the imitation of the antients—as standing indeed almost alone among them in that respect, and so earning Milton's well-known characterization in 'L'Allegro' of 'Jonson's learned sock.' Totally different as Jonson was from Shakspeare, both in his views of dramatic art and in his poetical constitution, he yet found a ready encourager in the latter, who was so far superior to all petty jealousy and rivalry. It was by Shakspeare's intervention that Jonson's first piece was brought upon the stage; a second even received touches from his hand; and in both he undertook the performance of a principal character. We have two tragical attempts of Jonson, and a number of comedies and masks. He could have risen to the dignity of the tragic tone, but had no turn for the pathetic. It is curious to observe how much, while he was constantly preaching up the imitation of the antients, his two tragedies differ both in substance and form from the antique models: we see here the irresistible influence which the prevailing tone of an age and the course already pursued in an art must exercise upon even the most independent minds. In the historical extent given by Jonson to his 'Sejanus' and his 'Cataline,' unity of time and place were altogether out of the question; and both pieces are crowded with a number of secondary personages. In 'Cataline,' indeed, the prologue is spoken by the spirit of Sylla, and much resembles that of Tantalus in the 'Atreus and Thyestes' of Seneca; while to the end of each act a moralizing chorus is appended, but not duly introduced or connected with the whole. This is all the resemblance to the antients; in other respects the form of Shakspeare's historical dramas is adhered to, but without their romantic charm. 'Cataline' and 'Sejanus' are in fact solid dramatic studies after Sallust and Cicero, and after Tacitus, Suetonius, Juvenal, &c.; but their author had not learned from Shakspeare the art of remaining true to history and yet satisfying the demands of poetry. Jonson was a strong advocate for the purity of the species, that is, for the alleged classical circumscription of tragedy and comedy; yet he had little talent for comedy in the antique spirit, and accordingly the later Roman satirists were his models rather than the comic writers. Fancy was less powerful in him than the spirit of observation, and hence in plot and incident he is often defective. He possessed a methodical head, and accordingly, when he had conceived a character in its leading idea, he followed out that idea with a strictness which excluded whatever might merely serve to give individual animation. He generally seized with accuracy the manners of his own age and country; but he attached himself so much to external peculiarities, then called *humours*, that a great part of his comic delineations soon became obsolete: his Captain Bobadil, however, in 'Every Man in his Humour,' forms an exception to this remark; and though less original and entertaining than Falstaff's comrade, Pistol, he is nevertheless a model in his way, and has been imitated by subsequent writers. In the *masks* of that day there seems to have been something congenial to the learned and rather frigid spirit of Jonson, and he was more distinguished in their composition than any other writer of the period: these were allegorical occasional pieces, usually designed for court festivals, decorated with machinery, masked dresses, dancing, and singing. This secondary dramatic species nearly expired with Jonson: the only subsequent production in this way of any celebrity is the *Comus* of Milton.

It is no mean honour to Beaumont and Fletcher, that after Shakspeare, who stands alone in all dramatic history,

they are entitled to the highest place among the romantic dramatists of England. They seem indeed to have had almost every dramatic quality short of that marvellously unerring instinct which Shakspeare possessed, and which appears to be vouchsafed to few. They began their career in Shakspeare's lifetime; Beaumont indeed died before him, and Fletcher survived him only nine or ten years. They followed his example in the whole form of their plays, regardless of the different principles of Ben Jonson and the imitation of the antients. Like him, they drew from tales and romances; they mingled burlesque with pathetic scenes, and endeavoured, by the concatenation of the incidents, to give an impression of the extraordinary and the wonderful. Shakspeare's own fame was in some degree eclipsed by them in the generation which immediately succeeded him; and in the time of Charles the Second they possessed a still greater proportion of popularity. 'Beaumont and Fletcher,' remarks Schlegel, 'were in fact men of the most distinguished talents: they hardly wanted any thing but a more profound seriousness of mind, and that sagacity in art which observes a due measure in every thing, to deserve a place beside the greatest dramatic poets of all nations. They possessed an uncommon fecundity and flexibility, and a felicitous ease, which however too often degenerated into levity. Poetry with them was not an inward devotion of the feelings and imagination, but a means to obtain brilliant results. Their first object was *effect*, which the great artist can hardly fail of attaining if he is determined above all things to satisfy *himself*. They were not players, like most of their predecessors, but they lived in the neighbourhood of the theatre, were in constant intercourse with it, and so had a perfect understanding of theatrical matters. They were also thoroughly acquainted with their contemporaries; but they found it more convenient to lower themselves to the public than to follow, in this particular, the example of Shakspeare, who elevated the public to himself. They are least successful in their tragic attempts, because their feeling is not sufficiently drawn from the depths of human nature, and because they bestowed too little attention on the general consideration of human destinies: they succeed much better in comedy, and in those serious and pathetic pictures which occupy a middle place between comedy and tragedy. The morality of these writers is ambiguous. Not that they failed to contrast in strong colours magnanimity and goodness with baseness and wickedness, or did not usually conclude with the disgrace and punishment of the latter; but they often exhibit an ostentatious generosity in lieu of duty and justice. Every thing good and excellent arises in their pictures more from transient ebullition than from fixed principle; they seem to place the virtues in the blood; and impulses of a merely selfish and instinct-like nature hold up their heads quite close to them as if they were of kindred origin. There is an incurably vulgar side of human nature which the poet should never approach but with a certain bashfulness where he cannot avoid letting it be perceived; but instead of this, Beaumont and Fletcher throw no veil whatever over nature: they express every thing bluntly in words; they make the spectator the unwilling confidant of all that more noble minds endeavour even to hide from themselves. The indecencies in which these poets allowed themselves to indulge exceed all conception: the licentiousness of the language is the least evil; many scenes, nay, even whole plots, are so contrived, that the very idea of them, not to mention the sight, is a gross insult to modesty. Their pieces had this convenience for performance in their time, that such great actors were not necessary to fill the principal characters as in Shakspeare's plays. To bring them on the stage in our days, it would be necessary to recast the greater part of them: with some of them we might succeed by omitting, moderating, and purifying various passages.'

Massinger, Shirley, Ford, and such other of the younger contemporaries of Shakspeare as we have not yet mentioned, have no characteristics sufficiently distinctive to admit of their being particularized in this general survey. There was then a grand school of dramatic art in England, of which Shakspeare was the real, though too frequently

* This assertion has been verified in a very recent instance by the successful production, at the Haymarket Theatre, of 'The Bridal,' a recasting of 'The Maid's Tragedy' of Beaumont and Fletcher. Their 'Rule a Wife and have a Wife' has kept the stage by similar means. It has also been brought upon the German stage, having been re-written by Schröder under the title of 'Still Waters are Deep' (*Stille Wasser sind Tief*), and, when well acted, has always as Schlegel informs us, been extremely well received.

unacknowledged, head; for Ben Jonson had scarcely a successor. One effect of mannerism in art is, to efface the marks of individual originality, and make the productions of various artists resemble each other; and from this mannerism no dramatic poet of that age who succeeded Shakespeare is altogether free. Nevertheless, in a general view of dramatic art, this first period of the English theatre is far the most important: it can hardly be doubted that some even of the secondary writers of that time are more instructive for theory and more remarkable in practice than the most celebrated of all the succeeding times.

Such was the general condition of the stage during the reign of Charles I. down to the year 1642, when the invectives of the puritans, who had long murmured against the theatre, and at last thundered loudly against it, were changed into prohibitory law; and in 1648 not only to act plays, but even to witness them, was made a penal offence. Nearly all the players now took arms on that side the interests of which seemed identified with the existence of their own profession. Many of them perished in the field; and after the final close of the war, one company of actors only was formed out of the remains of all the former ones, and occasionally, with great circumspection, performed at private mansions in the vicinity of London.

Davenant as manager, and Betterton as actor, form a slender link of connection between the old stage and that of the Restoration. Charles II. being considered, in his relation to the theatre, as a sort of restoring and tutelar deity, its character was now formed in absolute deference to the half foreign and wholly vicious taste of himself and his courtiers. Under these auspices, Davenant introduced the Italian system of decoration, the *costume* as then understood, the opera music, and the use of the orchestra in general. A still more important innovation in theatrical arrangements was, the permanent adoption of the practice, against which the puritans had directed the most violent of their anti-dramatic fury, but which had long been established in Italy, Spain, and France, of having the female parts personated by women instead of boys. At the same time, Betterton was sent over to Paris expressly to take a view of the French stage, in order to such other modifications of the English as the inspection might suggest. The result of this great neglect of the old dramatic and theatrical system of England, and assiduous study of that of France, was, for a long period, an almost entire denationalization, both in form and spirit, of the current dramatic literature. Davenant himself, who had resided very much at Paris, seems to have acquired this exotic taste long before the Restoration, as it is fully exhibited, amongst others of his productions, in his operatic piece, 'The Siege of Rhodes,' performed as early as 1656. Hence, in the theatrical restoration which accompanied the political, he set himself cordially to work, by altering old pieces, and writing new plays, operas, prologues, &c., to contribute towards the furnishing of that new theatrical repertory which the new dramatic system required. Of all his works, however, nothing has escaped a merited oblivion.

It was left for the industry and fertility of Dryden to give the new theatre a thorough establishment according to the new ideas, a task to which he applied himself with all possible diligence both by example and precept. The numerous essays on dramatic art which accompanied the publication of his several pieces, together with the larger treatise which he put forth separately, exhibit in a remarkable manner the anarchy which then prevailed in the notions of that art which then pervaded the public mind. The court indeed, whose taste it was now the leading object of the dramatic writers to seize and to follow, had no real knowledge of the fine arts; it merely favoured them, like other foreign fashions and inventions of luxury. Hence the drama of the day became a strange compound of the extreme license of the later writers of the earlier English school with the conventional stiffness and formality of the French, but without any of the natural and vigorous spirit which had animated either of those models. Dryden's fatal facility of rhyming, as in this case it may well be termed, materially aided him in effecting this incongruous combination, to which the absence in him of the highest poetic spirit likewise essentially conduced. It may be observed of his plays in general, that the plots are grossly improbable, and the incidents thrown out at random, while the most marvellous theatrical strokes drop, as it were, necessarily from the clouds. Scarcely a spark of nature is

to be found in any of his characters: passions, criminal and magnanimous, flow with indifferent levity from their lips without ever having dwelt in the heart: their chief delight seems to be in heroidal boasting. The tone of expression is by turns flat and madly bombastic: the author's wit is displayed in far-fetched sophisms, and his imagination in long-spun similes awkwardly introduced. The Duke of Buckingham, who, amongst other vigorous though wayward and generally misapplied talents, possessed high powers of ridicule, undertook to satirize these faults and absurdities of Dryden and his school, in his comedy of 'The Rehearsal,' wherein, although the structure of the piece itself might have been more artificial and diversified, the separate parodies are very ingenious and effective.

But the best-aimed satire, though it might correct in some degree, could not regenerate the stage. This could have been done only by the arising of some greater and more genuine dramatic genius, or at least by the successful appearance of some very great actor, capable of entering fully into the spirit of the elder drama. 'The Rehearsal' might indeed contribute to produce that nearer approach to nature which, among the compositions of Dryden's younger contemporaries, has preserved upon the stage one tragedy of Lee's and two of Otway's, while not one of Dryden's pieces has maintained its theatrical existence; but the essential constitution of the acting drama remained as before. The mixed romantic species being entirely laid aside, all was either tragedy or comedy. Dryden wrote comedies as well as tragedies; but as, with all his command of language and flow of rhyme, he did not possess in any perfection either the greatest dramatic or the highest poetical qualities, his dramatic writings, in this kind as well as in the other, have fallen, if not into absolute oblivion, at least into entire neglect. Shadwell's seventeen comedies, though he affected to imitate Ben Jonson in exhibiting humorous and eccentric peculiarities of character, are deservedly forgotten. Wycherley, so much in favour both with Buckingham and King Charles, and afterwards with King James, had much more genuine pretensions to the higher and more vigorous order of comic power, notwithstanding that his greatest performance, 'The Plain-dealer,' is a sort of counterpart of Molière's 'Misanthrope'; his next best piece, 'The Country Wife,' has been retained upon the stage, by means of adaptation and purification, under the title of 'The Country Girl.' Although the 'Sir Fopling Flutter' of Etherege is not yet forgotten, still Congreve deserves to be considered as the true father of 'genteel comedy' on the English stage, and was long regarded as the great model for imitation in that department, to which distinction he was much less entitled by any lively and humorous delineation of natural character than by a perpetual reciprocation of wit in his dialogue, together with originality of plot, and novel combinations of factitious manners: he drew little from common life; but his portraits of sharpers and coquettes—of men without principle and women without delicacy—are but too faithful representations of the fine gentlemen and ladies of his day. His 'Love for Love' is the only one of his pieces the licentiousness of which it has been found possible to prune sufficiently for performance in later years.

Of the poetic spirit and the moral tone of English comedy during the period we have just reviewed, we shall state our opinion in the words of Schlegel, because we think it useful to show to the English reader in what light that particular portion of our dramatic literature is justly received and represented by so able a continental critic:—'The greatest merit of the English comic poets of this period consists in the drawing of character; yet, though many of them have shown much talent in this way, I cannot ascribe to any of them a peculiar genius for character. Even in this department the older poets (not only Shakespeare, for that may well be supposed, but even Fletcher and Jonson) are superior to them. The moderns seldom possess the faculty of seizing the most hidden and involuntary emotions, and giving them comic expression; they generally draw merely the natural or assumed surface of men. The same circumstance that was attended with so prejudicial an effect in France after Molière's time came here also into play. The comic muse, instead of becoming familiar with the way of living of the middle and lower ranks, her proper sphere assumed an air of distinction; she squeezed herself into courts, and endeavoured to snatch a resemblance of the *beau monde*. It was now no longer an English national,

but a London comedy. The whole nearly turns on fashionable love-suits and fashionable raillery; the love affairs are either disgusting or insipid, and the raillery is always puerile and devoid of humour. These comic writers may have accurately hit the tone of their time: in this they did their duty; but they have reared a lamentable memorial of their age. In few periods has taste in the fine arts been at so low an ebb as towards the close of the seventeenth century and during the first half of the eighteenth. The political machine held its course; wars, negotiations, and changes of states, give to that age a certain historic splendour; but the comic poets and the portrait-painters have revealed to us the secret of its pitifulness, the latter in their copies of the dresses, the former in their imitations of the social tone. I am convinced that if we could listen to the conversation of the *beau monde* of that day in the present, we should find it as pettily affected and full of tasteless pretension as the hoops, the towering head-dresses, and high-heeled shoes of the women, and the huge perruques, cravats, wide sleeves, and ribbon-knots of the men. The last, and not the least, defect of the English comedies is their indecency. I may sum up the whole in one word by saying, that after all that we know of the licentiousness of manners under Charles II., we still are lost in astonishment at the audacious ribaldry of Wycherley and Congreve. Not merely is decency most grossly violated in single speeches, and frequently in the whole plot; but in the character of the rake, the fashionable *débauchée*, a moral scepticism is directly preached, and marriage is the constant subject of ridicule. Beaumont and Fletcher portrayed a vigorous though irregular nature; but nothing can be more repulsive than rude depravity coupled with claims to higher refinement.

The continuance, and even increase, of this moral depravation of the drama produced at length, in 1698, a severe castigation from the pen of the sturdy nonjuror, Jeremy Collier, under the title of 'A short View of the Immorality and Profaneness of the English Stage, together with the Sense of Antiquity on this Argument.' In this work, its author, armed with sufficient learning and sarcastic wit, attacked all the living dramatists from Dryden to D'Urfey; and although some of them, including Congreve, less candid on this occasion than Dryden himself, set up a petulant and sophistical defence, yet this publication of Collier's had a permanent effect on the stage as well as on the public mind. This effect, however, was operated only by degrees. Vanburgh followed in the line of Congreve, and, in spite of Collier's animadversions, did so with little more regard either to morality or decorum, though mingling more humour with his wit. This unbounded license has long banished from the stage his ablest production, 'The Confederacy,' while 'The Provoked Wife' and 'The Provoked Husband,' inferior in comic power, have survived by virtue of their greater decency. His contemporary, Farquhar, though displaying sufficient libertinism of language and sentiment, did not carry them to so gross an excess. A perfect gentlemanly ease of manner, lively spontaneity of wit, natural though not strongly drawn character, and a felicitous, uninvolved construction of plot, are his peculiar characteristics, and have preserved 'The Beaux' Stratagem' and two other of his pieces in public favour to the present time. His 'Sir Harry Wildair,' too, was the legitimate successor of the 'Sir Fopling Flutter' of the preceding generation; but in the true dramatic qualities Farquhar excels Etherege beyond all comparison. The Restoration period of English theatrical history had not only brought female performers for the first time before the public, but female dramatists also. The numerous comedies of Mrs. Behn, who wrote under Charles II., are remarkable only for the full share which they possess of the licentiousness of her time; nor need we remark upon two tragedies and a comedy, acted with some success, from the pen of Mrs. Manley, better known as a romantic memoir writer. But in Mrs. Centlivre, a prolific writer of comedy, exactly contemporary with Farquhar, we find more genuine dramatic talent, yet exhibited much more in a lively bustle of intrigue than in forcible delineation of character, although *Morplot*, in her 'Busy Body,' is still proverbial as a comic portrait, and some others of her plays, as 'The Wonder,' 'A Bold Stroke for a Wife,' &c., remain as well-known stock pieces. Just at the same period, also, Steele, among the other various exertions of his pen, wrote for the stage in a kindred spirit with Farquhar, but with inferior dramatic skill; and Cibber produced his best comedies, 'The Careless Husband' and 'The Non-

P. C. No. 585.

juror' (a sort of adaptation of the 'Tartuffe' of Molière), the very great success of which at that time was owing partly to its flattering the sentiments of the friends of the Hanoverian succession, and which, under an altered form and another title, 'The Hypocrite,' is still a favourite on the stage. Fielding, the novelist, commenced his literary career as a writer of comedy: he chiefly demands notice in dramatic history as one of the principal of those writers for the stage who afforded Sir Robert Walpole a pretext for obtaining the act to limit the number of theatres, and subject dramatic performances to the lord chamberlain's license. In a very similar predicament was Gay, after the appearance, in 1727, of his 'Beggars' Opera.' Its professed object was, by way of burlesque, to ridicule the Italian Opera, which had been established and maintained at great expense, and was thought by many to be rising in hurtful rivalry with the national drama. But amidst the general satire on political and fashionable selfishness and depravity which this composition implied, the persons then in power took so much of it to themselves, that while 'The Beggars' Opera' had the unprecedented run of sixty-three successive nights, and transformed the actress who represented the heroine into a duchess, the lord chamberlain refused to license for performance a second part of it entitled 'Polly.' This celebrated production, however, though still a standing favourite with the public, is now chiefly remarkable in dramatic history as the prototype (unwittingly, it seems, on its author's part) of a new species of dramatic composition upon the British stage, since known as 'the English opera.'

We must now revert for a moment to the history of modern English tragedy. After the example of Lee and Otway, Southern and Rowe endeavoured to return to a more natural tragic tone and style than those which Dryden had so long practised and inculcated. Southern even ventured to attempt the Shakspearian combination of the humorous and the ludicrous with the tragic, but was so deficient in that high mastery of the art which is necessary to accomplish this with success, that in his 'Oroonoko,' which, with another of his tragedies, under the altered title of 'Isabella, or the Fatal Marriage,' has kept the stage, the comic portions, being merely inserted or stuck on rather than interwoven or blended, have been simply dropped in performance, without being at all missed by the audience. Rowe was an honest admirer of Shakspeare, and in his 'Jane Shore' has even directly borrowed the part of Gloster from 'Richard the Third.' Without boldness and vigour, he possessed sweetness and feeling; he could excite the softer emotions; and hence, in his 'Fair Penitent' (a feeble remodelling, it must be observed, of Massinger's 'Fatal Dowry'), in 'Jane Shore,' and in 'Lady Jane Grey,' he has successfully chosen the weaknesses of heroines for his subject. Addison's 'Cato,' notwithstanding the great temporary celebrity and popularity which party rivalry conferred upon it, merits no attention in the history of dramatic art, except as having been the first, and, it should seem, the model, of a series of the most frigid productions in imitation of the French classic school, by Young, Johnson, Thomson, Glover, &c., that are to be found in our literary history. With some small poetic, they have no dramatic pretensions; yet the very excess of their formality and frigidity perhaps contributed to that decisive reaction of the public mind in favour of the elder dramatic school, which took place in the middle of the last century, and which now demands our attention.

Garrick's restoration of Shakspeare to his rightful supremacy over the English theatre has entailed upon his countrymen a permanent debt of gratitude which is yet more glorious to the memory of that great performer than the idolatrous admiration of his contemporaries for his unrivalled histrionic powers. It was nothing less than the removal of one great mark, worn for eighty years before, of national degradation, morally and intellectually. Here, too, we have a signal instance of the great degree in which the dignity and prosperity of a national theatre at any given period may depend on the taste and genius of a single actor, especially when that actor becomes a leading manager also. In the instance in question this was more peculiarly and necessarily the case. When the condition of the English stage for three generations before is considered, it is quite evident that no person but an actor of very high genius could achieve the theatrical resuscitation of the greatest of all dramatic poets. Had any such actor existed at the restoration of Charles II., he might probably have

Vol. IX.—3 K

done much to prevent the wretched denationalization of the theatre which was so much favoured by that king's exotic and vitiated taste. But it was one of the vital and lasting injuries inflicted on the theatrical system by the puritanical suppression, that the old line of actors which had risen and flourished along with the great and vigorous dramatic school of the age of Elizabeth and James, and had intimately imbibed its healthy natural tone, had grown with its growth, and strengthened with its strength, was violently and fatally interrupted: a new race of actors had to arise, who, not having, like their predecessors of the former period, the example and the awe of the great histrionic models of the old school before them, found it a much easier task to strut and rant in the delivery of unnatural bombast than to sound the depths and reach the delicacies of nature's favourite poet. And thus an additional facility was opened for the introduction and perpetuation upon the stage of the factitious taste of Dryden and his followers.

It was left for one qualified to be the great actor of nature to lead forth the sublime poet of nature from his long theatrical obscurity. The clear, deep, quick, and varied truth which appeared in Garrick's interpretation of Shakspeare's leading characters, after all the cold, leaden, formal declamation under which even the best-estimated performers had so long been accustomed to smother their spirit, was nothing less than a revelation to the play-going public of that day. The effect was electrical. Not only the leading dramatic taste, but the highest standard of acting, was raised at once to its antient elevation; nor has either of them, amidst all the minor vicissitudes of our theatrical history, ever since descended below it.

Of the genius and efforts of our dramatic writers during this latter æra it is not possible to speak so highly. It is perhaps too much to look once in a century, or even in several centuries, for a writer like Shakspeare, possessing such universal mastery over all human emotions as to be able to blend them in such endless variety as to move at will, in whatever order, in whatever alternation or juxtaposition that he pleases, our laughter and our tears. We know that there are myriads who can enjoy the tragic or the comic, more especially the latter, for one who can thoroughly relish both; and that yet smaller is the proportion among those who can relish both, of those who can excel in producing both. Yet it might not have been unreasonable to have expected among our later dramatic productions a greater number approaching the perfection of those models which other countries have produced within those narrower limits of tragedy and comedy which, as we have seen, were established as part of their dramatic system.

