ENTOMO'STRACA (Müller). Shell Insects; for such is the meaning of the term applied to certain aquatic animals forming, according to Latreille and others, the second general division of the crustaceans, and for the most part inhabiting the fresh water. The brain, or rather the nervous knots which supply its place, consists of one or two globules merely. The heart is in the form of a long vessel. The branchiæ, composed of hair-like processes, which are either isolated, or connected in a beard-like form, a pectinated shape, or one resembling aigrettes, form a portion of the feet, or of a certain number among them, and sometimes mandibles and the upper jaws. [CYPRIS, vol. v. p. 341.] Hence the term BRANCHIOPODA. [See the title, vol. v. p. 338.] The number of the feet varies, and in some of the genera is above a hundred. These feet, ordinarily, are proper for no purpose but swimming; and are sometimes ramified or divided, and sometimes furnished with pinnules, or composed of lamellar joints. Nearly all of them have a shell, consisting of from one to two pieces, very delicate, and most frequently almost membranous and transparent, or at least a large anterior thoracic segment, often confounded with the head and appearing to replace the shell. The integuments are generally rather horny than calcareous, a condition which, as Latreille remarks, approximates the Entomostracans to the Insects and Arachnids. In those which are provided with ordinary jaws, the inferior or external ones are always uncovered, all the jaw-feet (pieds-mâchoires) performing the office of true feet, and none of them being applied upon the mouth. The second jaws, with the exception of the *Phyllopoda*, resemble those organs, and Jurine has sometimes designated them under the name of hands. These characters, says Latreille, distinguish the masticating Entomostraca (Entomostracés Broyeurs) from the *Malacostraca*; the other Entomostraca which compose his order *Pœcilopoda* cannot, he says, be confounded with the *Malacostraca*, because they are deprived of organs fit for mastication, or because those parts which appear to perform the office of jaws are not collected anteriorly and preceded by a labrum as in the true crustacea and the masticating insects (insectes broyeurs), but simply formed by the haunches of the locomotive organs, and furnished, for the purpose of enabling them to execute that office, with small spines. The *Pœcilopoda*, he observes, represent in this class those of the class of insects which are denominated suctorial (suceurs). They are almost all parasites, and seem to lead us by degrees (par nuances) or shades of difference to the *Lernææ*; but the presence of eyes, the property of moulting or changing the skin, or even of undergoing a metamorphosis, and the faculty of being able to transport themselves from one place to another by means of feet, appear to Latreille to establish a well-defined line of demarcation between the animals last named and the preceding. With regard to the metamorphosis, he remarks, that the young of the *Daphniæ* and of some other nearly allied genera, those probably also of *Cypris* and of *Cytherina*, differ not at all or scarcely at all from their parents, in point of form, at the time of their exclusion from the egg; but the young of *Cyclops*, of the *Phyllopoda*, and of *Argulus*, undergo in their infancy remarkable changes, as well in the form of the body, as in the number of feet. These organs, indeed, in some (in the *Arguli* for instance) suffer transformations which modify their uses. The same author states that he has consulted, relative to these transformations, several well-informed naturalists, who have had frequent occasion to observe the *Lernææ*, and that those observers had never seen a *Lernæa* change its skin. The antennæ of the Entomostraca, the form and number of which vary much, serve in many for swimming. The

eyes are very rarely placed upon a pedicle, and when they are so placed, the pedicle is no more than a lateral prolongation of the head, and is never articulated at its base. The last-named organs are often very much approximated, and even compose one only. The tail is never terminated by a fan-shaped fin, and never presents the false feet of the *Malacostraca*. The eggs are collected under the back, or external, and under a common envelope, having the form of one or two small groups situated at the base of the tail. They possess the power of preserving their vitality for a long time in a state of desiccation. [BINOCULUS, vol. iv. p. 410.] It would appear that not less than three moults are undergone by many of these animals before they become adult and capable of propagating their species, and it has been proved, in the case of some of them, that a single copulation will fecundate many successive generations. [BRANCHIOPODA, vol. v. p. 342.]

In M. Latreille's second method, the Entomostraca were treated as a sub-class, with the following characters:—Mandibles naked or none; mouth formed of two rows of pieces; antennæ and feet of a branchial form; tarsi without a horny nail at the end; shell clypeaceous or shield-like, univalve or bivalve, or with annular horny or membranous segments of the body; eyes sessile, often united so as to form one.

1st SECTION. (*Operculæ*, shell univalve or bivalve.)

Shell univalve. (*Clypeacæ*.)

1st order, *Xyphosures*. (Example, *Limulus*.)

2nd order, *Pneumonures*. (Ex. *Ozulus*.)

3rd order, *Phyllopodes*. (Ex. *Apus*.)

Shell bivalve. (*Ostrachodes*.)

4th order, *Ostrachodes*. (Ex. *Cypris*.)

2nd SECTION. (*Nues*, body annulated throughout its length.)

5th order, *Pseudopodes*. (Ex. *Cyclops*.)

6th order, *Cephalotes*. (Ex. *Polyphemus*.)

In the last edition of Cuvier's 'Règne Animal' M. Latreille divides the Entomostraca into two orders.

I. BRANCHIOPODA. (See that title, vol. v., p. 338.)

II. PŒCILOPODA.*

The PŒCILOPODA he divides into two families.

1st. *Xyphosura*.

This family consists but of one genus, viz., *Limulus*.

2nd. *Siphonostoma*.

This family he separates into two tribes.

1. *Caligides*.

This tribe contains the genera *Argulus*, *Caligus*, and its sub-genera *Pandarus*, *Dinemoura*, &c., and *Cecrops*.

2. *Lernæiformes*.

This tribe consists of *Dichelestium* and *Nicothoe*.

M. Milne Edwards remarks, that at the first glance the branchial feet of *Apus* and of many other Entomostraca would appear to have hardly anything in common with the ambulatory feet or buccal members of the Decapods; but, nevertheless, the same parts are found among the former. In fact, he observes, in the great foliaceous laminæ or blades, the structure of which seems as complicated as it is anomalous, the analogues of the flagrum (fouet), palp, and stem (tige) are easily traced. The first of these appendages constitutes the flattened vesicle which occupies the basilar and external part of the foot: its form is the same as among the *Stomapoda*, and its structure further confirms the approximation.

The last-named author proposes the following method, differing from that of Latreille not only in the number of the orders under which the different Crustacea are arranged, but also in the limits assigned to many of those divisions:—

A

Mouth deprived of special organs of mastication.

Orders.

Xyphosures.

Siphonostomes.

B

Mouth armed with special organs of mastication, viz., with one pair of mandibles, and with one or more pairs of jaws.

* The reader will find those Pœcilopoda, which are not already noticed in this work, either under that title, or under their generic names.

Orders.
Ostrapodes.
Cladoceres.
Phyllopoies.
Copepodes.
Læmipodes.
Isopodes.
Amphipodes.
Stomapodes.
Decapodes.

M. Milne Edwards further states that Latreille, a little before his death, was again occupied with the subject, and introduced into his method many modifications, which made it approach nearly to that proposed by M. Milne Edwards. The latter says that Latreille in fact admitted into the class *Crustacea* 12 orders, viz., the *Decapods*, the *Stomapods*, the *Læmipods*, the *Amphipods*, the *Isopods*, the *Di cladopods*, the *Lophyropes*, the *Ostrapods*, the *Xyphosures*, and the *Siphonostomes*; and that the *Di cladopods* very nearly correspond to the *Copepods* of M. Milne Edwards. The last-named author, when speaking of Latreille's classification in the first edition of the 'Règne Animal,' speaks of Latreille's not attaching to the distinction of *Malacostraca* and *Entomostraca* an importance which those divisions do not deserve; but M. Milne Edwards still retains the term *Entomostraca*; for we find in his synoptical table (*Histoire Naturelle des Crustacés—Suites à Buffon*), under the sub-class of *Maxillated Crustaceans*, the legion of *Branchiopods*, containing the orders *Ostrapoda* and *Phyllopoia*, and the legion of *Entomostraca*, consisting of the orders *Copepoda* and *Cladocera*.

The reader who wishes to study the classification, economy, and anatomy of the Entomostraca, should more particularly consult, besides the works above alluded to, those of Swammerdam, Needham, Leuwenhoek, De Geer, Ramdhor, Schoeffer, Straus, Hermann, the younger Fabricius, the Jurines, father and son, Adolphe Brongniart, Slabber, Desmarest, De Blainville, Thompson, and Audouin.

ENTOZO' A (from the Greek words *entos* (ἐντός), within, and *zoon* (ζῷον) an animal). Under this name are designated the different living beings which are produced and developed within other living beings. It comprehends a series of animals differing greatly from one another in form and organization, and having but one character in common; which is, that they are all parasitic, or have their exclusive habitation in, and live at the expense of the bodies of other animals. They can scarcely be said to form a distinct class in the animal kingdom, some of the species being closely resembled both in external appearances and internal structure, by individuals placed in other classes, and only differing from them in the localities where they are found; thus the zoosperms, or seminal animalcules, which are enumerated by some zoologists with the entozoa, closely resemble the true cercariæ of vegetable infusions.

Entozoa are found in most animals; they have been discovered in all the mammalia from man down to the cetacea; they also occur in the other classes of the vertebrata; indeed, it seems that a greater number reside in birds, reptiles, and fishes than in mammals. The invertebrata have also their peculiar parasites; and they have been ascertained to exist in all the insect tribes, and in beings still lower in the scale. The best known species are those which inhabit the intestines of the human subject, and vulgarly go by the denomination of worms, which term was probably derived from the resemblance which the *Ascaris lumbricoides* bears to the common earth-worm, as this species is most frequently met with, and was the first described of the human entozoa, being mentioned by Hippocrates, who called it the *ἐλμινς στρογγύλος*, or round worm.

A short list of the different kinds of worms found in the human intestinal canal, with an enumeration of their causes, the morbid symptoms which they occasion, and the mode of treatment, are given under the article ANTHELMINTICS.

With regard to the causes of the formation, or the primary origin of the entozoa, nothing is known; and the whole subject is entirely involved in darkness; they must either be supposed to be the product of spontaneous generation, or the germs of them are introduced from without. Many arguments have been adduced on both sides of the question, but as the discussion would lead to no useful results, we shall leave it untouched, and proceed to give a short sketch of these curious and interesting animals.

According to the derivation of the word *Entozoa*, and the definition which we have given of it, this term should include every living creature found in the body of another (which has not been introduced from without): therefore the small microscopic animalcules detected in the semen of animals, called *Spermatozoa*, come under this head; and in a very able paper on the entozoa by Mr. Owen, we find them placed accordingly in this class, only situated in a separate group, denominated *Protelmintha*, and divided from the animals forming the class entozoa of Rudolphi. These minute beings, which, from their size and organization, rank with the assemblage of animalcules which are collected under the head Infusoria in the 'Règne Animal,' have been detected in the secretion of the testicles of various mammiferous animals arrived at maturity. When a drop of the secretion is expressed from a divided vas deferens shortly after death, and examined with a microscope, after being diluted with water, it is seen to be filled with minute beings resembling tadpoles, and swimming about in various directions, with different degrees of velocity, guided by the inflection of a slender tail. It has been doubted whether these are animated beings at all, or are to be considered as analogous to the moving filaments of the pollen of plants; but leaving this undecided, we may proceed to state that the body is always of a compressed form, which will distinguish these animalcules from the vegetable infusoria, in which the body is always ovoid or rounded. With regard to their organization, no alimentary canal or gastric cavities have been detected, nor organs of generation; they are said to be fissiparous, the body and tail spontaneously dividing, and forming two independent beings. The shape of these zoosperms differs in different animals, the large end, or body, being bigger in proportion to the tail in some than in others, and their size not being always in relation to that of the animal to which they belong: thus those of the rabbit are nearly as large as those from the bull. That these animalcules perform some office in the economy of nature seems probable from the fact that in those animals which are subject to periodical sexual development, as the hedgehog and mole (in which the testes undergo an alteration in size in different seasons), these creatures are not found during the period of quiescence, or partial atrophy of the glands; neither do they exist in the seminal passages before the age of puberty. But the part in the physiology of generation which these zoosperms perform is not so clear. The *spermatozoa* have been detected in the other orders of the vertebrate and in the articulate animals.

In the present group are also included those minute internal parasites which have been detected in the bodies of many of the entozoa themselves, and which, from their external form, are referrible to the infusoria.

The *Trichina Spiralis*, an entozoon, found inhabiting the muscles of the human subject, has been placed by Mr. Owen, who first described it, with the preceding animalcules; but further observations on its organization have discovered a complexity of structure which qualifies it to occupy a place in the highest instead of the lowest group into which the present class of animals is divided.

We now proceed to the more legitimate part of our subject, viz. the true parasites forming the class *Entozoa* of Rudolphi, and it is first necessary to arrange them according to some classification. Availing himself of the difference in their internal organization, Cuvier divided them into the 'cavitaires,' or those which have an abdominal cavity, and a distinct intestinal canal within it, and the 'parenchymateux,' or those in which no intestinal tube is traceable, and which for the most part consist throughout of an homogeneous structure; but this classification is any thing but a natural one, as worms the most dissimilar in their general appearance are here promiscuously congregated together. Mr. Owen, in the article which we have before alluded to (in the *Cyclopæd. of Anat.*), has adopted the arrangement of Cuvier, only inventing new Latin names derived from the Greek, instead of the French terms: thus he denominates the 'parenchymateux' 'sterelmintha,' from *elmins*, 'a worm,' and *stereos*, 'solid'; and the 'cavitaires' 'coelmintha,' from *elmins*, and *celos*, 'hollow.' Zeder laid the first foundation of a good classification of these animals, dividing them into five classes, afterwards called families, at Rudolphi's suggestion; and these were again subdivided into genera and species. Rudolphi himself doubted the possibility of ever reducing all the species of entozoa to absolutely natural and well-defined families,

but as Zeder's system seemed the most perfect, he has adopted it for his own; and it does not seem that we can do better than follow the arrangement of this great entozoologist in the present article.

According to this classification the entozoa are divided into five orders, or families, the Nematoidea, Acanthocephala, Trematoda, Cestoides, and Cystica. The only point in which we shall depart from this arrangement will be, that, instead of commencing with the most perfect, and descending to the most simple, we shall begin with the lowest in the scale of organization, and ascend to those possessing the most complicated structure, as this is most in accordance with the laws of the animal kingdom.

Order I. is *Cystica* (from *cystis* (κύστις) a bladder) hydatids: the characters are:—body flattish, or roundish, and terminating posteriorly in a transparent cyst filled with pellucid fluid, which is sometimes common to many individuals; the head is retractile, and provided with pits two or four in number, or four suckers and a circle of hooklets, or with four unarmed or uncinated tentacles. The organs of generation and nutrition are unknown. This is not a very natural family, the species being closely allied to those of the next order in the structure of the heads and the *Ecchinococcus*, or granular hydatid, though referred to it, is not hollow.

Order II. *Cestoides* (from *cestos* (κεστός), 'a band'; and *eidos* (εἶδος), 'form'), tape-worms. Characters:—body elongated, flattened, soft, continuous, or articulated, furnished with lateral or marginal pores, and erectile papillæ passing through them, supposed to be the male organs of generation. Head generally provided with two or four pits, or suckorial orifices, and sometimes with four retractile, unarmed, or uncinated tentacles; but the head is so dissimilar in different genera, and their shape varies so much, that they do not form a very natural family. There is no trace of intestinal canal; unless the vessels proceeding from the suckers be considered as such. In some species nutrient vessels and ovaries are to be seen. They are all androgynous.

Order III. *Trematoda* (from *trema* (τρίμμα), 'a foramen'), fluke-worms. Characters:—body soft, rounded, or flattened. Head indistinct, with a suckorial foramen; one or more suckorial pores on the under surface of the body, which furnish the grounds for their subdivision into genera: they have no intestinal canal, and the organs of generation of the two sexes co-exist in the same individual: this is a very natural order.

Order IV. *Acanthocephala* (from *acantha* (ἀκανθα), 'a thorn'; and *cephale* (κεφαλή), 'the head'), hooked-worms. Characters:—body elongated, round, subelastic; the anterior extremity or head has a retractile proboscis, furnished with hooks or spicula, arranged in rows. They have no intestinal canal, but distinct genital organs, and a separation of the sexes. This is a very natural group, and includes the most noxious of the internal parasites: there is only one genus, and fortunately no species is known to infect the human body.

Order V. *Nematoidea* (from *nema* (νήμα), 'a thread,' and *eidos*, 'form'), round-worms. Characters:—body cylindrical, elongated, and elastic; structure very complicated, there being a true intestinal canal, terminated by a distinct anus. The mouth, by its varieties, affords generic characters; the sexes are distinct; the females, which are longer than the males, being for the most part oviparous: they constitute a very natural order.

Having given the above brief view of the orders into which the class *Entozoa* is divided, with the leading or characteristic differences in their form and organization, we will now enumerate the principal genera contained in each group, and make a few observations on some of the most interesting species. Following the order of classification, we must commence with the most simple group, the *Cystica*; and here the first parasite which attracts our attention is the common hydatid, which consists of a globular bag, composed of condensed albuminous matter of a laminated texture, and contains a limpid colourless fluid. No head or appendices of any sort being attached to it, it is appropriately denominated an *acephalocyst*, that is, a headless cyst. This genus was established by Linneus, who regarded as animals those productions which before his time had been considered simply as cysts. Considerable diversity of opinion still exists as to their nature, and it is impossible to determine whether an hydatid is an animal or not, till we can agree what is the definition of an animal; if an animal must have sensation and motion, this is not one, as the best observers

agree that the *acephalocyst* is impassive under the application of stimuli of any kind, and manifests no contractile power, either partial or general. If an animal is characterized, on the other hand, by independent existence merely, the hydatid is one; and as such we shall regard it, for it is certainly an independent organized being, growing by intrinsic power of imbibition, and reproducing its species by gemmation: the young are developed between the layers of the parent cyst, and thrown off internally or externally, according to the species. It is a being certainly far inferior in the scale to the *Cysticercus*, but still not the less an independent creature. Its structure is very similar to that of some of the lowest forms of algae in the vegetable kingdom, as the *protococcus nivalis* or red snow of the arctic regions, which consists of simple and minute vesicles, which propagate their kind by gemmules developed from the external surface of the parent. *Acephalocysts* have been found in almost every structure and cavity of the human body, but particularly in the liver, uterus, kidneys, and cellular tissue. The species which resides in man is called *A. endogena*, the pill-box hydatid of Hunter, from the gemmules being detached from the internal surface of the cyst; and it is thus distinguished from those of the ox and other ruminating animals, which are exogenous, or have the gemmules excluded from the external surface.

2. The next genus is *Ecchinococcus*, which, as the name implies, is a round body covered with asperities. The *E. hominis*, or many-headed hydatid of the Germans, occurs in cysts in the liver, spleen, omentum, and mesentery: the cyst, which is externally yellow and coriaceous, is unprovided with head or mouth, and contains minute bodies, which are described as possessing the armed and suckorial head characteristic of the *Cœnuri* and *Cysticerci*. From observations made on another species, the *E. veterinorum*, found in animals, the particles adhering to the internal surface of the cyst being examined with a microscope, appeared to be minute animalcules, moving about by means of external vibratile cilia, having an orifice at each extremity of the body, and the centre occupied by large globular stomachs. From this structure these parasites ought to be classed with the Polygastric Infusoria.

3. *Anthocephalus* is the next genus. It occurs in fish, in the liver, mesentery, and peritoneum, and within hydatids in the viscera. Each animal exists solitarily in a double bladder, of which the outer layer is hard and elastic, the inner more thin and delicate. The body is long, flat, terminated behind by a caudal vesicle, and in front by a head with two or four fossæ, and four probosces furnished with spicular processes.

4. *Cœnurus*. This has the terminal cyst common to many bodies and heads; the former are elongated, flattish, and wrinkled; the latter are furnished with a rostrum, on which there are hooks and suckers, adhering in greater or less number to the surface of a bladder filled with fluid. The best known species is the *Cœnurus cerebialis*, commonly developed in the brain of sheep, and giving rise to the disease called the staggers.

5. *Cysticercus*. Here there is a dilated cyst forming the termination of a single entozoon: the head has four suckers, and a rostrum furnished with recurved processes or hooks. Of this genus one species is known to infest the human subject, the *C. cellulosæ*; it is developed in the interfascicular cellular tissue of the muscles, and is invariably surrounded by an adventitious capsule of condensed surrounding substance. This entozoon occurs much more rarely in this country than on the continent; it is not confined to the muscular structures, for several individuals have been detected in the anterior chamber of the eye, where they may occasion so much irritation and inflammation of the organ as to require extraction, which occurred in a recent case in the Glasgow Ophthalmic Infirmary. These parasites also occur in quadrupeds, particularly the hog, giving rise to that state of the muscles which is called 'measly pork.'

Of the *Cestoid* order of Entozoa, Rudolphi has described eight genera, two only of which contain each a single species that infest the human body:

1. *Bothriocephalus*, the species of which occur frequently in fishes and birds, in the branchiæ, œsophagus, pyloric appendices, intestines, and abdominal cavity. The one which affects the human subject, *B. latæ*, or *Tœnia latæ*, rarely falls under the observation of the English entozoologist, but is common in the intestines of man in Switzerland, Russia, parts of France, &c. It may be distinguished from the

Tænia solium by the form of the segments, which are broader than they are long, and by the position of the genital pores, which are on the under surface of the body, instead of at the sides; the head is also very different, for, instead of having four round oscula, characteristic of the true *tænia*, there are two lateral longitudinal fossæ, or bothria.

2. *Tænia*. This genus has the body flat, long, articulated, with four suckers on the head; it occurs in the intestines, biliary ducts, gall-bladder, and liver of vertebrate animals. The *T. solium*, common tape-worm, inhabits the human intestines, but not with equal frequency in all countries, though its distribution seems to be much more extensive than that of the *Bothriocephalus latus*. It occurs in England, Holland, Germany, Sweden, Italy, Greece, and most countries in Europe, and also in Egypt and the East; and in all these situations the other genus is comparatively rare.

The delicacy of their structure, and their so seldom being obtained entire, has thrown great obstacles in the way of their investigation. The head was for a long while unknown, and it was disputed whether nourishment was taken in by the lateral pores of the several joints, or by the mouth alone. Rudolphi says the latter, and it seems now pretty clearly determined that the former are mere outlets of the generative organs. The length to which the *T. solium* is capable of attaining is very considerable, but quite indefinite. Those passed now-a-days seldom exceed twenty feet, but in former times we read of much more gigantic specimens; but whatever may be thought of some of the accounts which are quite improbable, it indubitably has occasionally attained a very great length, having been found extending from the pylorus to within a few inches of the anus, and then by no means fully stretched out. Such cases are however very rare.

The determination of the species in this genus is very difficult: they may be divided for greater convenience into three sections: The first are without a proboscis, the *Tænia inermis*; the second have one, but unarmed, *T. rostellata*; the third are furnished with an uncinated proboscis, *T. armata*.

3. *Caryophyllæus* has the body flat, continuous; the head dilated, and divided into flattish processes; it is furnished with an upper and under lip; the species of this genus occur in the intestines of fishes (carp, &c.).

4. *Scolex*. The body is flat and continuous; the head has four fossæ on it; it occurs also in the intestines and abdomen of fishes, sepia, &c.

5. *Gymnorrhynchus*. This genus has the body very long, with a globular receptacle at the neck; head with two opposite fossæ, and four naked retractile probosces; the species occur in the muscular substance of many fish.

6. *Tetrarhynchus*. Body flat, continuous, head with four fossæ and four retractile probosces, furnished with recurved spicular processes; it occurs in reptiles, fishes, molluscs, in the muscles, branchiæ, stomach and its membranes, the liver, and peritoneum.

7. *Ligula*. In its first stage of development the body is elongated with a longitudinal fissure, without any appearance of head, or organs of generation. In its perfect state there is a simple fossa on each side of the head, and the ovaries and processes form a single or double row along the median line. The species occur very frequently in birds and fishes, but very rarely in mammalia.

8. *Triclinophorus* has the body elongated, flat, sub-articulated, mouth bilabiate, and furnished on each side with two tricuspid acicular processes; it is found in fishes.

The *Trematode* order is divided into six genera, which also include only two species infesting the human body.

1. The first genus is *Monostoma*, which has only a single anterior pore: it occurs in mammalia, birds, reptiles, and fishes.

2. *Amphistoma* is furnished with two pores, one anterior and one posterior. Found in the stomach, intestines, and abdomen, and in the hydatids of the viscera of mammals, birds, and reptiles.

3. *Distoma*. In this genus there are two pores: an anterior and a ventral. An immense number of species are known, occurring in mammalia, birds, fishes, &c. The *D. hepaticum*, or fluke-worm, frequents the gall-bladder and ducts very frequently in some animals, as the ruminating, and is particularly common in the sheep in the disease called the rot. It has been discovered in the gall-bladder of the human subject, though very rarely. It bears a considerable

resemblance in its shape to a melon-seed, being flat, and appearing lanceolate at each end, as seen with the naked eye, though, when magnified, the extremities are found to be obtuse, the tail being the broader of the two. The anterior pore, or true mouth, is round and small; the posterior cavity is imperforate, and only subservient to adhesion and locomotion; it is situated in the ventral aspect of the body, in the anterior half. Between these there is a third orifice, destined to the generative system, and from which a small cylindrical process is generally protruded. The fluke is hermaphrodite and oviparous: it lives upon the bile, which is absorbed by the mouth, and is at once so digested or modified by the vessels which go off from thence, as to become immediately fitting nourishment for the animal.

4. *Tristoma* has three pores, the anterior simple, and the posterior radiated: it is found in the gills of one or two species of fish.

5. *Pentastoma*. The mouth is here situated between two pores on each side, through which a spicular process comes out. It occurs in the frontal sinuses, lungs, and surface of the liver of the mammalia (dog, horse, wolf), and in reptiles.

6. *Polystoma*. This genus has six anterior pores, besides a ventral and posterior one. It mostly occurs in the throat and branchiæ of fishes, and the bladder of frogs; but one species, the *P. pingüicola*, was discovered by Treutler in the cavity of an indurated adipose tubercle, in the left ovary of a female aged 20, who had died in child-bed. The tumour, which was apparently formed entirely of indurated fat, was of a reddish colour and hollow within; the cavity was nearly filled by the above-named worm, which was about half-an-inch in length, and between one and two lines in width.

The 4th order, *Acanthocephala*, contains but one genus, *Echinorhynchus*, to which belong numerous species occurring in all classes of vertebrate animals except man; they are generally found in the intestinal canal, fixed between its membranes, and occasionally even in the peritoneal cavity; they have also been found in the neck under the skin.

We now come to the last and most highly organized group of the entozoa, the *Nematodea*, which contains a greater number of genera, and includes more species inhabiting the human body than any of the preceding. It has been divided into 11 genera, viz.

1. *Filaria*; these are of nearly equal thickness throughout their whole length; they occur in all parts of the vertebrata, though principally in the cellular membrane; they are also even found in insects and their larvæ.

2. *Trichostrongylus*. On its anterior extremity, which is very thin, is the mouth, resembling a minute point: it is found in mammalia, birds, and amphibia, between the coats of the stomach, in the intestines, and the urinary bladder.

3. *Trichocephalus*. This genus differs from *Filaria* in the capillary form of the anterior part of the body, and in its swelling out behind; it occurs principally in the cæcum of the mammalia.

4. *Oxyuris* is characterized by being subulate posteriorly, having the mouth orbicular, and the penis in a sheath. The *Ascaris vermicularis* is included in this genus by Bræmser.

5. *Cucullanus* is attenuated posteriorly. It occurs in the intestines and abdomen of reptiles and fishes.

6. *Spiroptera* is attenuated at each end. It occurs under the nictitating membrane of birds, in various parts of fish, and is said to have been found in the urinary bladder of man.

7. *Physaloptera* is attenuated at both extremities; the tail of the male is bent downwards, winged, and furnished below with a sort of bladder. The species are found in the stomach of mammalia, birds, and reptiles.

8. *Strongylus*. This has both ends attenuated: the tail of the male terminates in what Rudolphi calls a bursa, and through this the penis passes out; it occurs frequently in various situations in the three first classes of vertebrate animals.

9. *Ascaris*. This genus, which is the most numerous of the intestinal worms, 80 species having been already described, has the extremities attenuated, the mouth furnished with three valves or tubercles, and the penis double. The species occur in almost every part of the bodies of vertebrate animals.

10. *Ophistoma* is attenuated at the extremities, and has the mouth furnished with two lips. It is found in the intestines of mammalia and fishes.

11. *Liroyynchus* has the mouth at the end of a sort of erectile and polished tube. It occurs in the stomach and intestines of some of the mammalia and of many fishes.

In the above list of the genera of the caviary, intestinal, or round worms, we have not made any particular mention of the species parasitic in man, and as several of them possess considerable interest, we need no apology for giving a short description of them. We may begin with the genus *Filaria*, three species of which are enumerated as human inhabitants, though two of them have been only once detected. The *Guinea Worm* (*Filaria Medinensis*) frequently occurs in hot climates, but the countries where it most abounds are Arabia, Upper Egypt, Abyssinia, and Guinea. Its general habitation is the subcutaneous cellular tissue, particularly of the lower extremities; but it is also found in the scrotum, and very rarely beneath the tunica conjunctiva of the eye. The length of this worm varies from six inches to twelve feet: it is about as thick as the string of a violin. Its colour is generally white, but occasionally brown; it is round, and of nearly equal dimensions in its whole length, but becomes a little attenuated towards the anterior extremity. The tail of the male is obtuse, and armed with a spiculum; in the female it is acute and bent. The mode of development of this entozoon is unknown. It seems that it may exist for many months without being detected, cases occurring where it has not been discovered till more than a twelvemonth after leaving the country where it was contracted. After a time it produces irritation; in some point of the skin a vesicle, pustule, or small abscess forms, breaks, and then the end of the worm makes its appearance, which may be taken hold of, and cautiously and gradually extracted. If the filaria is broken, the portion remaining beneath the skin dies, and produces inflammation, sinuous abscesses, and often great constitutional disturbance, requiring amputation of the limb. It seems to be capable of slowly shifting its situation in the cellular membrane. According to Rudolphi, its coming out through the skin is not to be attributed to perforation of that membrane, which it is not at all capable of effecting, but only to the irritation which it excites in approaching the integuments. It seems sometimes to affect people within the tropics in an endemic or even epidemic form, nearly half the men in a regiment having been attacked at the same time by it. This species has been mentioned as having been found occasionally beneath the conjunctiva of the eye; but another, and much smaller kind, has been detected within the eyeball itself, viz. the *Filaria oculi humani*, which Nordman met with in the liquor Morgagnii of the capsule of the crystalline lens of a man who had had the operation of extraction for cataract performed. Two minute worms were discovered coiled up together. This species differs from the large *Filaria* found in the eye of the horse. The third species is the *F. bronchialis*, which was once detected in the enlarged bronchial glands of a man by Treutler; its length was about an inch. The *Trichocephalus dispar*, or long thread-worm, is about an inch and a half or two inches in length, the male being smaller than the female. The capillary portion makes about two-thirds of the whole length of this species. This worm is very common in the cæcum and large intestines, but does not seem to occasion any inconvenience, though inflammation of the intestinal follicles and fever has been erroneously ascribed to it. The existence and history of the following entozoon are involved in a good deal of mystery. *Spiroptera hominis* is the name given to some small intestinal worms which were sent to Rudolphi, together with some other vermiform bodies of an elongated form and solid homogeneous texture, which were passed from the bladder of a poor woman still living in St. Sepulchre's work-house, London. There were also discharged, together with these substances, numerous small granular bodies, considered by Rudolphi as mere morbid concretions, but which subsequent examinations have caused to be regarded as ova. The small nematoid worms, which were six in number, and of different sexes, are supposed to have been expelled from the woman at the same time; they were from eight to ten lines in length, slender, white, and elastic; the other elongated bodies varied in length from four to eight inches. Some of the latter substances and ova are preserved in the Museum of the College of Surgeons; but none of the former entozoa, denominated *Spiroptera hominis*, are to be found among them.

The *Strongylus gigas* also inhabits the urinary apparatus.

Before Rudolphi's time it was generally confounded with the *Ascaris lumbricoides*, to which it bears some resemblance. It occurs, though rarely, in the substance of the kidneys, where it sometimes attains an enormous size, having been met with three feet long, and half an inch in diameter. The more ordinary dimensions however are about fifteen inches in length and two lines in thickness. The common colour is blood-red, arising from the nature of their food, as they obtain their nourishment from the contents of the renal vessels: they occasionally find their way into the bladder, and are discharged with the urine. This entozoon occurs much more frequently in some animals, as the dog, horse, &c., than in man. Their presence in the kidneys does not seem to give rise to any peculiar symptoms differing from those of other renal diseases.

The *Ascaris lumbricoides*, the common round worm so frequently met with in children, is so well known as to require a very brief notice here. It occurs in the hog and the ox, as well as in man, and chiefly inhabits the small intestines. The male is smaller than the female, and much more rare; it may be distinguished by the end of the tail being curved, and terminating in an obtuse point, at the apex of which a small black speck may be frequently observed. In the female this extremity is straighter and thicker. The anus is situated close to the tail in both sexes. In the female there is generally a constriction in the centre of the body where the organs of generation are placed. This worm, when minutely examined, will be found to consist of integuments, muscles, digestive organs, genital apparatus, and a nervous system consisting of an œsophageal ring and a dorsal and ventral cord. It has been supposed to feed on the chyle or mucus in the intestines, and to adhere to the coats of the bowels, but on these points there is considerable doubt. They are often found in great numbers.

The last human species in this group is the *Ascaris vermicularis*, the maw-worm, thread-worm, or ascarides. It is very minute, the male seldom exceeding two lines, and the females five lines in length, and being proportionally slender. Their colour is white; they are so small that there is great difficulty in detecting their structure, but Rudolphi says that he has repeatedly observed the three tubercles round the mouth characteristic of the genus. Their abode is the large intestines, particularly the rectum, where they sometimes occur in immense numbers, and occasion great irritation.

We have now enumerated all the genera of *Entozoa* described by Rudolphi and other Entozoologists, but before we conclude our subject we will say a few words on the *Trichina spiralis* which we have before mentioned. It is a microscopic parasite, infesting the muscles of the human subject, belonging to the voluntary class, and found in greater numbers in those that are superficial than in the deep seated. Their nidus seems to be in the interfascicular cellular tissue. A portion of muscle affected by these animals appears beset with whitish specks, which, if examined with a microscope, are found to be little cysts containing a minute worm coiled up. The cysts are of an elliptical shape, and attenuated towards the extremities; their length is about $\frac{1}{16}$ th of an inch, and breadth $\frac{1}{16}$ th. By cutting off one extremity of the cyst, the *trichina* may be extracted entire, when it is generally found rolled up in two or two and a half spiral coils. Being straightened out, it will be found to measure $\frac{1}{16}$ th of an inch in length and $\frac{1}{16}$ th of an inch in diameter. From the minuteness of the object, it is necessary to employ a magnifying power of considerable intensity to examine it satisfactorily, and from the difficulty of managing the investigation, and the deceptive appearances produced under the microscope, it is not easy to detect its organization. Mr. Owen never succeeded in discovering an intestinal tube, or cavity, and therefore, as we have stated, placed this entozoon in his first group along with the seminal animalcules. (See *Zool. Trans.*, vol. i.; and *Zool. Proceedings*, Feb. 1835.) Dr. Arthur Farre observed by very patient and minute observation with the microscope, under favourable circumstances, that it possesses an intestinal canal with distinct parietes, (*Med. Gazette*, Dec. 1835), and upon this ground it ought to occupy a higher station among the nematoid or intestinal worms; but further researches are necessary, before it can be stated with confidence in which group this entozoon should be placed. It seems that this parasitical affection of the human body is unconnected with age, sex, or any particular form of disease, and it appears that it may exist without giving rise to any debility of the vital powers, or even with-

out interfering with the enjoyment of robust health, as has been shown in a case lately met with.

All the known parasites residing within the human body have now been mentioned, and we have given a general outline of the groups and genera of the class Entozoa. It would far exceed our limits to attempt to enumerate all the species which have been discovered, and described by authors; which would even then probably include but a small number of those which exist. In fact, if we assent to the theory of their being the product of some irregular process of nutrition or secretion within animal bodies, or, as it is called, spontaneous or equivocal generation (which is perhaps more probable than that they are introduced from without), new and dissimilar species may be formed every day, by some unknown modification of the nutritive process which gives birth to them. The laws which, according to this hypothesis, regulate the difference of structure in these beings, from the simple accephalocyst to the complicated ascaris, are as much involved in obscurity as those which cause the varieties of organization in morbid productions connected with and participating in the life of the rest of the body; for instance, the various classes of tumours.

ENTRE DOURO E MINHO, a province of Portugal, bounded on the north by the river Minho, which separates it from Galicia in Spain, and on the south by the Douro, which divides it from the province of Beira. From its position between these two rivers the province has derived its name, although it is sometimes also called the province of the Minho, for brevity's sake. To the east it is bounded by the province of *Tras Os Montes*, and to the west by the Atlantic Ocean. Its length is about 60 miles from north to south, and its breadth is about 40 miles. Its area is, according to Miñano, 240 square leagues, of 20 to 1 degree of latitude, or about 2880 English square miles. Its population, by the same authority, as well as that of Antillon, is about 900,000, which is nearly one-fourth of the whole population of Portugal, it being by far the most thickly inhabited province of that kingdom. It is divided into five comarcas, or districts, namely, Braga, Viana, Penafiel, Guimarães, and Oporto. The principal towns are, Braga, the capital of the northern division of the province [BRAGA]; Porto or Oporto, the capital of the southern division, by far the most important town in it [OPORTO]; Guimarães, on the river Ave, an ancient town, once the cradle and the capital of the monarchy, at present an industrious busy place, with manufactures of linen, leather, and cutlery, and 6000 inhabitants; Viana, with 8000 inhabitants, and a harbour at the mouth of the Lima, carrying on a considerable trade; Villa do Conde, with a small harbour, and 3000 inhabitants; Barcelos, with 3900; Valença, on the Minho, a frontier town and fortress, with about 1600 inhabitants; Penafiel, with 2300; Caminha, at the mouth of the Minho, with a harbour, and about 1000 inhabitants; S. João da Foz, at the mouth of the Douro, below Oporto, with 3300 inhabitants; Amarante, on the Tamega, with about 1000 inhabitants. The surface of the province is hilly, but there are some plains near the sea-coast. One ridge of mountains, the Serra de Marão, runs from north to south through the east part of the province, near the borders of *Tras Os Montes*; the rivers Cavado, Ave, and Neiva have their sources in these mountains. The river Lima, which, next to the Douro and the Minho, is the largest in the country, has its source in the mountains of Galicia; it enters the province of Entre Douro e Minho at its north-east extremity near Lindoso, runs through the north part of the province, passes by Ponte de Lima, and enters the sea near Viana. The river Tamega, which has its source in *Tras Os Montes*, flows through the province of Entre Douro e Minho in a southern direction, passes by Amarante and Canavezes, and then enters the Douro.