Garrick himself, having made no great attempt in dramatic composition, exposed himself to no considerable failure: one or two of his small afterpieces have kept possession of the stage; but his labour of this kind most worthy of mention is probably the share which he took in the composition of one of Colman's best comedies, 'The Clandestine Marriage.' Cumberland's comic powers were respectable; but in his most successful pieces, 'The West Indian,' brought out by Garrick in 1771, and 'The Wheel of Fortune,' to which John Kemble's masterly personation of the principal character gave so decided a popularity, he scarcely rises above mediocrity. Horace Walpole's tragedy, 'The Mysterious Mother,' though its subject necessarily excluded it from representation, set the first example of a vigorous attempt to return to a natural and healthy tragic tone and style. As for the 'Douglas' of Home, it has no such qualities to recommend it, but acquired and has retained the public favour chiefly by dint of one truly and deeply pathetic situation wherein the strongest domestic affections are profoundly and permanently interested. Sheridan gave new life and spirit to 'genteel comedy,' in which department he remains at the head of the writers of the present æra. Though perhaps his pieces are less perfectly finished than those of Congreve, already characterized as the chief of this class of dramatists in the preceding period, and although, especially in 'The School for Scandal,' he is subject to the same imputation as his predecessor, of being too indiscriminately lavish of epigrammatic wit, yet he has more truly comic wit, more force of genuine humour, than Congreve, as is more particularly felt in his play of 'The Rivals,' and should therefore, we conceive, be ranked above him as regards the more essential qualities of comedy. The dramatic merits of Goldsmith were of a totally different

cast: a certain eccentric drollery of character and whimsical extravagance of plot are the distinctive characteristics of his two comedies, one of which, though by no means among the most excellent productions of his pen, has kept an honourable place in the public favour. Of the elder Colman's pieces, two, 'The Jealous Wife' and 'The Clandestine Marriage,' are still deservedly esteemed; and the latter in particular is frequently acted: they combine much elegance of composition with considerable comic power. Nor among the comic dramatists of the latter half of the last century must we forget to mention the once celebrated Samuel Foote, who has been more commonly than appropriately called the English Aristophanes, seeing that such a designation conveys much too high a compliment to Foote, and a very indifferent one to the great master of the elder Grecian comedy. So little had Foote's pieces of that burlesque ideality which constituted the essential character of the latter, that his exercise of the *vis comica* reduced itself almost exclusively to a contemporary personal satire, amounting to little more than a refined species of mimicry, which, from the merest mercenary motives, he directed quite as readily against the most innocent peculiarities of living individuals as against the most injurious vices or follies. Hence it is, that of the many farces which he wrote, chiefly to exhibit in them his own powers of satirical mimicry as an actor, not more than one survives upon the stage.

It was towards the close of the century that the sentimental comedy of the German school of Kotzebue, with little but its novelty to recommend it, acquired a footing in England. In this kind, among the direct adaptations from the German, 'The Stranger' has had the most general success, and is the most perfect representative of the species. Among the native efforts in the same line, Holcroft's 'Road to Ruin,' still popular, is one of the most meritorious. The same writer has the credit also of having first introduced on the English stage the melo-drama, which has since filled so large a place upon it. Mrs. Inchbald, among many pleasing original pieces in the lighter comedy, has likewise given us an adaptation from Kotzebue. M. G. Lewis, in his tragedies, as in his romances, drew from a very different German source, in his taste, we might almost say his rage, for the marvellous and the terrific. A kindred spirit is displayed in the late Charles Maturn's tragedy of 'Bertram,' to which Kean's acting gave high success. As regards Lord Byron's tragedies, we have only to remind the reader that as their author never designed them for representation, he is by no means chargeable with their dramatic failure.

We abstain from individual criticism of living English contemporaries. As regards modern efforts in the Shakspearian drama, the flight in this case is so lofty and so bold, that even to attempt it may be said to require almost as vigorous and as rare a genius as to succeed. But on the ground next in elevation, that of tragedy in the mere limited sense, aspirants, if not very numerous, are yet, from time to time, presenting themselves: however, we have not yet anything that approaches in natural vigour or in poetic richness, either to the masterpieces of Schiller, or even to the most successful efforts of the new romantic school of France. In the higher comedy the experiments are yet more rare. Decency has long been thoroughly established in this department; but since Sheridan's time, we look in vain either for the raciness of humour, the brilliancy of wit, or the happiness of invention which seasoned the licentiousness of our earlier comic writers. Of the occasional pieces written to show off the talent of particular actors, the numerous adaptations of French farces and vaudevilles, and the many trifles that are continually coming forth into an ephemeral popularity in the form of comic opera or burletta, we shall merely remark that, with much that is lively and amusing, they have little that indicates either vigour or originality of dramatic talent.

The late and continued decline of dramatic art in England, which it is common to speak of as if it were tending to the utter abasement of that art, if not to its total extinction, seems to demand that we should point out distinctly the leading considerations relative to this subject. It is true that since the age of Elizabeth, for instance, the spread of printing and of reading, and above all, the rise and progress of novel and romance writing since the middle of the last century, have reduced the theatre to the occupation of a much smaller relative space among the sources of

public amusement. Novel and romance reading, in particular, has become its most immediate and powerful rival, as approaching nearest to it in the nature and vividness of the stimulus afforded to the feelings and imagination, and as having the convenient capability of administering that excitement in all times and all places. Nevertheless, theatrical representations, besides those more general attractions which they may be said to share with some branches of reading, have their peculiar charms, for which no absolute equivalent is elsewhere to be found, and which therefore seem to place their perpetuity beyond all reasonable doubt. Besides that the perfect performance of a drama of the first order supplies the noblest enjoyment that art can offer to the mind through the medium of the senses, the pleasure which an audience derives from even an inferior dramatic production on the stage, is so much more vivid and immediate than reading can supply, as to free the former from all danger of being superseded by the latter. Nor are we inclined to lay much stress upon the favour extended by the more peculiarly aristocratic classes to the Italian opera, as a circumstance having any fatal or very injurious tendency as regards the national drama. The entire subordination in this foreign entertainment of every truly dramatic feature to musical effect (not to mention the unintelligibility of the language to most English ears), quite excludes it from the sphere of dramatic rivalry. Mere fashion apart, and as far as real pleasure is concerned, it is music and dancing, not acting, that people go expressly to enjoy at the Italian opera.

A much more evident, if not indeed an all-sufficient cause of the decline in question, is to be found in one remarkable result, which we must briefly state, of the monopoly of the higher dramatic performances possessed by the patentees of the two great winter theatres of the metropolis. The interpretation which for so long a period has been given to this privilege, of being not merely permissive, but exclusive, led at length to an enormous enlargement of the houses, with a view to obviate complaint as to want of accommodation for the increased and increasing metropolitan population. Now, it is plain that nature in fixing the average powers of vision and of hearing, has appointed certain limits beyond which the most scientifically constructed theatre for the performance of the regular drama cannot be conveniently nor even safely extended: yet this most important consideration has been altogether overlooked or neglected in the instances before us; and the inevitable and merited consequence has followed, in the desertion of the *great* houses, and of those higher and more genuine dramatic performances which they at once monopolized and marred by their very magnitude. 'The falling off in the attendance of the public was gradual, though somewhat fluctuating. There was a large play-going audience who could not readily give up their amusements at the theatre—persons to whom this kind of entertainment had become almost a necessary of life, which they relinquished very slowly and with great reluctance, even when they could no longer see and hear as they wished to see and hear. Some did, however, give up their enjoyments; some died; some fell off from other causes, and their places were not supplied by others; many found new modes of being entertained; and thus the play-going audience was gradually reduced, and the theatres were abandoned and forgotten by a very large portion of those who, under other circumstances, would have supported them.* Hence, at Covent-Garden theatre, for example, during the twelve seasons from its rebuilding in 1809 to the year 1821, as shown from the accounts of the theatre, by the manager himself, the whole receipts of the house, including the performance of pantomimes, for which indeed its enormous magnitude was better adapted, was unequal to the current expenses of 'the legitimate drama' alone. Yet during that period the company was remarkably strong in excellent performers. Captain Forbes, in his evidence before the House of Commons' Committee on Dramatic Literature, in 1832, named the principal ones thus: 'John Kemble, Charles Kemble, Cooke, Lewis, Ingleton, Munden, Fawcett, Young, Jones, Blanchard, Emery, Liston; Mrs. Siddons, Mrs. Dickens, Mrs. C. Kemble, Mrs. H. Johnstone, Mrs. Gibbs, and Mrs. Davenport.' Nor was this an expensive company made up for the new house; for all, or nearly

all, of the performers thus enumerated had belonged to the old one. It should be further observed, that in this same period the income of the theatre declined, on an average of the last six seasons as compared with the first six, at the rate of nearly 21,000*l.* a year. The ten following seasons, however, when the theatre was held by Messrs. Kemble, Willett, and Forbes, present a much more deplorable account. Captain Forbes himself, in the evidence already quoted, states the loss at 20,000*l.* per annum. It also appears, from the statements of the interested parties themselves, that during the first twelve seasons the house was not, on an average, much more than half filled with spectators; and that during the last three of the seasons alluded to by Captain Forbes it was considerably less than half filled. The case of Drury-Lane theatre is so exactly parallel to that of Covent-Garden, as to require no separate illustration.

That the relish of the public for theatrical representations in general, if diminished at all, has not declined in a degree at all proportionate to the decay in the prosperity of the larger establishments, is manifest from one fact, of which the proprietors themselves complain—the extraordinary success of some of the minor theatres during the same period, which had risen, it would seem, in much the same proportion as the attendance at the great houses has fallen off,—showing, what indeed is plain enough without such demonstration, that people will more willingly attend even an inferior dramatic representation which they can see and hear perfectly, than a superior one which they cannot so hear and see.

The remedy for this preposterous state of things lies with the legislature, by opening a free theatrical competition which shall lead to the erection of houses for the regular drama, capable of holding little more than half the number of spectators necessary to fill houses so large as those of Covent-Garden and Drury-Lane. A bill to permit the erection of other playhouses was, indeed, recently passed by the House of Commons, but was rejected by the Lords, owing in this case, we must suppose, to indolence or indifference in the hereditary House, rather than to hostility. This is, however, a question upon which the best interests of dramatic art, the care of the nation for its noblest scenic enjoyments, and a just regard for its character as to general cultivation in the eyes of the civilized world, should cause the public opinion to be expressed loudly, distinctly, and unceasingly, until the legislature does apply the remedy in its power.

Under these circumstances, the higher walks of dramatic composition could expect and have indeed received but little encouragement from the directors of the privileged theatres. Their first solicitude has necessarily been to fill the treasuries of their respective establishments; and this they have long been striving, though vainly, to effect by the production of all manner of dazzling and stunning spectacles, with performers two-footed and four-footed, which should at least possess, as they seem to have thought, the requisites of being *visible* and *audible*. But the few concluding suggestions which we proceed to make are offered in the firm conviction that the present injurious and degrading theatrical system 'as by law established' is too monstrous in itself and too insulting to the national taste and reason to be much longer maintained; so that any dramatist who is capable of deserving, may rely upon shortly obtaining, the most effective medium for communicating his creations to the minds of his countrymen.

One leading error, then, which still begets the practice of dramatic composition is directly derived from the grandest and most glorious event in the intellectual history of modern times, the revival of art and letters in the fifteenth and sixteenth centuries. We may well excuse many of the greatest minds of that period if, in the ardour with which they applied themselves to the wondrous and long-hidden stores of physical and intellectual beauty which had suddenly opened upon them, their first irresistible impulse was to emulate the external graces of the antique models by close and devoted imitation—if often they mistook the form for the essence, or at least confounded them together. But it is not easy to extend the like indulgence to the artist of the present age. Let him, indeed, study the antients; but let him study them to the *bottom*. 'These time-bettering' days demand that he should be able not only to raise his view above the maxims of Horace and Aristotle to that of the works from the consideration of which those maxims

* See an accurate and able exposition of the operation of the theatrical monopoly upon the interests of the proprietors and houses themselves, in the Monthly Magazine, of March, 1834.

were formed—not only to see distinctly how ancient criticism was merely a product of ancient art—but also to perceive how that art itself had grown out of, and drew its vital energies from, the peculiar spirit of the artist's age and country. Thus it is that in order to give vitality to any modern imitation of the Grecian tragedy for instance, the Greek mythology itself must first be established in the belief of the auditory. Until the poet can first accomplish this, the noblest grace of conception, the highest beauty of language cannot render his work a living and breathing creation.

The fundamental contrast between the religious principles of the ancients and those of the moderns is found, on attentive examination, to be the leading source of the essential difference between the spirit of ancient and that of modern art, especially of dramatic art. The more directly and exclusively any species of human composition is addressed to the feelings and imagination of a people, the more it must necessarily be influenced by the predominant character of that people's religious system, which, of all things whatever, has upon those feelings and that imagination the most uniform and the deepest operation. Now, among the primary characteristics of the Grecian system, those which especially demand our attention in relation to the present subject are these two—the absolute overruling power of fate, to which we have already had occasion to allude, and the absence of any clear notion or anticipation of a desirable future state. Were it more immediately to the present purpose, we might here show how thoroughly these two leading principles pervaded the philosophy as well as the poetry of the Greeks—how Stoicism, which we may call the art of endurance, was but a matured fruit of the former conviction, as Epicureanism, the economy of enjoyment, was of the latter—and that it is pretty clear that the most intelligent individuals of either profession united in their conduct these two great branches of practical wisdom. But Christianity reversed this order of ideas. It substituted for the impassive omnipotence of fate an almighty will, thus making passive fortitude give place to hope and fear; and further, to give to these two grand springs of imagination and enthusiasm, as well as action, the highest exaltation and most unlimited scope, many of those who expounded the Christian doctrines made the happiness of this life an object of contempt rather than of solicitude, representing its very miseries as conducive to the attainment of everlasting bliss. It was a necessary result of the exclusive rigour with which these notions were so long inculcated that the sciences which illumine life and the arts which refine it rapidly expired. Both knowledge and taste might well cease to be cultivated, when their very neglect was held up to mankind in the light in which so many fanatics have represented it, as one means of securing eternal happiness.

And when the strictness with which these principles were interpreted for so many ages began to relax, and men began to think that some effort to ameliorate their worldly state was not inconsistent with the profession or practice of Christianity, the boundless dominion of hope and fear still gave that predominant hue to their imaginations and their passions which they have ever since retained. The fierceness of fanaticism has indeed subsided, but the firmness of philosophy has not succeeded it.

Vain, then, is the attempt to exhibit on a modern stage 'the unconquerable will' of a Grecian tragic hero. The antique spirit animated the Grecian spectator as well as the Grecian poet. But the modern poet has a *romantic* audience, and cannot have any other—an audience that sympathises not with the triumph of will over passion, but with that of passion over will. Well did Shakspeare know this when achieving his grandest tragic successes in *Lear*, *Macbeth*, *Othello*, &c., wherein we see, not the triumph of the hero over fortune and over passion, but that of malignant fortune and conflicting passions over the hero.

In short, an intimate acquaintance with the pervading spirit of that public of his own time from whom his audience must be supplied, is the primary condition of all successful dramatic writing. It is indeed necessarily included in the perfect possession of that highest dramatic faculty which is essential to form a dramatist of the first order; for he must know, or have the sagacity to discover, the habits, mental as well as physical, of all classes and degrees of men, whether the distinctions be marked by difference of race, of country, of rank, of profession, or occupation. He

should have a nice perception of the moral distinction between the characters of either sex, and of the modifications which age produces in that of each individual. In fine, he should possess that pervading insight into all the elements of character and all their combinations—that Shakspearian instinct—which can feel, not only *for*, but *with*, every variety of human nature and human condition.

Supposing that a writer could now arise, possessing the natural powers of a Shakspeare,—what are the principles by which he should be guided in cultivating those powers so as to give them the greatest effectiveness in the present day? We should answer,—Study, on the one hand, living man and his history; on the other hand, study Shakspeare; but study him on a juster and more liberal principle than has hitherto been followed; study him, above all things, to find how *he* studied human nature and human life;—to discover which thoroughly, his *age*, as well as himself, must be diligently and patiently examined; for the true use of Shakspeare to the artist of the present day is, by viewing his works in relation to his time, to divine, if possible, how Shakspeare would have written for an audience of the nineteenth century. We have neither the space nor the presumption to indicate how he would have done this; only we assert with the fullest confidence that such, and such only, is the mode of studying him calculated to aid the progress and elevate the standard of contemporary dramatic art. This observation, it will be seen, applies more especially to his selection and construction of character and plot, and to the general tone of manners. As regards the amazing force, delicacy, variety, and flexibility of his expression, it is plain that they are much less liable to be studied in an erroneous sense. Happy the writer that should succeed in transfusing their essence into his own diction!

But if a dramatic artist have not this all-comprehensive faculty, which seems given to few, it is, in the next place, important that he should be aware of his deficiency, and should perceive distinctly the nature and limits of the field which his powers really do embrace. Next, in short, to well understanding his public, the dramatist should, if possible, correctly appreciate himself; then, at least, if he do not reach greatness in performance, he will escape absurdity in failure.

Among those orders of dramatic power that fall short of that highest capability which we have endeavoured to characterize, the infinitely numerous and various degrees of deficiency are for the most part assignable to two principal causes: first, to the absence of a lively and delicate sensibility, in some individuals to the serious, in others to the comic, elements of character and plot; secondly, to a limited acquaintance with the diversities of human character and fortune in general. The former deficiency seems in all ages to have been scarcely less prevalent than the latter; and among the early Greeks, as well as among the modern Europeans, was a most influential cause of the two grand dramatic circumscriptions of tragedy and comedy. It is also the defect which it is of the first and most urgent importance that the writer in whom it exists should be thoroughly aware of; since, of all failures in dramatic productions, the exhibition of false wit, and, above all, of false pathos, is the most disastrous. The next great danger to be shunned by the dramatist is that of attempting the delineation of a character, with the features of which, individual, professional, national, &c., he is not completely and accurately acquainted. The judicious selection or contrivance of a plot, which shall be neither languid on the one hand nor improbable on the other, neither too bare of incident nor too crowded with it, and at the same time shall have, if possible, some feature of decided novelty, is next to be attended to. The character and incident of any meditated piece being once clearly determined in the author's mind, the dialogue (supposing him to have the requisite command of diction) will then be a natural, and, as it were, spontaneous result of the series of circumstances under which his personages are brought into contact; and if the latter be really conceived with truth and distinctness, it may indeed be more or less flexible and harmonious, according as the author's mastery of expression is more or less complete, but it cannot fail to be varied and interesting.

Such are the conditions fundamentally requisite for succeeding in any department of dramatic composition. The next class of qualifications arises from an exact and thorough

knowledge of the restrictions imposed upon the writer, both as to the literary extent of his composition and the mode of handling his subject, by the very nature of theatrical representation in general. In this respect, it is unquestionable that the peculiar fortune of Shakspeare in being so long a manager as well as a dramatist, contributed materially to that remarkable *theatrical* fitness and completeness of effect which are found in all his mature productions.

And finally, to pass for a moment from the business of dramatic writing to that of acting, let us observe that the theatrical manager, simply as such, ought, no less than the dramatic writer, to be a genuine artist, though in an inferior walk. If true taste and knowledge be wanting in the manager, the best efforts of the dramatist's genius will be marred on the one hand; and on the other, histrionic excellence will neither be brought forward, cultivated, nor encouraged.

ENGRAVING, the art of executing designs by incision upon plates of copper, steel, or other substance, for the purpose of obtaining therefrom impressions or prints upon paper. Although, in this sense of the term, the art is only coeval with that of printing, it has been practised with a more limited object from the earliest periods on record, in a similar manner and with similar instruments to those used at the present time. That an art so abundantly capable of diffusing all kinds of knowledge should have been extensively practised from the most remote antiquity without its applicability to printing having been discovered, is so curious a subject of reflection, that it would be improper to omit giving in this place a slight sketch of its early history.

On referring to sacred history we find in the writings of Moses rather detailed accounts of the character of the engraved works executed in his time, and of the substances whereon they were wrought; nor are we left in ignorance even of the names of the practising artists among the Israelites. Thus from the book of Exodus we learn that when Moses had liberated the Jews from Egyptian bondage, he was commanded to 'make a plate of pure gold, and grave upon it, like the engravings of a signet, holiness to the Lord.' He was also commanded 'to take two onyx stones, and grave on them the names of the children of Israel according to their birth, with the work of an engraver on stone, like the engravings of a signet.' Both these passages distinctly imply the practice of gem and seal engraving, and also of engraving on metal plates, a knowledge of which, among other arts, was, without doubt, acquired by the Israelites during their captivity in Egypt; and specimens of the art as practised in that nation, perhaps at as early a period as that now under notice, still exist. In the book of Exodus also honourable mention is made of one Bezaleel, who appears to have united the callings of the engraver, the jeweller, and the lapidary; and it is said 'that he was filled with wisdom of heart to work all manner of work with the graver, as well as to devise cunning works; to work in gold, and in silver, and in brass, and in cutting of stones to set them.' 'And it was put into his heart that both he and Aholiab might teach them that were filled with wisdom to work all manner of work of the engraver.' These few are selected from numerous other passages in Scripture as sufficiently attesting the practice of several branches of engraving at this early period: from the same source indeed we learn that some of them, as, for example, the engraving of signets, was practised at a time anterior to that of Moses.

From Herodotus (v. 49) we learn that one of the earliest uses to which engraving was applied among the Greeks was the delineation of maps on metal plates. He says that 'Aristagoras appeared before the king of Sparta with a tablet of brass in his hand, on which was inscribed every part of the habitable world, the seas, and the rivers; and to this he pointed as he spoke of the several countries between the Ionian Sea and Susa.' The date of this event was 500 B.C.

The hieroglyphics and other remains of Egyptian engraving are among the most ancient relics now extant, and our own British Museum is particularly rich in specimens of them. Some of these are engraved on metal, and have been chiefly found in the chests or coffins of mummies. Mr. Strutt, in his *Dictionary of Engravers*, describes one of them very minutely. These engravings of hieroglyphics on metal, as well as those on the ancient sarcophagi, are evidently

executed with similar instruments to those now in use; some of the lines narrowing downwards have clearly been cut with the lozenge-shaped graver now chiefly used; but other lines being of the same width through their whole depth, must have been produced with that species of graver called a scoop, still used for effecting broad incisions.

There is, it must be confessed, some difficulty in determining of what substance the instruments were made with which they engraved on porphyry and jasper, no mode of tempering steel being now known by which it can be rendered sufficiently hard, and at the same time tough enough, to penetrate those substances. Mr. Landseer is of opinion nevertheless that the incisions were produced by patient perseverance with steel gravers impelled by blows with a mallet, and that the work was afterwards rendered smooth by friction with some hard substance pulverized (such as the powder of the corundum stone) and applied with lead.

But it is believed that some of the relics of Etruscan art in the British Museum are of as high antiquity as any existing specimens of engraving. Mr. Strutt gives a description of two of these, the one a parazonium or dagger sheath, on which is represented a story from Homer; the other is supposed to be a patera or instrument used by the priests in their sacrificial ceremonies. This latter is rather a specimen of sculpture than engraving, being embossed in high relief; but portions of the drapery and hair on the figures are evidently executed with the graver. Mr. Strutt is of opinion that the subject is the combat between Hercules and Hippolyte, the queen of the Amazons, 'whose girdle he was enjoined by Eurystheus to unloose and take from her.' Others have supposed that it represents Minerva leaning on the head of Hercules and urging him forward in the paths of glory. It is apparently of brass, seven inches in diameter and about half an inch thick, and is declared by Mons. D'Hancarville to be, 'without contradiction, the richest and most remarkable remnant of antiquity, and of all the Etruscan bronzes the best executed and most happily preserved.' The circumstance of the inscription running from the right hand towards the left furnishes additional testimony of its great antiquity. The dagger-sheath is thus described by Strutt:—'It is more than three inches and three quarters wide at the top, and decreases gradually to an inch and a quarter at the bottom. Its present length is eight inches and a half. The story engraved upon it appears to be taken from Homer. The trophy at the bottom is symbolical of war. Above the trophy two warriors are delineated with a woman, who seems to accompany them with great reluctance; which I conceive may represent Paris, with his accomplice, conducting Helen to the ship, in order to make their escape to Troy; and at the top, the messenger, a servant of Menelaus, is relating to his lord the ungrateful behaviour of his Trojan guest. The figures are exceedingly rude, and seem to indicate the very infancy of the art of engraving, for they are executed with the graver only upon a flat surface, and need only to be filled with ink and run through a printing-press (provided the plate could bear the operation) to produce a fair and perfect impression. The print so produced, says Mons. D'Hancarville, would certainly be the most ancient of all that are preserved in the collections of the curious, and demonstrate to us how near the ancients approached to this admirable art, which in the present day forms so considerable a branch of commerce. We may indeed say, that they did discover it, for it is evident from the valuable relic before us that they only wanted the idea of multiplying representations of the same engraving. After having conquered every principal difficulty, a stop was put to their progress by an obstacle which, in appearance, a child might have surmounted.' Prints which indeed we have ourselves seen, taken with ink from Etruscan specula, of which there are several in the Museum, sufficiently prove the capacity of these early engravings to deliver impressions.

But while the world was so slow to discover a mode of taking impressions from engraved works, on substances offering natural facilities for such an object, the art of impressing more obdurate substances appears to have been understood and practised at a very early period in most parts of the civilized globe. This is evidenced in the practice of numismatic engraving, or the art of sinking dies, from which coins are impressed, which is of very ancient

although uncertain origin. The mode of impressing the metal was by the stroke of a hammer, the die or engraving being cut on a sort of punch; and it is remarkable that the operation of coining is performed in the same manner at the present time, in such parts of the globe as are backward in improvement. The first Greek coins were struck, according to some authors, at Ægina, by Pheidon, king of Argos, about eight centuries before the Christian era. But this is a much less remote antiquity than what is ascribed to other antient coins. Mr. Landseer describes a gold coin in the collection belonging to the East India Company, to which the Hindoos ascribed an antiquity of 4000 years, and paid it superstitious homage. It is understood to have been dug up near the royal palace of Mysore, and was found among the treasures of Tippoo Sultan. In Rome, a mint every way commensurate with the greatness of the empire was established in the reign of the emperor Augustus. The extravagant fondness of the Roman matrons for engraved gems was satirised by Juvenal, and gave rise to the remark of Pliny, that they 'loaded their fingers with princely fortunes.' This profusion gradually extended itself to the wearing apparel of both sexes; and among the opulent classes almost every article of use or dress glittered with engraved gems.

In the peninsula of India, also, the art of engraving on plates of copper appears to have been practised long before the Christian era. It would appear that it was there customary to ratify grants of land by deeds of transfer actually engraved on plates of copper, as we now write them on skins of parchment. A copy of one of these very interesting relics is given with an English translation by Mr. Wilkins, in the first volume of the *Asiatic Researches*, page 123. It is in the Sanscrit language, and bears date twenty years before the birth of Christ.

The engraving of signets, although considered by many to be rather a mode of sculpture than of engraving, is sufficiently allied to it to claim a slight notice in this place; the more so, as being of higher antiquity even than die-sinking. Mention is made of the use of signets in the sacred writings as early as the time of the patriarchs. They were then probably engraved on metal, and appear to have been used at this time, and at all subsequent periods, as instruments of ratification. When through the dark ages the knowledge of the Roman sealing substance was lost, recourse was had to lead, as a substitute for wax, to receive the impressions. The emperor Charlemagne wore his signet in the pommel of his sword; and it was in allusion to this as an instrument of ratification that he was accustomed to say, 'With the point I will maintain that which I have engaged with the hilt.'

The state of engraving in our own country previous to the Conquest must not be entirely overlooked. Our knowledge of it is principally derived from such ornaments of dress as buckles, clasps, rings, and military accoutrements, sometimes found in antient tumuli. These frequently bear the marks of the graver: but if other proofs were wanting their coins would sufficiently attest their knowledge of the art; for although exceedingly rude, they are evidently impressed from engravings cut upon iron or steel. 'Under the protection of that good and excellent monarch Alfred the Great (says Strutt), the arts began to manifest themselves in a superior degree, notwithstanding the load of intestine troubles which destroyed the nation.' The works of the Anglo-Saxon goldsmiths, who were the principal engravers of that day, were held in the highest estimation; and there is yet preserved in the museum at Oxford a very valuable jewel made by command of Alfred, and which was indeed one of the few treasures which he took with him when he retreated to the Isle of Athelney, where it was found. It is of gold, richly adorned with a kind of filigree work, in the midst of which is the half figure of a man, supposed to be St. Cuthbert. The back of this jewel is ornamented with foliage, and is pronounced to be very skillfully engraved, on the authority of Mr. Strutt, who has given a faithful representation of it in the second volume of the *Chronicles of England*.

'Soon after the Conquest,' (according to the authority just quoted, but we ourselves have never met with a specimen of earlier date than A.D. 1284,) 'a new species of engraving was introduced into England, much more perfect in itself than any which had preceded it, and in every respect distinct from the work of the carver or chaser.' The author alludes to the engraving of the sepulchral brass-

plates, so frequently found in our churches upon the tombstones. Their economy, as compared with the carved images which preceded their introduction, probably brought them into such general use that very few churches in this country are without them. They are executed entirely with the graver, and in precisely the same manner that a copper-plate is now engraved that is intended to be printed from; but as they were commonly exposed to the feet of the congregation, the strokes were cut deep, that they might endure the longer, and consequently very neat workmanship is not to be expected. Some of them, however, bear evidence of considerable ability in the workmen by whom they were executed; but who these workmen were is quite unknown. It has been conjectured even, that they were not produced in England at all, but executed by foreigners, who took British produce in exchange for their labours. However this may be, certainly no churches more abound with them than those of this country; but we have never met with more than one, even with a *monogram*, and that is insufficient to lead to a knowledge of the artist, who was not improbably, in this and in most other cases, an ecclesiastic.

We now approach the period when the invention of *printing* gave to engraving a new direction, and produced an effect on the civilization of the world as astonishing as it is incalculable. The chief obstacle to printing had already been removed by the manufacture of paper from linen rags, which had become generally known in Europe at the latter end of the fourteenth century. It must be remembered, as giving additional interest to this subject, that it is to a certain class of engravers that we are immediately indebted for the first printed books, which were actually impressed from engraved wooden tablets—a method which was afterwards improved by substituting movable metal types; and thus the arts of engraving and printing, at the same time that they constitute the sole means by which all kinds of knowledge may be extensively diffused, have placed it within the power of us all to possess the best thoughts of the best men in literature, science, and art.

The first prints, as we have already intimated, were obtained from engraved wood blocks. This might naturally be expected, because the process of printing from such works is so simple and obvious, not requiring even a press, that persons of reflection are astonished, not that printing was invented so soon, but that it had not been discovered sooner. To obtain impressions from the incised hollows of an engraved metal plate, on the contrary, is a much less obvious process, requiring the aid of a somewhat complicated machine, called a rolling-press. We need not wonder, therefore, that its discovery should have been later; and, indeed, the two processes are so very different, that when one was discovered it did not lead necessarily to the other.

The earliest print with a date attached to it is one known as the St. Christopher, which is from a wood block, and dated 1423; but no impression from an engraved *plate* has been found with a date anterior to 1461. The art of engraving on metal plates for taking impressions on paper was, according to Vasari, first practised by Maso or Thomaso Finneguerra, a Florentine goldsmith, about the year 1460; and although many writers have advocated the claims of Germany to the honour of the invention, it seems now to be conceded by nearly universal consent to Italy. The arguments of the Abate Luigi Lanzi, in his work on the history of painting in Italy, appear to us to be quite conclusive in confirmation of Vasari's opinion. However this may be, there has never existed a doubt that the art had its origin in the workshops of the goldsmiths about the middle of the fifteenth century. Many of these goldsmiths were *niellatori*, or workers in *niello*—a mode of ornamental engraving usually performed on silver plates—the design engraved on which was afterwards filled in with a black composition, said to have been composed of silver and lead, which from its dark colour was called by the antients *nigellum*, a word curtailed by the Italians into *niello*. This being incorporated with the silver, that is, run into the engraved lines, produced the effect of shadow, and had very much the appearance of a print. 'These nielli,' says Lanzi, 'were used as silver ornaments to articles of furniture, sacred vessels, such as holy cups and vases, to missals and other devotional books, and to reliquaries; as well as to profane purposes, as adorning the hilts of swords, table utensils, and many kinds of female ornaments.' Now Maso Finneguerra was a worker in *niello*, and, according

to Vasari, his discovery of the art of printing from engraved plates was the result of accident. It was usual with the artists who worked in this style to rub a mixture of charcoal and oil into the design engraved on the silver plate, that they might ascertain what would be the effect of the work previous to inlaying with the nigellum or mixture of silver and lead. It is said that on one occasion Finneguerra, having rubbed in the charcoal and oil, by way of thus proving his work, accidentally let fall upon it some melted sulphur, which upon removal brought with it the ink out of the hollows, and exhibited the exact impression of his work. It occurred to him to try if the same result would follow on a piece of moistened paper if laid over the design thus filled with ink, and pressed by a roller. The experiment succeeded; and the consequence was the gradual improvement of the new art both in his hands and those of Baccio Baldini, Sandro Botticelli, Antonio Pollajuoli, and Andrea Mantegna, to whom he communicated the process. Other accounts, however, make the discovery of chalcography much less the result of accident. According to these, Finneguerra, as well as other workers in niello of his time, were in the habit of proving their works by means of *sulphur casts* previous to the ultimate inlaying. For this purpose the engraved plate was pressed with earth or clay, upon the top of which some melted sulphur was then thrown, which on removal presented a fac-simile of the work on silver; into the lines of this sulphur cast something black was then rubbed, and the artist was thus enabled to form a correct opinion of the progress and perfection of his work. These facts are now placed beyond all doubt by the discovery of some sulphur casts from the nielli of Finneguerra, although there is no fully-authenticated impression upon paper from any plate engraved by him. Thus it would appear that the workers in niello were long advancing on the verge of this invention. Engraving was henceforth to constitute a distinct and honourable profession, or to have those energies further developed by the greatest masters of design which had hitherto only manifested a feeble existence in the workshop of the goldsmith.

Our limits will not allow us to dwell on the merits or performances of those early masters, contemporaries of Finneguerra, to whose exertions we are nevertheless much indebted for the rapid approaches of the art towards excellence. Of these Baldini, Botticelli, and Andrea Mantegna, have already been named among the Italians; and while we disallow the claims of the Germans to the discovery of copperplate engraving, we willingly admit that it was very early and very greatly improved in that country by Martin Schoen, Israel Van Mecheln, Leydenwurf, and Wolgemut. This is not surprising when we reflect that wood engraving had been first practised there, forty years earlier, and consequently that they had anticipated the Italians in a knowledge of printing-ink and the press; nay, it is remarkable that the first book printed at Rome (an edition of Ptolemy's Geography) was also illustrated by the first *plate engravers*, twenty-seven in number, which were maps, and were executed there by two Germans, Sweynheym and Buckink; the latter completing what the former left unfinished at his death. This work is dated 1478, but was commenced in 1472.

One of the first books illustrated with designs on engraved plates was indeed the production of Italian artists; this was an edition of Dante's 'Inferno,' published at Florence in 1481, and embellished with engravings by Baccio Baldini, after the designs of Botticelli. It is worthy of remark that these plates were not printed on the same paper as the letter-press, but blank spaces were left at the head of each canto, over which the prints were pasted. As we believe the greatest number of embellishments ever found in a copy of this work does not exceed nineteen, it is to be presumed that the intended series of illustrations was never completed. Omitting farther notice of those early masters who flourished at the end of the fifteenth, we shall pass on to the sixteenth century, at the commencement of which the art was carried to a very high degree of excellence; in Italy by Marc Antonio Raimondi, and simultaneously by Albert Dürer in Germany, and Lucas Van Leyden in Holland: a constellation of talent, the appearance of which marks the most memorable epoch in the history of engraving.

Marc Antonio, like so many of his predecessors, was originally a worker in niello, in which art he was instructed by Francesco Francia, and acquired considerable skill; but quitting it for engraving on metal, he at first copied some

of the works of his master, and afterwards imitated those of Andrea Mantegna and Albert Dürer. He finally perfected himself in design under Raphael d'Urbino, who appreciated his talents so highly as to lend him every assistance; he even permitted his own grinder of colours to manage the press for him, that he might devote his time wholly to the more intellectual parts of the art.

The great merit of Marc Antonio lay in the correctness and beauty of his outline: so great is his excellence in this respect, that it is believed that Raphael himself assisted him with his own hand on the copper. The character of his heads is admirably preserved, and the extremities marked with the truest precision: but his lights are not enriched with that variety of fainter tones which indicate local colour, nor do his prints possess the harmony arising from the chiaroscuro or the beauty of reflex light. The consequence is somewhat of monotony in his darks and baldness in his lights, which produce an appearance of hardness; but the rude state in which he found engraving must be remembered in forming an estimate of his merits, nor should it be forgotten that the then recent disinterment of the great works of antique sculpture and the fame of Raphael and of Michel Angelo rendered *form* and *character* the great objects of pursuit, as they were indeed at that time, from these causes, thought to be the only ones worthy of consideration.

Thus happily favoured with the patronage, instruction, and friendship of the 'divine Raphael,' he devoted himself almost exclusively to engraving after his matchless productions; and although, as we have seen, his prints want so many of the blandishments and conventionalities of more modern art, and are more deficient in these respects even than his contemporaries of the school of Germany and Holland, yet such was the truth and purity of his outline, that it is doubtful if the works of Raphael have ever since been rendered with so much justice to their author. M. Antonio died about 1527. Our space will not allow even a list of the engravers and painters who engraved or etched (a mode of engraving hereafter to be described) who flourished in Italy during the two centuries which succeeded the death of Marc Antonio: the principal of these however were Agostino de Musis, Marc de Ravenna, Caraglio, Giulio Bonasoni, and Enea Vico, all pupils of Marc Antonio; Georgio Ghisi of Mantua and his relatives Diana and Adam Ghisi, Cornelius Cort, &c. &c. But although by these and others the executive part of the art was continually though slowly improved, their powers in design or drawing, (in which the chief excellence of the school at all times consisted) declined, at least as fast as they advanced in mechanical skill, until at length in the 18th century the intellectual and mechanical excellencies of the art were united in the works of Giacomo Frey; and from that time the credit of engraving in Italy has been well maintained by succeeding artists. The names of the principal painters who have practised engraving in Italy are Agostino Carracci, Stephano della Bella, Spagnoletto, Guercino, Salvatore Rosa, Claude Lorraine, Swaneveldt, Canaletti, Piranesi, &c. &c.

In Germany engraving made more rapid strides towards excellence, in the mechanical parts of it; and at the commencement of the 16th century appeared Albert Dürer, a man whose universality of talent extended the boundaries of every department of art, and carried all to a degree of perfection previously unknown in that country. The defects of Albert Dürer, who was a painter as well as an engraver, were the defects of the school to which he belonged; the dry and Gothic taste of which is equally observable in their paintings and engravings. But in all that relates to the executive part of the art of engraving the works of Albert Dürer deserve the highest praise. The Italian artists having the finest specimens of antique sculpture constantly before their eyes, appear to have been very early impressed by them with a sense of the beauty of flowing lines; and perhaps nothing is so well calculated to convince us of the advantages to be derived from the study of the antique sculptures as a comparison of the works of German and Italian artists. The draperies, for instance, in the German works, are represented by abrupt rectangular forms, and have been well described as *snapt*, rather than *folded*; resembling the appearance of crumpled-up paper more than drapery. The pains which they evidently bestowed upon their works forbid us to ascribe that want of attention which was certainly the result of a vitiated taste in design.

Albert Dürer had great command of the graver, and carried his plates to a much higher degree of finish than his Italian contemporaries, as his print of 'St. Jerome in the Room,' as it is called, the execution of which has scarcely ever been exceeded, will sufficiently attest. To his other honours we have little hesitation in adding that of being the inventor of etching by corrosion, an art which has contributed most powerfully to the perfection of engraving. We are aware that the discovery of etching has been by some attributed to Michael Wolgemut, the master of A. Dürer, but we never heard of any etching from his hand having been seen; nor do we know of any etching by any other hand which bears date so early as the celebrated Cannon landscape, by Dürer, which is 1518; while from his own hand we have two others still earlier, viz. Christ praying on the Mount, 1515; and the Rape of Proserpine, 1516. All these were evidently performed in the very infancy of the art, before the discovery of stopping out, as it is called, an expression which will be intelligible to the reader on a reference to our account of the process of etching. On examining the etchings of Albert Dürer, we see that they have all been corroded at one biting in; which sufficiently explains their monotonous appearance, and proves that stopping out was not understood, or it would have been had recourse to, as its advantages could not have been overlooked. It is most probable that the defective and monotonous tone occasioned by the want of this knowledge is the reason that so few corroded etchings were executed by Albert Dürer, who must have been otherwise fascinated by the facilities which this mode of engraving offered; as it is, his corroded etchings are much inferior to his other works, both on copper and wood.

The principal German engravers, after Albert Dürer, are his pupil, Henry Aldegraver, together with Bartholomew and Hans Sebald Beham, Albert Altdorfer, James Bink, George Penz, Virgil Solis, &c. &c. But the history of pure German art is very short, for most of these German engravers travelled to Italy for improvement, attracted by the fame of Marc Antonio; several of them are indeed his reputed disciples; and the consequence is, that the two schools may be said to have immediately, in some measure, blended; as under the influence of Italian taste the peculiar characteristics of German art in a great measure disappeared. From the small size of most of the works produced by these German engravers, they are generally distinguished as the 'little masters,' although many large plates were executed by them.

Lucas Jacobs, best known by the name of Lucas Van Leyden, was the father of the Dutch and Flemish schools, and the contemporary and friend of Albert Dürer, whose defects he fully possessed, while he fell short of his excellencies. The same vulgarity of form, and general want of grace and propriety of design, which has been noticed in the German school, is equally observable in the works of Lucas Van Leyden; while they are deficient in the spirit and firmness which characterize the works of Dürer. But notwithstanding these drawbacks he was a man of great abilities. After Lucas Van Leyden the art was maintained in the Low Countries by the Wierinxes, the Sadelaers, whose works are multifarious, and embrace every class of subject; the elder and younger Jode, Cornelius, Theodore, and Philip Galle, and Abraham and Cornelius Bloemart. The latter, perhaps less actuated by the commercial spirit in which the art was at this time practised, attempted improvements with success; and by working delicate tints on the lights, which had hitherto been left only as so many white spots, he brought his works to a degree of finish and harmony not previously attained. This artist studied and indeed died at Rome, whither also Goltzius travelled for improvement, who imparted a boldness to engraving which forms a striking contrast to the neat stiff manner of his predecessors. Goltzius was a man of great abilities, and drew the human figure admirably; but in endeavouring to avoid the dry Gothic taste of his countrymen, he went into the opposite extreme, and aiming at the sublime of Michael Angelo, took the one step beyond, and occasionally fell into the ridiculous. The same observations will apply to the works of Spranger; and these faults were exaggerated and carried to the extreme of bombast by the disciple of Goltzius, Müller; but the freedom with which he handled the graver is truly surprising. To these succeeded Lucas Kilian, Matham and Saenredam; and at the commencement of the seventeenth century the two Bolswards, who had

formed their style on that of Goltzius, improved themselves under the instruction of Rubens.

Etching, at this period, was practised by many of the painters in the Low Countries with great success; and we need scarcely say, that it is principally to this process that we are indebted for those treasures of art, the engraved works of Rembrandt: not that in his finished works he confined himself to etching; he also called in the assistance of the graver and the dry point. His etchings being very numerous, are of unequal merit; and many, the subjects of which are of a sacred or dignified nature, are debased by the vulgarity of the characters introduced: but notwithstanding these and other defects, his best works are greatly and deservedly prized, for they are inimitably fine, and possess the excellencies of the best paintings, even by his own hand, in a degree not equalled by the works of any other engraver. To mention the artists of this school from whose hands we have etchings would be to name nearly all the most eminent painters belonging to it. Berghem, Cuyp, Karel du Jardin, Paul Potter, Ruysdael, Ostade, Waterloo, Adrian Van de Veldt, with many others, have all enriched the portfolio of the collector with works of great taste and skill. Among the more professedly engravers not already noticed we must mention Count Goudt as possessing extraordinary skill, although he cultivated the art less as a profession than for pleasure. The family of the Visschers produced many and excellent works, from the pictures of various masters; and Cornelius Visscher stands particularly distinguished for the accuracy of his drawing and the fidelity with which he has rendered the character of the pictures after which he engraved.

In France engraving has been practised with pre-eminence success in the departments of history and portraiture. The celebrity of the school dates from the time of Louis XIV.; for although several engravers had appeared before that time, it was only under the fostering influence of that monarch, assisted by the fine taste of Colbert, his minister, that a school arose surpassing in excellence any which had preceded it. The family of the Audrans produced six eminent engravers, but of these the most distinguished was Gerard Audran. He was an admirable draftsman himself; but the great excellence of his works in other respects was enhanced by the absence of all *manner*, except such as belonged to the painter after whom he engraved. He was the first engraver who successfully united, to any extent, the use of the graver and the etching point, and by thus availing himself of the facilities arising from the use of the aquafortis, produced numerous works of great excellence and some of prodigious size, among which we may mention the battles of Alexander, after Le Brun, each subject of the series being engraved on three or four large plates. The Abbé Fontenac remarks of him that, 'far from conceiving that a servile arrangement of strokes, and the too frequently cold and affected clearness of the graver, were the great essentials of historical engraving, he gave worth to his works by a bold mixture of free hatchings and dots, placed together apparently without order, but with an inimitable degree of taste, and has left to posterity most admirable examples of the style in which grand compositions ought to be treated.'

Gerard Edelinck, although born at Antwerp, may be fairly considered of the French school, and was an engraver of the highest order. In portrait Nanteuil is no less celebrated than his contemporaries: the beauty and clearness of his style has perhaps never been exceeded. The Drevets (Peter Drevet in particular) are scarcely less distinguished: nor must we omit the name of John Louis Rouillet, whose engraving of the 'Dead Christ with the fainting Virgin,' after Annibal Carracci, is one of the finest specimens which the art has produced. In addition we can only notice the names of Le Clerc, Simoneau, Chereau, Cochin, Dupuis, Beauvais, Balechou, Le Bas, John George Wille, &c. &c. The modern and existing French school has produced very able engravers, whose chief defect is, that, deviating from the course pursued by Gerard Audran and all the first artists, they allow that which is merely mechanical to predominate in their works; and aiming at great dexterity in the use of the *graver* as the chief objects, they make an ostentatious display of lines, the uniformity and regularity of which is offensive to the eye of true taste, imparting, as it often does, even to the flesh, the appearance of net-work, when viewed closely.

The English school of engraving dates only from about

the middle of the eighteenth century, previous to which time the arts had not flourished indigenously in our country; and such engravers as practised here were chiefly foreigners. With a school of painting however has arisen an assemblage of engravers in all the departments of art who may safely challenge comparison with those of any time or nation. It is true we had previously the Faithornes, Payne, and the Whites; but Hollar, Simon, and Crispin de Passe, Wallerant Vaillant, Blooteling, Gribelin, Dorigny, and Vanderbank, were all foreigners; and the principal engravings of the time were their productions.

The reign of George III. was however auspicious to the arts, and since then we can boast of a numerous train of engravers whose works do honour to the country and to the painters from whose works they are engraved. One of the earliest of these was Hogarth, an artist of most original genius, whose engravings were all from his own designs, in a walk of art entirely new. Landscapes had hitherto never been engraved in a satisfactory manner, the older engravers adhering to the use of the graver *only*, which was inadequate to express with sufficient freedom the playful luxuriance of foliage, the ruggedness of rocks, or the dash of foaming waters. These objects were first accomplished by Francis Vivares, who was a most accomplished etcher, and may be regarded as the father of English landscape engravers, who have unquestionably surpassed all their predecessors in this department of art. Woollett followed in the same tract, carrying his landscapes very forward with the etching point, and finishing them only with the graver. His best works are unrivalled; nor was he inferior in history, as his print of the death of General Wolfe, after West, sufficiently attests.