This province is the most fertile in Portugal, the climate is healthy, and the soil is irrigated by numerous streams. The principal productions are wine, oil, flax, Indian corn, some wheat and oats, and vegetables and fruits of all sorts. Pastures are rather scarce, yet a considerable quantity of cattle, both large and small, are reared. The principal article of exportation is wine, which is made chiefly from the vineyards which are planted all along the valley of the Douro, and which is shipped at Oporto under the name of port-wine. There are fisheries along the coast, which occupy a great number of hands. The natives of Entre Douro e Minho are considered, together with their neighbours of *Tras Os Montes*, as the finest race of men in

Portugal: they are industrious, civil to strangers, and orderly. The province is divided into two administrative divisions, Braga and Oporto, called also Alto Minho and Baixo Minho, each having its military and civil governors and its courts of justice. The division of Alto Minho includes Braga and Viana, and all the northern part of the country from Braga to the Minho; that of Baixo Minho, which is by far the larger, includes Oporto, Guimarães, Penafiel, Amarante, and all the country southwards as far as the Douro.

ENTRESOL, a French term used to signify a floor between other floors. The entresol consists of a low apartment or apartments, usually placed above the first floor. In street architecture it is desirable to form the basement story on a scale of grandeur, and in so doing a greater space than necessary would be given to the first floor, if it were not for the entresol.

There is a very good example of an entresol under the colonnade of the Quadrant in London. In continental cities the entresol is frequently employed, especially in Paris.

The term *Mezzaninro* (or little middle floor) is used in Italy to indicate the same arrangement of floor, as well as the attic story of a house. The windows of the entresol, or mezzaninro, are usually, from the lowness of the floor, either square, or a little more or less than a square.

ENTRY, from the French *entrés*, and Latin *intrare*, to enter, in law, is a taking possession by the legal owner of lands and tenements when another person is wrongfully in possession of them. At the common law this might be effected by force; but as it was the cause of great abuses, forcible entries were made punishable by fine and imprisonment by two statutes of Richard II., enlarged by a statute of 8 Henry VI. c. 9. (See 1 Ad. and E. 627, and 3 Ad. and E. 817.)

A party availing himself of this summary process against an aggressor must enter upon some part of the property claimed, and the safer course is formally to declare that thereby he takes possession of the whole. The entry must be repeated in each county in which the lands lie. This remedy, however, can only be adopted in certain cases, namely, where the original entry of the holder of the land was by unlawful means.

In other cases, where the original entry is lawful, and possession held by an apparent right, the owner of the estate must proceed by an action, as an apparent right cannot be legally overthrown by the mere act of a claimant.

The Statute of Limitations, 21 James I., c. 16, and the statute 4 and 5 Anne, c. 16, and the more recent enactment 3 and 4 William IV., c. 7, regulate the law on this subject, and also the periods within which entries may be made.

Entry, forcible, is an entry made with a strong hand, with unusual weapons, an unusual number of servants, or with menace of life; if effected with violence, and the entry only amounts in law to a trespass, it is not within the meaning of the statutes of Richard II. above referred to. The remedy for parties aggrieved, and the mode of obtaining restitution, is either by an action at law, by indictment, or by justices of the peace upon the view. If made by more than three persons, they may be proceeded against as in a case of a riot. (Bacon's *Abridgment*; Burn's *Justice*.)

Entry, writ of, was another method of gaining possession of disputed property by trying the title of the occupant. The earliest mention of this writ occurs in the third year of the reign of Edward III. This writ was directed to the sheriff, requiring him to command the tenant that he render to the demandant the premises in question which he claims to be his right and inheritance, &c. The tenant thereupon was either compelled to deliver up the possession of the land, or to show cause why he refused to do so. This might be done by justifying his own title or that of others under whom he claimed. The claims of the respective parties were then tried before a jury, and the possession of the land was awarded to him who produced the clearest evidence of his right.

There were several writs of entry both at the common law and by statute; but they appear to have long fallen into disuse, and but few instances have occurred in modern times of their being resorted to in practice. The learning respecting them, which is somewhat curious, may be found in *Reeve's History of the English Law*.

Under the provisions of the 3rd and 4th William IV..

c. 27, all writs of entry as well as writs of right were abolished, from the 31st December, 1834.

ENVOY, a diplomatic minister or agent, inferior in dignity to an ambassador, but generally invested with equal powers. [AMBASSADOR, DIPLOMACY.]

ENYED, NAGY-ENYED, ENIED, or STRASZBURG, a town in the county of Carlsburg or Unteralben, in Transylvania. It is situated in 46° 18' N. lat., and 23° 42' E. long., in a valley on the right bank of the Marosh: it is built in the old-fashioned style, is the seat of the district government, and is governed by its own magistracy, the head of whom is styled 'Doctor Nobilium.' Enyed contains a Roman Catholic, a Lutheran, and a Reformed Lutheran church; but is most celebrated for its richly endowed college (founded in 1622) for Protestant students, the number of whom is above 1000, and they are accommodated in 84 halls and chambers. The college has a library, and collections of coins and in natural history and experimental philosophy. On the market-place are the remains of the antient burg or castle, with its towers and loopholes, in which the Saxons, who built the town, were accustomed to defend themselves against their Transylvanian assailants in former days. It now contains the parish minister's residence and two places of worship. The streets still retain their Saxon names, although the town is now inhabited principally by Magyars or Hungarians. The population is about 6100, among whom are some Saxons, Armenians, Greeks, and Walachians. There are a paper-mill and some manufactures in the town, and extensive vineyards in the neighbourhood. The Magyar language is said to be spoken here with remarkable purity.

EOLIDIA, Cuvier's name for a genus of *Nudibranchiata* (the second order of his *Gastropoda*) [NUDIBRANCHIATA]. In De Blainville's arrangement *Eolidia* is placed next to *Cavolina*, under his family *Polybranchiata*, with the name of *Eolidia*, and it forms, under the appellation of *Eolis*, the second genus of Lamarck's *Tritonians*, the first section of his *Gastropoda*, with external branchiæ placed above the mantle, either on the back or on the sides, and not being in a particular cavity. Cuvier describes his *Eolidiæ* as having the form of small snails or slugs (Limaes) with four tentacula above, and two at the sides of the mouth. Their branchiæ, he observes, are laminae, or foliations disposed like scales, more or less close set on each side of the back. Rang, who includes under *Eolidia* two subgenera, viz., the *Eolidiæ*, properly so called, and Bruguière's *Cavolinae*, gives the following generic character.

Animal pelagian, limaciform, gelatinous; head distinct, furnished with two or three pairs of tentacula; foot entire, and occupying nearly the whole length of the animal; branchiæ formed of flattened or conical cirrhi, disposed in rows on the superior part of the body; organs of generation united in the same tubercle on the right side anteriorly; vent a little more backwards.

Geographical Distribution.—Cuvier, speaking of his *Eolidiæ*, says, that there are some of them in all seas. Rang observes, that the genus is composed of a great quantity of small pelagic and littoral animals. The masses of *fucus natans*, which are so often met with between the tropics, always present, he states, a great number of them, and it is easy to recognize them from their elongated and creeping form, as well as from the tentaculiform branchiæ with which they are beset. They do not swim, according to the last-named author, but they suspend themselves at the surface of the water, with the foot uppermost, and move well by means of sudden undulations.

Eolidiæ properly so called.

Branchiæ disposed in transverse rings distant from each other.

Eolidia.

Example.—*Eolidia Cuvieri*.

Locality.—European seas.

Eolidia Cuvieri, magnified.

Cavolina.

De Blainville, who says that *Cavolina* is to be found in all P. C., No. 589.

seas, remarks, that this closely approaches the preceding, and might without inconvenience be united with it, thus confirming the arrangement of M. Rang.

Example.—*Cavolina peregrina*. (*Doris peregrina*, Gme. *Cavolin*. polyp. mar. 3, p. 190, t. vii., f. 3.)

Locality.—The Mediterranean.

Cavolina peregrina.

De Blainville states that he has examined a very small species brought home by MM. Quoy and Gaimard (Voyage of the Uranie).

EOLIPILE. [ÆOLIPILE.]

EOPSA'LTRIA (Zoology). [PACHYCEPHALINÆ.]

EPACRIDA'CEÆ, a natural order of monopetalous exogens, very closely allied to *Ericaceæ*, with the small-leaved genera of which they entirely agree in habit, and from which they are scarcely distinguishable by any character beyond their anthers being in all cases one-celled. Dr. Brown, in founding the order in the year 1810, explained his motives for doing so as follows:—'The family of *Ericaceæ* is now so vast that it seems to constitute a class rather than an order, of which one part, although not a very natural one, has been already separated by Jussieu under the separate name of *Rhododendra*, on account of some diversity in the structure of the fruit. I therefore may be allowed to propose another order (*Epacridæ*) which is truly natural, although it depends upon the single character of the unusual simplicity of the anthers; a character, however, which is of the greater value as opposed to the two-celled anthers of *Ericaceæ*, which are generally divided and furnished with appendages; the propriety of the measure is moreover confirmed not only by the number of *Epacridæ*, large as it is, but also by their geographical disposition; for all, as far as we at present know them, are inhabitants of Australasia or Polynesia, countries in which not more than one or two species of *Ericaceæ* are found.' (*Prodr.* p. 536.)

Sprengelia incarnata.

1. A flower with a calyx as long as the 5-parted corolla, and several bracts imbricating the base. 2. An anther. 3. The stamens and ovary.

The species consists of shrubs with alternate or occasionally opposite leaves, which are either articulated with the stem, like those of *Ericaceæ* or broad at the base and half-surrounding the stem in a kind of hood or sheath. Their flowers are usually monopetalous, but as in the order *Ericaceæ*, it is not unfrequent to find them with their corolla divided or divisible into several pieces, and therefore truly polypetalous. The size and colour of the corolla are often striking, and the species then become exceedingly showy, and are favourites with gardeners. None of them are of any particular use, unless those are considered an exception whose succulent fruit is eatable, like *Lissanthe sapida* and others, which constitute the Australian cranberries.

Dr. Brown mentions 24 genera and 144 species of this order in his work upon the New Holland Flora, but a considerable number has to be added.

EPACT, the number of days in the moon's age at the beginning of the year.

EPAMINONDAS, a Theban statesman and soldier, in whose praise, both for talents and virtue, there is a remarkable concurrence of antient writers. Nepos observes that, before Epaminondas was born, and after his death, Thebes was always in subjection to some other power: on the contrary, while he directed her councils, she was the head of Greece. His public life extends from the restoration of democracy, by Pelopidas and the other exiles, B.C. 379, to the battle of Mantinea, B.C. 362. In the conspiracy by which that revolution was effected he took no part, refusing to stain his hands with the blood of his countrymen; but thenceforward he became the prime mover of the Theban state. His policy was first directed to assert the right and to secure the power to Thebes of controlling the other cities of Bœotia, several of which claimed to be independent. In this cause he ventured to engage his country, single-handed, in war with the Spartans, who marched into Bœotia, B.C. 371, with a force superior to any which could be brought against them. The Theban generals were divided in opinion whether a battle should be risked: for to encounter the Lacedæmonians with inferior numbers was universally esteemed hopeless. Epaminondas prevailed with his colleagues to venture it; and devised on this occasion a new method of attack. Instead of joining battle along the whole line, he concentrated an overwhelming force on one point, directing the weaker part of his line to keep back. The Spartan right wing being broken, and the king slain, the rest of the army found it necessary to abandon the field. This memorable battle was fought at Leuctra. The moral effect of it was much more important than the mere loss inflicted on Sparta, for it overthrew the prescriptive superiority in arms claimed by that state ever since its reformation by Lycurgus.

This brilliant success led Epaminondas to the second object of his policy—the overthrow of the supremacy of Sparta, and the substitution of Thebes as the leader of Greece in the democratical interest. In this hope a Theban army, under his command, marched into Peloponnesus early in the winter, B.C. 369, and, in conjunction with the Eleians, Arcadians, and Argians, invaded and laid waste a large part of Laconia. Numbers of the Helots took that opportunity to shake off a most oppressive slavery; and Epaminondas struck a deadly blow at the power of Sparta, by establishing these descendants of the old Messenians [ARISTOMENES] on Mount Ithome, in Messenia, as an independent state, and inviting their countrymen, scattered through Sicily and Italy, to return to their antient patrimony. Numbers, after the lapse of 200 years, obeyed the call. This memorable event is known in history as the return of the Messenians.

In 368 B.C. Epaminondas again led an army into Peloponnesus; but not fulfilling the expectations of the people, he was disgraced, and, according to Diodorus (xv. 71), was ordered to serve in the ranks. In that capacity he is said to have saved the army in Thessaly, when entangled in dangers which threatened it with destruction; being required by the general voice to assume the command. He is not again heard of in a public capacity till B.C. 366, when he was sent to support the democratic interest in Achaia, and by his moderation and judgment brought that whole confederation over to the Theban alliance without bloodshed or banishment.

As the narrowness of our limits forbids us to trace the motives which led to the formation of so powerful a Theban party in Peloponnesus, so we cannot enter into the causes of its decline, except by saying, that it soon became plain that a mere change of masters, Thebes instead of Sparta, would be of no service to the other states. Achaia first, then Elis, then Mantinea and great part of Arcadia, returned to the Lacedæmonian alliance. To check this defection Epaminondas led an army into Peloponnesus for the fourth time, B.C. 362. Joined by the Argians, Messenians, and part of the Arcadians, he entered Laconia, and endeavoured to take Sparta by surprise; but the vigilance of Agesilaus just frustrated this scheme. Epaminondas then marched against Mantinea, near which was fought the celebrated battle in which he fell. The disposition of his troops on this occasion was an improvement on that by which he had gained the battle of Leuctra, and would have

had the same decisive success, but that in the critical moment, when the Lacedæmonian line was just broken, he received a mortal wound. The Theban army was paralyzed by this misfortune; nothing was done to improve a victory which might have been made certain, and this battle, on which the expectation of all Greece waited, led to no important result. 'Each party,' says Xenophon, 'claimed the victory and neither gained any advantage: indecision, trouble, and confusion, more than ever before that battle pervaded Greece.'

Whether Epaminondas could much longer have upheld Thebes in the rank to which he had raised her, is very doubtful: without him she fell at once to her former obscurity. His character is certainly one of the fairest recorded in Greek history. His private life was moral and refined; his public conduct uninfluenced by personal ambition, or by personal hatred. He was a sincere lover of his country, and if, in his schemes for her advancement, he was indifferent to the injury done to other members of the Grecian family, this is a fault from which, perhaps, no Greek statesman, except Aristides, was free. (Xenophon, *Hellen.*; Plutarch, *Pelopidas*, *Agis*, &c.)

EPAULEMENT originally signified a mass of earth, about 7 feet 6 inches high and 18 or 20 feet thick, which was raised for the purpose either of protecting a body of troops at one extremity of their line, or of forming a wing or shoulder of a battery to prevent the guns from being dismounted by an enflading fire. The term is now, improperly however, used to designate the whole mass of earth or other material which protects the guns in a battery both in front and on either flank; and it can only be distinguished from a parapet by being without a banquette, or step, at the foot of the interior side, on which the men stand to fire over a parapet. That part of the epaulement which is between every two embrasures is called a merlon; and the part under the embrasure is called the genouillère.

EPE'E, CHARLES MICHEL DE L'. A comparative estimate of L'Epée's character and labours has been given under DEAF AND DUMB: the following are a few biographical particulars respecting him.

He was born at Versailles, in November, 1712. His father was the king's architect, a man of talent and probity. Young L'Epée was educated for the church, a profession for which his mild, cheerful, and pious disposition peculiarly fitted him. There were difficulties at first in the way of his admission to the priesthood. He was required, according to the established practice of the diocese of Paris, to sign a formulary of faith; and this being opposed to his own opinions (which were Jansenist), he could not do so conscientiously. He was however admitted to the rank of deacon, but was told never to pretend to holy orders. This obstruction led him to the study of the law, but this profession did not suit the bias of his mind. At last he succeeded in obtaining holy orders, being ordained by the bishop of Troyes, a nephew of Bossuet. From him M. de L'Epée received a canonry in the cathedral of Troyes.

An accidental circumstance led him to devote himself to the instruction of the deaf and dumb. Business took him one day to a house where he found only two young women, who were busily engaged in needlework, but paid no attention to his questions. The mother of the young women arriving shortly afterwards, explained to him with tears that they were deaf and dumb. An ecclesiastic named Vanin had commenced the education of these young persons by means of pictures; but death had removed him, and no other person had offered to instruct the mutes. 'Believing,' says M. de L'Epée, 'that these two children would live and die in ignorance of their religion, if I did not attempt some means of instructing them, I was touched with compassion, and told the mother that she might send them daily to my house, and that I would do whatever I might find possible for them.'

John Paul Bonet's book came in the way of M. de L'Epée; a person offered a copy of it to him, urging him to buy it, which he at first refused, not knowing the nature of the work, and alleging that he did not understand Spanish, and that the book was therefore of no use to him. Opening it casually, he found the copper-plate engraving of Bonet's one-handed alphabet. The book was immediately bought, and De L'Epée learned Spanish to enable him to read it.

M. de L'Epée was persevering and disinterested in his instruction of the deaf and dumb. He persevered until he converted opposition and contempt into approbation. His

'income was about 400*l.*, of which he allowed about 100*l.* for his own expenses, and appropriated the remainder to the support and instruction of indigent mutes. 'The rich,' he said, 'only come to my house by tolerance; it is not to them that I devote myself—it is to the poor; but for them, I should never have undertaken the education of the deaf and dumb.'

M. de l'Épée died December 23, 1789, aged 77. His memory received various honours; his funeral oration was pronounced by the Abbé Fauchet, the king's preacher. He ranks deservedly among those whose lives have been devoted to the amelioration of the condition of their fellow men, and the fruit of whose labours do not die with them. (*Gallery of Portraits.*)

EPERIES, or Pressova, a royal free town, and the capital of the county of Sáros, in Upper Hungary: in 48° 58' N. lat., and 21° 15' E. long. It is situated in an agreeable country on the banks of the Tartaşa, is surrounded with walls defended by bastions, which are encircled by extensive gardens and inclosures, among which are the suburbs. It contains about 960 houses and 7660 inhabitants. The streets are broad, and embellished with several handsome buildings, among which are the county hall, four Roman Catholic churches, a Lutheran church, a synagogue, the quadrangular buildings of the Protestant college, a Roman Catholic high-school, attached to the monastery of Franciscans, who conduct it, a head Normal school, a chapter-house, town-hall, orphan asylum, and refuge for the indigent. It is the seat of a Greek Catholic bishopric erected in 1807, has a good episcopal library, and is frequented by the pious for the sake of an imitation of Mount Calvary, on which several chapels are built. Eperies manufactures woollens and linens, and possesses a large earthenware manufactory and breweries, as well as a considerable trade in cattle, wine, and grain, to which the annual fairs greatly contribute. About four miles from the town, the environs of which are agreeably diversified, there is an esteemed chalybeate, called Cremete or Krasyna-voda, with baths.