These two artists carried landscape engraving at once to perfection. Browne may be mentioned as a worthy follower; he produced many excellent plates after the old masters, and sometimes worked in conjunction with Woollett. In history and portrait Sir Robert Strange ably vindicated the honour of the art in this country: his engraving of flesh has perhaps never been equalled, certainly never excelled by any master: his works are however often much deteriorated by his defective drawing. Mezzotinto engraving, although not strictly born among us, has been in no other country practised with a degree of success at all approaching that attained by M'Ardell, Earlom, Smith, Valentine, Green, and others. Bartolozzi, Ryland, Sharpe, Paul Sandby, Middiman, Milton, Fidler, are among the most eminent of deceased engravers; and Mr. Wilson Lowry is entitled to most honourable mention as a great benefactor to the art, by the invention of the ruling-machine, an instrument of great value for many purposes, and the operation of which is perfect. At present every department of engraving is filled with artists of great abilities, any of whom it would be invidious to name to the exclusion of others: it is enough to say that their talents and their numbers have given the art a commercial importance in this country to which it never attained in any other.

A modern engraving is usually the result of two processes, viz. of direct incision with the graver, or the dry point, and of etching by corrosion. These we shall proceed to explain; and first we will enumerate and point out the uses of the different implements required. The principal instrument is the *graver*, or *burin*, which differs in size and shape according to the character of the line which it is intended to produce, but the ordinary graver is of the form of a quadrangular prism, both square and lozenge-shaped, and fitted into a short handle, the whole being about five inches and a half long. The square graver is used in cutting broad lines, and the lozenge-shaped for more delicate ones. In making the incision, it is pushed forward in the direction of the line required, being held by the handle at an angle very slightly inclined to the plane of the copper. It is requisite that the graver be well tempered, and great address is necessary in whetting it for use. The angle at the meeting of the two lower sides of the graver forms what is called its belly, and the breadth of the end is called its face. The two sides which form the belly are to be laid flat upon the oil-stone, and rubbed firmly until the belly slightly rises, so that if it were laid flat upon the copper the light could be seen underneath the point; otherwise it would be impossible to use it with freedom, as it would dig unequally deep into the copper. The face is next to be whetted, which is done merely by laying the face of the graver flat upon the stone, with the belly upward, and rubbing it steadily upon

a moderate slope until it acquires a very sharp point, taking care that the stone be properly supplied with oil all the while. The gravers sold in the shops are commonly too hard for use, which is known by the frequent breaking of their points: when this is the case they should be tempered by holding them on a red-hot poker, at a distance of half an inch from the point, until they acquire a faint straw colour; they should then be put into oil to cool; or they may be tempered in a candle and cooled in the tallow. But it is best not to be hasty in tempering; for if the graver is only a little too hard, whetting alone will frequently bring it into good condition. An instrument called a *scraper* is required to scrape off the barb or burr which is formed by the action of the graver and dry point. The *burnisher* is used to polish the plate and to erase any scratches which it may accidentally receive, and also to make lighter any part of the work which may have been made too dark. An *oil-stone* is requisite for sharpening the instruments upon. *Etching-points* or *needles* are nearly similar in appearance to sewing-needles, but fixed into handles four or five inches long; some are made of an oval form, to produce broader lines with: their use will be explained when we are describing the process of etching. *Dry point* is, in fact, nothing more than the common etching-needle brought to a very fine point. It is used to cut or scratch the more delicate lines with, such as skies, &c. &c. It does not, like the graver, cut the copper clean out, but throws it up on each side of the line produced by its progress through the metal: this is called the burr, which is removed by a scraper. This burr was left on by Rembrandt, until it wore away in the progress of printing, which it soon does; but by his management it added greatly to the effect of the etching, and impressions from his works with the burr on are much valued. A *cushion* is a bag of leather filled with sand; its use is to support the plate so that it may be freely turned in any required direction; but it is not now much used by artists, being chiefly confined to engravers of writing. A *rubber* is a roll of cloth tied up tight, one end being kept in olive oil. It is useful to polish off more completely the burr and also to show the appearance of the work as it proceeds.

Etching is one of the greatest improvements in modern art, almost all plates of every size and description being now commenced by this process, and indeed brought by it to a very considerable effect, and afterwards carried on to the necessary degree of finish and strength with the graver and dry point. Etching is the superaddition of the chemical process of corrosion to drawing, when performed on a plate of copper over which a substance called *etching-ground* is laid, and through which the design is traced with an etching-needle, so as to expose the surface of the copper wherever it has passed. This etching-ground is a substance composed of wax, asphaltum, gum mastic, resin, &c. incorporated by melting over a fire, and capable of resisting the action of aquafortis. The *laying of the ground*, as it is called, is thus effected:—The plate must be heated over a charcoal fire, so that it may not be smoked. For this purpose a hand-vice is fixed to the most convenient part of the plate, by which it may be held in the hand. A piece of the etching-ground, rolled into the form of a ball, and tied up in a little silk bag, is then rubbed over the surface of the plate, the heat of which causes the ground to melt and come through the silk on to the copper. In order to effect a more equal distribution of the wax, a small dabber made of cotton wool, tied up in a piece of taffety, is quickly dabbed all over the face of the plate while yet warm, so as to leave the wax or etching-ground of uniform thickness; the ground is then rendered black, by being held over the smoke of a wax candle, or, if necessary, two or three wax candles tied together, care being taken to move the plate about, so that it be equally smoked all over; and this operation of smoking must be commenced before the plate has had time to cool. The whole operation of laying the ground requires address and dexterity. When cold, the plate is now ready to receive the design. To transfer the design to the copper, an outline is made with a black-lead pencil on a piece of thinnish and even paper, and laid with the face downwards on the etching-ground; the whole is then passed through a rolling-press, the effect of which is to transfer an impression of the outline on to the smoked ground. After this the design is completed with the etching needles, which remove the ground from the copper wherever they pass, and expose it to the action of the acid during the process o.

biting in, which is thus performed:—A substance called *banking wax*, which when cold is quite hard, but which on immersion in warm water becomes soft, and may be moulded into any form, is first rendered soft by being so immersed in warm water, and then banked up all round the margin of the plate, so as to form a trough capable of preventing the escape of the acid, a gutter only being formed at one corner for the purpose of pouring it off when requisite. This being done, the nitrous acid, reduced with water to the proper strength, is poured on, and its action on the copper becomes visible by the rising of innumerable bubbles. The aquafortis must be allowed to continue on the plate until the fainter parts are supposed to be corroded sufficiently deep; after which it is to be poured off, the plate washed with water and left to dry. The parts which are bitten-in enough, are now to be covered with what is called *stopping-ground*, which is a mixture of lamp-black and Venice turpentine; this is applied with a camel-hair pencil, and allowed to dry. After this the acid is again poured on, and this process of *stopping-out* and *biting-in*, is repeated until even the darkest parts are sufficiently corroded. After this the plate is again warmed, when the border of wax may be readily taken off. It is then made warm enough to melt the ground, which is removed by being wiped with a rag and a few drops of olive oil. The work is now complete, unless it is intended to finish it still further with the graver. We might here offer rules for the strength of the acid, and state the length of time it ought to remain on the plate, but we are convinced of the inefficacy of such instructions. Nothing but experience joined to some chemical knowledge of the effect of the acid will avail the artist on this point, which requires the greatest nicety and attention.

Biting on soft ground is a mode of etching formerly much in use, by which imitations of drawings in chalk and pencil were produced. It is now superseded by lithography, which is more successful in attaining the same objects. Soft ground etching is quite a distinct process from

Engraving in stipple, as practised by Bartolozzi, Ryland, and others, in imitation of chalk drawings of the human figure. Stipple is performed with the graver, which is so managed as to produce the tints by small dots, rather than by lines, as in the ordinary method. It is very soft in its effect, but is on the whole much inferior to the more legitimate mode of engraving.

Engraving on steel and *etching on steel* are performed in the same manner as on copper, for which steel has of late years been often substituted on account of its yielding a greater number of perfect impressions, owing to its superior hardness.

Medallic engraving is a species of etching lately practised by M. Collas and Mr. Bate. By this mode very beautiful representations are obtained of medals, &c., by means of a machine of peculiar construction, the principle of which is known; but minor inventions for the purpose of counteracting certain local tendencies to inaccuracy in the machine have been hitherto kept secret.

For account of *engraving on stone*, see LITHOGRAPHY; and for *engraving in mezzotinto*, see MEZZOTINTO.

Etching on glass is performed by laying on the glass a ground of bees' wax, and drawing the design thereon with the needle, as in etching upon copper. Sulphuric acid is then poured on, and fluor spar, or fluoric acid, sprinkled on it. After four or five hours it is taken off, and the work cleaned with oil of turpentine.

ENGROSSING; copying in a large hand; the writing a deed over fair, and in proper legible characters; from the French *grossir*, to make bigger. Among lawyers it more particularly means the copying of any writing fair upon parchment or stamped paper.

In statute-law *engrossing* means the purchasing of large quantities of any commodity, in order to sell it again at a high price. ('An Inquiry into the Laws, antient and modern, respecting Forestalling, Regrating, and Ingrossing: together with adjudged Cases, Copies of original Records, and Proceedings in Parliament relative to that subject.' by William Illingworth, 8vo., Lond., 1800.)

ENHARMONIC, the third in order of the three genera of antient music. The enharmonic genus of the Greeks was distinguished by quarter tones, while the modern scale admits these small intervals theoretically only, not practically, except by a fiction. Thus c sharp and d flat are with the moderns practically the same note, at least on keyed instruments, though, strictly, the former is $\frac{1}{4}$ of the

whole string sounding c, the latter $\frac{1}{4}$. The passage from one to the other of these intervals is called an *enharmonic change*, and a change of key so effected is designated by the term *enharmonic modulation*. Examples:—

ENHYDRA. [OTTER.] ENIGMA. [ENIGMA.]

ENLISTMENT, an engagement to serve as a private soldier either during an unlimited period or for a certain number of years, on receipt of a sum of money. Enlistment differs from enrolment, inasmuch as it is a voluntary act, whereas the latter is, under some circumstances, rendered compulsory: as in the case of men who are selected by ballot for the militia in this country, or by the conscription, for military service generally, on the continent.

The practice of impressing men to serve as soldiers, on sudden emergencies, was formerly very common in England; and it is well known that within the last half century young men were entrapped and secretly conveyed away to recruit the armies employed in the east. The discovery of this illegal and disgraceful method of obtaining soldiers was speedily followed by its abolition; and now, the East India Company's troops, as well as those of the regular army, are obtained by voluntary engagement.

The number of young men who are induced to enlist by the ambition of entering upon a course of life which appears to hold out a prospect of distinguishing themselves by gallant achievements in the field is, however, too small for the wants of the military service; and the allurements of a bounty must necessarily be presented in order that the ranks of the army may be filled. But the profession of a soldier can never possess such advantages as might induce an industrious man who can obtain a subsistence in another way to embrace it; and it is to be regretted that too frequently those who enter the service are thoughtless youths or men of indolent habits or desperate fortunes. Some attention, however, to the character of a person offering himself for enlistment is necessary if it be desired to render the service honourable; for it is found that idle and dissipated men are with difficulty brought to submit to the necessary restraints of discipline; their frequent desertions entail heavy losses on the government, and they often corrupt those who are compelled to associate with them. When circumstances render it necessary to enlist such men, it is obvious that they ought to be distributed in small numbers among different regiments, and quartered in places remote from those from which they were taken.

By the 34th clause of the Mutiny Act, every person who has received enlisting-money from any military man employed in the recruiting service is considered as having enlisted; but within forty-eight hours afterwards notice is to be given to the recruit, or left at his place of abode, of his having so enlisted; and again, within four days from the time of receiving the money, the recruit, attended by any person employed as above-said, is to appear before a magistrate (not being a military man), when, if he declare that he has voluntarily enlisted, the magistrate is to question him concerning his name, age, and condition, and particularly to inquire of him whether he is then serving, or whether he have ever served, in the army or navy. The magistrate is then to read to the recruit the articles of war relating to mutiny and desertion, and administer to him an oath of allegiance, of which a form is given in a schedule to the act: if the recruit refuse to take the oath, he may be imprisoned till he do so.

But as the young and simple have been sometimes inveigled by illusory promises, or persuaded, while deprived of judgment by intoxication, to enlist, if a recruit, on reflection, wish to withdraw from the engagement into which he may have been surprised, it is provided by the 35th

clause of the Mutiny Act that when taken before the magistrate as above he shall be at liberty to declare his dissent from such enlistment; on making which declaration and returning the enlisting-money, with 20s. in addition for the charges which may have been incurred on his account, he shall be forthwith discharged. But if he omit within twenty-four hours after so declaring his dissent to pay such money, he is to be considered as enlisted, as if he had given his assent before the magistrate.

If a recruit, after receiving the enlistment-money, and, after notice of having enlisted has been left at his place of abode, shall abscond, he may be apprehended and punished as a deserter, or for being absent without leave; and if it be discovered that he is unfit for active service, in consequence of any infirmity which he had not declared before the magistrate, he may be transferred to any garrison, or veteran or invalid battalion, though he may have enlisted for some particular regiment. If it be proved that the recruit concealed the fact of his being a discharged soldier, he may be sentenced to suffer punishment as a rogue or vagabond; and if, at the time of enlisting, he falsely denied being in the militia, he may be committed to the house of correction for a period not exceeding six months; and, from the day in which his engagement to serve in the militia ends, he is to be deemed a soldier in the regular forces.

An apprentice who shall enlist denying himself to be such is deemed guilty of obtaining money under false pretences; and, after the expiration of his apprenticeship, he is liable to serve in her Majesty's forces; but a master is not entitled to claim an apprentice who may have enlisted unless the claim be made within one month after the apprenticeship shall have left his service.

In the third clause of the Mutiny Act it is stated that no man enlisted as a soldier is liable to be arrested on account of any process for leaving a wife or child chargeable to a parish, or on account of any engagement to work for an employer (except that of an apprenticeship), or on account of any debt under 30*l*. And in the 39th clause it is declared that Negroes, purchased on account of the crown and serving in any of the regular forces, are deemed to be free, and are considered as soldiers having voluntarily enlisted. Every military officer acting contrary to the provisions of the Mutiny Act, in what regards enlisting recruits, is liable to be cashiered.

During the reign of Queen Anne it was the custom to enlist recruits for three years; but this period seems too short, considering the time unavoidably spent in training the men, to afford the government an advantage adequate to the expense of maintaining them; and the present practice is to enlist either for an unlimited period, as during the continuance of a war, or for certain defined numbers of years which vary in the different classes of troops. For the infantry the period is seven years; for the cavalry ten years, and for the artillery twelve years; but if the person enlisting be under eighteen years of age, the difference between his age and eighteen years is added to each period. The enlistments for the Honourable East India Company's service are also for unlimited periods, or for twelve years, provided the recruit be not less than eighteen years of age.

The advantages of a limited period of service are, that a greater number of recruits are obtained under that condition, probably because men are more willing to engage themselves for a certain number of years than for life; and that, during the period, opportunities are afforded of discovering the character of a man. Should this be such as to render it not advisable to retain him, he may be discharged at the end of his time of service; while an additional bounty, strengthened by the unwillingness of most men to leave the comrades with whom they have been long accustomed to associate, will probably induce a good soldier to re-enlist should the continuance of his services be desired.

By an act passed in 1836 a man is allowed to enlist in the navy for a period not exceeding five years, after which he is entitled to his discharge and to return home, if abroad, unless the commanding officer should conceive his departure to be detrimental to the service; such officer is then empowered to detain the man six months longer, or until the emergency shall cease, in which case the man is entitled, during such extra service, to receive an increase of pay amounting to one-fourth of that which he receives according to his rating. At the end of his time of service a seaman may re-enlist for a like period, and he will then be allowed the same bounty

as at first. Seamen entering as volunteers within six days after a royal proclamation calling for the services of such men receive double bounty. In the year 1819 was passed that which is called the Foreign Enlistment Act, by which British subjects are forbidden to engage in foreign service without license from the crown: this is that act which is yearly suspended in favour of the troops now (1837) employed in the service of the queen of Spain. Lastly, a bill has recently passed, confirming the act of 55 Geo. III., by which her majesty is empowered to grant the rank of field and general officers to foreigners; and to allow foreigners to enlist and serve as non-commissioned officers and soldiers in the British service in the proportion of one foreigner for every fifty natural born subjects.

ENNIS, the assize town of the county of Clare in Ireland; situated in the barony of Islands on the west bank of the river Fergus, about three miles above the small town of Clare, at which place this river is navigable. [CLARE.] The direct distance from Dublin is 136 English miles. The borough, as settled under the Boundary Act, embraces 469 statute acres, and comprises 1390 tenements, of which 564 only are slated houses. It is incorporated by charter of the 10th January, and returns one member to the Imperial Parliament. The corporation, consisting of provost and free burgesses, is virtually extinct.

The name of the place was originally Ennis Cluainruadha, so called from Clonroad, a favourite dwelling-place here of the O'Briens, Lords of Thomond. In 1240 Donogh Carbrac O'Brien built a monastery at Ennis for Franciscan friars, the erection of which probably gave origin to the town. It was repaired in 1305 by Turlogh Mac Tiege, and destroyed in 1306 by Dermot Mac Donogh, both of the same family. The ruins are still standing.

Ennis consists of two chief streets, one parallel to the Fergus, over which are three bridges, and one diverging towards Kilrush. Near the latter are the county gaol and court-house, the only buildings of consequence in the town. The suburbs consist of wretched cabins. There is no police, neither is Ennis watched, lighted, or regularly cleansed. There are no manufactures; but there is a moderate trade in grain and cattle. In 1821 the population of Ennis was 6701; and in 1831 it was 7711; the total population within the boundary of the borough in the latter year was 9727. In the parish of Drumcliffe, in which Ennis is situated, there were, in 1834, 21 schools educating 772 males and 428 females. Of these schools, four were Sunday-schools, seven were hedge-schools, and one was in connection with the National Board of Education. (*Statistical Survey of Clare; Parliamentary Reports and Papers.*)

ENNISCORTHY, a borough town in the baronies of Scarewalsh and Ballaghkeen in the county of Wexford in Ireland; situated about 12 English miles above Wexford on both banks of the river Slaney, which is here navigable for sloops. The direct distance from Dublin is about 67 English miles.

Enniscorthy was incorporated by charter of the 11th James I. The corporation consists of a portreeve and 11 burgesses. The portreeve holds a court once a week with jurisdiction to the amount of 3*l*. 6*s*. 8*d*. late Irish currency. The corporation has no revenue. The boundary is very irregular and extends in some directions two and three miles from the town.

Enniscorthy took its origin as a town from the erection of a castle here by Raymond le Gros, one of the early Anglo-Norman conquerors, about the end of the twelfth century. Gerald de Prendergast, another Anglo-Norman noble, founded a monastery here for Augustinian friars about 1230; and Donnell Cavanagh, an Irish potentate, founded a Franciscan convent for friars of the strict observance in 1466. On the dissolution of religious houses, the possessions of the Augustinians were granted to Edmund Spenser, the poet, and those of the Franciscans to Lord Henry Wallop. Some ruins of both edifices still remain. The castle also is still standing and in good preservation. It consists of a square keep flanked by round towers, and stands at the west end of the bridge, on the bank of the Slaney, opposite the remains of the Franciscan convent. Enniscorthy was taken by Cromwell in 1649, and was stormed and burned by the Irish rebels in 1798. On the latter occasion it is said that 478 dwelling-houses were destroyed. In the immediate neighbourhood is Vinegar-hill, the scene of a sanguinary engagement in the latter year. [WEXFORD.]

Enniscorthy is at present a thriving and handsome town. It has a very considerable trade in grain with Wexford. The population of that part of the town which lies in the barony of Scarewalsh, in 1821, was 3557; and in 1831 was 4375. The population of the entire town as situated in the baronies of Scarewalsh and Ballaghkeen was in the latter year 5955. In 1834 there were in the parishes of St. Mary's, Enniscorthy, and Templeshannon, in which the town is situated, 13 schools educating 499 males and 469 females. Of these schools that attached to the nunnery of Enniscorthy educates 230 females. (*Brewer's Beauties of Ireland*; *Inglis's Ireland in 1834*; *Parliamentary Reports, &c.*)

ENNISKILLEN, the assize town of the county of Fermanagh in Ireland; situated in the baronies of Tyrkenney and Magheraboy, on an island in the narrow channel which connects the upper and lower lakes of Loch Erne. The direct distance from Dublin is about 87 English miles.

The antient borough comprises the island of Enniskillen, the site of the castle excepted: under the Boundary Act the borough now includes the two suburbs which are situated north-east and south-west of the island, in the parishes of Enniskillen and Rossory respectively.

Prior to the plantation of Ulster, the only building on the island of Enniskillen was a small fortalice of the Maguires, which came into the hands of the English during the last rebellion of Tyrone in 1602. The town was altogether the work of the Protestant settlers introduced by the new patentees. [FERMANAGH.] It was erected into a corporation while still in its infancy in 1612; but had increased so far as to cover the greater part of the island in 1641, when, through the exertion of Sir William Cole, it proved a most important asylum for the Protestants on that border of Ulster. In the subsequent war of the Revolution the inhabitants of Enniskillen were among the first to take decided measures against the government of James II., having refused admission to two companies of the Roman Catholic army sent thither by Tyrconnell, and immediately chose Sir Gustavus Hamilton their governor, and proclaimed William and Mary. Throughout the contest which ensued, the local levies of Enniskillen and its neighbourhood did excellent service; particularly in their defeat of Lord Galmoy, before Crom Castle, and in the battle of Newtown-Butler or Lisnaskea, where, under the command of Wolsey, they routed the army of Macarthy advancing to the siege of the town with a slaughter of nearly 3000 Irish. Their exploits have been recorded in Hamilton's 'Actions of the Enniskilleners.'

The corporation consists of a portreeve and 14 free burgesses, but does not exercise any civil or criminal jurisdiction. The annual revenue is 596*l.* 10*s.* 9*d.*, arising chiefly from tolls: the expenditure 595*l.* 2*s.* Enniskillen is not watched or lighted. The principal road through the town is repaired at the expense of the county.

Enniskillen is well built and beautifully situated. Two bridges connect the island, which is covered to the water's edge with the buildings of the town and its defences, with the suburbs on each side. The country around swells into highly cultivated eminences; and numerous seats of gentry occupy the shores of the lake above and below. There is a brisk retail trade in the supply of those comforts required by the superior order of farmers who occupy the neighbouring districts, and everything wears a prosperous and decent appearance, which contrasts very strongly with the wretchedness of other towns lying but a short distance farther south. Three newspapers are published in Enniskillen, which in 1835 used 26,600 stamps. From its position, commanding the only pass into Ulster within a distance of 50 Irish miles, Enniskillen is a place of considerable military importance.

In 1821 the population of Enniskillen was about 4399; and in 1831 the entire town contained 6056 inhabitants, and the borough 6116. In 1834 there were in the parishes of Enniskillen and Rossory 50 schools, educating 1186 males and 728 females. Of these schools three were in connection with the National Board of Education, nine were Sunday-schools, and fifteen were hedge-schools. The royal school of Enniskillen is supported by the estates of the foundation. The head master receives 500*l.* yearly, a house, and 33 acres of land; the assistants receive 350*l.* yearly; and 400*l.* is annually divided among ten scholars of the house; 41 males were receiving instruction here in 1834.

Enniskillen is represented in the Imperial Parliament by

one member. (*Cox's History of Ireland*; *Leland's do.*; *Inglis's Ireland in 1834*; *Reports, &c.*)

ENNIUS, QUINTUS, the old epic poet of Rome, was born at Rudia, now Ruvo, in Calabria, in the year 239 B.C., two years after the termination of the first Punic war. He was a Greek by birth, and is one among many instances how much Roman literature was indebted even directly to foreign talent. History does not inform us what his original Greek name was, for that of Ennius is evidently of Latin form, and was probably adopted by him when he was admitted to the privileges of a Roman citizen. Of his early life little is positively known. He entered the military service of the Romans, and in the year 204 was serving as a centurion in the island of Sardinia, where his abilities attracted the notice of Cato, who was then acting as quaestor under the first Scipio Africanus. When Cato left the island, the poet accompanied him to Rome, and fixed his residence on the Aventine hill. The introduction of Cato, his military character, and his poetical abilities, won for him the friendship and intimacy of the first men of Rome, and he was largely instrumental in introducing letters among a nobility who had hitherto gloried as much in their ignorance as their courage. Cato himself learned Greek from him. Scipio Africanus found in him a companion in peace and the herald of his glories in war. Scipio Nasica, the son of Africanus, delighted in his society; and M. Fulvius Nobilior, the consul, 189 B.C., himself possessing a high literary character, prevailed on the soldier-poet to accompany him in the war against the Aetolians. It was to the son of this Fulvius that he was indebted for his admission to the citizenship of Rome. His great social qualities unfortunately led him into intemperance, for which he paid the penalty in great sufferings from gout. Still a hardy constitution enabled him to complete his seventieth year, and to the very last to devote himself to his favourite muses. He died in the year 169, and was buried in the Cornelian sepulchre, one mile out of Rome, on the Appian road, where his statue still appeared with those of Publius and Lucius Scipio, even in the age of Livy, a lasting monument of his intimacy with those great men. He lived, as we have already said, in the splendid dawn of Roman literature. Nævius, the first poet of Rome, and Lævius Andronicus were his predecessors by not many years. The tragic poet Pacuvius was his sister's son. Plautus was his contemporary, and the comic writer Cæcilius his companion in arms. The writings of Ennius were numerous and various. His great work called, somewhat unpoetically, by the name of *Annals* was an historical epic in eighteen books, written in hexameter verse, a form of metre which he is said to have been the first to introduce into Roman literature. This work traced the history of Rome from the mythical age of Æneas down to his own time. His labours in tragedy were extensive. He gave the Romans a translation, but evidently a very free one, of the *Eumenides* of Æschylus, the *Medea*, *Iphigenia in Aulis*, and *Hecuba* of Euripides, the *Ajax* *Flagellifer* of Sophocles, besides as many as nineteen from other Greek poets. He also wrote comedies. His other works were *Phætica*, a poem on gastronomy, especially on the merits of fishes; an epic, or panegyric, entitled *Scipio*; a metrical translation from a philosophic work of Epicharmus, partly in dactylic hexameters, partly in trochaic tetrameters; poems entitled *Asotus*, *Sotadicus*, *Protreptica*, and *Præcepta*; also satires, epigrams, and acrostics; and a prose translation of the sacred history of Euemerus. Of all these works there is only an unconnected mass of fragments collected from quotations in Cicero and other writers. The work entitled *Annals* was for a long time the national epic of Roman literature, and Virgil has not scrupled to borrow freely from it. The best edition of Ennius is that by Hesselius, 4to., Amsterdam, 1707.

ENNUI, a French word adopted of late into the English language, signifies mental lassitude or languor, produced either by depression of spirits or satiety of enjoyment, or over excitement, and which leaves no relish for any mental pursuits or pleasures. 'Mourir d'ennui' is a French phrase, which means that the mind sinks under this kind of depression, without any apparent cause of either misfortune or grief. Persons in the upper ranks of society who have pursued a life of dissipation, or who have lived much in what is called the fashionable world, are often subject to this complaint. Madame du Deffand used to complain bitterly of ennui. Ennui in French means care, or disappointment in general; and a tiresome person is often

called ennuyeux or ennuyant. The word 'noja' in Italian answers to the French ennui.

ENOCH, the Book of, is one of the Hebrew Scriptures which, with the book of Wisdom, of Tobit, Judith, Maccabees, and several others, were designated Apocryphal, that is, hidden books (Βίβλοι Ἀπόκρυφτοι) from the fact that, after the destruction of the temple at Jerusalem by the Romans, the Jews having established at Tiberias their sacred archives, called by the Greek Fathers Gazophylakia (Γαζοφυλάκια), they there concealed in a cell, under the seal of their patriarch, such books as it was considered expedient to withdraw from public inspection. (Epiphanius, *Hæres*, 30, § 6 and 4.) The Scriptures deemed canonical were here deposited in a new ark, called the Aron (Ἀρον), or ark of the Covenant (διαθήκη κεινῶς), but the holy books (ἁγίαγραφα), which were not included in this chest, and which, about the close of the first century, were suppressed by the Jews, and thus concealed, were thence called the Apocrypha (Ἀπόκρυφτοι). It is stated that the use which was made of some of these scriptures by the zealous advocates of Christianity occasioned an anxiety among the Jews to hide them, and that the predictions of the Messiah in the book of Enoch were considered to be so obvious that it was on this account concealed. (See on this point Pezron, 'L'Antiquité des Tems défendue,' 4to, p. 430.) During the apostolic age the book of Enoch was commonly read by Jews and Christians. St. Jude, in his catholic epistle, cites it as the work of a divine prophet ('Enoch the seventh from Adam prophesied, saying,' &c., v. 14, 15,) so Tertullian (*De Idolatria*) refers it to the inspiration of the Holy Spirit: however, in another treatise (*De Cultu Fœminarum*) he states that by some it was not received. Irenæus, Jerome, and other Fathers, respectfully notice it, though not as canonical; and Origen (*contra Celsum*, lib. v.) observes that, in his time, it was not of great authority in the churches, which Pezron attributes to the fact mentioned by Syncellus (*Chronographia*), that it was maliciously corrupted by the Jews and Christian heretics. Whiston published in 1727 a learned Dissertation to prove it to be quite as canonical as any book to which that epithet is applied. In the Testament of the Twelve Patriarchs, translated by Robert Grotthead, bishop of Lincoln, the sons of Jacob speak often of reading in the book of Enoch. It was extant among Christian writers until the eighth century, when it appears to have been lost. Several fragments however remained, which, with a few citations collected from the Fathers and succeeding writers, supplied the only data for the critical discussions of learned divines during several centuries. All these relics, amounting to about 20, are inserted in the 'Codex Pseudopigraphus Vet. Test. of Fabricius, tom. i. p. 160—224.

At the end of the 18th century Bruce brought from Abyssinia three complete and beautiful copies of the book of Enoch, in the Ethiopic language, one of which he presented to the Bibliothèque du Roi at Paris, and another to the Bodleian Library at Oxford. Transcriptions and partial translations into Latin were made by Dr. Woide of Oxford and Dr. Gesenius of Halle; but the Ethiopic MS., which at first excited much curiosity, lay undisturbed during more than a quarter of a century, until the professor of Hebrew at Oxford, Dr. Lawrence, broke in, as he informs us, upon its repose, and published in 1826 an English version of the whole, entitled 'The Book of Enoch the Prophet, supposed for ages to be lost; translated from an Ethiopic MS. by the Rev. Richard Lawrence, LL.D., archbishop of Cashel.' A second and revised edition appeared in 1833. That this book is identical with that which, in the primitive ages of Christianity, was cited by Jude and the Fathers, is considered by Dr. Lawrence to be completely evident. His critical prolegomena and notes are incorporated in a more recent translation into German, which is accompanied with a much larger mass of learned researches, forming two thick volumes 8vo. ('Das Buch Henoch, in vollständiger Übersetzung mit fortlaufenden Commentar, ausführlicher einleitung und erläuternden excursen, von Andreas Gottlieb Hoffmann, Doct. Philos. Profess. Theol. an der Univers. zu Jena,' 1833.) As the allegorical statements of the book, as far as any meaning is clearly assignable, appear to relate to historical events which extend to the time of Herod the Great, it is supposed by those who reject the supposition of its being the antediluvian production of Enoch himself that it was anonymously written in Hebrew, shortly before the commencement of the Chris-

tian æra. (Scaliger and Lawrence.) The subject matter consists chiefly of relations of Enoch's prophetic and celestial visions, in the most remarkable of which the angel Uriel (lxx. et seq.) shows to the prophet all the mysterious scenes in heaven, including a survey and explanation of the solar and lunar revolutions according to the ancient astrological theory. A view is also exhibited of the interior of hell. Occasionally religious and moral precepts are enjoined, but all sense of propriety is continually shocked with such preposterous combinations that Scaliger, judging merely from the fragments then possessed, scrupled not to designate the book as a tissue of disgusting lies and nonsense. (*Scaligeriana*.) It commences with some historical statements of which the following, from chap. 7, is a specimen:—'To the sons of men were born elegant and beautiful daughters, and when the angels, the sons of heaven, beheld them, they became enamoured of them, saying to each other, Come, let us select wives for ourselves and beget children.' Accordingly a band of 200 angels having descended on Mount Arnon, and sworn to accomplish this project, 'they then took wives, each choosing for himself; with whom they cohabited, teaching them sorcery and incantations; and the women conceiving, brought forth giants whose stature was each three hundred cubits (550 feet): these, when they had devoured all the produce of man's labour, began to devour men, birds, beasts, and fishes, eating their flesh and drinking their blood.' In representing persons and events by animals and inanimate objects of nature, combinations are introduced of such a monstrous nature, that, in comparison, the metamorphoses of the Pagan mythologies appear to be rational. The history of the prophet to whom this book is attributed, or rather whose visions it relates, is briefly recounted as follows, in Genesis v. 18—24:—Jared at the age of 162 begat Enoch, who at the age of 65 begat Methuselah, and afterwards walked with God 300 years, and begat sons and daughters. All the days of Enoch were 365 years; he walked with God, and was not, for God took him. (Compare Ecclesiasticus xlv. 16; Heb. xii. 5.) From the fact of his being the seventh from Adam, from the number of the years of his age being precisely the number of days in the year, and from several other points of curious coincidence, the sceptical Boulanger asserts, in a learned treatise on the subject (Enoch, in *Œuvres Diverses*), that the name is but a variation of the Phrygian Annac, a symbolical personification in Sabianism, representing the solar period; and identical with the Oriental Anusch, the Phœnician Anac or Enac, the Etruscan Anus, and the Latin Janus. The names of the seven patriarchs, Adam, Seth, Enos, Cainan, Mahalaleel, Jared, and Enoch, are etymologically resolved into mythical symbols of the seven planets, that is, the Sun, Moon, Mars, Mercury, Jove, Venus, and Saturn. The translation of Enoch has also been compared with the ancient mysterious burial at sunrise of noble and comely youths who prematurely died. (Eustathius, *Comment. in Odyss.*, tom. iii, p. 1527, § 51, ed. Rom., 1549.) They were said to have been not really dead, but carried up alive to the region of light in consequence of their being loved by the Supreme Being. The story of Ganymede is an instance. (See the learned disquisition on the subject in Montfaucon's *Religion des Gaulois*, tom. ii. p. 305, &c., and in his *Explication des Textes difficiles*, tom. i. p. 332.) Hence the well-known axiom, 'He whom the Gods love dies young,' (Plutarch, *De Consolatione Philosoph.*)

ENROLMENT, in law, is the registering, recording, or entering a deed, judgment, recognizance, acknowledgment, &c., in the Chancery, or any other of the superior or inferior courts being a court of record. But the enrolling of a deed does not make it a record, though it thereby becomes a deed recorded; for there is a difference between a matter of record and a thing recorded to be kept in memory; a record being the entry of judicial proceedings in a court of record; whereas an enrolment of a deed is the private act of the parties concerned, of which the court takes no judicial notice. Various statutes have directed instruments to be enrolled, as the 27th Henry VIII. c. 16, relating to deeds of bargain and sale of freehold lands; and the 53rd George III. c. 141, relating to memorials of annuities, &c. All deeds also relating to property in the counties of York and Middlesex are registered in the register-offices there established by statute. Wills affecting lands should, by the direction of the statutes, be registered both in Middlesex and Yorkshire, and also at Kingston-upon-Hull. A bill to establish a general register has several times within

the last five years been introduced into parliament, but hitherto without success, owing chiefly to the opposition of the landed interest.

ENS (river). [AUSTRIA, p. 136.]

ENS, the PROVINCES of the, constitute the archduchy of Austria, which, with Styria, Carinthia, Carniola, Görz, Trieste, part of Istria, the Tyrol, and Vorarlberg, form what are denominated the hereditary dominions of the house of Austria. The archduchy is divided into the two provinces of the Lower and Upper Ens, commonly called Lower and Upper Austria, has altogether an area of about 14,881 English square miles, and about 2,147,000 inhabitants (in 1827, 2,075,335), and contains 52 towns and 12,143 market and other villages. Lower Austria is the most ancient possession of the house of Austria, and was acquired by conquest from the Avari in the year 796. Charlemagne, who subjected it, formed it into a margraviate; it became a Bavarian fief, and so continued until Count Leopold of Babenberg was recognised as its independent possessor in 944. It continued in the possession of the princes of Babenberg, who added Upper Austria to it, and raised the whole into a duchy, until Ottokar, king of Bohemia, expelled them in the middle of the thirteenth century. In 1276, however, Rudolph of Habsburg wrested the duchy out of his hands, and his descendants have remained in possession of it to the present day. They assumed the title of archdukes in 1359, but were not recognized as such until the year 1453.

The province of the LOWER ENS, or LOWER AUSTRIA, lies nearly in the centre of the Austrian dominions, on both sides of the Danube, between 47° 26' and 49° 0' N. lat., and 14° 26' and 17° 1' E. long. It is the eastern portion of the archduchy, and its boundaries are, on the north, Bohemia and Moravia; the east, Hungary; the south, Styria; and the west, Upper Austria. According to the new admeasurement made by the quarter-master-general's department, the area of this province, which is very little less than Wales, is 7251 English square miles, of which 3651 are on the northern, and 3600 on the southern bank of the Danube. The subdivisions are as under:—

| Subdivisions. | sq. m. | Population. | Chief Towns. |
|--------------------------------|--------|-------------|----------------------|
| Vienna Township | 87 | 345,000 | |
| Circle of the Lower Wienerwald | 3,542 | 190,000 | Trakirchen . . 1,000 |
| Ditto Upper ditto | | 232,000 | St. Pölten . . 4,400 |
| Ditto Lower Mannhartsberg | 3,652 | 226,000 | Kornsburg . . 1,400 |
| Ditto Upper ditto | | 238,000 | Krems . . . 3,800 |
| | 7,251 | 1,280,000 | |

52 towns, 287 market villages, and 4360 villages.

The Lower Ens is walled in both on the north and south by ranges of mountains. A branch of the Noric Alps, of limestone formation, not only occupies its southern districts, but spreads its branches over the whole country south of the Danube, with the exception of the most eastern parts. Its most elevated points are the Schneeberg, in the south-west of the Lower Wienerwald, which has two peaks, the Alpengipfel (Alpine peak), 7383 feet, and the Grosser Riese (great giant), 7331 feet high; the Goeller, 6327 feet, in the southern extremity of the same circle, and the Wecksel, in the same quarter, 6203 feet. A series of wooded heights, denominated the Wiener Wald (Vienna Forest), separate the Upper from the Lower Circles of the Wienerwald, and run from south-west to north-east. On the left bank of the Danube, and throughout the western and nearly the whole of the eastern districts of the northerly portion of the Lower Ens, the Bohemian and Moravian chains of the great Sudetah range extend their last offsets in all directions until they subside in the valley of the Danube. A succession of these heights, called the Mannhart group, and running from north to south, divide the Upper from the Lower Mannhart circles, and give their name to them. The most elevated point in this quarter is the Yauerling, close to that river, in the south of the Upper Mannhartsberg circle, which is 3330 feet high. In the northern and eastern parts of the Lower Mannhartsberg circle the ranges of hills are of inferior height. The Cetian mountains on the right bank of the Danube are connected with the Noric Alps. Many of these chains are densely wooded; others are entirely naked. The most extensive forests are the Wiener (Vienna), Ernstbrunn, Hochleiten, and Mannhart; the line of the first of these divides the Lower from the Upper Wienerwald circle. It is estimated that the area occupied by the mountains of the Lower Ens is at least one-third of its whole surface—

they are furrowed by numberless valleys, which give the province a beautifully varied and picturesque appearance.

The fine valley of the Danube spreads out on both banks of the river in a continuous level from Korneuburg as far as Krems, and the greater part of the streams which water the Lower Ens discharge themselves into that river. The Danube itself traverses the province from west to east for about 156 miles, entering it a little to the north-east of Neustädte, and quitting it between Hainburg and Theben, which latter town is within the Hungarian borders. Between those towns it has a fall of more than 510 feet (450 Vienna feet), and its current is accordingly so rapid that it flows beneath St. Sophia's bridge, in Vienna, at the rate of nine feet per second. Its breadth across the island of Lobau, close to Vienna, is 3050 Vienna fathoms (18,986 English feet): but in some parts, particularly below Marbach and at Thaler below Krems, its channel is so narrowed by the high lands that it rushes forwards with a violence which, in former times, rendered the navigation extremely perilous. The tributaries of the Danube, so far as the Lower Ens is concerned, are of no great length or volume of water. On the right bank are the Ens, Ips, Erlaf, Billach, Trasen or Traisen, Schwechat, great Fischa, and Leitha: all these streams flow down from the Alpine mountains in the southerly districts of the Lower Ens, and are remarkable for the green colour of their waters; the great Fischa has also the peculiar characteristics of seldom varying in the body of its water and never freezing. The Danube, on its left bank, receives the Krems, which irrigates the south of the Upper Mannhartsberg circle, flowing through the beautiful valley of the Krems, antiently called the 'Vallis Aurea,' or Golden Valley, and falling into the Danube at Krems; the March, which, next to the Danube, is the largest river in the Lower Ens, and which, entering the province from Moravia, forms its boundary on the side of Hungary for about 48 miles, and is navigable to its mouth, where its breadth is about 1420 feet; and the Kamp. The only streams which are not tributary to the Danube are some rivulets which, like the Salza and the Mürz, flow down from the Alpine heights in the south of the province, and join the Mürz; and the Lainsitz in the north-west, where it takes the name of the Braunau at Gmünd and of the Schwarzbach at Schwarzbach, under which designation it ultimately falls into the Moldau, a tributary of the Elbe.

Independently of the Donau-canal (canal of the Danube), near Vienna, which is merely an enlarged arm of the Danube, the only canal in the Lower Ens is the Vienna or Neustadt canal, which opens out from the preceding and terminates at Wiener-Neustadt, about 34 miles south of the capital. The original plan was to carry this canal to the Adriatic, and thus connect the Danube with that sea.

There are some large natural sheets of water, but none deserving of the name of lakes: the largest is the Erlaf or Zellersee, which is about 4998 feet long, 1890 broad, and from 620 to 630 deep. Near the Mittersee there is a beautiful waterfall 200 feet high, and close to it is a spot called the Brüllender Stier (roaring bull), whence the roar of a subterranean cascade is heard.

Among the mineral waters of the Lower Ens none are in such repute as those of Baden, in the Lower Wienerwald, about 19 miles south-west of Vienna, or 15 in a straight line. (Vol. iii., p. 261.) The waters of Medling (first discovered in 1805), Deutschaltenburg, Heiligenstall, Döbling, &c., are also used.

The varied character of the surface occasions considerable difference of climate. The mountainous nature of the north-western and southern parts of the province renders the temperature colder than it is in the low lands about the Danube and in the eastern districts. There is no mountain which attains the limit of perpetual snow, which would in this latitude be found at an elevation of about 9400 feet. By observation at the Vienna observatory, which stands at a height of 570 feet above the level of the sea, it has been ascertained that the average annual temperature in Vienna is about 51° Fahr.: in 1824 it rose to 52° 44'; the summer heat is between 77° and 83°, and the maximum heat does not exceed 97°; the winter cold varies between 10° and 12° below the freezing point, and has never been greater than 22°. The weather is very variable, and on the lofty summit of the Schneeberg it changes, says Blumenbach, almost every hour. About Annaberg, in the south of the Lower Wienerwald, the country is so desolate that it goes by the name of the Siberia of Austria.

The soil of the Lower Ens differs much in productiveness. The richest tracts are in the centre of the province, from the confluence of the Ens eastwards as far as the Pulnafeld on the right bank of the Danube; and on the left bank, from Krems they extend until they spread over the south-eastern parts of the Upper Mannhartsberg to the efflux of the March into the Danube. The lands about the lower March, indeed, which are called the Marchfeld, are a Delta, which, under efficient cultivation, might become the granary of the Austrian metropolis. There is an extensive level also in the vicinity of Vienna, which, in parts, is extremely fertile. On the whole, the Lower Ens does not rank among the more productive provinces of the empire. It is a manufacturing rather than an agricultural province.

The inhabitants of this province, as well as those of the other division of the Archduchy of Austria, are of German descent. After the Avari were driven out, it was re-peopled by Bavarians, Swabians, Saxons, and Franconians, principally indeed by the first mentioned; a circumstance which accounts for the similarity in language and manners between the native Austrian and his Bavarian neighbour. The majority is of the Roman Catholic persuasion, and the minority, Protestants, Greeks, and Jews, with a few Armenians. In 1800, the number of native born inhabitants was 1,016,512, besides about 30,000 settlers from the other parts of Austria and foreign parts. In 1808 it was 1,059,440; 1810, 1,073,294; and in 1825, 1,182,595, besides about 50,000 persons not born in the province: the present population is about 1,280,000. The proportion of males to females is as about 46 to 58. The number of houses in 1816 was 150,385; in 1827, 153,168; and it is at present about 155,500. In the eastern and north-eastern districts there are many Slavonians, here denominated Croats. In 1828 the births amounted to 47,566, and in 1831 to 46,789; while the deaths amounted in 1828 to 45,520, and in 1831 to 49,063. In 1830 the marriages were 12,604.

Nearly one half of the province is devoted to the production of grain, vegetables, and wine; and of this about 1,900,000 acres are under the plough: yet, in spite of good husbandry, the soil and climate are so little favourable to the growth of corn, that wheat and rye do not yield more than five, barley not more than eight or nine, and oats not more than six or seven grains for each grain sown. The province, in fact, does not produce corn enough for its own consumption. The quantity of meadow-land is estimated at about 550,000 acres; the pastures at about 392,000; and the woods and forests occupy about 1,228,000. Peas and beans and potatoes are universally cultivated, particularly in Upper Mannhartsberg. Vegetables are abundant, and fruit likewise. Hemp and flax are cultivated, but the quality is indifferent and not equal to the demand. Saffron of very superior kind is raised near St. Pölten and Melk. The vineyards occupy about 112,230 acres of ground, and on an average yield 2,000,000 aulms (about 31,000,000 gallons) annually. The finest vineyards are those of Weidling, Klosterneuburg, Grinzing, and some others in the Lower Wienerwald; and the wines of Burgundy and Champagne have long been acclimatised in some parts. The mountain districts produce a very full-bodied durable wine. The woods and forests, which supply both fuel and timber, have suffered so much from neglect that they do not suffice for the consumption of the country. The most extensive, which lie in the circles of the Wienerwald, are chiefly composed of the beech, oak, maple, linden, elm, alder, pine, and fir.