EPERNAY, a town in France, in the department of Marne, on the south bank of the river Marne, 73 miles in a straight line east by north of Paris.

The antient name of the town is said to have been Aquæ Perennes, from which came first Aixperne and afterwards Epernay. At an early period Epernay belonged to the archbishops of Reims, by whom a fortress was built here. In the wars of the English in France Epernay was twice besieged. In the earlier part of the sixteenth century it was burnt by Francois I. in order to destroy the stores which the Emperor Charles V. had established here. In the religious contests of the same century it was also an object of contest: it was besieged and taken by the Spaniards and Leaguers; and retaken in 1592 by Henri IV. In 1657 Epernay was ceded to the duke of Bouillon in exchange for the sovereignty of Sedan; but the duke never exercised all his rights.

Epernay is in a small valley in the midst of a romantic country, well wooded, and producing the finest Champagne wines. It is a handsome town. It has a church of modern construction, built in the place of one of greater antiquity, of which only the gate remains. There are some remains of the antient fortifications of the town, consisting of a gate and two towers. The population in 1832 was 5318. The inhabitants carry on a considerable trade in wine, which is deposited in deep and extensive cellars hollowed out in the chalk on which the town is built. They manufacture a great quantity of earthenware. Of the utensils manufactured half are sent to Paris in boats which descend the Marne, and a quarter into Lorraine; the rest is sent into Picardie or is retained for home use. The clay of which it is made is dug about fifteen miles from Epernay: large quantities of it are sent in an unwrought state to Paris and into the departments of Meurthe and Aisne. Millstones are quarried in the neighbourhood of the town; and sand is dug, which is much sought after for making glass, and is sent by land-carriage into Lorraine and even into Alsace. Many women are employed in making hats, purses, bags, &c., of silk twist. Hosiery and woollen yarn are manufactured.

There are at Epernay a theatre, a high-school, and a library of 10,000 volumes. It is the capital of an arrondissement, which contained in 1832 a population of 83,278.

EPHEMERIS (*ἡμερησία*, from *ἡμέρα*, and *ἡμέρα*), a name given to almanacs, from their containing matter for each day. In astronomy it is usual to call any table which

assigns the place of a planet for a number of successive days an ephemeris of the planet. [ALMANAC.]

EPHESIANS, ST. PAUL'S EPISTLE TO THE, is the fifth, in numerical order, of the fourteen apostolical letters of St. Paul, contained in the canon of the New Testament. Throughout the primitive ages of Christianity it was generally regarded by the principal fathers as being of genuine and sacred authority. According to Dr. Lardner (*Credibility of Gosp. Hist.*, vol. ii.) the writings of Ignatius, who was St. Paul's contemporary, contain seven citations from this epistle. It is also cited by Irenæus, Clemens Alexandrinus, Tertullian, Origen, and many subsequent Christian writers. There were, however, several important and numerous sects, as the Nazarenes, or Ebionites (paupers and the Severians, Encratites and other followers of Tatian, who, in the first and second centuries, denied both the genuineness and the authenticity of this and the other writings of St. Paul; rejecting them as a tissue of errors, and denouncing St. Paul himself as an apostate, and a perverter of the original system of Jesus of Nazareth. (Origen *contra Celsum*, l. v.; Euseb. *Eccles. Hist.*, l. iii., c. 21 and 27; Epiphanius, *Hæres.* 30; Hieron. in *Math.*, c. 12; Nicephorus, *Hist. Eccles.*, l. iv., c. 4, l. v., c. 12; Toland's *Nazarenus*, p. 25—29.) A second epistle of St. Paul to the Ephesians is mentioned by Jerome (*De Scripturis Eccles.*) and by Epiphanius (*Hom.* 42). The place and date generally assigned to this epistle by biblical critics are Rome, A.D. 61, that is, in the first year of the apostle's imprisonment at Rome (ch. iii. 1, ch. iv. 1, ch. vi. 20, and the postscript), but Mr. Greswell, in his elaborate chronological disquisition on the harmony of the Gospels, says, 'St. Paul wrote no epistles in his first imprisonment.' Much has been written by commentators for and against the opinion that St. Paul addressed this letter to the Ephesians; and notwithstanding the words of the first verse, 'to the saints at Ephesus' (*τοῖς ἁγίοις ἐφῆσου*), appear in all the antient MSS., and that the postscript says, 'written from Rome unto the Ephesians,' this is doubted and denied to be the fact by Grotius, Müll, Wetstein, Vitringa, Benson, Paley, and Greswell, who adopt the statement, said by Tertullian to have been made by Marcion, that it was written to the Laodiceans. Macknight, Lardner, Hartwell Horne, and many others, see no difficulty in believing it to have been addressed to the Ephesians, though Greswell (vol. ii. p. 67) maintains that by its internal evidence it is undoubtedly shown to have been addressed, not to the Christians at Ephesus, where Paul had resided three years (*Acts* xx. 31), but to personal strangers (i. 15, iii. 2, &c.); that it has been miscalled by mistake; and that, if it be not the epistle which Paul wrote to the Laodiceans (*Coloss.* iv. 16), that apostolical epistle must have been lost, for the one with this title inserted in the 'Codex Fabricii' and in Jones's work on the Canon, though of a very early date, is regarded as a forgery. Usher, Bengel, Michaelis, and Hug suppose it to be *encyclical*, that is, intended for circulation. The style is exceedingly animated and fluent, and has less of the metaphorical obscurity which generally characterizes the compositions of St. Paul. The object appears to be to establish an earnest faith in the doctrines of Christianity, by giving exalted notions of their importance and moral excellence, and to encourage a perseverance in the Christian warfare with temporal and spiritual enemies. The three first chapters are occupied in especially setting forth the principles of predestinarianism (i. 4, 5, 11, iv. 30), and the three last are devoted chiefly to the enjoining of moral duties with respect to husbands, wives, parents, children, masters, and servants. 'No real Christian,' says Dr. Macknight, 'can read the doctrinal part of this epistle without being impressed and roused by it, as by the sound of a trumpet.' On the undesigned coincidences with the 'Acts' see Paley's *Horæ Paulinæ*, p. 208—234. The moral and doctrinal precepts of this epistle, with respect chiefly to election, have occasioned theological critics, especially those of Germany, to write elaborately on its proper interpretation. See the comments of Bucer, Röell, Bosc, Schütze, Cramer, Rosenmüller, Koppe, Müller, Brinkmann, Ziegler, Krause, and Bemmelin, cited in Seiler's *Biblical Hermeneutics* by Dr. Wright; also Macknight's *Translation and Commentary on the Epistles*, 4to., vol. ii.; Michaelis's *Introduct.*, vol. iv.; Horne's *Introduct.*, vol. iv.; and the *list of Commentaries and Sermons on Ephesians* in Watt's *Biblioth. Britannica*.

EPHESUS, a city of Asia Minor, and one of the twelve that belonged to the Ionian confederation. (Herod. i. 142.)

The ruins of the city are situated near the river Cayster, at a short distance from the place where it falls into the Bay of Ephesus, and near a modern village called Aiasalouk. The city, according to Pococke's plan, was irregularly enclosed with solid walls. Towards the east the external wall crosses a hill, called Lepre, which has a channel or hollow in the middle. The wall is then continued southward on the edge of a valley, which is bounded by another hill, called the Corresus. (Strab. 640.) Other internal walls extend further south across another valley, and communicate with wall-works running east and west along the side of Mount Corresus. The walls then turn northward, and extend along the side of a lake, probably Lake Selinusia, near the temple of Diana, which is about a furlong to the west of the hill Lepre. On this, the west wall, is a tower, called the Prison of St. Paul, which is a building with Gothic or pointed arches. The walls, after leaving the lake, curve on the north, and run straight toward the east on a slight eminence. Near the circus the walls are set back a short distance, and then are continued straight till they turn with a curve, and join the boundary on the Lepre hill.

The whole compass of the walls, according to Pococke, is about four miles. They are built in a rough manner, but cased with hewn stone, and defended in places with square towers. In some parts the walls remain almost entire; in others the foundations only are visible, and are ten feet thick. The site of Ephesus has been frequently changed, and Lysimachus, one of Alexander's generals, is said to have adopted the expedient of stopping the drains in the low parts of the city, in order to drive the inhabitants into the higher, or, what he conceived, the most advantageous situation for the city, which he had enclosed. (Strab. 640.) Pococke is of opinion that the ruins of the present walls are the work of Lysimachus. Part of one of the entrance-gates, adorned with some bas-reliefs remarkable for their fine taste, still remains. Within the city there were extant, at the time of Pococke's visit, ruins of theatres, a circus, and other public buildings; and without the city, on the south-east side of Lepre, are the ruins of an extensive and magnificent edifice, which Pococke supposed to be a gymnasium. The outer walls are of brick and stone, formed of four or five courses of each, laid alternately, and constructed with great solidity.

In 'The Antiquities of Ionia,' vol. ii., published by the Dilettanti Society, there is an interesting view of this gymnasium, and also a plan. (See Plate 40, and following plates.) The Cryptoporticus is full of Exedrae. There is also a Palæstra and an Ephebeum, with rooms on the right and left, having a communication with the Palæstra only. A passage leads from the Ephebeum to the apartments of the baths, of which there were two sets for bathing. There is however only one Laconicum. In the niche of the Calidarium, on the right hand, are painted several sorts of fish, and boys swimming on dolphins: the colours of the painting are so well preserved as to show the water to be of a light green. The Laconicum is vaulted, and is totally dark. Plate 43 gives some details of the architecture of this building.

The remains of a temple at Ephesus are given in plates 44 and 45 of the same work. This temple was 130 feet long and 80 broad. The cella is constructed of large coarse stone; the portico is of marble, and of the Corinthian order. The columns are nearly 47 feet high, and the shafts are fluted, and of one piece of stone. The style is Roman, and the temple was constructed, probably with the permission of Augustus Cæsar, to the deified Julius.

The circus is a very curious building, 780 feet long, and 290 broad: the width of the chariot-course is 135 feet. On the north side the seats are constructed on a series of arches, but on the south they are laid on Mount Lepre. The circus was entered by descending the hill side, as the boundary was surmounted with a wall, having arched openings three feet wide at about forty feet distant from each other. The masonry consists of rusticated stone-work, and the Ionic order appears to have been used in some of the decorative parts of the architecture. The great theatre, which is partly constructed, and partly hollowed out of the hill, is about 330 feet in diameter, the plan being a large segment of a circle, with thirty rows of seats.

The temple of Diana has a lake on the west side of it, which is now a morass, extending westward to the Cayster. This building and the courts about it were surrounded with

a strong wall, which was a double wall to the south. Within the enclosure were four open courts, that is, one on each side of the temple; and on each side of the court to the west there was a large open portico, or colonnade, of four columns deep, extending to the lake: on these columns arches of brick were turned. The front of the temple was to the east. The temple was built on arches, and the foundation appears to have been most solidly constructed. This agrees with the statement of Pliny (xxxvi. 14), who, speaking of the great temple which existed in his time, said that it was built on marshy ground, as being thus more secure against earthquakes, and that the foundations were formed of rammed charcoal and wool. In the narrow archways of the foundation Pococke saw a great number of earthen pipes. In the front of the temple was a large portico, constructed with grey and red granite columns, some of the fragments of which are fifteen feet long and three feet six inches in diameter. Similar columns form part of the mosque of St. John at Aiasalouk, with a most beautiful composite capital. Pococke judges from the remains which he saw, that the whole building was cased with marble, and that arches were turned on the columns. The temple itself has something of the figure of a cross, and is divided into several chambers. There was probably a portico on the side opposite to the great entrance. The length of the temple, according to Pliny, was 425 feet, the breadth 220, and it contained 137 columns 60 feet high.

Ruins still remain on the lower part of the hill Lepre, and there seems to have been a suburb on the south side of Lepre, and near a mile from the south-east corner of it towards that hill, about which the present village of Aiasalouk is situated. On another hill is a Turkish castle, and round the top of the hill are extensive ruins of thick brick walls, with numerous small arches, which Pococke judges to be of the time of the Greek emperors. To the east of Mount Lepre are the burial-places. Pococke saw there a very large marble coffin (sarcophagus), with an imperfect inscription on it, and he says he has reason to think that they cut holes in the rock in order to deposit their dead there. There are several arches all round the hill, and on some of them are ruins of an aqueduct. On the low ground between the hill Lepre and the village of Aiasalouk there are remains of many square piers, made of single stones laid one on another. Not only on the sides of Mount Lepre, but on Mount Corresus, as well as in the valley between them, there are still great ruins of the ancient city.

Mounts Lepre and Corresus being of marble, probably supplied abundant materials for building. (Pococke's *Travels*; and *The Antiquities of Ionia*, by the Dilettanti Society.)

According to Strabo, the oldest inhabitants of the site of Ephesus were Carians and Leleges, most of whom were ejected by the settlers from Greece under Androclus. Lysimachus, as Strabo observes, built the walls which existed when he wrote, and which are doubtless those described by Pococke. He also gave the place the name of his wife Arsinoë, but the old name was afterwards restored. The first great temple of Diana was built by Chersiphron, which having been set on fire by Herostratus and destroyed, the great edifice described by Pliny was erected. Strabo says that the priests of the temple were once eunuchs, but that in his time the usages of the place were somewhat changed. This temple was a noted asylum for malefactors and for debtors, till this privilege was taken away by Augustus. In Strabo's time Ephesus was a place of great trade, and the chief commercial city of the western part of Asia Minor; and it would appear from the Acts of the Apostles (xix.) that it was a place of some note for workers in silver.

Coin of Ephesus.

E'PHORI (ἑφοροι), a body of magistrates at Sparta, who were possessed of great privileges. The institution of this office is usually ascribed to Theopompus, the grandson of

Charilaus the Proclid. but it has been inferred from the existence of an ephorality in other Dorian states before the time of Theopompus, and from its being apparently placed among the institutions of Lycurgus by Herodotus (i. 65) and Xenophon (*de Rep. Lac.*, viii. 3) that it was an antient Dorian magistracy. Dr. Arnold supposes (Thucyd., vol. i., p. 646) that the ephori, who were five in number, were coeval with the first settlement of the Dorians in Sparta, and were merely the municipal magistrates of the five hamlets which composed the city (see Müller, *Dorians*, ii., p. 550, Engl. transl.); but that afterwards, when the Heraclidæ began to encroach upon the privileges of the other Dorians, and, it would seem, in the reign of Theopompus, who endeavoured to diminish the powers of the general assembly of the Spartan aristocracy, the Dorians, in the struggle which ensued, gained for the ephori an extension of authority which placed them virtually at the head of the state, although the nominal sovereignty was still left in the hands of the Heraclidæ. Thus the ephori were popular magistrates as far as the Dorians themselves were concerned, and were in fact the guardians of their rights from the encroachments of the kings, though they were in relation to the Periæci (*περιεῖκοι*) the oppressive instruments of an overbearing aristocracy. (Plato, *Legg.*, iv., p. 712 D.) The ephori were chosen in the autumn of every year; the first gave his name to the year; every Spartan was eligible to the office without any regard to age or wealth. They were empowered to fine whom they pleased, and exact immediate payment of the fine; they could suspend the functions of any other magistrate, and arrest and bring to trial even the kings. (Xenophon *de Rep. Laced.*, viii. 4.) They presided and put the vote in the public assemblies (Thucyd., i., 87), and performed all the functions of sovereignty in receiving and dismissing embassies (Xen. *Hell.*, ii., 13, 19), treating with foreign states (Herod., ix., 8), and sending out military expeditions. (Xen., *Hellen.*, ii., 4, 29.) The king, when he commanded, was always attended by two of the ephori, who exercised a controlling power over his movements. (Herod., ix., 76.) The ephori were murdered on their seats of justice by Cleomenes III., and their office overthrown (Plutarch, *Vit. Cleomen.*, c. viii.); but they were restored by Antigonus Doson and the Achæans in 222 B.C. (Polyb., ii., 70; Pausan., ii., 9, 2); and the office subsisted under the Roman dominion. (See Böckh, *Corpus Inscriptionum*, i., p. 604-613.) On the ephorality, the reader may consult Müller's *Dorians*, book iii., c. 6; Plass's *Geschichte des alten Griechenlands*, vol. ii., p. 113; and Tittmann's *Darstellung der Griech. Staatsverfassungen*, p. 104-117.

E'PHORUS, a Greek historian, born at Cyme in Æolis, in the year 405 B.C. (Suidas.) He survived the passage of Alexander into Asia (333 B.C.), which he mentioned in his history (Clem. Al., *Strom.*, i., p. 337 A.). He studied rhetoric under Isocrates, but with so little success that after he had returned from Athens his father Demophilus sent him back to the rhetorician for fresh instructions. (Plutarch, *Vit. Isocratis*, p. 366 Wytténb.) Isocrates perceiving his unfitness for public speaking, recommended him to turn his attention to historical composition (Seneca *de Tranquillit. Animi*, c. vi.); but his style was low and slovenly even in his histories (Dio., i., p. 479); and Plutarch remarks upon the silliness of the set speeches which he introduced. (*Polit. Praecon.*, p. 803 B.) Polybius observes that, though in his account of naval matters he is sometimes happy, he always fails in describing battles by land, and was entirely ignorant of tactics. (*Excerpt. Vatican.*, p. 391.) Ephorus wrote—1. A History of Greece, in 30 books, beginning with the siege of Troy, and terminating with the siege of Perinthus (340 B.C.). Part of the thirtieth book was written by his son Demophilus. (Diod., xvi., 14.) 2. On Inventions, in 2 books. 3. On Goods and Ills, in 24 books. 4. On remarkable Objects in various Countries, 15 books. 5. The Topography of Cyme. 6. On Diction. The fragments of these works have been collected by Meier Marx, Carlsruhe, 1815.

E'PHYRA. [MEDUSA.]

EPIALTUS. [MAIDÆ.]

EPIC POETRY is that form of art which produces an imaginative description of external facts and occurrences, as distinguished from lyric poetry, which employs itself in registering, in an imaginative manner, all those internal facts and occurrences which go by the name of feelings and emotions.

Those who find this definition insufficient must remember

that it does not and is not intended to apply to any single epic or lyric poem. With the exception perhaps of some of our old national romances, there does not exist an epic poem of any length which is perfectly free from lyrical passages; but this is no reason why we should confound the two forms of art, and not assign to poetry the one name or the other according to the proportion which it contains of either element.

From what we know of the operations of our own minds, and of the analogy which subsists between the growth of individual and national intellect, it appears most natural that epic should be the earliest species of poetry. A child, borne into a crowd of circumstances all claiming his attention and exciting his interest, busies himself with the external world long before it ever occurs to him to examine what is going on within himself. Nay, more than this, his imagination, the idealizing faculty, takes the models of its exertions entirely from the external world. His dreams, his reveries, his waking fancies are active and epic, as any one who has watched the movements of children must acknowledge; but the time when he begins to notice his own thoughts and feelings—the lyrical age—does not come till later.