The rearing of horned cattle has never recovered from the blow which it received during the repeated invasions of the French armies. The whole stock does not exceed 300,000 heads. A portion of it is of a very superior native breed. Although the establishments for breeding horses belonging to the crown and several noblemen have done something towards improving the race, this branch of economy is not pursued with much activity. Some writers do not estimate the stock at more than 57,000 or 60,000. Independently of several extensive sheepwalks in many of the upland districts, every peasant feeds his little flock of 10, 20, or 30 sheep. Upwards of one half of the whole stock, estimated at 450,000, are of breeds improved by crossing with merinoes and other foreign races. The largest flocks are those on the imperial estates. The yearly weight of wool obtained is about 1,190,000lbs., and much of it is exported. Goats and swine are not bred in great numbers. Poultry is fed on a large scale for the Vienna market. Some honey and wax are made: the stock of game is much diminished.

The mines of the Lower Ens are not of any great importance. The Annaberg no longer yields silver. There are iron mines at Reichenau, Pütten, Schottwien, Erdweis, Weitra, and other spots, but the quantity raised is but inconsiderable. There are numerous quarries of marble and freestone, &c., particularly in the south; gypsum and calcareous rocks, from which much lime is made are abundant; mill-stones, granite, slate, alum, potter's clay, quartz for making glass and china, and porphyry, are among the other mineral products. Coals are raised in the south and in some other parts.

The Lower Ens ranks next to Bohemia in a manufacturing point of view; and the principal seats of industry are the districts south of the Danube, the northern being chiefly agricultural. In 1811, the number of individuals employed in these districts was 163,171, about one-sixth of the then population of the whole province. Flax and hemp yarns are spun wherever the materials are grown; in the Upper Mannhartsberg 3800 hands are employed, besides those who spin for their domestic wants. Cotton wool is also spun in the same circle by hand, and employs between 5000 and 6000 persons. In 1828 the province had 30 factories, in which 224,518 spindles were at work. Much linen is woven, but mostly for home use; and the linen-tape manufactures of Siegharts occupy above 1000 hands. Cottons, particularly of the finer sorts, are manufactured on an extensive scale at Vienna: large printing-works are carried on at Neunkirchen, Friedau, St. Pölten, Kettenhof, &c. Cotton embroidery, stockings, &c., are made at Vienna and elsewhere. The woollen manufacture has never prospered to any great extent, although there are some large factories in Vienna, at Rittersdorf, &c., but the silk manufacture has risen to great perfection in the capital, where, even as far back as 1827, it employed above 8000 looms: it is brisk also at Leobersdorf, Neustadt, Katzeldorf, &c. Lace, ironware, and cutlery; tools, copperware, brasswork, buttons, jewellery, and trinkets; articles of wood, leather, glass, mirrors, porcelain, earthenware, paper, musical instruments, soap, &c., form so many additional branches of industry.

The Lower Ens has a considerable trade with the neighbouring countries and foreign parts, by means of its communications by land with the Adriatic, Germany, Poland, &c., and by the Danube with Hungary, Turkey, and the East.

The various scientific institutions and schools, both in Vienna and the several towns in general, afford advantages to this province which must at all times promote its prosperity.

Among the towns not before mentioned are, in the Lower Wienerwald, Hainburg on the Danube 2800, Bruck on the Leitha 2600, Neustadt 10,503, Klosterneuburg on the Danube 3350, Schwechel 2100, Baden 4600, and Medling 2050; in the Upper Wienerwald, Baierisch-Waidhefen 2100, Tuln on the Danube 1500, Ips at the confluence of the Ips and Danube 1100, and Melk on the Danube 1020; in the Lower Mannhartsberg, Meissau 700, Rötz 2260, Labb on the Thaya 1250, Feldsberg 2600, Zistersdorf 1700, Stockerau 1550, and Mistelbach 2650; and in the Upper Mannhartsberg, Stein on the Danube 1700, Egenburg 2000, Weitra 1800, and Lagenlois 2150.

The province of the UPPER ENS, or UPPER AUSTRIA, forms the western part of the Archduchy, and is situated on both banks of the Danube, but chiefly on the south, between 46° 57' and 48° 46' N. lat. It comprehends the duchy of Salzburg, which was incorporated with it in the year 1816. Its boundaries are, on the north, Bohemia; on the east the Lower Ens or Lower Austria; on the south Styria, Carinthia, and the Tyrol; and on the west Bavaria. Its area, according to the estimate of the quarter-master-general's survey, is 7630 English square miles, or about 205 more than that of Wales. The three eastern circles, the Mühl, Traun, and Hausruck, are called Old Austria; and the new circle of the Inn and Salzburg or Salsach, is termed New Austria.

Sub-divisions, &c.

| Circles. | Sq. Miles. | Pop. | Chief Towns. | Towns. | Mar- ket Vill. | Vill. & Ham. |
|----------|------------|---------|-----------------|--------|----------------------|--------------------|
| Mühl | 1,302 | 205,000 | Linz 21,500 | 17 | 120 | 7498 |
| Hausruck | 777 | 184,000 | Wels 4000 | | | |
| Traun | 1833 | 185,000 | Steyer 10,100 | 1815 | 183,779 | dwelling |
| Salsach | 4018 | 292,000 | Salzburg 13,300 | 1825 | 124,987 | houses. |
| | 7630 | 867,000 | | | | |

• Commonly called the Duchy of Salzburg.

The Upper Ens is a mountainous country: the parts south of the Danube contain the most elevated alpine regions in the Austrian dominions, and those north of it are intersected by lower ranges which are offsets of the great Bohemian forest range. The Rhetian Alps occupy a small portion of the south-west, and terminate at the Dreiherrnspitz, from which point the Noric Alps occupy the whole of the southern circles of Salzburg, Hausruck, and Traun. The highest summits in this part are the Grossglockner, 12,221 English feet above the level of the sea, on the most southern part of the Salzburg circle; the Ankogel, 11,798 feet; the Grosse Wiesbach or Krummhorn, about 11,770; the Hochkar, 11,270; and the Murauekopf, 10,070 feet. All these are situated in the southern part of the Salzach circle. There are many wide and numerous small valleys, especially the noble valleys of the Salzach, Gastein, Saal, &c., among the mountain masses that overspread the land south of the Danube, which constitutes five-sixths of the whole surface of the Upper Ens. The only level country in the province is the immediate borders of the Danube. In the Mühl circle, which is north of the river, the most elevated point is the Plöckenstein, close to the common boundary of Bavaria, Bohemia, and the Upper Ens; its height does not exceed 2177 English feet.

Among the numerous streams of the Upper Ens there are five navigable rivers: the Danube, which enters the province in the north-west, below Passau, and quits it after receiving the Ens at the south-eastern corner of the circle of the Mühl; the Inn, which forms the western frontier for a short distance, and receives the Saal, another navigable river that divides the Upper Ens in part from Bavaria; the Ens; and the Traun, which last stream flows out of a small lake not far from Aussee, in Upper Styria, then crosses into the circle of the Traun, at its south-western end, turning from the west to the north, passes through the Lakes Halstätt and Traun, takes a north-easterly direction along the western side of the circle, throws itself over a precipice 60 feet high near Lambach, washes the eastern side of the town of Wels, in the Hausruck circle, and ultimately falls into the Danube, opposite Steyeregg, after a course of about 70 miles. It is navigable after quitting the Traunsee, and the obstruction from the fall at Lambach has been obviated by a side canal 1020 feet in length. Among the minor streams are—the Ayer, which unites the Mond and Kammer lakes, and joins the Danube near the Zizelau, the Salzach or Salza, which waters the south of the circle of that name, then flows through it in a north-westerly direction past Salzburg, and falls into the Inn a few miles south-west of Braunau, the Saal and Lammer, tributaries of the Salzach, and the Rana.

The Upper Ens abounds in lakes, of which the following are the largest. The Traun or Gmunder See, in the west of the Traun circle, 6310 Vienna fathoms long (39,437 English feet), 1570 fathoms (9812 feet) in its greatest breadth, and 598 Vienna feet (620 feet) in its greatest depth. The Halstätt See at the south-western extremity of the same circle, inclosed between high mountains, 4260 Vienna fathoms (26,622 feet) long, 1130 fathoms (7062 feet) broad, and 600 Vienna feet (622 feet) in its greatest depth. The Atter or Kammer See, in the south of the Hausruck circle, 10,300 fathoms (64,375 feet) long and 1745 (10,906 feet) broad; and the Matt or Mond See (Lake of the Moon, from its crescent-like shape), which lies west of the southern end of the Atter See, and is 5600 fathoms (35,000 feet) long and 1070 (6687 feet) broad. There is an immense number of smaller lakes, of which, in the Traun circle alone, 27 have been counted. Swamps and morasses of considerable extent occur in many parts, particularly near the Mond and Traun lakes, and in the Pinzgau, near the banks of the Salzach, in the south-west of the circle of Salzburg.

The most celebrated mineral springs of the Upper Ens are those of Gastein, which lie deeply embosomed in the valley of that name among the most southern mountains of Salzburg in 47° 5' N. lat. and 13° 8' E. long. The waters are of a sulphurous nature, perfectly pure and translucent, and the six springs vary from 95° to 112° of Fahrenheit in temperature. The cold mineral waters of St. Wolfgang are also in much repute.

The climate of the Upper Ens is much colder than that of the Lower Ens, though it lies in the same latitude; and much more so in the south than in the north. The warmest parts are in the valley of the Danube. On the whole it is not insalubrious, although not so healthy as the

adjacent provinces. The annual mortality is one in thirty four.

Many extensive tracts, particularly among the alpine masses of the south, are extremely sterile. The valleys north of the Tauern group in the Salzach circle abound in clay, limestone, slate, quartz, &c. The low lands of that circle, the northern parts of the Traun, and several districts in the Hausruck, and the western tracks along the Inn, are highly fertile.

The Upper Ens is not rich in native products. Marble however of peculiarly fine quality is found in the Salzach circle, where black, red, blue, and parti-coloured kinds are obtained. In the same circle are found alabaster, crystal, gypsum, garnets, beryls, topazes, emeralds, &c. Granite and sandstone occur generally. There was formerly a much larger produce of metals in the western parts of the province: gold and silver are however still found on the Gastein range at Kauris and Schellgaden, and gold dust in the Salzach and other streams; copper abounds on the Gerlos and in the valleys of Brunn, Stubach, Leogang, and Ramingstein, in the two last of which much lead is got; a plentiful supply of iron is procured from the mountains about Hüttau and Flachaw, the Hinteralp and Bundschuh, &c., as well as in the Traun circle, whence copper and lead are also obtained. Salt abounds in the hills of Ischil and Hallstätt, and in the Thunburg near Hallein, and the yearly produce is about 55,000 tons. Cobalt is found at Zinkwand. Coals are dug in several quarters; sulphur at Mühlbach and Grossarl in the Salzach; and there are extensive peat-mosses.

The Upper Ens contained 755,891 inhabitants in the year 1815; 826,575 in the year 1825; and the present number is estimated to be 867,000. The births in 1828 were 24,460, and in 1831, 24,035: the deaths in 1828 were 22,177, and in 1831, 21,080: and the marriages in 1829 were 5448. The majority of the inhabitants are of the same stock as the Bavarians. On the banks of the Ens and Traun are some villages peopled with individuals of Slavonian extraction. The proportions throughout the province are said to be five agricultural labourers to two operatives, one of noble blood in every 438 persons, and one ecclesiastic in every 260. The Roman Catholic is the predominant religion, and there are not above 30,000 protestants in the whole province. The average issue of each marriage is estimated at from four to five children.

Agriculture is said to be in a more advanced state in the Upper than in the Lower Ens. The quantity of land under the plough is estimated at 1,162,510 acres: wheat, barley, oats, and rye are the chief crops; and agriculture is conducted on the largest scale in the circles of the Mühl, Hausruck, and Traun. About 35,600 acres are occupied as garden-ground; about 115 only for vineyards in the Mühl and Hausruck; about 510,600 as meadows; and 1,106,800 are used for grazing cattle. It is calculated that 1,346,900 are covered with woods and forests. Very considerable quantities of potatoes and fruit are raised in the Upper Ens. In some parts the produce of grain is so small, for instance in the Viechtal on Lake Traun, that in the best years it does not yield above three grains for every grain sown; in the northern parts of the Traun, on the contrary, wheat produces eightfold, and oats tenfold and upwards. The quantity of grain raised is about 1,480,000 quarters annually.

The province abounds in pastures and the rearing of cattle is general. The race of horses bred in the Pinzgau, a district among the Alps north of the Salza, is reputed to be the largest and tallest in Europe: they are generally 19 hands high. In 1830 the stock of horses of all kinds in the Upper Ens was 46,950. The horned cattle are of a large breed: the stock in 1830 was 85,579 oxen and 293,604 cows. The sheep are of an inferior race, and none of them yield fine wool: the stock in 1830 was 199,925, a diminution of 15,498 since 1827. Goats abound in the upland parts. The lynx, wolf, and bear are occasionally met with; foxes, stags, deer, marmots, polecats, squirrels, martens, hares, and wildfowl are more or less plentiful. Fresh water fish are abundant: and the beaver and otter are at times seen on the banks of the Danube, Mühl, and Aschach. The pearl muscle is found in some of the rivulets in the upper part of the Mühl circle.

The manufactures of this province, though less extensive than those of the Lower Ens, are considerable. The peasantry in general manufacture their own linens and

woollens, and make what leather articles they require. Much linen thread is spun as well as woollen and cotton yarn, on which above 15,000 hands are employed in the Mühl circle alone, where there are upwards of 5000 looms for weaving linens, &c., and numerous factories where linens and cottons are printed. The manufacture of cotton cloths is most extensive at Schwanenstadt in the Hausruck, Lintz, Urfahr in the Mühl, Wels, Steyer, and Hallein. There is a considerable manufactory of woollens and carpets belonging to the crown, in Lintz; and others in Wels, Lanhausen in the Mühl, Neuhof, &c. About St. Wolfgang in the Traun cloth of goats' hair is prepared. Large quantities of steel and ironware tools, &c., are made in the Upper Ens, particularly in Steyer and the districts to the south of it, at Steinbach, Sierning, Neuzeug: Steyer, in fact, has been called the Birmingham of Austria, but its manufactures are of coarser workmanship. There are copper and brass works at Ebenau in the Salzach, Reichraming, and near Wels. The preparation of wood for domestic and other purposes gives considerable employment to all the parts south of the Danube. Bleaching-grounds and tanneries are numerous. Paper, glass, leather, earthenware, chemicals, beer, and spirits are manufactured pretty extensively.

The exports of the Upper Ens are very considerable, and consist principally of salt, timber, and wood for fuel, yarns, linens, woollens, carpets, ironware, tools, nails, and screws, cutlery, flax, cotton-yarn, cottons, stockings, cheese, beer, cattle, earthenware, mill and polishing stones, stone for building, marble, and fruit.

The principal towns, independently of the chief towns in the several circles, are, in the Mühl circle, Freistadt on the Feldaist, 2200 inhabitants; Urfahr, or Ufer. Lintz, united by a bridge to Lintz, 2600; and Steyeregg on the Danube, 850: in the Hausruck circle, the towns of Efferding, 1000; Schwanenstadt; and Grieskirchen: in the Traun circle, Ens, on a steep hill on the left bank of the Ens, with five suburbs, 380 houses and 3000 inhabitants; Gmunden, at the efflux of the Traun from Lake Traun, 1300 feet above the level of the sea, with six suburbs, 440 houses and 3250 inhabitants, with saline springs and baths; Kremsmünster, built round a hill on the left bank of the Krems, with several public schools, a rich abbey, an observatory, and collections in natural history, &c., and 950 inhabitants; Kirchdorf, St. Florian, Serning (1200 inhabitants), and Grünau on the Alben, 1750. In this circle lies the Salzkammergut (Salt-domain of the Crown), between lakes Traun, Atter, and St. Wolfgang, the Salzach circle, and Styria; it contains an area of 236 square miles, and has 79 villages and hamlets, 2450 houses, and 16,200 inhabitants: there is no level land whatever in this district. The salt-mines yield about 40,000 tons of salt, and it is said a clear revenue of upwards of 70,000*l.* annually. Coals, alabaster, and gypsum are also obtained from this district. It contains the market-towns of Ischil on the Traun, with 250 houses and 1800 inhabitants, two salt-works, saline baths, and a theatre and hospital. Hallstätt, on the lake of that name, 1050 inhabitants; Laufen, with 370, and salt and coal-works; Goisern, a village of 756, on the Traun, and Langbath, on the southern side of Lake Traun, with salt-boiling-houses, saw-mills, &c., and a population of 1100. The Salzkammergut lies between 47° 29' and 47° 51' N. lat., and 13° 29' and 13° 51' E. long. In the Salzach circle are the towns of Hallein on the Salzach, where there are salt-works and boiling-pans, 330 houses and 5000 inhabitants, and Radstadt, on a hill on the left bank of the Ens, with about 920. In this circle lies the beautiful valley of Gastein among the Alps, from 30 to 40 miles in length and about two in breadth, in which are 21 villages and hamlets, including Hof or Hof in der Gastein, the chief place in the valley, and the baths called Wildbad-Gastein, which have upwards of 1200 visitors in the season. Gredig, with its rich marble quarries and prince's well, the source of the Glaubach, Ebenau, where there is a manufactory of copper, brass, and ironware, and the esteemed springs of St. Wolfgang on the Weichsel brook are also in this circle.

(Blumenbach; Lichtenstern; Hassel's *Archduchy of Austria*; Röhrer's *Statistics; Historical and Statistical Survey of the Austrian Monarchy*; Jenny's *Manual*; &c.)

ENSIGN, a commissioned officer, the lowest in degree, and immediately subordinate to the lieutenants in a regiment of infantry. One of this rank is appointed to each company, and the junior ensigns are charged with the duty

of carrying the colours of the regiment. Ensigns in the regiments of foot guards have also the rank of lieutenants. In the rifle brigade, and in the royal corps of artillery, engineers and marines, in place of an ensign, a second lieutenant is attached to each company.

Among the Spaniards and Italians, in the seventeenth century, it appears that no officer existed like the lieutenant of a company, whose rank is between that of a captain and ensign, any such being considered superfluous, and as tending to diminish the importance which was attached to the post of the officer who had the charge of the colours, on the preservation of which, in action, the honour of the regiment was made greatly to depend.

When, as formerly, a battle partook far more than at present of the nature of a *melee*, the loss of a standard, which served as a mark for the soldiers under each leader to keep together in the fight or to rally when dispersed, must have been a serious misfortune, and probably was often attended by the total defeat and destruction of the party; and hence, no doubt, arose the point of honour respecting the colours. A French military author, who served and wrote in the time of Charles IX., intending to express the importance of preserving the colours to the last, observes that, on a defeat taking place, the flag should serve the ensign as a shroud; and instances have occurred of a standard-bearer who, being mortally wounded, tore the flag from its staff and died with it wrapped about his body. Such a circumstance is related of Don Sebastian, king of Portugal, at the battle of Alcazar, and of a young officer named Chatelier at the taking of Taillebourg, during the wars of the Huguenots.

In the ancient French service, the duty of carrying the oriflamme at the head of the army was confided to a man of rank, and also of approved valour and prudence; the post was held for life.

The price of an ensign's commission in the foot guards is 1200*l.*, and his daily pay is 5*s.* 6*d.*; in the regiments of the line the price is 450*l.*, and the daily pay 5*s.* 3*d.*

ENTABLATURE. [CIVIL ARCHITECTURE; COLUMN.]

ENTAIL. [ESTATE.]

ENTALOPHORA. [SERTULARIÆA.]

ENTERITIS, *Inflammation of the Intestines.* The inflammatory affections of the whole alimentary canal constitute an extensive and highly important class of diseases, several of which are properly designated by specific names, since they have a peculiar seat, and require a peculiar treatment. Enteritis is one of these. This term is employed to denote an acute inflammation of the external or peritoneal coat of the intestines. When inflammation is seated exclusively or chiefly in the peritoneal coat of the intestines, both the local and the constitutional affection is widely different from that which is produced when inflammation is seated in the mucous coat. It is therefore with good reason that these diseases are distinguished by different names.

The distinctive characters of enteritis are pain in the bowels, vomiting, invincible constipation, fever, and sudden and great prostration of strength.

The pain is often exceedingly severe, and is usually especially acute about the navel. The inflammation may be confined to a small portion of the intestines, or its seat may be very extensive. The pain is felt in the part in which the inflammation is seated; hence the pain is occasionally restricted to a particular part of the abdomen; but far more commonly it is spread over a large portion of it, and, as has just been stated, is peculiarly severe about the navel. The pain is constantly present; it is never for a moment entirely absent; but it is occasionally very much aggravated in paroxysms. It is always greatly increased by pressure over the seat of the part inflamed. Though severe pain be a very constant attendant on enteritis, yet occasionally cases occur in which the pain is never so great as to occasion much alarm, and these insidious attacks are the most dangerous.

The vomiting, though occasionally absent, is pretty constantly present, and is sometimes frequent and most distressing. In the intervals between the acts of vomiting there is a sense of nausea. It has been thought that when the vomiting is urgent, it is an indication that the inflammation has extended to the stomach; but the inspection of the body after death has fully shown that there may be most distressing vomiting when not the least appearance of disease can be traced in the stomach.

Obstinate constipation is a diagnostic mark of enteritis

It is not indeed invariably present, but it is present in so large a proportion of cases, that when absent it must be considered as an exception to the general rule. Its absence should leave no doubt upon the mind of the nature of the attack if the other symptoms are present.

More or less fever is always present. The skin is usually hot and dry, and the heat is often preceded by a sense of chilliness or by a distinct rigor. The tongue is usually white and furred; there is much thirst, and the pulse is quick, small, sharp, and incompressible.

The expression of the countenance is peculiar. The features are sharp and compressed; in severe cases, and in almost all cases in the advanced stage quite sunk; the expression is anxious and wild, and the first glance conveys to the beholder an irresistible conviction that the individual is labouring under some intense internal disease.

The impression upon the powers of life is so great and rapid that the patient is far more exhausted after a few hours' illness in this disease than after an attack of as many days' duration in most other acute maladies. This rapid and extreme prostration is highly characteristic of enteritis, and if it be combined with any one of the symptoms which have been described, should leave no doubt of the existence, in an intense form, of one of the most dangerous diseases to which the human body is subject.

As the inflammation advances the pulse becomes more rapid and feeble; the abdomen swollen, tense, and tympanitic; the prostration increases; the skin, instead of being hot, becomes cold and clammy, and the extremities, more especially, are cold.

The inflammation has a peculiar tendency to terminate in gangrene. Before this event happens it is usually conceived that the inflammatory action extends from the peritoneal to the muscular coat, and that in the most intense cases all the coats of the intestine become involved. The signs that mortification has taken place are cessation of pain, hiccup, increased frequency and weakness of the pulse, greater collapse of the countenance, and increased prostration. But it is remarkable that often when the patient dies under the ordinary symptoms of mortification, on the examination of the intestine after death, nothing can be detected but the usual appearances of inflammation; there is no trace of a gangrenous spot; death is produced by the intensity of the inflammation.

The brain usually remains unaffected to the end; the mental faculties are but little impaired; but sometimes, as the disease advances, the mind becomes confused and wandering, and occasionally delirium sets in early—a certain sign that the disease is of extraordinary intensity.

The exciting causes of the disease are acrid and indigestible matters taken into the stomach in large quantity; habitual full living on highly seasoned food; the accumulation of hardened feces, cold drinks, especially when the body had been previously overheated. But perhaps the most common cause of the disease is cold, combined with moisture, applied either directly to the abdomen, or to the body generally, and more especially to the lower extremities. It is also frequently superinduced by strangulated hernia; and on the sudden occurrence of the symptoms of enteritis the abdomen should always be carefully examined with a view to ascertain whether hernia be present. It may also be caused by an event which cannot be known until after death—the involution of one fold of the intestine within another (intus-susception or volvulus), so as to occasion a complete obstruction to the passage of the contents of the bowels.