The progress of literature bears a close analogy to that growth of an individual mind which we have just described. Men look round them before looking within, and thus it is that natural philosophy has always preceded metaphysics, and epic poetry, as far as we know, been prior to lyrical. Again, the imagination gets the start of the logical faculty. Men can invent before they can argue, and thus it appears that facts, real or supposed, are usually put in the imaginative form of epic poetry before they are recorded and examined with regard to the conclusions which they suggest, as in political history. (Schelling, *Vorlesungen über die Methode des Academischen Studiums*, p. 226.) It may be objected to this theory, that if we assert every individual to have gone through both epic and lyrical periods, there is no reason why the two forms of art which we suppose to have arisen from the prevalence of either set of feelings should not have been contemporaneously produced; but it will be seen that a sufficient reason is supplied for the priority of that form which addresses itself to the spirit of action, in the fact that this spirit predominates in the earliest ages of society, to the complete repression—we might almost say destruction—of those contemplative feelings which in after ages are allowed full and unrestrained exercise. The heroic age of Greece, for instance, as far as we know anything about it, was very little likely to encourage reflection, much less reflective poetry, and accordingly we hear nothing of such poetry for centuries after it had ceased.

The earliest specimens of this form of art, which probably consisted of tales rhythmically arranged and recited to a very simple musical accompaniment, no doubt belonged to the unconscious æra, during which the poet, setting before him no aim, or seeing it at best but very imperfectly, acts purely from the stirring impulse of his own imagination. Into this class we may perhaps admit some of our oldest and simplest romances, but the poetry of Homer and Hesiod, the twofold epic of the Greeks, cannot be denied to be, in great measure at least, the work of conscious artists. We shall notice the writings of the early Greeks first in order; and as it would swell this article to an unnecessary length were we to examine in detail the principal epic poems which we possess, we shall confine ourselves, in a great measure, to those which were composed during the periods both of antient and modern history, when epic poetry could be said to be the poetry of the age, and leave those detached productions which owe their existence to the imagination of isolated men, in times long after the disappearance of the living epos, for a separate examination.

There are two divisions into which the epic poetry of the Greeks naturally falls; the heroic or romantic epos of Homer and of the Cyclic poets, and the hieratic epos of Hesiod. The attention of that age was centered, as ours is at present, on two grand ideas, the state and religion; whence we find a political and a hieratic epos. The Iliad and Odyssey are the two poems which remain as specimens of the former kind, and they are particularly worth the attention of all who are interested in the history of epic

* We are aware that this is opposed to the assertion of a late German writer (Wilhelm Müller, *Homeriche Forschungen*, p. 5); but he not adduced any arguments which lead us to change our opinion on the point.

poetry, as they afford by far the most perfect instance of poems of that kind composed in an age differing but little in its characteristics from that to which they refer, and stand consequently in strong contrast to the *Æneid*, a poem with which they are most frequently compared. The *Æneid*, in common with most Latin poetry, depends more on beauty of language and arrangement than on anything in the story, exquisitely managed as it is, to excite the interest of its readers. As it traces the life of an individual, it stands in closer juxta-position with the *Odyssey* than with the *Iliad*; but how superior is Ulysses to *Æneas*, and how much more romantic are the adventures of the Greek than those of the Trojan hero!

Perhaps there is not in the whole compass of literature a more perfectly drawn character than Ulysses, certainly none proceeding from so early a source. His touching exhibitions of feeling, the inimitable circumstantiality of the fictions which he spins in such profusion, apparently for no purpose except to confound his auditors; the manner in which all the interest of the story winds around him, the comic nature of the interludes, and the peculiarities attaching to the supernatural parts of his adventures, all unite to render the *Odyssey* a poem more fitted perhaps than the *Iliad* itself to interest an age like ours, when everything which gives a lyrical character to poetry is so much although so unconsciously sought for.

It usually happens that sacred poetry partakes strongly of a lyrical character, and Hesiod has perhaps struck out the only path which an epic writer in a simple age could follow without lapsing into the lyrical spirit as he approached theological subjects. The only poet of antiquity with whom he can be compared is Lucretius, but the '*De Rerum Naturâ*' approaches so much more nearly to the character of a treatise on philosophy; that it is hard to give it the name of an epic poem, although it, as well as all didactic works like Virgil's *Georgics*, come under the definition. The reason why we are slow to recognize them as epics arises from the habit of taking the heroic epos, one species, although the primary one, for the whole class, which really includes other species, as a reference to our definition cannot fail to show.

It has been observed by a German writer (Schelling, *Vorlesungen*, &c., p. 224) that, properly speaking, an epic poem has no regular beginning or end; it is a metrical and imaginative production, which, if it consist of narrative, may take it up and lay it down at any period. This is the case with the *Iliad*, as well as with the *Odyssey* and *Æneid*, although the two last are considerably more complex in the arrangement of the narrative, and evidently draw to a more decided close than the *Iliad*. There appears however to be a greater unity in the plot of the *Odyssey* than in that of Virgil's poem, in this respect, that the events never get the upper hand of the hero. We are interested in his adventures because they are his; while in the *Æneid* they strike us rather as embellishments intended to possess independent merit.

The early romantic epos deserves notice as the first distinct form of modern art. Much discussion has been expended in order to ascertain whence arose those cycles of metrical romances which have for their subjects the exploits of Alexander the Great, King Arthur, and other heroes; but it rather concerns us here to notice that the second birth of civilization which ensued on the breaking up of the Roman empire was productive of a series of events in literary history, parallel, as far as we can judge, to those which occurred in the times of Homer.

The traces of heroic poetry which remain in Livy's History are plain enough to enable us to infer with considerable probability that a series of epic poets appeared in Rome about the time of the Tarquins onwards; but as no fragments remain, we are too much in the dark as to the nature of their writings to enable us to refer to them as we do to Homer.

We find that the northern nations possessed numerous poems of an epical kind, some of which remain, and are or might be read with considerable interest. The cycles of romances on Troy and Alexander the Great compose a form of art which could only exist in a revival of imaginative spirit, as they derive their subjects from an older date and a different country, although, as regards every thing but the name of Greek or Trojan, the hero is usually the countryman of the bard; but the numerous poems on Arthur, with '*Havelok the Dane*,' and '*Horn Child*,' in our own language,

'*Beowulf*,' in Anglo-Saxon, '*The Poem of the Cid*,' in Spanish, and the '*Nibelungen Lied*,' in old German, are quite sufficient proofs of the coincidence of epic spirit with an early stage of society.

The Italian epic arose somewhat later than that of any of the northern nations, which may be attributed to the fact that it was only to a strong admixture of barbarian blood that the Italians owed their restoration to political existence. The dregs of a nation never possess a national literature.

Coleridge has observed that '*Gothic art depends on a symbolical expression of the infinite*,' or what cannot be circumscribed within the limits of actual sensuous being, while in ancient art everything was finite and material. (*Lit. Remains*, vol. i. p. 68.) This applies more directly to architecture, but in a measure also to literature, although we think that the introduction of Christianity had more to do with it than the cause which Coleridge assigns, namely the wild liberty of the Northman's habits and manners and the imagery of nature which surrounded him. Perhaps the greatest difference which is traceable between the ancient and the modern epic has been produced by that spirit of devotion to the female sex which characterizes all the Gothic nations; and arising as it does, partly from the refinement of an instinct and partly from religious impressions,* is very superior, as a motive of action, to the mere unmitigated instinct for war which constitutes the prevailing feature of the ancient epic, or at least of the heroic poems.

We have been at no pains to notice those detached epic poems which have appeared at different times since the revival of learning, although some of the most noble specimens of this style of poetry are to be numbered amongst them; still less have we intended to give anything like sketches of any which we have mentioned, as this is properly done under the heads of the several authors.

(Thirlwall's *History of Greece*, vol. i.; Ulrici, *Geschichte der Hellenischen Dichtkunst*; Dunlop, *History of Roman Literature*; Bæhr, *Abriß der Römischen Literatur-Geschichte*; *History of Spain in the Cabinet Cyclopædia*, vol. ii., Appendix H.)

EPICHRMUS, the son of Helothales, was born in the island of Cos, and accompanied Cadmus, the son of Scythos, to Sicily about the year 485 B.C. He must have arrived at maturity by this time; for he was a pupil of Pythagoras (who died in 497 B.C.), and according to Aristotle (*Poet.* iii. 5), lived long before Chionides and Magnes (who, if we may believe Suidas, began to exhibit in 487 B.C.); so that there can be no truth in the statement of Diogenes, that Epicharmus was brought from Cos to Sicily when a child of three months old (viii. 78). He and his brother were physicians, and therefore, perhaps, belonged to the Coan house of the *Asclepiads*. It appears that he resided some short time at Megara, and possibly removed to Syracuse when Gelo transported the inhabitants of Megara thither (484 B.C.). It was at Megara that Epicharmus probably got the idea of writing comedies; for the Megareans, as well in Greece as in Sicily, are always spoken of as the originators of that branch of the drama. Epicharmus is called by Theocritus (*Epigram.* xvii.) the inventor of comedy, and Plato says that he was the chief comedian, just as Homer was the chief tragedian. (*Theætet.* p. 152, E.) The latter remarks refer, we believe, to his having first furnished the *comus*, or band of revellers, who were the original chorus in comedy, with a systematic dialogue and a plot of an epic character. That the comedies of Epicharmus had a chorus, and that this chorus was the representative of the *comus*, as in the old Athenian comedy, appears probable from the fact that one of his dramas was called '*Vulcan*,' or the '*Comæstæ*.' 'The subjects of the plays of Epicharmus,' says Müller (*Dorians*, iv. 7, §. 2), 'were mostly mythological, i. e., parodies or travesties of mythology, nearly in the style of the satirical drama of Athens. Thus, in the comedy of "*Busiris*," Hercules was represented in the most ludicrous light, as a voracious glutton; and he was again exhibited in the same character (with a mixture, perhaps, of satirical remarks on the luxury of the times) in "*The Marriage of Hebe*," in which an astonishing number of dishes was mentioned. He also, like Aristophanes, handled political subjects and invented comic characters like the later Athenian poets; and indeed the extent of his subjects was very wide. The piece called

* The worship of the virgin is particular. (Coleridge, *ubi supra*.)

"The Plunderings," which described the devastation of Sicily in his time, had a political meaning; and this was perhaps also the case with "The Islands;" at least it was mentioned in this play that Hieron had prevented Anaxilas from destroying Locri. In his "Persians" also there were allusions to the history of the times. Epicharmus also introduced and almost perfected characters which were very common in the drama of later times; and if the plot of "The Menæchmi" of Plautus was, as the poet seems to state in the prologue, taken from a comedy of Epicharmus, it must be granted that the ingenious construction of plots was not beyond the powers of that poet. Epicharmus lived to the age of ninety (Diog., *Laert.*, viii. 78) or ninety-seven (Lucian, *Macrobi.*, xxv.). The titles of thirty-five of his comedies are given in Fabricius (ii. p. 300).

EPICETETUS was born at Hierapolis, a city of Phrygia. The year of his birth is not known, nor are we able to make any very close approximation to it. He must have been born however before the end of the reign of the emperor Nero, 68 A.D.; else he could not have been more than twenty-one when Domitian published that edict against philosophers, in the year 89 A.D., in consequence of which Epictetus retired from Rome. At the age of twenty-one, he was not likely to have attained sufficient notoriety to bring him within the operation of such an edict.

Epictetus was born most probably during the last eight years of Nero's reign. The names and condition of his parents are unknown; neither do we know how he came to be brought to Rome. But at Rome he was for some time slave to Epaphroditus, who was a freedman of Nero's, and one of his body-guard. An anecdote related by Origen, which illustrates the fortitude of Epictetus, would also show, if it is true, that Epaphroditus was a most cruel master. 'Epictetus, when his master was twisting his leg one day, smiled and quietly said, "you will break it;" and when he did break it, only observed, "Did I not tell you that you would do so?"' (Origen *c. Cels.* vii. p. 368.) We are not told how or when Epictetus managed to effect his freedom; but he could not have been still a slave when he left Rome in consequence of the edict against philosophers. This, which is the only event in his life whose date we can assign, took place, as has been said, in the year 89 A.D., being the eighth year of Domitian's reign. Epictetus then retired to Nicopolis, in Epirus; and it is a question whether he ever returned to Rome. The chief ground for believing that he did is a statement of Spartian (*Vit. Hadr.* 16), that Epictetus lived on terms of intimacy with the emperor Hadrian; while it is argued on the other hand, that there is no evidence of any of his discourses having been delivered at Rome, but that they contain frequent mention of Nicopolis. This argument is however hardly sufficient to overthrow the express testimony of Spartian.

We do not know when he died. Suidas says that he lived till the reign of Marcus Aurelius; and a confirmation of this statement has been thought to be furnished by Themistius, who says (*Orat. V. ad Jovian. Imp.*) that the two Antonines patronized Epictetus. But if, as there is good reason to believe, Epictetus was born before 68 A.D., the adoption of Suidas's statement would make him almost a hundred years old at his death; and what is said by Themistius might very well be true, even though Epictetus did not live under either of the Antonines. It may be added, that Suidas's account of Epictetus is in other respects inaccurate. But the strongest argument against Suidas is derived from Aulus Gellius, who, writing during the reign of the first Antonine, speaks of Epictetus in two places as being dead. (*Noct. Att.* ii. 18; xvii. 19.)

Epictetus led a life of exemplary contentment, simplicity, and virtue, practising in all particulars the morality he taught. He lived for a long while in a small hut, with no other furniture than a bed and lamp, and without an attendant; until he benevolently adopted a child whom a friend had been compelled by poverty to expose, and hired a nurse for its sake. There is a story connected with his lamp which illustrates the equanimity of Epictetus. He had bought one day an iron lamp, which was very soon after stolen from his hut, while he was himself standing in a corner wrapped in meditation; and when on looking up he came to miss it, he observed with a smile, 'I shall disappoint this thief to-morrow, for if he comes back for another lamp, he shall only find an earthen one.' (Arrian, *Epict.* ii. 6.) Neither was it in trifles alone that his equanimity was manifested, as the anecdote of his patience

under his master's cruelty may suffice to prove. The biographers of Epictetus have taken particular care to commemorate his love of neatness.

Epictetus was a teacher of the Stoic philosophy, and the chief of those who lived during the period of the Roman empire. An anecdote given in the 'Discourses' collected by Arrian (i. 7) seems to show that he had been a pupil of Musonius Rufus, a Stoic philosopher whom Nero banished to Gyara, and who was subsequently recalled to Rome by Vespasian. The lessons of Epictetus were principally, if not solely, directed to practical morality. His favorite maxim, and that into which he resolved all practical morality, was 'bear and forbear,' *ἀνίχου καὶ ἀνέχου*. He appears to have differed from the Stoics on the matter of suicide. (Arrian, *Epict.* i. 8.) We are told by Arrian in his Preface to the 'Discourses,' that he was a powerful and exciting lecturer; and, according to Origen (*c. Cels.* vi. ad init.), his style was superior to that of Plato. It is a proof of the estimation in which Epictetus was held that, on his death, his lamp was purchased by some more eager than wise aspirant after philosophy for three thousand drachmæ. (Lucian, *adv. Indoct. libr. ement.*, tom. ii., p. 386.)

Though it is said by Suidas that Epictetus wrote much, there is good reason to believe that he himself wrote nothing. His Discourses were taken down by his pupil Arrian, and published after his death in six books, of which four remain. The same Arrian compiled the *Encheiridion*, and wrote a life of Epictetus, which has been lost. [ARRIAN.] Some fragments have also been preserved by Stobæus.

The best edition of all the remains of Epictetus is that by Schweighæuser, in six volumes, Leipzig, 1799. The same editor has published the *Encheiridion*, together with the *Tablet of Cebes*, in a separate volume. Coray published an edition of the *Encheiridion*, with a French translation by another hand, in the seventh volume of the *Parerga* of his *Bibliotheca Græca*, Paris, 1826, 8vo. There is an English translation of the *Encheiridion*, or *Manual*, by Mrs. Carter. (*Bayle's Dictionary*; Fabricii *Bibliotheca Græca*, ed. Harles. vol. v. p. 64.)

EPICURUS was born in the year 341 B.C., seven years after the death of Plato. He was born in the island of Samos, whither his father had gone from Athens in the year 352 B.C., among 2000 colonists then sent out by the Athenians. (Strab., xiv. p. 638.) He was however an Athenian born, belonging to the deme Gargettus, and to the tribe *Ægeis*. His father Neocles is said to have been a schoolmaster, and his mother Chæristrata to have practised arts of magic, in which it was afterwards made a charge against Epicurus that, when he was young, he assisted her. (Diog. Laert., x. 4.) Having passed his early years in Samos and Teos, Epicurus went to Athens at the age of eighteen. We are told that he had begun to study philosophy when only fourteen, having been incited thereto by a desire, which the teachers whom he had applied to had failed to satisfy, of understanding Hesiod's description of chaos; and that he began with the writings of Democritus. In Samos he is said to have received lessons from Pamphilus, a follower of Plato. (Suidas; *Cic. de Nat. Deor.*, i. 26.) At the time when Epicurus arrived in Athens, Xenocrates was teaching in the academy, and Theophrastus in the Lyceum; and we may suppose that he did not fail to avail himself of the opportunities of instruction which were thus within his reach. Indeed it was stated by Demetrius Magnes (Diog. Laert., x. 13) that Epicurus was a pupil of Xenocrates. He is also said, on the testimony of Apollodorus, to have received lessons from Lysiphanes and Praxiphanes; and again it is stated that he was a pupil of Nausiphanes. (Id. x. 14; Suid.) It was however Epicurus's wont to boast that he had learnt from no man but himself.

On the occasion of his first visit to Athens, Epicurus stayed there for a very short time. He left it in consequence of the measures taken by Perdiccas after the death of Alexander the Great, and went to Colophon to join his father. In his thirty-second year, 310 B.C., he went to Mitylene, where he set up a school. Staying only one year at Mitylene, he next went to Lampascus, where he taught for four years. He returned to Athens in the year 306 B.C.; and now founded the school which ever after was named from him. He purchased a garden for 80 minæ, wherein he might live with his disciples and deliver his lessons, and henceforth remained in Athens, with the exception only of two or three visits to his friends in Asia Minor, until his death in the year 270 B.C. The disease

which brought on his death was the stone. He was in his seventy-second year when he died, and he had been then settled in Athens as a teacher for thirty-six years.

Epicurus is said by Diogenes Laertius (x. 9) to have had so many friends 'that even whole cities could not contain them.' Pupils came to him from distant places, very many from Lampsacus; and while men often deserted other schools to join that of Epicurus, there were only two instances at most of Epicurus being deserted for any other teacher. So remarkably was this the case, (and it continued to be so as long as the Epicurean school lasted,) that it is related as a question put to Arcesilaus, 'why men change from other sects to that of the Epicureans, but never leave this?' (Diog. Laert., iv. 43.) Epicurus and his pupils lived together, in the garden which has been mentioned, in a state of friendship, which, as it is usually represented, could not be surpassed; abstaining from putting their properties together, and enjoying them in common, for the quaint yet significant reason that such a plan implied mutual distrust. The friendship subsisting between Epicurus and his pupils is commemorated by Cicero (*De Fin.*, i. 20). In this garden too they lived in the most frugal and virtuous manner, though it was the delight of the enemies of Epicurus to represent it differently; and though Timocrates, who had once been his pupil, and had abandoned him, spread such stories as that Epicurus used to vomit twice a day after a surfeit, and that many immodest women were inmates of the garden. (Diog. Laert., x. 6, 7.) An inscription over the gate of the garden told him who might be disposed to enter, that barley-cakes and water would be the fare provided for him (Senec., *Ep.* 31); and such was the chastity of Epicurus, that one of his principal opponents, Chrysippus, endeavoured to account for it, so as to deny him any merit, by saying that he was without passions. (Stob. *Serm.* 117.) Epicurus did not marry, in order that he might be able to prosecute philosophy with less interruption. His most attached friends and pupils were Hermachius of Mitylene, whom he appointed by will to succeed him as master of the school; Metrodorus, who wrote several books in defence of his system, and for whose children Epicurus in his will liberally provided; and Polyænus. Epicurus's three brothers, Neocles, Chæredemus, and Aristobulus, followed his philosophy; as also one of his servants, Mys, whom at his death he made free. Besides the garden in Athens, from which the followers of Epicurus in succeeding time came to be named the philosophers of the garden (Juv. *Sat.* xiii. 122, xiv. 319), Epicurus possessed a house in Melite, a village near Athens, to which he used often to retire with his friends. On his death, he left this house, together with the garden, to Hermachius, as head of the school, to be left by him again to whomsoever might be his successor.

Epicurus divided the whole field of knowledge into three parts, to which he gave the names respectively of *canonics*, *physics*, and *ethics*. The first two were subordinate to the third. The end of all knowledge, of ethics directly or immediately, of canonics and physics indirectly or mediately through ethics, was, according to Epicurus, to increase the happiness of man.

Canonics, which was a subject altogether introductory both to physics and ethics, treated of the means by which knowledge, both physical and ethical, was obtained, and of the conditions or (as they were called by Epicurus) *criteria* of truth. These conditions or *criteria* were, according to him, sensations (*αἰσθήσεις*), ideas or imaginations (*προλήψεις*), and affections (*πάθη*). From these three sorts of consciousness we get all our knowledge. What Epicurus then called canonics, viewed in relation to physics and ethics, is, viewed absolutely or in itself, psychology. Epicurus seems to have explained rightly the dependence of ideas upon sensations (Diog. Laert., x. 33); but in accounting for sensations, he, like Democritus, left the path of sound psychology, and introduced the fanciful hypothesis of emanations from bodies.

In physics he trod pretty closely in the footsteps of Democritus [Democritus]; so much so that he was accused of taking his atomic cosmology from that philosopher without acknowledgment. He made very few and unimportant alterations; and of these Cicero remarks (*De Fin.* i. 6), 'Democrito adjicit perpaucā mutans, sed ita ut ea quæ corrigere vult mihi quidem depravare videatur.' According to Epicurus, as also to Democritus and Leucippus before him, the universe consists of two parts, matter and

space, or vacuum, in which matter exists and moves; and all matter, of every kind and form, is reducible to certain indivisible particles, atoms, which are eternal. These atoms, moving, according to a natural tendency, straight downwards, and also obliquely, have thereby come to form the different bodies which are found in the world, and which differ, in kind and shape, according as the atoms are differently placed in respect of one another. It is clear that in this system a creator is dispensed with; and indeed Epicurus, here again following Democritus, set about to prove, in an *a priori* way, that this creator could not exist, inasmuch as nothing could arise out of nothing, any more than it could utterly perish and become nothing. The atoms have existed always, and always will exist; and all the various physical phenomena are brought about, from time to time, by their various motions.

It remains to speak of the Epicurean system of ethics. Setting out from the two facts, that man is susceptible of pleasure and pain, and that he seeks the one and avoids the other, Epicurus propounded that it is a man's duty to endeavour to increase to the utmost his pleasures and diminish to the utmost his pains; choosing that which tends to pleasure rather than that which tends to pain, and that which tends to a greater pleasure or to a lesser pain, rather than that which tends respectively to a lesser pleasure or to a greater pain. He used the terms pleasure and pain in the most comprehensive way, as including pleasure and pain both of mind and of body; and he esteemed the pleasures and pains of the mind as incomparably greater than those of the body. Making, then, good and evil or virtue and vice depend on a tendency to increase pleasure and diminish pain, or the opposite, he arrived, as he easily might do, at the several virtues to be inculcated and vices to be denounced. And when he got thus far, even his adversaries had nothing to say against him. It is strange that they should have continued to revile the principle, no matter by what name it might be called, when they saw that it was a principle that led to truth. But even in our own age and country the same cry has been raised; and men, ignorant of the principles of the ancient and of the modern philosopher alike, have endeavoured, by bringing to bear on it as a hard name the name Epicurean, to crush the philosophy of Bentham.

Though Epicurus dispensed with a Divine Being as creator of the world, he yet did not deny the existence of gods. That there was an inconsistency in this is obvious. But he professed that the universal prevalence of the ideas of gods was sufficient to prove that they existed; and thinking it necessary to derive these ideas, like all other ideas, from sensations, he imagined that the gods were beings of human form, hovering about in the air, and made known to men by the customary emanations. He believed that these gods were eternal and supremely happy, living in a state of quiet, and meddling not with the affairs of the world. He contended that they were to be worshipped on account of the excellence of their nature, not because they could do men either good or harm. (Cic. *De Nat. Deor.* i. 41; Senec. *De Benef.* iv. 19.)

The two chief sources of knowledge concerning the doctrines of Epicurus are the tenth book of Diogenes Laertius, and the poem of Lucretius 'De Rerum Naturā.' In the first of these are letters from Epicurus himself to three of his friends, which give a brief account of all the parts of his system. Information is furnished also by the writings of Cicero, principally the 'De Finibus' and the 'De Naturā Deorum,' by those of Seneca; and the treatise of Plutarch entitled 'Against Colotes.'

Epicurus was, according to Diogenes Laertius, a more voluminous writer than any other philosopher, having written as many as 300 volumes, in all of which he is said to have studiously avoided making quotations. All that now remains of his works are the letters contained in the tenth book of Diogenes Laertius, and parts of two books of his treatise on Nature (*πρὸς φύσιν*), which were discovered at Herculaneum. The last were published at Leipzig in 1818, being edited by Orelli. A critical edition of the first two letters of Epicurus was edited by J. Glo. Schneider, Leipzig, 1813.

Diogenes Laertius is the principal authority for the life of Epicurus; brief and incidental notices are also supplied by Suidas, Cicero, Seneca, and Plutarch. There is an account of the life and defence of the character of Epicurus, in eight books, by Gassendi (Lugd. Bat. 1647), and a life

by a Frenchman of the name of Randal (Par. 1679). It is unnecessary to mention the accounts given in Fabricius, Bayle, and all the common histories of philosophy.

The Epicurean school was carried on, after Hermachus, by Polystratus and many others, concerning whom nothing particular is known; and the doctrines which Epicurus had taught underwent few modifications. When introduced among the Romans, these doctrines, though very much opposed, were yet adopted by many distinguished men, as Lucretius, Atticus, Horace; and under the emperors, Pliny the Younger and Lucian of Samosata were Epicureans. A list of Epicureans among the Greeks and Romans will be found in Fabricius, 'Bibliotheca Græca,' ed. Hædles. vol. iii. p. 598-614.

EPICYCLE, a circle, the centre of which is carried round upon another circle: a term of the PROLEMAIC HYPOTHESIS.

EPICYCLOID. [TROCHOIDAL CURVES.]

EPIDAUROS, a celebrated city of ancient Greece, situated on the eastern coast of Argolis, on a small bay in the Saronic gulf, and surrounded by mountains on the land side. (Strabo, p. 374.) Its more ancient name was Epicaeus, and its earliest inhabitants were Carians, who were subsequently joined by some Ionians from Attica. (Aristot. apud Strab.) When the Dorians got possession of Argos, Epidaurus yielded without resistance to them, and admitted a Dorian colony under Deiphontes. (Pausan. ii. 26, 1.) The constitution of Epidaurus was originally monarchical; in the time of Periander of Corinth his father-in-law, Procles, was tyrant of Epidaurus. (Herod. iii. 53.) Afterwards the government was aristocratical; the chief magistrates were called Artynæ, or Artyni, as at Argos (Thucyd. v. 47), and were the presidents of a council of one hundred and eighty; the common people were termed *konipodes* (κοινοπόδες), or dusty-feet, in allusion to their agricultural pursuits. (Plutarch, *Quæst. Gr.* 1.) Epidaurus was the mother-city of Ægina and Cos, the former of which was once dependent upon it. (Strabo, p. 375.) As the chief seat of the worship of Æsculapius, Epidaurus was for a long period a highly important place. The temple of Æsculapius was situated at the upper end of a valley about five miles from the city, and was one of the richest and most renowned sanctuaries in Greece. In 293 B.C. it was so celebrated that during a pestilence at Rome a deputation was sent from that city to implore the aid of the Epidaurian god. (Liv. x. c. 47.) The temple was always crowded with invalids, and the priests, who were also physicians, contrived to keep up its reputation, for the walls were covered with tablets describing the cures which they had wrought, even in the time of Strabo. Near the temple was a remarkably beautiful theatre, built by Polycleitus (Pausan. ii. 27, 5), which is in better preservation than any other theatre in Greece, except that at Tramezus, near Joannina, and was capable of containing 12,000 spectators. Of the temple itself and the other buildings mentioned by Pausanias there are but few remains. (Leake's *Morea*, vol. ii., p. 423.) Epidaurus sent ten ships to Salamis, and 800 hoplites to Plataea. (Herod. viii. i. ix., 102.) The inhabitants were for a long time the allies of Sparta. (Thucyd. i. 105, ii. 56; Xen. *Hell.* iv. 2, 16, vii. 2, 2.) In the time of Aratus they joined the Achæan league. (Polyb. ii. 5.) The territory of Epidaurus was covered with vineyards in the time of Homer (*Il.* B. 561), and the vine is still cultivated on the site (Leake, *Morea*, ii. p. 430), which is indicated by a small village called Pidnavro.

There were two other cities of this name; one in Laconia, called Epidaurus Limera, which had also a well-known temple of Æsculapius. There are still some remains of the fortifications. (Leake's *Morea*, i. p. 211.) This Epidaurus had a capital harbour, from which, according to Apollodorus, it derived its name Limera. (Strabo, p. 368.) The third Epidaurus was a maritime city of Illyria, mentioned by Hirtius. (*De Bello Alexandrino*, c. 44.)

Coin of Epidaurus.
British Museum. Actual Size. Silver. Weight, 38½ grains.

EPIDEMIC (ἐπιδήμιος, *epidēmios*; from ἐπὶ, in the sense of 'over' 'all through,' and δῆμιος, 'people') diseases are those
P. C., No. 590.

which prevail among a large portion of the people of a country, rage for a certain time, and then gradually diminish and disappear, to return again at periods more or less remote. Thus cholera and influenza lately prevailed as epidemic diseases in this country; and the continued fevers called synochus and typhus, and what are termed the eruptive fevers, as scarlet fever, the small-pox, the measles, frequently prevail as epidemics in different parts of the country. It is essential to the medical notion of an epidemic disease that it be dependent on some common and widely-extended cause, of a temporary in contradistinction to a persistent nature. [ENDMIC.]

EPIDENDRUM, an old name for all the orchidaceous plants which grow upon the branches of trees, and which are now called Epiphytes. [EPHYPHYTES.] In its modern sense, it is restricted to a considerable genus of the order with the labellum united to the column, and four pollen masses adhering to as many little straps bent back upon them. Some of them are showy and interesting, particularly *E. Skinneri*, *oncidoides*, *cochleatum*, *aromaticum*, *bifidum*, *auropurpureum*; but many are inconspicuous, and of no importance except to botanists.

EPIDERMIS, the external covering of the skin, commonly called cuticle. [SKIN.]

EPIDOTE (*Thallite*, *Pistazite*), a mineral which occurs crystallized, massive, and granular. The primary form of the crystal is an oblique rhombic prism, variously terminated and longitudinally striated. Its colour is of various shades of green, greenish grey, brownish yellow, and blackish red. The streak is greyish white. Specific gravity, 3.425 to 3.45. It is transparent or opaque. Lustre vitreous. Hardness, 6.0, 7.0. Fracture uneven. The massive varieties are amorphous; structure granular, compact, or fibrous. Before the blowpipe it fuses at the extreme points, then intumesces, but does not fuse even at a very high temperature. Epidote occurs in many parts of Europe, as in Norway, Switzerland, France, and England, and also in North America and the East Indies. According to Vauquelin, it consists of

EPIGRAM (ἐπιγράμμα, *Epigramma*; from the Greek ἐπὶ, on, and γράφειν, write), in its proper sense, is—a writing on—an inscription; whence it comes to signify a short poem, such as might be comprised within the limits of an inscription. For an account of the class of poems called epigrams by the Greeks, see ANTHOLOGY; they are dedicatory, descriptive, amatory, elegiac; rarely humorous or satirical; and their merit consists 'in the justness of a single thought, conveyed in harmonious language.' (Preface to Bland and Merivale's *Anthology*.) Much of early Greek history was preserved in epigrams, to which Herodotus and Thucydides often refer; as for instance those concerning the battle of Thermopylæ (Herod. vii. 228), one of which is thus literally translated: 'Here once four thousand from Peloponnesus fought with three millions.'

The Latin epigram approaches nearer to the English acceptance of the term, being much oftener dependent for its merit upon humour and personality. The most distinguished Latin epigrammatists are Catullus and Martial, in whom there is much wit, disfigured by much scurrility and obscenity; but many of the epigrams of Martial are epigrams in the Greek sense, and some of them are characterized by a propriety of thought and felicity of expression that could not easily be surpassed. The Latin Anthology of Peter Burman the younger contains a large collection of epigrams, by numerous authors, of which many resemble in simplicity the Greek epigrams.

In English the word signifies a short poem, which, to be good in its kind, must be clear, concise, and elegant in expression, and must contain a point, i. e. some striking and unexpected turn of thought. Whether it be humorous or serious is indifferent. The following terse and elegant compliment addressed by Pope to Lord Chesterfield, on being asked to write with that nobleman's pencil, may serve as well as any for a specimen:—

Accept a miracle: instead of wit,
See two dull lines by Stanhope's pencil writ.

EPILEPSY, *epilepsis* (ἐπιληψία), 'a seizing.' Synonyms: *morbus divinus*, *herculeus*, *comitialis*, *caducus*; 'falling sickness. Sudden abolition of sensation and consciousness, with convulsions [CONVULSION] of the muscles of voluntary motion, ending in a state of sopor or apparent sleep, the attack recurring in paroxysms more or less regular. The attack of epilepsy is usually quite sudden. The person, while in his ordinary health, and perhaps engaged in his usual occupation, utters a piercing scream. If standing, he falls to the ground, where he lies for a moment in a state of extreme rigidity, almost amounting to tetanic stiffness; but this state is quickly succeeded by convulsions, which variously agitate the limbs and the trunk of the body. The head is generally thrown backwards; the eyes are open, fixed, and staring; the pupils are dilated; the vessels of the head and neck are swollen, rendering the countenance flushed, and sometimes of a dusky hue; the muscles of the face are in violent action, producing frightful distortions of the countenance; the muscles that move the lower jaw close the mouth with violence, producing gnashing of the teeth; the tongue, which is swollen and livid, is thrust out forcibly between the teeth, and is often grievously wounded; the arms are sometimes tossed violently about the chest, or struck against it; the hands and fingers are in a state of rapid alternation, between the motions of flexion and extension; the lower extremities are agitated in a similar manner; the thumbs are drawn inwards, and the toes incurved; and a quantity of frothy saliva flows from the mouth, which is often bloody from the wounds inflicted on the tongue. The muscles on one side of the body are commonly more violently agitated than those of the other. Several cases are on record in which the muscular contractions were so violent that the bones of the limbs were broken, the teeth fractured, and the joints dislocated. Generally the convulsions have for a few moments some remission, when they are again suddenly renewed with great violence. The breathing is disordered in consequence of the convulsion of the muscles of respiration. At first heavy and difficult as if a load were placed upon the chest, it becomes at length quick, short, irregular, and stertorous, and is often accompanied with sighing and moaning. The diaphragm, the muscles of the abdomen, and the muscular fibres of the bladder, contract with so much violence, that the fæces and the urine are discharged involuntarily and with great force. The pulse, always difficult to be felt, is commonly quick and small; but it becomes distinct towards the end of the paroxysm, and is then more slow and languid. The action of the heart is irregular, tumultuous, and loud, and the carotids throb vehemently. After the contractions of the muscles have continued for some time, the convulsions diminish in violence, and at length cease altogether. Perspiration breaks out about the head, neck, and breast; the convulsive respiration is followed by sighs, and the spasms of the muscles by subsultus. The patient is now restored to a slight degree of consciousness; but, as if exhausted by the violence of the struggle, he soon sinks again into a state of profound insensibility, and lies in a deep sleep. During the state of sleep, the perspiration becomes copious and general over the whole body; the pulse fuller, softer, and slower, and the respiration freer and easier. After a time the person awakes, sometimes suddenly, but in general it is only by degrees that sensation, consciousness, and the power of motion return. Commonly there is no consciousness whatever of anything that has passed during the paroxysm. On coming out of the fit there is generally headache, and always languor. The convulsive stage may last from one or two minutes to fifteen or twenty, and the sleep from one to several hours. The duration of the whole paroxysm is generally from five to ten minutes; but often two or three attacks follow each other in such rapid succession, that the paroxysm seems to be protracted for several hours. Occasionally death takes place unexpectedly in the midst of the fit, either in consequence of injury inflicted on the brain by congestion of the cerebral blood-vessels, or by the suspension of the respiration through the spasm of the muscles of the larynx, which close the opening of the glottis so completely and for so long a time as to induce the state of asphyxia.

Such are the general circumstances which accompany an epileptic attack, and the general form of the disease is pretty much the same in all the persons afflicted by it; the chief difference is in the slowness or severity of the phenomena, in which there is every possible variety from an

attack so severe as to produce instantaneous death to one which is so slight that it can scarcely be perceived. Sometimes, for example, instead of the regular and violent fit just described, the seizure consists merely of loss of consciousness, slight rigidity, spasms or convulsions of a few muscles or of a single limb, the attack lasting only a minute or two. At other times the patient is seized with sickness or a sensation of faintness, the sight becomes dim, the recollection imperfect, and the power of voluntary motion so far impaired, that the person slips from his chair, or falls from his horse, and lies on the ground insensible, pale, perspiring, but without convulsions. Or the attack may be so slight that consciousness is not wholly lost; but the mind becomes confused, the power of articulation suddenly diminished, and instead of finishing the sentence he was uttering, the person continues to mumble for half a minute or a minute the last words he was attempting to speak, in a slow, monotonous, gibbering manner; and then recovering, he takes up the thread of his discourse, being soon aware of an interruption of consciousness, which interruption there is often an effort to conceal. This state is described by the persons subject to it as one of great mental distress and depression, like a frightful dream: they feel perplexed and afflicted by an imperfect reminiscence of some overwhelming calamity, or a sense of remorse for which they cannot assign a cause. A paroxysm of this kind is like a short mood of extreme melancholy, and such is the impression that the countenance of the patient, which is full of sadness, makes upon the spectator. These slighter paroxysms may recur only at very distant intervals; but they more commonly return often, and sometimes three or four times a day.