Enteritis can scarcely be confounded with any other disease excepting colic, and the relation between these two affections is so close that severe colic is very apt to lapse into enteritis; and this it is very important that the practitioner should bear in mind. But when colic exists as a distinct disease it is clearly distinguished from enteritis by the absence of fever, and of the prostration so characteristic of enteritis; by the occurrence of the pain more decidedly in paroxysms with intervals of complete ease; by the diminution, not the increase, of the pain on pressure, and by the strikingly different state of the pulse.

Enteritis may attack persons of all ages, from the infant a day old, to the man who reaches the extreme term of human life. It may occur at all seasons of the year. Its attack is often sudden, and it sometimes proves fatal with frightful rapidity. It is by no means uncommon for a person apparently in sound health to be destroyed by this disease

within twenty-four hours from the commencement of the attack.

Hence the importance of a knowledge of its early symptoms, and the necessity of attacking it with the utmost promptitude and vigour. The ordinary remedies for inflammation must be employed with decision. The character of the pulse, the sunk countenance, the prostration of strength may appear to contra-indicate blood-letting; but these are false indications, and if regarded, the event will be fatal. After a copious bleeding the pulse often diminishes in frequency and increases in strength; the expression of the countenance improves, and the vital energies recover, as if the system were relieved of an oppressive load. Bleeding must be carried as far as possible, until it appears to have made an impression upon the inflammatory action. It is a very useful practice to bleed from the arm two or three times in succession, after an interval of two or three hours, if the symptoms of inflammation do not abate.

It is without doubt highly desirable to procure evacuations from the bowels; but the disease is to be cured by the removal of the inflammation, not by opening the bowels. Death often takes place though the bowels are opened, and the fatal event is not unfrequently hastened, if not brought about, by the acrid nature of the cathartics given to remove the constipation. These acrid cathartics, if they open the bowels, do not necessarily save the patient; and if they do not open the bowels they greatly increase the inflammation. Only the mildest aperients should be employed. This is one of the diseases in which the judicious employment of calomel and opium is attended with the best results.

Colic is often converted into enteritis, or a case of enteritis mistaken for colic is frightfully aggravated, by taking spirituous cathartics, as tincture of rhubarb, for the relief of the pain. In no case whatever should any vinous or spirituous cathartic be taken for pain in the bowels, however slight, without the sanction of a medical man. Persons continually sacrifice their lives by taking brandy, or a large dose of some tincture, for what they call spasm of the stomach or bowels. The so-called spasm oftentimes is inflammation, which the stimulus of the alcohol increases to such a degree that the disease is no longer to be restrained by any remedies that can be employed.

ENTOMOLOGY, that branch of science which treats upon insects. The term *entomology* literally signifies a discourse upon insects, it being derived from the two Greek words *éntomon*, an insect, and *logos*, a discourse.

The term *entoma* was first applied to these animals by Aristotle, and is synonymous with the Latin word *insecta* (whence is derived the English name *insects*), both having reference to a striking character exhibited in the insect tribe, that of having the body *insected*, or, as it were, cut and divided into numerous segments. [INSECT.]

ENTOMOSTOMATA, De Blainville's name for his second family of his first order, *Siphonobranchiata*, of his first subclass, *Paraccephalophora Dicoica*, of his second class, *Paraccephalophora*, of *Malacozoa*. This family appears to be nearly the same with the genus *Buccinum* of Linnæus, and is thus characterized by De Blainville:—

Animal spiral, with the foot, which is shorter than the shell, rounded in front. *Mantle* provided in front of the respiratory cavity with a long canal always uncovered, which the animal uses as an organ of prehension. *Head* furnished with a single pair of blackish tentacula, which carry the *eyes* on an enlargement (renflement) of the half of their base. *Mouth* armed with a proboscis, as in the preceding family (*Siphonostomata*), without any labial tooth, but with a small tongue. *Organs of respiration* formed by two unequal pectinated branchiæ. *Organs of generation*—termination of the oviduct in the females at the right side, at the entrance of the branchial cavity. Termination of the deferent canal at the extremity of a long flattened contractile excitatory appendage, situated at the right side of the neck. *Shell* very variable in form, whose opening sometimes very large, and sometimes very small, is without an apparent canal, or with a very short one suddenly recurved upwards, but always more or less deeply notched anteriorly. *Operculum* horny, unguiform, oval, subconcentric, with the summit a little marked and marginal.

De Blainville observes that this family differs evidently very little from that of the *Siphonostomata*, whether in the soft parts or in the shell. The species which it embraces are not all absolutely marine, though a very great number

of them are: some live at the mouths of rivers, and a very small number are entirely fluviatile

Genera.

Turriculafed.

Cerithium

Animal very much elongated, the mantle prolonged into a canal at its right side, but without a distinct tube; the foot terminated by a depressed, proboscideiform muzzle; tentacula very distant, with large rings, swollen, as it were, in the lower part of their length, and carrying the eyes at the summit of this enlargement. Mouth terminal, in the form of a vertical slit, without any labial tooth, and with a very small tongue furnished with regularly disposed reflexed teeth. A single straight branchia.

Animal of *Cerithium Telescopium*, and shell of *Cerithium palustre*.

Shell more or less turriculated, tuberculous; aperture small, oval, oblique; the columellar border very much excavated, callous; the right lip sharp-edged, and dilating a little with age. *Operculum* horny, oval, rounded, subspiral, and striated on its external surface, sunk, and bordered on its internal surface.

a.

Species which have evidently a small canal very short, and obliquely recurved towards the back.

Example, *Cerithium Vertagus*. Locality, Indian Ocean and Moluccas (Lamarck).

β.

Species which have a still smaller canal, but straight throughout, and a well-formed sinus at the posterior union of the two borders.

Example, *Cerithium Aluco*. Locality, Indian Ocean and Moluccas (Lam.).

γ.

Species whose aperture is divided into three by the shutting of the short anterior tube, and that of the posterior sinus. (Genus, *Triphore*, or *Tristoma*, Deshayes.)

Example, *Cerithium Tristoma*.

δ.

Species which have a small straight canal, and the whorls of the spire flat and ribanded, with a deep umbilicus, two decurrent plaits on the columella, and one on the right lip. (Genus, *Nerinea*, Defrance.)

Example, *Cerithium Nerinea*.

ε.

Species which have no canal, but a simple notch, and whose right lip is much dilated in age. (Genus, *Potamides*, Brongniart; *Pyraxus*, De Montfort.)

Example, *Cerithium palustre*. Locality, coasts of the East Indies, in the salt marshes (Lam.).

ζ.

Species whose aperture, without a canal, is a little notched in front and rear, the notch being replaced by a sinus; the columellar border curved in its middle; the right lip not dilated. (Genus, *Pirena*, Lam.)

Example, *Cerithium Madagascariense*.

De Blainville makes the genus *Cerithium*, as established by him, contain fifty-six species characterized by Lamarck: adding that the greater part are marine, but many from the

mouths of rivers, and some entirely lacustrine, and that there is but one belonging to the French seas (nos mers), whilst more than a hundred fossil species are found in France and Italy. M. Defrance's genus *Nerinea*, he remarks, would be better placed among the *Pyramidellæ*.

a, *Cerithium Madagascariense* (Lam.); b, *C. Madagascariense* (Pirena, Lam.), according to De Blainville. N.B. It is not clear that these are not the same species, notwithstanding the comparative smoothness of b.

Lamarck places *Cerithium* at the commencement of the first section (Canalifères) of his *Zoophagous Trachelipods*, immediately after *Turritella*, the last of his *Phytiphagous* (Plant-eating) *Trachelipods*.

Cuvier gives it a position after *Purpura*, *Cassis*, and *Terebra*, and before *Murex*. This, as the Rev. M. J. Berkeley and Mr. Hoffman observe in their interesting paper on the anatomical structure of *Cerithium Telescopium*, would imply a structure of the parts of the mouth adapted for boring shells, according to the known habits of *Murex*, and certain allied genera; but, they remark, a single glance at Adanson's figure is sufficient for conviction that the animal is much more nearly allied to the *Trochoides*; and that Lamarck judged rightly, according to the evidence before him, in placing it on the confines of his two great classes. This is corroborated, they add, by the little additional information of M. Sander Rang, who describes the mouth as toothless, but furnished with a small tongue.

M. Sander Rang states that this genus, so numerous in species both living and fossil, contains only marine animals; but, nevertheless, there are some of them which live at the mouths of rivers, and these are precisely the individuals which M. Brongniart has united to form the genus *Potamides*, which cannot be adopted in zoology, inasmuch as it does not rest upon sufficiently marked characters. M. Rang adopts, generally, the divisions of De Blainville with approbation, but he rejects the sixth group (ζ), which comprehends the genus *Pirena*, which Rang, following the example of M. de Férussac, places with *Melanopsis*. Rang agrees with De Blainville in thinking that the division containing Defrance's *Nerinea* is, perhaps, doubtful, and that its position would be better near the *Pyramidellæ*. He observes that they have in France but two or three living *Cerithia*; but a great number of fossil species.

Deshayes makes the number of living species eighty-seven; not reckoning *Triforis*, of which he gives three species, nor *Pirena*, of which he also gives three; of the latter Lamarck records four.

Anatomy, Habits, &c.—Our limits make it necessary to refer the reader to the paper of the Rev. M. J. Berkeley, A.M., and G. H. Hoffman, Esq., for the anatomy of *Cerithium* (*Zool. Journ.*, vol. v., p. 431). Adanson, speaking of the habits of one of the species, says that it lives in the sand amongst grass and mangroves, feeding on 'scolopendres,' and other small marine worms. The individual which formed one of the subjects of the investigation by Mr. Berkeley and Mr. Hoffman, and which was brought from Calcutta, though placed in fresh sea-water, the utmost care being taken to renew it frequently, and though all kinds of marine substances were supplied to the animal for food, refused all nourishment, contenting itself with simply walking over the substances, and, in so doing, touching them

with its proboscis. As it would not feed, this individual was killed by immersion in spirit. The other specimen, which was anatomized by the zoologists above mentioned, was brought from Ceylon. Mr. Gray (March 25, 1834) read a note to the Zoological Society of London, giving an account of the arrival in England of two living specimens of *Cerithium armatum*, which had been obtained at the Mauritius, and had been brought from thence in a dry state. That the inhabitants of *land shells* will remain alive without moisture for many months, is, he remarked, well known. [BULINUS, vol. vi., p. 8]. He had had occasion to observe that various marine *Mollusca* will retain life in a state of torpidity for a considerable time; some facts, in illustration of which, he had communicated to the Society (*Zool. Proc.*, part i., p. 116). The present instance included, however, a torpidity of so long a continuance as to induce him to mention it particularly. The animal, though deeply contracted within the shell, was apparently healthy, and beautifully coloured. It emitted a considerable quantity of bright green fluid, which stained paper of a grass-green colour: it also coloured two or three ounces of pure water. This green solution, after standing twelve hours in a stoppered bottle, became purplish at the upper part; but the paper retained its green colour though exposed to the atmosphere. A specimen of *C. telescopium*, sent from Calcutta to Mr. G. B. Sowerby in sea-water, lived out of water in a small tin box for more than a week. *Cerithium* has been found in the sea on various bottoms, and in estuaries, at a depth ranging from the surface to seventeen fathoms.

FOSSIL CERITHIA.

Deshayes in his tables gives the number of fossil (tertiary) *Cerithia* at 220, and of these he records *Cerithia vulgatum*, *Latreillei*, *doliolum*, *giganteum*, *alucaster*, *granulosum*, and *bicinctum*, as both living and fossil. He gives two fossil (tertiary) species of *Pirena* and two of *Triforis*. The form is found from the Supracretaceous to the Oo t c group, both inclusive. *Potamides* is recorded in the weald-clay Sussex (Mant.); and *Nerinea* in the Oolitic group (Bailey), near Auxerre, St. Mehiel (Meuse), Kimmeridge Clay, Coral Rag, Bernese Jura, Forest Marble, Oxford oolite, Dorset (*Nerinea*, *Goodhallii*), Inferior colite.

Mr. Lea (*Contributions to Geology*) describes and figures from the Claiborne beds a shell which he names provisionally *Cerithium striatum*; observing that he is by no means satisfied in placing this shell among the *Cerithia*. It has a stronger resemblance in the mouth to the genus *Melania*, but being a marine shell cannot, he remarks, with propriety be placed in that genus. De Blainville, he adds, figures a shell (*Malacologie*, pl. 21, bis, fig. 2), under the name of *Potamides fragilis*, which certainly ought to belong to the same genus with this, the mouth being very nearly the same. Until more species shall be obtained, Mr. Lea has forborne to create for it a new genus. He further states, that there have been no *Cerithia* yet found in the beds at Claiborne, although they abound in England and on the Continent in the tertiary formation, there being 137 species in the Paris basin alone.

Melanopsis.

Animal furnished with a probosciform muzzle, with two contractile, conical, annulated tentacula, having each at their external base an oculated peduncle; foot attached to the neck; respiratory orifice in the canal formed by the union of the mantle with the body. *Shell* with an epidermis, elongated, fusiform or conico-cylindrical, with a pointed summit; whorls of the spire from six to fifteen, the last often forming two-thirds of the shell; aperture oval, oblong; columella solid, callous, truncated at its base, separated from the anterior border by a sinus, the callosity prolonged upon the convexity of the penultimate whorl, forming a canal backwards; sometimes a sinus at the posterior part of the right border. *Operculum* horny, subspiral.

Habits, &c.—The genus is rather fluviatile than marine, contrary to *Cerithium*, according to De Blainville. Lamarck, who gives but two species, *M. costata* and *M. levigata*, speaks of them decidedly as fluviatile. Rang says that the genus was established by M. de Férussac for freshwater shells, whose callous and truncated columella did not permit their arrangement with *Melania*. The latter, in his monograph, divides them into two groups, the first consisting of those species which have a single sinus at the border of the aperture, separating it from the columella

(*Melanopsis*, Lam.; *M. buccinoidea*); the second consisting of those species which have two distinct sinuses at the external border of the aperture, one which separates it from the columella, the other situated near the union of this border with the penultimate whorl. (*Pirena*, Lam.) De Blainville gives the following division of the genus.

a. Subturriculated species.

Example.—*Melanopsis costata*.

Locality.—Syria in the Orontes (Lamarck).

Melanopsis costata.

β. Oval species.

Example.—*Melanopsis buccinoidea*.

γ. Convex species (Espèces rouflées).

Example.—*Melanopsis Bouei*.

It appears to us that *Pirena* comes more appropriately in the place assigned to it by M. de Férussac and M. Rang than in that allotted to it by M. de Blainville.

M. Deshayes gives ten living species of *Melanopsis*, and, as has been stated above, three of *Pirena*, Lamarck giving four.

FOSSIL MELANOPSIDES.

M. Deshayes, in his tables, gives eleven fossil (tertiary) species of *Melanopsis*, and of these he records the following species, *Melanopsides buccinoidea*, *Dufourei*, *costata*, *nodosa*, *acicularis*, and *incerta*, as both living and fossil (tertiary). Of *Pirena*, he records two fossil (tertiary) species. Dr. Fitton, in his Systematic and Stratigraphical List of Fossils of the strata below the chalk (*Trans. Geol. Soc.*, 2nd series, vol. iv.), mentions two species with a note of interrogation after the generic name, viz., *M. attenuata* and *M. tricarinata*, from the weald-clay, Dorsetshire, and the Hastings' sand, Sussex. He also alludes to a third unnamed species with a query, from the Purbeck, Bucks.

Planaxis.

Animal unknown. *Shell* oval, conical, solid, transversely furrowed; aperture oblong; columella flattened and truncated anteriorly, separated from the right border or lip by a sinus; right lip furrowed or rayed within, and thickened by a decurrent callosity at its origin. *Operculum* horny, oval, delicate, subspiral.

Lamarck established this genus for certain small shells approximating closely to the *Phasianella*, but differing from them by the truncation of the anterior part of the columella. He only records two species, viz., *P. sulcata* and *P. undulata*. M. Rang states that he possesses six well-distinguished species.

Habits, &c.—*Planaxis* is a littoral shell, and is sometimes found under stones. M. Rang says that he had had occasion to observe the animal at the Isle of France, where the rocks are sometimes covered with them, but, having lost his notes, he is unable to give its principal characters. According to his recollection, the animal differed very little from that of *Phasianella*. M. Deshayes in his tables puts the living species at four.

Example.—*Planaxis sulcata*.

Planaxis sulcata.

FOSSIL PLANAXES.

Deshayes in his tables gives five fossil (tertiary) species.

Subula.

Animal spiral, very much elevated; foot very short and round; head with extremely small triangular tentacula, bearing the eyes at their summit; a long labial proboscis without hooks (crotchets), at the bottom of which is the mouth equally unarmed. *Shell* without an epidermis, turriculated, and with a pointed spire; whorls smooth, ribbed, bifid; aperture oval, small, deeply notched anteriorly; external lip thin and sharp-edged; internal or columellar lip with an oblique *bourrelet* at its extremity. *Operculum* oval, horny, lamellar, and as it were imbricated.

M. de Blainville thus characterizes a genus which he says he found himself compelled to establish upon examining the animal brought home, by MM. Quoy and Gaimard, the shell of which had been hitherto confounded with the *Terebræ*; and he arranges under this new genus all those species whose shell is very much elevated, whose spire is very pointed, and whose whorls are ribbed; and, consequently, the greatest number of the twenty-four living species characterized by Lamarck, and which nearly all belong to the East Indies and Australasia.

Example.—*Subula maculata* (Lam.), *Buccinum maculatum* (Linn.).

Locality.—Moluccas and Pacific Ocean, according to Lamarck, who speaks of his possession of a specimen taken on the shores of Owhyhee.

Shell of *Subula maculata*, and last whorl of the shell with the animal and operculum a.

M. Rang observes that it is much to be desired that new observations on the animals of these shells may lead to the decided line of separation between the *Subulæ* and the *Terebræ*

* *

Turbinaceous; or genera whose spire is moderately elongated, rarely subturriculated.

Terebra.

Animal spiral, rather elevated; foot oval, with a trans-

Animal of *Terebra* (*Vis Miran*) from Adanson, and shell of *Terebra vittata*.

verse anterior furrow and two lateral auricles; head bordered with a small fringe; cylindrical tentacula terminated in a point and very distant; eyes but little apparent at the origin and outside of the tentacula; mouth without a proboscis; tube of the respiratory cavity very long. *Shell* without an epidermis, inclining to oval; spire sharp, not much elevated or subturriculated; aperture large, oval, strongly notched anteriorly; columella with an oblique bourrelet at its extremity. No *operculum*. (De Blainville.)

M. De Blainville only leaves in this genus, which he thinks ought perhaps to belong to the family of non-operculated *Entomostomata*, those species of Lamarck's *Terebræ*, which, in their general form, bear some resemblance to the *Buccina*, such, for example, as his *Vis buccinée* (*Terebra vittata*); because De Blainville supposes that the animal resembles that of the *Miran* of Adanson, which is the type, and which differs much from that of the subulated species to which De Blainville gives the generic name of *Subula*, *Alène*, in French.

Habits, Locality, &c.—The species, De Blainville observes, appear to come from warm climates only, like the *Subula*. *Terebra* (Lamarck) occurs at depths ranging from the surface to 17 fathoms. The species sometimes creep on reefs out of the water, but within reach of the spray.

Since the publication of the works of M. De Blainville and of M. Rang, Mr. Gray, on the 8th July, 1834, exhibited an extensive series of the shells of *Terebra*, and enumerated 45 species (21 of them new), all of them either in the British Museum or in his own private collection. He stated that the animal has a small foot, and a very long proboscis, at the base of which are seated two very small tentacula; the operculum is ovate, thin, horny, rounded behind, and rather tapering in front. The shell is covered by a very thin, pellucid, horn-coloured periostraca: it is usually white, variously streaked with brown, the streaks being often interrupted or broken into spots by the two spiral bands of the shell; one of these bands is placed near the spiral groove and the other on the middle of the whorl. The apex of the cavity is frequently filled up by a calcareous deposition; but this deposition has never been observed in *Ter. duplicata*. Mr. Gray divides the species into the three following sections. 1st. *Anfractibus sulco spirali cingulum posterius efformante; labio interiore, tenui concavo*. He observes upon this section, that the cingulum is most conspicuous in young shells; and that the internal lip is very rarely thickened in adults. To this section he refers 30 species (*Terebra maculata*, Lam., &c.), 15 of them new. 2nd. *Anfractibus sulco spirali cingulum posterius efformante; labio interiore incrassato, subelevato*. He observes that the species of this section (seven, five of which are new) somewhat resemble the *Cerithia* in the aperture. 3rd. *Anfractibus sulco postico nullo*. These last he divides into two sub-sections * with a thin internal lip, which he subdivides into (a) those species which have an elongated slender shell, and (b) those which have a short shell, and * * with the internal lip thickened and elevated, and the shell short; and he observes that these approximate somewhat to the *Nassa*, but have neither the internal dilated lip, nor the external thickened lip. This third section contains eight species, one of which is new.

Mr. Gray does not notice *Subula* of De Blainville, and it may therefore be considered that he does not admit the generic distinction.

FOSSIL SUBULÆ AND TEREBRÆ.

De Blainville refers to his genus *Subula* many of the fossil species which had been considered as *Terebræ*, and which coincide with his definition of the former genus; but he does not enumerate the species, nor draw any distinct line of demarcation between the fossils of these respective genera. He remarks that M. DeFrance makes the fossil species of both these genera seventeen, of which five are identical, three from Italy, one from Grignon, and one from Bourdeaux. The 'vis scalarine fossile de Parnes' De Blainville thinks should be referred to the genus *Terebra*. M. Deshayes, in his tables, makes *Terebra* (of Bruguière and Lamarck we presume, for he does not notice *Subula*) consist of 44 living species and 16 fossil (tertiary), of which last he considers two new species, and *Terebræ Favai*, *strigilata* and *pertusa*, to be both living and fossil (tertiary). Dr. Fitton, in his stratigraphical and local distribution of the fossils of the strata below the chalk, records *T. Port-*

landica as occurring in the Portland stone in Dorset, South Wilts, North Wilts, Oxford, and Bucks. Mr. Lea describes and figures three additional species of *Terebra* (Lamarck) from the Claiborne beds, remarking that four species of the genus have been observed in England, three in the Oolitic group, and one in the London clay. He refers to the 16 species given for the tertiary by M. Deshayes, and says that ten of these are found at Baden (Miocene) and seven at Bourdeaux (Miocene). Here is evidently an error in the number. He adds that Mr. Conrad had observed one species, which he calls *simplex*, in the tertiary of Maryland, 'being the only one heretofore observed,' adds Mr. Lea, 'in our formations.'

Eburna.

Shell oval or elongated, smooth; spire pointed, whorls running together as it were, without a marked distinction of suture; aperture inclining to oval, elongated, widened, and deeply notched in front; right lip entire; columella callous posteriorly, umbilicated subcanaliculated at its external part.

Geographical Distribution.—The seas of warm climates; sandy mud? Of the five living species, Lamarck refers the locality of three to the East Indies and one to South America and perhaps India.

Eburna glabrata.

FOSSIL EBURNÆ.

De Blainville states in his 'Malacologie' (1825) that no *Eburnæ* had then been discovered in a fossil state. M. Rang remarks (1829) in his 'Manuel' that there are fossil species. Deshayes, in his tables, records five living species and one (new species) fossil (tertiary).

Buccinum.

To avoid repetition the reader is referred to the character of the family at the beginning of the article for a general description of the animal. Dr. Buckland observes that the organ by means of which the carnivorous Trachelipods bore holes through shells for the purpose of extracting the juices of the animal is well exemplified in the English species *Buccinum Lapillus* (*Purpura Lapillus*) and *Buccinum undatum*. The proboscis is armed with a number of minute teeth set upon a retractile membrane for the purpose of perforation. Mr. Osler (Phil. Trans., 1832) gives a figure of the rasp-like perforating tongue of *B. undatum*. See also Dr. Buckland's *Bridgewater Treatise*.

Shell oval, elongated, with a pointed but moderately elevated spire; aperture oblong or oval, deeply notched anteriorly; right lip entire, sometimes thick; columella simple or callous; *Operculum* horny, oval, subconcentric; summit but little marked and marginal.

Geographical Distribution.—Very wide. Species occur in almost all seas. *Buccinum glaciale* and *Buccinum Sabini* are noted in the supplement to the appendix of Captain Parry's first voyage as having been met with during the period in which the expedition remained within the Arctic circle.

Habits.—The species have been found at depths ranging from the surface to 17 fathoms. The greater part of the genus is littoral.

M. De Blainville subdivides the species into many sections comprehending the true *Buccina*, including the genera *Alectron* (*B. papillosum*) and *Cyclops* (*B. neritium*) of De

Montfort, and the genus *Nassa*, Lamarck. M. De Férussac divides the genus into two subgenera, viz., *The Buccina properly so called*, of which *B. undatum* may be considered the type, and the *Eburnæ*. M. Sander Rang adopts this arrangement. We confine ourselves to the true *Buccina*.

The species are very numerous. Deshayes, in his tables, gives 140, and new species are continually arriving. Mr. W. Lytton Powys, for instance, describes (Zool. Proc., 1835,) four new species from Mr. Cuming's collection.

Example.—*Buccinum undatum*. *The Waved Whelk*.

Shell of *Buccinum undatum*, and animal (male) creeping with its shell and operculum.

This is the species so commonly exposed for sale as food on the street stalls in the metropolis. Pennant, speaking or another species that occurs in vast abundance on our rocks near low-water, namely, *B. Lapillus* (*Purpura Lapillus*) above alluded to, remarks that it is one of the English shells that produces the purple dye, analogous to the *Purpura* of the antients; and Mr. William Cole, of Bristol, thus describes (1684) the process of obtaining the English *Purpura*:—'The shells, being harder than most of other kinds, are to be broken with a smart stroke with a hammer, on a plate of iron or firm piece of timber (with their mouths downwards), so as not to crush the body of the fish within; the broken pieces being picked off, there will appear a white vein, lying transversely in a little furrow or cleft, next to the head of the fish, which must be dug out with the stiff point of a horsehair pencil, being made short and tapering. The letters, figures, or what else shall be made on the linen (and perhaps silk too), will presently appear of a pleasant light green colour, and, if placed in the sun, will change into the following colours, *i.e.*, if in winter, about noon; if in the summer, an hour or two after sun-rising, and so much before setting; for in the heat of the day, in summer, the colours will come on so fast, that the succession of each colour will scarcely be distinguished. Next to the first light-green it will appear of a deep-green, and in a few minutes change into a sea-green; after which, in a few minutes more, it will alter into a watchet-blue; from that, in a little time more, it will be of a purplish-red; after which, lying an hour or two (supposing the sun still shining), it will be of a very deep purple-red, beyond which the sun can do no more. But then the last and most beautiful colour, after washing in scalding water and soap, will (the matter being again put into the sun or wind to dry) be of a fair bright crimson, or-near to the prince's colour, which afterwards, notwithstanding there is no use of any stiptic to bind the colour, will continue the same, if well ordered, as I have found in handkerchiefs that have been washed more than forty times; only it will be somewhat allayed from what it was after the first washing. While the cloth so writ upon lies in the sun, it will yield a

very strong and foetid smell, as if garlic and *asafoetida* were mixed together.' (Phil. Trans., Abr. II. 826.)

We have inserted this account here, because the shell which is the subject of it may be more familiar to our readers under the Linnæan name of *Buccinum Lapillus* than of *Purpura Lapillus*, but it is properly arranged under the genus *Purpura*.

FOSSIL BUCCINA.

M. Deshayes in his tables makes the number of fossil (tertiary) species 95, and he records the following as both living and fossil (tertiary), *Nassa* not appearing as a genus in his list,—*Buccina undatum, reticulatum, maculosum, mutabile, clathratum, neriteum, Desnoyersi, prismaticum, asperulum, musivum, inflatum, polygonum, D'Orbignii, Linnei, politum*, and five new species, the names of which are not given. Dr. Fitton in his 'Stratigraphical and Local Distribution' notes two species below the chalk, viz., *B. angulatum* and *B. naticoides* in the *Portland stone* (N. Wilts, S. Wilts, Bucks), and the last-named species in the *Portland sand* (Bucks). Mr. Lea notes one species (new), *B. Sowerbii*, in the Claiborne Beds, Alabama. He observes that of the genus 27 species, including *Nassa*, have been observed in Great Britain, several as low as the mountain limestone, but chiefly in the London clay and the crag. After repeating the number given by Deshayes, Mr. Lea says that the genus appears to be much more abundant in the upper formations. The Pliocene of the sub-apennines furnishes 27 species. Bourdeaux (Miocene) 21. Paris (Eocene) 9. In America, he adds, four species have been found, Mr. Say having described two from the older Pliocene, Maryland, and Mr. Conrad two from York Town, Virginia, also older Pliocene.

NASSA.

Animal very much depressed, with a very large foot extending beyond the body on all sides, but especially in front, where it is large and angular, whilst posteriorly it is insensibly narrowed. For the rest like the animal of *Purpura*. *Shell* globular, oval or subturriculated; aperture oblong, notched anteriorly; right lip sharp-edged, often plaited within; columellar lip covered with a large callous plate, extending more or less far. *Operculum* horny.

Mr. Lea (*Contributions to Geology*) says, 'I have not hesitated to separate this genus from *Buccinum* (although Lamarck united them after having made the division) because they certainly form a very natural group. Cuvier separates it, as M. de Blainville also does, into a sub-genus.' M. de Blainville certainly makes one of his sections of *Buccinum* consist of the genus *Nassa*; but Rang separates it decisively.

Geographical Distribution. There are many living species mostly from the warmer climates. A very small number belong to Europe.

Habits. Much like those of *Buccinum*. The species have been found on reefs, coral sand, sand, sandy mud, and under stones, at depths ranging from the surface to 15 fathoms.

Mr. Powys has lately described eight new species from Mr. Cuming's collection. Example. *Nassa nodifera*. Locality. The Gallapagos Islands and the shores of Panama.

FOSSIL NASSÆ.

There are many fossil *Nassæ*, as the reader must have collected from the notice of the genus among the fossil *Buccina*. Mr. Lea describes and figures a new species from Claiborne, and adds that Mr. Conrad has observed in the tertiary of Maryland four species, three of which have been described by Mr. Say, in a recent state, upon the American shores. The genus occurs among the Gosau fossils, and Dr. Fitton in his Stratigraphical Table records two species below the chalk, viz., *N. costellata* and *N. lineata*, both from Blackdown.

**

Ampullaceous Entomostomata, or those whose shells are, in general, globular.

Harpa.

Animal with a large head, without a proboscis, having the mouth opened below; two anterior tentacula, conical and very much approximated, carrying the eyes upon an enlargement situated externally a little below the middle; foot large, furnished anteriorly with a sort of heel; siphon rather large and a little elongated; branchial pectinations

unequal, two in number; orifice of the oviduct at the entrance of the branchial cavity of the right side, orifice of the deferent canal at the extremity of a very voluminous excitatory organ; vent on the same side.

Shell oblong, more or less convex, generally rather delicate, enamelled, furnished with regular longitudinal ribs; spire a little elevated and pointed, the last whorl very large; aperture oval, elongated, widely notched anteriorly, the right lip with an external *bourrelet*, columella simple, pointed anteriorly. No *operculum* according to M. Reynaud.

Shell of *Harpa ventricosa*, and animal crawling with its shell.

Geographical Distribution, Habits, &c.—The genus is found in the seas of warm climates, and is more especially abundant at the Mauritius and the neighbouring islands, whence the finest of the more common species and the many-ribbed harps are procured. The animal is said to be of a rich vermilion red. The fishery is principally carried on at low water with a small rake, to which a net is attached, on sand-banks at night, and at sunrise when the harps are probably out upon their feed. They have been known to take the bait on the fishing lines laid for olives (*Oliva*). MM. Quoy and Gaimard, and, afterwards, M. Reynaud state, that the animal of the harp can, sometimes, when attacked by an enemy, disembarass itself of the posterior part of the foot, and completely withdraw itself into the shell. M. Reynaud explains this phenomenon by giving his opinion that the transverse laceration which causes, in the movement of contraction exerted by the animal, the separation of the posterior part of the foot, arises from the resistance which that part, too voluminous to enter the shell after the animal, encounters from the edges of the shell. M. Rang observes, that though no operculum has been found, (and the animal appears to have been carefully examined,) he does not hesitate to leave the genus among those which are provided with one, because, in the first place, *Harpa* is similarly organised, and, in the next, if deprived of that appendage, it has, at least, the posterior part of the foot to take, in some sort, its place.

Authors generally make the number of living species eight, and of these the most precious, though lately greatly depressed in value, is the *Many-ribbed Harp* (*Harpa imperialis*.) But some of the species are very difficult of definition, though others are well marked. The shells when in fine condition are great favourites with collectors, and, indeed, a drawer of fine harps in all the freshness of their beauty is a sight worth seeing. Care should be taken to keep them with their mouths downwards and from the sun and light, or their brilliant colours will soon fade.

Example, *Harpa ventricosa*. Locality Mauritius, &c

FOSSIL HARPS.

Only two species are recorded, in the tertiary formation.

De Blainville adds, that one of these is an analogue, but Deshayes, who gives Paris as the locality for both, does not rank either of them among the species found both living and fossil.

Dolium.

Animal generally resembling that of *Purpura*. *Shell* delicate, nearly globular, ventricose, furrowed transversely; spire but little elevated, pointed, the last whorl forming nearly the whole of the shell; aperture large, oval, right lip undulated; columella often twisted, *operculum* horny.

Geographical Distribution.—The seas of warm climates, especially those of India. One species, *Dolium galea*, inhabits the Mediterranean. The species are often found on reefs, some of them are very large. Seven seems to be the greatest number hitherto recorded, and Cuvier has separated the species into two sections, viz.: The Tuns (*Dolium*) and the Partridge Tuns (*Perdix* of De Montfort).

Examples, *Dolium galea*. and *Dolium perdix*.

Shell of *Dolium Galea*, and animal denuded (diminished).

FOSSIL DOLIA.

Deshayes gives but one fossil (tertiary) species, and that (*D. pomum* ?) he gives doubtingly, placing it in the column headed 'species found both living and fossil (tertiary).' De Blainville alludes to four fossil species, two of which are analogues, according to Brocchi.

Cassidaria.

Animal supposed to bear a general resemblance to that of *Buccinum* and *Purpura*. *Shell* ovoid, ventricose, with the spire but little elevated; aperture long, rather narrow, with the anterior canal recurved; right lip furnished with a *bourrelet*; columellar lip covered by a large callosity, often granulous or wrinkled. *Operculum* horny.

Cassidaria echinophora.

Geographical Distribution.—The seas of comparatively warm climates. Lamarck gives the Mediterranean as the locality of two species. Rang states that only one species is European. De Blainville speaks of the genus as inhabiting all seas except that of the North.

The number of living species recorded appears to be seven.

Example, *Cassidaria echinophora*. Locality, the Mediterranean.

FOSSIL CASSIDARIAE.

Deshayes, in his tables, states the number of fossil (tertiary) species to be eight; and of these, two, viz., *C. echinophora* and *C. Tyrrhena*, he records as both living and fossil (tertiary).

Oniscia.

A genus separated from *Cassidaria* by Mr. G. B. Sowerby, and considered by him as having its place next to that genus in the natural system. It differs from *Cassis* in the canal not being suddenly reflected; but Mr. Sowerby states that he has seen *Cassides* which very nearly approach *Oniscia* in the form of the aperture, and in the short, scarcely reflected canal. He thinks that the genus is intermediate between *Cassidaria* and *Cassis*.

Shell oblong, subcylindrical, apex generally rather obtuse, spire short, sometimes very short; base rather acuminate; aperture longitudinal, elongated, extending at the base into a very short canal: outer lip thickened, denticulated within, and rather contracted in the centre; inner lip expanded and covered with granules (Sowerby). The outside of the shells is tuberculated, cancellated, or ribbed. 'Of the animal,' says Mr. Sowerby, 'we know nothing; but there is every reason for believing it to be related to that of *Cassis*, and that it has an operculum, though we have never seen it.'

Habits.—Littoral. Found in coarse sand.

Three living species are recorded, one from the South Seas.

Example, *Oniscia cancellata*. (Sowerby's Genera, *Oniscia*, fig. 1, 2, adult; 3, young. N.B. the specimens figured were from Mr. Broderip's collection, now in the British Museum.)

Oniscia cancellata, adult.

FOSSIL ONISCIA.

One fossil species only is recorded. It is figured by Mr. G. B. Sowerby from the Italian tertiary.

Cassis.

Animal said to resemble generally that of *Purpura*.

Shell inclining to oval, convex, with a spire but little projecting, nearly flat; aperture oblique, long and narrow, with the anterior canal very short and recurved towards the back; right lip thick, furnished with an external *bourrelet*, and toothed within; columellar lip callous, nearly straight, and marked nearly throughout its length with transverse long teeth. *Operculum* horny, very rudimentary.

Geographical Distribution.—The genus occurs principally in very warm latitudes; two or three are said to be found in the Mediterranean.

Habits.—The species have been found at depths ranging from five to eight fathoms on sands.

Deshayes gives thirty as the number of living species. These are divided into two groups by Lamarck; the first consisting of those species whose spire is marked by *bourrelets* (*C. cornuta*, for example); and the second of those whose spire is without *bourrelets* (*C. rufa*, for example).

De Blainville divides the species into two groups also; the first consisting of those whose aperture is long, and

external lip nearly straight (*C. tuberosa*, for example); the second of those whose aperture is suboval, and the external lip excavated (*C. flammea*, for instance).*

Example, *Cassia tuberosa*. Locality, West Indian Seas.

Shell of *Cassia tuberosa*, and animal, denuded, of *Cassia sulcosa* (diminished).

FOSSIL CASSIDES.

Deshayes, in his tables, states the number of fossil (tertiary) species to be fifteen, of which he records *Cassides flammea*, *granulosa*, *crumena*, *saburon*, *bisulcata*, and a new species, as both living and fossil (tertiary).

Ricinula.

Animal nearly entirely resembling those of *Buccinum* and *Purpura*. Mantle provided with a tube; foot much wider, and auriculated, as it were, anteriorly; head semi-lunar, with conical tentacula, supporting the eyes at the middle of their external surface; excitatory organ of the male very large, recurved in the branchial cavity. Such is De Blainville's description, who made his observation on 'la Ricinule horrible,' *Ricinula horrida*.

Shell oval or subglobular, thick, beset with points or tubercles, with a very short spire; aperture narrow, long, with a notch (which is sometimes subcanaliculated) anteriorly; right lip often digitated externally and toothed within; the left lip callous and toothed or wrinkled.

Operculum horny, oval, transverse, concentric. De Blainville describes the elements of the operculum as a little imbricated.

Geographical Distribution.—De Blainville says that of nine species of this genus, all those whose locality is known come from the Indian Seas.

Habits.—The species have been found on coral reefs and rocks.

Deshayes, in his tables, gives the number of recent species as fourteen. De Blainville separates the species into three sections: the first consisting of those with an evident canal anteriorly and behind the aperture (en arrière de l'ouverture) *Ricinula digitata*; the second of those without a canal and beset with spines, *R. horrida*; and the third of those without a canal and tuberculous, *R. morus*. He observes that this genus is evidently artificial: thus it contains one species which is a true *Murex*, whilst others are closely approximated to certain species of *Turbinella*; in fact, they have two or three plaits on the columella; finally, some of them scarcely differ, he says, from the true *Purpura*.

Example, *Ricinula horrida*.

* Mr. R. Stutchbury distinguishes *Cassides rufa*, *testiculus*, and *coarctata*, &c. generically under the name of *Cypræacidae*, which, he says, has no operculum. Mr. G. B. Sowerby objects to this genus.

Ricinula horrida

Fossil Ricinulae.

De Blainville and Rang both say that there is no fossil *Ricinula*. Deshayes, in his tables, records one, a new species, in the tertiary formations. (Bordeaux, Dax, Turin.)

Cancellaria.

Animal said to resemble generally that of *Purpura*.

Shell oval or globular, rather convex, reticulated, thick with a spire slightly elevated and pointed; aperture semi-oval, notched or subcanaliculated anteriorly; right lip sharp-edged, striated within; columella nearly straight, with many well defined plaits. *Operculum* horny.

Geographical Distribution.—The species are all exotic, and the inhabitants of warm seas. The localities of the bulk of those known are said by De Blainville to be inhabitants of the Indian and African seas (but see below).

Habits.—The species have been found on sandy bottoms, at a depth ranging from seven to sixteen fathoms.

De Blainville speaks of twelve recent species. He observes that the genus as adopted by him is not entirely the same as that of Lamarck, who gives that number. De Blainville withdraws from the genus the species whose aperture is evidently canaliculated, such as *C. senticosa*, which, as it appears to him, ought to remain among the *Murices* or the turriculated *Turbinella*. Deshayes, in his tables, makes the number of living species thirteen. Mr. G. B. Sowerby ('Zool. Proc.' 1832) describes twenty-two new species from the collection of Mr. Cuming, most of them from the warm latitudes of the Pacific side of South America. One of them, *C. uniplicata*, dredged in sand near Panama at a depth of ten fathoms, is the only species known to Mr. Sowerby with a single fold on the columella.

Example, *Cancellaria reticulata*. Locality, Southern Atlantic Ocean (Lamarck).

Cancellaria reticulata.

FOSSIL CANCELLARIAE.

Lamarck records seven fossil species. Rang says there are a good number. De Blainville observes that, according to Deffrance, there are twenty species, two of which are identical, one from Italy, the other from Grignon, and one analogue from Italy. Deshayes makes the number of fossil (tertiary) species forty-two, one of which he notes as both living and fossil (tertiary). Mr. Lea describes and figures, in addition, eight species from the tertiary formation of Alabama (Claiborne). He observes that the genus has been observed in England only in the London clay, from whence three species have been described; and, referring to Deshayes' Tables and his forty-two species, remarks that sixteen are from the Subapennines (Pliocene), twelve from

Bourdeaux (Miocene), and five from Paris (Eocene). In America, he observes, a single species only, *C. lunata* (Conrad), had been theretofore observed. It was from the tertiary beds of Saint Mary's.

Purpura.

Animal rather elongated, widened in front; head large with a very short proboscis; two tentacula, generally in front and approximated, conical, and supporting the eyes on an enlargement situated at the middle of their external part; mouth below, nearly always hidden by the foot, which is rather large, very much advanced and bilobed, as it were, anteriorly; branchial pectinations two, unequal; orifice of the oviduct at the entrance of the branchial cavity on the right side; orifice of the deferent canal at the right side of the neck, at the extremity of the exciting organ, which is generally voluminous; vent on the same side.

Shell of *Purpura Persica*, and animal of *Purpura hemoctoma*.

Shell oval, thick, unarmed or tubercular, with a short spire, the last whorl larger than all the others together; aperture very much dilated, of an oval form, terminated anteriorly by an oblique notch; columella flattened, finishing in a point anteriorly; right lip sharp-edged, often thickened and furrowed internally, or strongly armed anteriorly with a conical point. *Operculum* horny, demicircular, the summit posterior.

Geographical Distribution.—The form is widely distributed, but the number of European species is very small; the greatest development takes place in warm seas where the species are most abundant, particularly in South America.

Habits.—The larger proportion of the species of this genus are littoral. The true *Purpura* have been found at depths ranging from the surface to twenty-five fathoms, and the division which forms the genus *Monoceros*, generally on rocks, at depths ranging from the surface to seven fathoms.

De Blainville states that there are fifty living species of ordinary *Purpura*, of which four only belong to the French seas. The species of *Monoceros*, he states, to be five; all from South America. Deshayes, in his tables, gives seventy-six as the number of living species of the genus *Purpura* (Lam.), and six as that of the living species of *Monoceros*. Mr. Lea states that his cabinet has nine. We are not sure whether M. Deshayes includes among his seventy-six species *P. granatina*, *P. squamigera*, and *P. squamosa*, described by him. Mr. Broderip describes two new species, and Mr. Powys one, from Mr. Cuming's collection (Port St. Elena, Valparaiso, and Maldon Island, in the Pacific), and Mr. Broderip another, *Purpura Gravetti*, figured under the name of *Murex cariniferus*, in Mr. Sowerby's *Conchological Illustrations*. (Zool. Proc.) Mr. Sowerby describes nine species of *Monoceros*, among them, *M. punctulatum* (Gray), from Mr. Cuming's collection.

De Blainville divides the species into four sections:—1st. Those whose right lip, near the notch, is armed with a conical horn, or tooth, which is pointed, and more or less curved. This section is the genus *Monoceros* (De Montfort), the animal of which, according to M. Rang and others, differs in nothing from that of the other *Purpura*. 2nd. The *Buccinoid Purpura*, whose lip is without a tooth, and whose aperture is moderately widened. *Purpura Lapillus*

(*Buccinum Lapillus*, Linn.) for example. (See above, *Buccinum*.) 3rd. The *Patulous Purpura* also without a tooth at the lip, and whose aperture is very wide; *Purpura Persica*, for instance. 4th. The ventricose tuberculated species, of which he gives *P. neritoides* as the type. M. Rang divides the species into two groups only. The first, consisting of those which have the right lip simple, or only furrowed internally: the second, of those whose right lip is always thickened and armed anteriorly with a conical point.

Example of the first, *Purpura Persica*. Locality, East Indian Seas.

Example of the second, *Purpura imbricata* (*Monoceros imbricatum*, Lam.). Locality, South America.

Purpura imbricata, *Monoceros imbricatum*.

FOSSIL PURPURA.

De Blainville states (Malacologie) that no fossil species of *Monoceros* were then known. Deshayes, in his tables, records one (tertiary) from Italy. Mr. Lea describes and figures three new fossil species from the tertiary of Claiborne, Alabama (Eocene of Lyell). Of the ordinary *Purpura*, De Blainville states that there are nine fossil species, one of which is the analogue of *P. Lapillus* (*Buccinum Lapillus*, Linn.), so common on our coasts, as well as those of France. Deshayes, in his tables, gives the number of fossil (tertiary) species as four, of which he records one, *P. hémastoma*, as both living and fossil.

Patelloid Entomostoma; that is, one whose shell is very large in its totality, very flattened, with a spire but little marked, and without a columella.

Concholepas.

De Blainville speaks of the animal as entirely unknown; but according to Lesson, it resembles that of *Purpura*. *Shell* thick, rude, and wrinkled transversely on its external surface; spire very small, hardly projecting; aperture oval, very large, notched anteriorly, where there are two dentiform appendages; no columella; muscular impression of a horse-shoe shape, and very visible. *Operculum* horny, transparent, trapezoidal, concentric, with a marginal summit.

Geographical Distribution.—South America is the locality of *Concholepas*. It is very abundant on the coasts of Peru and Chile, and sometimes attains to a very large size.

Habits.—*Concholepas* is, as yet, only known as a littoral species.

Lamarck first placed *Concholepas* near *Purpura*. Cuvier gives it very nearly the same position. M. Rang remarks that he might have well united the genus to *Purpura*, after the example of De Férussac. In fact, he adds, M. Lesson's communication touching the animal which the latter brought home from the South Sea had proved to M. Rang that it differs in nothing from that of *Purpura*; its operculum alone affords a well-defined character.

There is but one species known; but M. Rang states that there are two distinct varieties.

Example, *Concholepas Peruviana*.

Concholepas is not known in a fossil state, properly so called. It occurs among other species of the coast, at considerable elevations above the sea.

Gonocholepas Peruviana.