The return of the regular epileptic paroxysm is exceedingly various in different individuals. Several years may intervene between the seizures; or they may recur once every month, week, or day. It is stated that they sometimes recur periodically, and with remarkable exactness to the very day; once a year, or once a month. When they recur monthly, and observe a stated day, that day sometimes coincides with the new or full moon, a coincidence to which great importance was attached in former times. The interval of a lunar month is more commonly noticed among females, from the connexion of the disease with the uterine functions. In some instances, the paroxysms occur every week, on the same day; and occasionally every day, or night, at the same hour; but they most frequently come on when first falling asleep, and are often for a time unsuspected or overlooked. Sometimes several slight seizures take place in one day; but their recurrence is often extremely irregular. When they are neglected, they usually either become more and more severe, or occur after shorter intervals. Consciousness and sensation being abolished, pain cannot be felt during the fit.

Though the epileptic attack usually comes on suddenly, yet it sometimes gives distinct warning of its approach. The symptoms premonitory of an epileptic fit are analogous to those which precede an attack of apoplexy [APOPLEXY], namely, headache, giddiness, flushing of the face, throbbing of the temples, drowsiness, sense of weight or heaviness of the head; flashes of light before the eyes, sleeplessness, fretfulness, irritability, or unusual cheerfulness and hilarity; disorders of the digestive organs, as voracious appetite, sickness, vomiting, constipation, or diarrhoea. But there is one peculiar sensation, termed the *aura epileptica*, of which many epileptics are conscious immediately before the fit. This consists of a feeling as if something were moving in some part of the limbs, or trunk of the body, and creeping thence upwards towards the head. Sometimes it is described as a sensation of a current of air, a stream of water, or a slight convulsive tremor; at other times no distinct idea can be given of the feeling further than that it is a sensation of something moving along. This remarkable sensation does not appear to follow very distinctly the course of a nerve, but it seems to pass along the integuments. When it reaches the head, the patient is instantaneously deprived of sense, and falls down in convulsions. The sensation arises in different parts of the body, in the toe, foot, leg, and groin; in the finger, hand, and arm; at the bottom of the spine; in the uterus, loins, abdomen, and chest. But, in the great majority of cases, the attack of epilepsy is preceded by no such warning; and even where the premonitory symptoms do exist, the attack does not by any means always follow.

Epilepsy rarely occurs in a person otherwise in sound health. Out of three hundred cases, the early history of each of which was carefully investigated, very few had been perfectly well previously to the accession of the disease. Convulsions during the first dentition, eruptions on the skin, mental excitement, diseases of the glands, chorea, hysteria, tremor, cramp, vertigo, palpitation, headache, flushing, bleeding from the nose, precede the first epileptic attack, and perhaps may be considered, at least in part, as predisposing causes of the malady.

As this disease is often long preceded by other maladies before the actual seizure, so, after it has subsisted for some time, it induces a peculiar state of the constitution, and more especially, it would appear, in the nervous system, which predisposes to the recurrence of the attack, and the signs of which internal state are manifest in a peculiar expression of the external features. The eyelids become swollen: the eyes prominent and unsteady; the look vacant; the cheeks pale, the lips thick; and the individual features, however originally beautiful, grow coarse, and lose their fine expression. The steadiness and energy of the mind progressively diminish; the purpose becomes irresolute, and the power of continuous application for the accomplishment of a given object is lost. Instances are recorded in which, though the disease recurred frequently for a long series of years, neither the memory nor any other mental faculty appeared to be impaired; but this is exceedingly rare. In general, in the severe and protracted cases, the following melancholy description, given by an ancient author, is but too correct: 'If the disease be of long duration the patients become torpid, languid, and dejected; they avoid the sight and the society of men; time does not afford any mitigation of their sufferings; they are often oppressed with watchfulness, and when they do sleep they are terrified with horrible dreams; they loathe food, and digest with difficulty; their natural colour disappears, and changes to a leaden hue; they have a difficulty of comprehension, on account of torpor of mind and of sense; they are dull of hearing, are affected with a ringing of the ears and a confused sound in the head; the tongue is unable to do its office, either on account of the nature of the disease, or from injuries which it may have received in the paroxysms; they are agitated by convulsions, and sometimes the mind is so disturbed by the complaint, that persons labouring under it become fatuous or idiotic.' It is an old observation that those who become insane at an early age are first epileptic; and it is certain that epilepsy often terminates in mania, a violent attack of mania often immediately following the epileptic paroxysm. 'Of 298 epileptics in the Salpêtrière, in 1813, 80 were maniacal, and 56 in various states of mental alienation and imbecility. In 1822, out of 339 cases in the same hospital there were 2 monomaniacs, 30 maniacs, 34 furious maniacs, 129 insane for some time after the paroxysms, 16 constantly insane, 8 idiotic, 50 upon the whole reasonable, but with impaired memories, and liable to occasional slight delirium and tendency to insanity, and 60 without aberration of intellect, but irascible, capricious, obstinate, and presenting something singular in their characters.' In this country a very common termination of epilepsy is apoplexy or paralysis.

Authors commonly divide epilepsy into two species: first, idiopathic, where the disease depends on some primary affection of the brain, and, secondly, sympathetic, in which it depends on an affection of some remote part, as the stomach, the liver, the bowels, the generative organs, the circulating system, &c.

The state of the brain on which epilepsy depends is unknown. Dissection shows that the brain of the epileptic is seldom sound; but much as this subject has been investigated, little light has hitherto been shed upon the pathology of the brain as connected with this disease. The most common morbid appearances are the thickening of the bones of the skull; spiculae or morbid growths of the bone from the inner table of the skull; vascular turgescence, or inflammation of the membranes of the brain; preternatural hardness or softening of the substance of the brain and of the spinal cord; effusion of serum, blood, jelly, or pus between the membranes, upon the surface or into the ventricles of the brain; tumors or morbid growths in its substance; adventitious deposits, as tubercles, or parasitic animals, as hydatids. Recent researches appear to indicate that the parts of the brain which most commonly undergo morbid changes of structure in this disease are the parts more immediately in the neighbourhood of the sphenoid bone, and especially

the pineal and the pituitary glands, and particularly the latter. But occasionally, where violent epilepsy has existed during life, the most careful examination of the brain after death has led to the discovery of no appreciable change in its structure; while even the morbid appearances which are manifest are often observed to be present without being accompanied with epilepsy; so that the relation between any known morbid change in the structure of the brain and epilepsy is not yet certainly established. It follows, as has been stated, that nothing is really known of that condition of the brain which causes epilepsy.

But many of the causes of the malady are well ascertained, and the knowledge of these is of great importance in the prevention and cure of the disease. It is conceived that there is a constitutional predisposition to epilepsy, although it does not seem easy to assign with exactness in what this predisposition exists. Several of the exciting causes are weak impressions which are applied to most persons with little or no effect. 'I conclude therefore,' says Cullen, 'that the persons affected by those causes are more easily moved than others, and therefore that in this case a certain mobility gives the predisposition. It is clear that there is a greater mobility of constitution in some persons than in others, as is manifest in the state of the mind. If a person is readily elated by hope and as easily depressed by fear, and passes equally and quickly from the one state to the other; if he is easily pleased and prone to gaiety, and as easily provoked to anger and rendered peevish; if liable from slight impressions to strong emotions, but tenacious of none; this is the boyish temperament, *qui colligit ac ponit iram temere, et mutatur in horas*; this is the *varium et mutabile fœmina*; and, both in the boy and woman, every one perceives and acknowledges a mobility of mind. But this is necessarily connected with an analogous state of the brain; that is, with a mobility, in respect of any impression, and therefore liable to a ready alternation of excitement and collapse, and of both to a considerable degree. There is therefore, in certain persons, a mobility of constitution, generally derived from the state of original stamina, and more exquisite at a certain period of life than at others; but sometimes arising from, and particularly modified by, occurrences in the course of life. And this mobility consists in a greater degree of either sensibility or irritability.' Dr. Cheyne conceives that epilepsy is as certain a manifestation of the strumous diathesis as tubercular consumption, psoas abscess, hereditary insanity, or certain congenital malformations or defects of organization which are inherited only from scrofulous parents. Epileptic patients are of the habit of body in which scrofula occurs. It is an hereditary disease. If due inquiry be made, it will generally be found that although the direct progenitors, father or mother, may have escaped, yet that some member of the family, uncle or aunt, grandfather or grandmother, has been subject to fits; and if epilepsy occur for the first time in a family it is probably in consequence of the strumous diathesis having been exalted by the intermarriage of two persons inheritors of that condition or tendency of the constitution, and which it has been in a yet more remarkable degree if the parents were of the same blood and nearly related; we may then expect, if an epileptic patient has several brothers and sisters, that his case will not be a solitary one in the family.

The exciting causes consist of two classes, those which act by exciting the energies of the brain, and those which act by depressing the brain. Those which act by over-stimulating the brain are mechanical, chemical, and mental stimulants, and the peculiar stimulus of over-distention; as sharp-pointed ossifications, arising either from the internal surface of the cranium or formed in the membranes of the brain; powerful mental emotions, such as joy and anger; congestion of the blood-vessels of the brain; suppressed discharges; violent exercise; too large a quantity of highly nutritious food or of stimulating drink. 'I have observed,' says Fothergill, 'that epileptics are often extremely incautious with respect to diet; that children highly indulged are liable to the disease; that in every other period of juvenescence, and in middle-aged adults, if they were attacked with the disease, it was when they had either committed some excesses or by one means or another were plethoric, and that in habits subject to epilepsy, the disease seldom recurred without either an habitual indulgence in eating or a neglect of necessary exercise.'

But the very opposite causes, those which manifestly

weaken the energy of the brain, occur in epilepsy, as hæmorrhage, whether spontaneous or artificial; terror, horror, disgust; any powerful and disagreeable sensations, and especially certain disagreeable odours; excessive evacuations, great fatigue, inanition, and sedative poisons.

The medical treatment of a case of epilepsy must of course differ essentially according as it is idiopathic or sympathetic, and connected with a plethoric and robust, or debilitated and exhausted state of the system. Unless he previously ascertain the condition of the brain and spinal cord, or the nature of the affection of the remote organ in sympathy with which the brain is suffering, the practitioner must work entirely in the dark, and must be liable to adopt the very opposite course of treatment to that which the case really requires. When the appropriate remedies are judiciously employed, and the proper regimen is strictly adhered to, epilepsy is often permanently cured, and the suffering is greatly mitigated even in those forms of the disease which do not admit of cure. Dr. Cheyne has laid down some excellent rules for the management of epileptic patients, of which, as they are of a popular nature, and applicable to the great majority of cases, we give the substance.

In prescribing a rule of diet suitable to all epileptics, moderation in quantity and simplicity in the preparation of the food are indispensable points. The diet best calculated to preserve an individual liable to scrofula from an attack of that disease is best suited to a patient liable to epilepsy. Fermented liquors should in general be altogether withheld. Flesh-meat ought to form the principal part of one if not two meals in the day; and milk, if it do not retard digestion, which it is less liable to do when fermented liquors are laid aside, is the article next in value. The epileptic ought to be trained so as to be in good wind, so as to put his muscles in a state of the utmost strength and firmness. Epileptics should be put under a regular course of training like the athletic of antient, and the gentlemen of the fancy in modern times. When the patient leaves his bed in the morning, he may have a rusk or a slice of toasted bread with an egg beat up in a teacup full of warm water; then let him dress, make all needful arrangements, and walk three or four miles. Two hours or more after he has left his bed, let him have his second meal, milk or cream in water, or cocoa with bread a day old and butter. Rest for three hours after breakfast. This will be the best time to devote to business or education. Then he must again walk, if an adult possessed of sufficient "gour, from five to eight miles. At from five to six hours after his second meal, let him have a third, consisting of meat of the best quality, mutton, poultry, game, or very tender beef, roasted or boiled, of which an adult must not eat more than six ounces; bread, and one moderate helping of tender well-boiled vegetables; of drink, not more than a common tumbler full of distilled water, Seltzer water, with a little milk, or toast and water. Then rest for two hours; that is, stroll in a garden, read an amusing book, or engage in any occupation which will not raise the pulse by one beat; then resume more active exercise for an hour or two. In five or six hours after dinner, a light supper may be taken, consisting of not more than four ounces of meat with bread, or of a cup of milk with a water biscuit. The rest of the evening may be spent in cheerful society, in a large airy room, not over lighted nor over heated, but sufficiently warm to prevent that chill which in the latter part of the day often follows very active exercise; and every occupation by which the mind is depressed or is excited, and thereby subsequently exhausted, must be avoided. The patient must be in bed at eleven and up at six, nothing in general being more hurtful to epileptics than sleep unnecessarily prolonged.

The scalp in all epileptics ought to be shaved once a week, and daily well rubbed with a flesh-brush after the tepid shower bath, or, what answers nearly as well, after pouring a flaggon of tepid water on the head inclined over a large basin. The patient may gradually bring himself to sleep without a night-cap and without curtains, with the shoulders and head raised and the feet well protected from the cold, in a chamber as large and airy as possible and without a fire.

A patient liable to epilepsy must not be permitted to ride nor to hold the reins in a carriage. The grates in all the apartments which he frequents ought to be guarded by a deep and strong sander: he ought to avoid the streets of a

crowded city, in which the whirl of carriages, the tide of human beings, and the multiplicity and distraction of objects produce a vertiginous hurry of thought, which to him is ever dangerous. He ought not to walk near water. A fine young man of twenty came to an untimely end in his own garden, by falling into a runnel, in which he was drowned, although the water was not more than four inches deep.

If an attack of the disease come on while the patient is in his chamber, he ought immediately to be laid on his back on a bed, with an attendant standing on each side to prevent him from injury during the struggle. If he is much flushed, his head and shoulders ought to be elevated, the warmth of his extremities supported, while at the same time air is freely admitted into the room. All attempts to make him swallow or to stimulate the nostrils are improper. A medical practitioner ought to be sent for, and ought to remain in attendance while the struggle lasts. In a first attack, if the fit is severe, blood ought to be procured from the temporal artery, a precaution which will also be necessary in patients of an apoplectic diathesis whenever they labour under a prolonged fit of apoplexy. (Cheyne, *Cyclopæd. of Pract. Med.*; Copland, *Dict. of Pract. Med.*; Prichard, *Diseases of the Nervous System*; Cooke, *Hist. and Method of Cure of the various Species of Epilepsy*.)

EPILOGUE (ἐπίλογος, epilogus) (compounded of *ἐπι*, *on or after*, and *λόγος*, *speech*) signifies, in Greek, a summing up, the end or peroration of a discourse. In English it is applied only to the short poems or copies of verses (invariably, we believe, written in the heroic couplet) which formerly were commonly subjoined to new plays, and recited on the stage at their conclusion. An epilogue is usually written in a lively tone, with such allusions to the play, the author's circumstances, the news or fashions of the day, or other subjects of existing interest, as are thought likely to conciliate favour, and send the audience away in good humour. 'If it be true that good wine needs no bush, 'tis true that a good play needs no epilogue: yet to good wine they use good bushes, and good plays prove the better by the help of good epilogues.' (*As You Like It*.)

EPI'MACHUS. [PROMETHEUS.]

EPIMENIDES was born in the year 659 B.C. (Suidas), at Phæstus, in Crete, according to some accounts; or at Cnossus, according to others; at all events, he was a citizen of the latter place, though his father appears to have been a Phæstian. (Diog. Laërt., i. 109.) He passed his youth in solitary retirement, which is explained in the antient account as a supernatural sleep into which he fell when a youth, and did not awake till more than fifty years after, when he made his appearance among his fellow-citizens with long hair and a flowing beard, and with knowledge of medicine and natural history, which then appeared more than human. The event of his life for which he is best known, was his visit to Athens at the request of the inhabitants, in order to pave the way for the legislation of Solon by purifications and propitiatory sacrifices. These rites were calculated, according to the spirit of the age, to allay the feuds and party dissensions which prevailed there; and although what he enjoined was mostly of a religious nature (for instance, the sacrifice of a human victim, the consecration of a temple to the Eumenides, and of two altars to Hybris and Anædeia, the two evil powers which were exerting their influence on the Athenians), there can be little doubt but that his object was political, and that Solon's constitution would hardly have been accepted had it not been recommended and sanctioned by some person who, like Epimenides, claimed from men little less than the veneration due to a superior being. The Athenians wished to reward Epimenides with wealth and public honours, but he refused to accept any remuneration, and only demanded a branch of the sacred olive-tree and a decree of perpetual friendship between Athens and his own country, Cnossus. Epimenides visited Athens about the year 596 B.C., and died soon after his return to Crete. He wrote a poem on the Argonautic expedition, and other works, which are entirely lost. For a more detailed account of this remarkable personage the reader is referred to C. F. Heinrich's *Epimenides aus Kreta*, Leipzig, 1801.

EPINAL, a town in France, the capital of the department of Vosges. It is on the bank of the Moselle, about 190 miles in a straight line, east by south of Paris, 232 miles by the road through Meaux, Château Thierry, Epernay, Châlons sur Marne, Bar sur Ornain (otherwise Bar le

(Due), Domremy, and Mirecourt; or 243 miles through Bar sur Ornain, Nancy, and Charmes.

No mention occurs of Epinal earlier than the end of the tenth century, when it was the residence of the bishops of Metz: the lordship however passed subsequently into the hands of the dukes of Lorraine. It was formerly well fortified, and had a fine castle; but the fortifications have been rased.

The town is situated at the foot of the chain of the Vosges, and in a district abounding with delightful situations. The rapid stream of the Moselle, whose clear and shallow waters here roll over a bed of large pebbles, divides the town into two unequal portions: the part on the right bank is called 'la Grande Ville'; it is at the foot of an eminence on which stand the ruins of the castle: the part on the left bank is called 'la Petite Ville'; it is on an island formed by the main channel of the Moselle, and a smaller arm of that river: on the left bank of this arm is a suburb, formerly named 'the Suburb of the Capuchins,' from a convent of the monks of that order. The streets of Epinal are well laid out. The office of the prefect is the finest edifice in the place; the court of justice is tolerably handsome; the church is of Gothic architecture, mingled with some parts in the style of a later age. There is a theatre; also an hospital on an eminence on the right of the Moselle. There are some public walks. The population in 1832 was 8670 for the town, or 9070 for the whole commune. The manufactures are lace, paper, and earthenware; and, in the neighbourhood, block tin, wrought iron, paper, earthenware, and leather. There are several establishments for the purposes of public instruction, a library of 17,000 volumes, a collection of paintings and antiquities, and a drawing-school.

The neighbourhood produces wheat, rye, oats, buckwheat, peas, lentils, Jerusalem artichokes, hemp, and flax: and trade is carried on in the town in grain, wine, oil, fir planks (for sawing which there are several yards round Epinal), linen yarn, linen cloth, and cattle. The arrondissement of Epinal had in 1832 a population of 91,578.

EPIPHANIUS, SAINT, a Christian bishop and author of the fourth century, was born of Jewish parents at a village called Besanducan, near Eleutheropolis, in Palestine. He spent his youth under the discipline of the Gnostics in Egypt, where he acquired a great fondness for the monkish asceticism then so prevalent in that country. Having become a zealous disciple of Hilarion, the patriarch of the monks of Palestine, he founded and long presided over a monastery near his native village. About the year 368 he was made bishop of Salamis, the metropolis of the island of Cyprus, where he continued about 36 years, and composed most of his writings. His spirit of opposition was especially excited by the Platonic doctrines of the learned and laborious Origen, against which he wrote and preached with implacable bitterness. On this subject he hotly quarrelled, in 391, with John, bishop of Jerusalem, who favoured Origen's views; but he found in Theophilus, the violent bishop of Alexandria, a worthy coadjutor, who in 399 convened a council, and condemned all the works of Origen. Epiphanius himself then called a council in Cyprus A.D. 401, and reiterated this condemnation, after which he wrote to St. Chrysostom, then bishop of Constantinople, requesting him to do the same; and on finding this prelate disinclined to sanction his violent proceedings, he forthwith repaired to Constantinople for the purpose of exciting the bishops of that diocese to join in executing the decrees which his Cyprian council had issued; but having entered a church in the city in order to repeat his anathemas, he was forewarned by Chrysostom of the illegality of his conduct, and was obliged to desist. Exasperated at this disappointment, he applied to the imperial court for assistance, where he soon embroiled himself with the Empress Eudoxia; for, on the occasion of her asking him to pray for the young Theodosius, who was dangerously ill, he replied that her son should not die provided she would not patronise the defenders of Origen. To this presumptuous message the empress indignantly answered, that her son's life was not in the power of Epiphanius, whose prayers were unable to save that of his own archdeacon, who had recently died. After thus vainly endeavouring to gratify his sectarian animosity, he resolved to return to Cyprus, when, according to Sozomen (lib. 8, cap. 15), the following farewell colloquy occurred between the bishop of Salamis and the bishop of Constantinople:—'I hope,' said Epiphanius to Chrysostom, 'you will never die a bishop.' Chrysostom, returning the

compliment, replied with equal courtesy, 'I hope you will never get back to your own country;' and it is remarkable that each of these malevolent wishes was accomplished; for Chrysostom was deposed, and died in exile, and Epiphanius died at sea, on his passage to Cyprus, A.D. 403. His works in Greek were first printed in fol. at Basle, in 1544. Several editions, with a Latin translation by Cornarius, subsequently appeared at Basle and at Paris during the sixteenth century; but the best is by Petavius, who made a new Latin translation of the Greek text, and added a biography of the author and critical notes. This edition is in 2 vols. fol., Paris, 1622, and Cologne, 1682. In the 'Epiphani Opuscula, ex editione Petavii,' are some very curious and valuable old prints. The principal works of Epiphanius are, 1. The *Παναριον*, Panarion, or a treatise on Heresies, that is, peculiar sects (*αἵρεσις*). This is the most important of the author's writings. It treats of 80 sects, from the time of Adam to the latter part of the fourth century. The first section of the first of the three books into which the treatise is divided contains an account of 20 heretical sects before the birth of Christ; the remaining portion is occupied with the description of 60 heresies of Christianity. 2. 'Anacephalæosis,' or, an Epitome of the Panarion. 3. 'Ἀγκυρωθὲν', Ancoratus, or, A Discourse on the Faith; explaining the Doctrine of the Trinity, Resurrection, &c., in confutation of the Pagans, Manicheans, Sabellians, and Arians. 4. A Treatise on the ancient Weights, Measures, and Coins of the Jews, with a Catalogue of Canonical Scriptures. Besides these there are several treatises and epistles, some of which are falsely attributed to Epiphanius. (See Riveti *Crit. Sacr.* c. 28 and 29.)

Epiphanius was an austere and superstitious ascetic, and, as a bitter controversialist, he often resorts to very false arguments for the refutation of heretics. That his inaccuracy and credulity were equal to his religious zeal is apparent from his numerous mistakes in important historical facts, and his reliance on any false and foolish reports. He gravely relates the story of the seventy-two translators having been shut up each in a separate cell for the production of the Greek Septuagint version of the Hebrew Scriptures; and in the 'Panarion' (Heres. 39) he observes, that the Devil, before the coming of Christ, lay quietly by, in expectation of being pardoned; but that, finding no chance of salvation from the Saviour, he at once became fearfully refractory, and has ever since done his utmost to occasion all possible mischief to Christ and his church. Jerome admires Epiphanius for his skill in the Hebrew, Syriac, Egyptian, Greek, and Latin languages, and accordingly styles him, Pentaglottos (*πεντάγλωττος*), or the Five-tongued; but Scaliger calls him an ignorant man, who committed the greatest blunders, told the greatest falsehoods, and knew next to nothing about either Hebrew or Greek. However, his writings are of great value as containing numerous citations from curious works which are no longer extant. (Du Pin, *Bibliothèque Eccles.* tom. 2; Cave's *Lit. Hist.*; Bayle's *Dict.*; Dr. A. Clarke's *Succession of Sacred Literature.*)

EPIPHANY, from the Greek *ἐπιφάνεια* (*Epiphaneia*), appearance, or manifestation, a church festival, celebrated on the twelfth day after Christmas, in commemoration of our Saviour's being manifested to the world by the appearance of a miraculous star; likewise denominated Twelfth Day. This day is said to have been first observed as a separate feast in the year 813. The customs of this day, though various in different countries, all agree in the same end, namely, to do honour to the eastern magi, or kings, who visited and made offerings to our Saviour at his birth. (Brady's *Clavis Calendaria*, 8v., London, 1812, vol. i., p. 145; Brand's *Popular Antiq.*, 4to. edit., vol. i., p. 18.)

EPIPHYLOSPERMOUS PLANTS, so called by the old botanists, because they bore their seed upon the back of their leaves. They are what have more recently been called dorsiferous ferns. [*FILICES*.]

EPIPHYTES are plants found growing upon other vegetables, adhering to their bark and rooting among the scanty soil that occupies their surface, in which respect they are distinguished from parasitical plants, which, like Mistletoe and the various species of *Loranthus*, strike their abortive roots into the wood, and flourish upon the blood of the individual to which they attach themselves. In this sense of the word, mosses, lichens, ferns, and plants of many other families, are epiphytes; but as in this country at the present day the word is principally employed with reference to those *Orchidaceæ* which grow upon trees, it is

to plants of that description that we propose to devote the present article.

It had long been known, from the reports of travellers, that orchidaceous epiphytes were plants of extremely curious organization, and that great numbers were also remarkable for the singular beauty and fragrance of their flowers; but when imported into this country, their habits were found to be so unlike those of other plants, that no gardener could succeed in keeping them even alive for any considerable time, except in a very few instances; and it was not till about the year 1820 that the real method of managing them successfully began to be understood. About that time the late Mr. Cattley and the writer of this notice began to direct their attention to the subject with some success: since that period the difficulties of cultivating orchidaceous plants have been gradually disappearing, and at the present day they may be said to be almost entirely overcome; so that in the gardens of the duke of Devonshire at Chatsworth, of Mr. Bateman at Knypersley, of Lord Fitzwilliam at Wentworth, of Mr. Harrison of Liverpool, and of many other amateurs, they have acquired a beauty quite unknown to them in a wild state. Species which in their native woods yield no more than two or three of their curious blossoms in a cluster have been found to produce from nine to between twenty and thirty, and the whole order has in short been found willing to submit to domestication with as much advantage as has ever attended roses, hyacinths, tulips, or dahlias,—those well-known flowers which we have from time to time reclaimed from their wild habits, and by the arts of cultivation invested with a splendour of appearance that never could have been anticipated from their original appearance in a savage state. Previously to the year 1820 it is doubtful whether any garden in England could at any one time have produced twenty species of these plants, and now at least a thousand are successfully preserved in the collections of the Messrs. Loddiges, Rolisson, Knight, and other nurserymen near London.

We do not propose in this place to give any botanical account of these curious plants; for such particulars we refer to the article on ORCHIDACEÆ. Upon the present occasion we shall confine ourselves to an account of their natural habits, and of those methods of cultivation which appear to have met with so much success. In preparing the following account, we depend in part upon our own experience, in part upon the information contained in the writings of botanical travellers, and in part upon the useful communications which within the few last years have been made to the current horticultural publications, especially the 'Transactions of the Horticultural Society' and the 'Gardener's Magazine.'

Orchidaceous Epiphytes grow naturally upon trees in the recesses of tropical forests. They establish themselves upon the branches, and either vegetate amidst masses of decayed vegetable and animal matter, or cling by their long succulent grasping roots to the naked branches of trees, from which and the humid atmosphere together they exclusively derive their food. It appears from the testimony of Mr. Henchman that they are never found upon dead erect trees in forests; but if upon dead wood at all, then only upon fallen trunks, which, from their situation near the ground, are constantly damp. Such situations are, however, said to be by no means favourable to their growth. They will also flourish upon rocks and stones in hot and damp climates. Mr. W. Harrison of Rio Janeiro is said, by one of the Horticultural Society's collectors who visited him, to have cultivated with the most perfect success above seventy species upon a wall in his garden at Boto Fogo.

We even see some of them germinate and grow most luxuriantly in damp places, in the stove, upon the sides of the garden-pots, and among gravel; some genera, such as *Brasavola*, are even reported to prefer stones; and Dr. Wallich found them in all cases growing equally well in Nepal upon trees and stones, provided the latter had a certain quantity of mould and moss adhering to them. In the botanic garden at Calcutta they are said to be cultivated with success in raised beds of solid brickwork, so contrived as to insure a perfect drainage; the soil being rich vegetable matter mixed with at least two-thirds small pebbles, and covered with a dense layer of moss. A certain quantity of shade seems, in many cases, essential to them, their natural situation being in forests, or among the branches of growing trees. In Brazil numbers of them occupy damp

woods and rich valleys, among vegetation of the most luxuriant description, by which they are embowered. Reinwardt describes others as inhabiting in great abundance those deep shady gloomy forests which form the lower zone of vegetation in Java, where the air is heavy and damp with vapours that cannot ascend, and where the thickness of the vegetation is really frightful; where, in short, heat, moisture, and a most extraordinarily deep and rich vegetable soil combine to produce wood of a fungus-like softness and an inconceivable abundance of twining plants and epiphytes. In those forests more especially where huge fig-trees constitute the principal part of the timber, intermingled with the most tropical forms of vegetation, such as *sterculiaceæ*, *sapindaceæ*, and *artocarpææ*, tufts of orchidaceous plants abound, in company with *aracææ*, *acanthaceæ*, and *zingiberaceæ*.

In Nepal Dr. Wallich states that orchidaceous epiphytes grow in company with ferns; and the thicker the forest, the more stately the trees, the richer and blacker the natural soil, the more profuse the orchidaceæ and ferns upon them. There they flourish by the sides of dripping springs in deep shady recesses, in inconceivable quantity, and with an astonishing degree of luxuriance. It would however be a great error to suppose that it is only in very shady places that orchidaceous epiphytes appear. On the contrary, it is probable that the cases just cited are extreme, and that they more commonly prefer situations where the broken rays of the sun can readily reach them. Mr. John Henchman states (*Gardener's Mag.* ii. 139) that he has observed in Demerara 'that orchidaceæ appear to rejoice in a light situation and a free circulation of the atmosphere; but are decidedly adverse, with few exceptions, to exposure to the intense rays of the sun. We may except from this remark *oncidium luridum*, the *catasetuma*, and a fine pseudo-bulb found on the Spanish Main (which I suppose to be an *epidendrum*), which seem not only to exist, but to rejoice, in exposure to the sun.' Mr. Bateman also found, from the report of his collector, Colley, that the situations in which they are most usually seen are those parts of a forest where old and broken wood occurs, or on the skirts of savannas. These savannas are large open breaks in the woods, covered with fine white sand, which has, at night, the appearance of snow. They contain also many low and stunted bushes. The orchidaceæ seem to like an airy and exposed dwelling-place; being found on the more prominent parts of a tree, and not in the shade, as is generally supposed. Mr. Colley only found in one instance an orchidaceous plant in the heart of a forest, and this was growing on the prostrate trunk of a tree so rotten as to fall to pieces when pressed with the foot. (*Gard. Mag.* ii. 4.)

This quite corresponds with the statements of travellers in Brazil, who speak of their occurring most abundantly in open glades of the forests, and on the faces of naked rocks, or on shaded banks, although they are also met with 'in sombre glades where heated vapours are incessantly circulating.'

Where the climate suits them, they are sometimes prodigiously numerous. Descourtiz, in his manuscripts, speaks of a whole tree being overrun with a single species; and Henchman also assures us that in Demerara masses of *oncidium altissimum* and *maxillaria parkeri* are to be seen, which would defy any attempt at intrusion; on the Spanish Main he saw the epiphyte commonly called the spread eagle, which will possibly prove an *epidendrum*, clasping enormous trees, and covering them from top to bottom; and he also met with two or three species, supposed to be *maxillarias*, which were growing with uncommon vigour. But, he adds, 'with the above exceptions, I have not found orchidaceæ growing in such quantities as it has been reported they do; often, as Mr. Bateman justly observes, single specimens only are to be obtained. This cannot be more strongly illustrated than in the case of a beautiful *oncidium*, which I was happy enough to meet with on the Spanish Main; its leaves are nearly six inches in width, of a very firm texture, and possessing an uncommonly strong nerve; and though the plant, judging from the remains of the original stem, which had gradually decayed as the plant progressed, must have occupied its station for nearly half a century, yet I searched the neighbourhood in vain for another specimen, nor did I see another plant of it on the Main.'

This altogether corresponds with what we know of such plants in other countries, and with the general habit of the whole order, which is extremely local in the majority of cases

Upon comparing the orchidaceous plants of Java, of Ceylon, and of the Burmese country, it is quite extraordinary how few species those countries possess in common; and the quantities of species found exclusively in every large collection are a corroboration of the same fact. Mr. Bateman assures us that in Guiana 'a river may be ascended for twenty miles without an orchidaceous plant being seen; while, on a sudden turn of the stream, every tree becomes covered with them: yet they do not appear to have a favourite aspect; for on some of the rivers which Mr. Colley visited he found them exclusively on the northern exposure, while on others they occupied the southern.' The part of the tree on which they are principally found is as uncertain as their station. It is said that they love the loftiest branches, and are hardly found near the bottom, and M. Descourtilz confirms this statement by describing some of them as swinging in the air from the top of the old patriarchs of the forest, or exposed to all the violence of storms in the most exposed situations. But Mr. Henschman asserts that in Demerara at least they 'do not grow in such high situations upon trees as is generally supposed. Twenty or twenty-five feet is the greatest height, with few exceptions, at which I have seen them growing. Some of the bulbous epidendrums, the spread eagle plant, and oncidium papilio, attain a much greater height. The other oncidiums I have not seen growing above seven feet or eight feet from the ground, and generally on some of the small closely interwoven branches, and not on the stem or main branches of the tree. The various species of *Gongora*, *Coryanthes*, and *Rodriguezia*, are, almost without exception, found in the same position; while, again, the genera *Maxillaria*, *Fernandesia*, *Epidendrum*, *Ceratophilus*, *Cattleya*, *Zygopetalon*, *Brassavola*, *Ornithidium*, *Camaridium*, *Pleurothallis*, *Brassia*, *Ornithocephalus*, *Trizeuxis*, *Catasetum*, and many other genera supposed to be new, I have found always attached to the trunk or strong limbs of the tree, which they clasp with surprising tenacity. It may be also observed that rough and soft barked trees are favourite habitats of orchidaceæ. The calabash tree, which has a peculiarly soft and woolly bark, often possesses many of the more minute species. Indeed, I sent home pieces of the calabash tree, about a foot long, on some of which were six and on others seven distinct species of orchidaceæ.'

A high mean temperature throughout the year, and a climate either constantly humid or at least periodically so, are also atmospheric elements eminently favourable to the production of these plants. All those species which simply exist clinging by their roots to the branches of growing trees, and probably others also, must necessarily derive their nourishment in a great measure, if not entirely, from the moisture, in a very elastic state, that surrounds them. And although nature seems in general to have provided for the scantiness of their food by the construction of them with a cuticle only capable of parting by slow degrees with the fluid they receive by their roots, yet it is obviously requisite that they should be so situated as to be within reach of an abundant supply, not only at the time when they are growing, but also at all other times to a certain extent. Hence we find that the hottest countries if dry, and the dampest if cold, are destitute of them, while there is no instance of a country both hot and damp in which they are not plentiful. For example, in Africa they are unknown in its sandy deserts and parched atmosphere, notwithstanding the high temperature of that part of the world; yet they abound in Sierra Leone, where the climate is damp, and even at the Cape of Good Hope they occur not unsparingly in all that jungly district to the eastward of the Cape Town to which the name of Outniqualand is applied.

In the West India Islands they exist in great quantities, particularly in Jamaica and Trinidad, not however so much on the coast as upon the lower ranges of hills. This is in conformity with their habits elsewhere: in these islands the air of the level of the sea is dry, while that of the mountains is humid. Captain Sabine found the air of the level of the sea at Trinidad indicate 5° of dryness, and that of Jamaica 7°; while the atmosphere was saturated with humidity in the first of these islands at 1060 feet above the level of the sea, and in the second at an elevation of 4080 feet. At Rio Janeiro the mean temperature is 74° 3', and much higher inland; the woods are so damp that it is difficult to dry plants; and in such situations multitudes of orchidaceous epiphytes spring up. But in the immediate vi-

cinity of Buenos Ayres, where the mean temperature is 67° 6' and the air dry, they are unknown; and in the high dry land of Mendoza, where the aridity is still greater, the whole order disappears, with the exception of a single species. On the west coast of South America, as high as Lower Peru, orchidaceous epiphytes are unknown, a circumstance which is not surprising when we consider the effect of the currents setting round Cape Horn, which bring the mean temperature of even Lower Peru itself down to 60° at night, and how arid the whole of that region is, with the exception of a few valleys. No country however exhibits in a more striking manner than India the necessity of a hot and damp climate for the production of orchidaceous epiphytes. In the Malayan Archipelago, the mean temperature of which is estimated at between 77° and 78°, and is very damp, they are found in profusion. In Nepal it is upon the sides of the lower mountains that they occur, where they vegetate amongst clouds and constant showers; while on the continent of India they are almost unknown, their place being occupied by parasitical *Loranthi*. The traveller finds himself in the morning on the dry plains of Hindustan, where the mean temperature is 80°, and where all the trees are destitute of orchidaceæ; and at noon he is at the foot of the first range of the Nepaulese hills, where every tree teems with that class of plants. There are however places on the continent of India where they are not less numerous than in Nepal; at the æstuaries of the Ganges, the Brahmapootra, the Irawaddi, and the rivers of Martaban, they exist in vast quantities: but all these stations are excessively damp. In the Botanic Garden at Calcutta they grow most vigorously during the rainy season, but in the fiercely hot season, which begins in March and lasts till the 10th of June, they perish, notwithstanding all the care they receive. Madagascar and the Isle of France offer similar evidence to the same effect.

While however these statements are applicable to a very large part of orchidaceous epiphytes, there are some striking exceptions that require to be pointed out, both with regard to atmospheric moisture, and to the temperature requisite for their production.

Mr. Allan Cunningham has shown in the 'Botanical Register,' fol. 1699, that in New Holland there are three of these plants which require a very dry atmosphere, and it is probable that others exist in other countries. 'These are *Dend. æmulum*, Br., an epiphyte uniformly found upon the rugged trunk of *Eucalyptus resinifera*, or Ironbark, in the open very dry forest grounds of the older colony at Port Jackson; *Cymbidium canaliculatum*, Br., which, of late years, has been observed beyond the Tropic, both at Moreton Bay and still further to the southward at Hunter's River, growing upon the principal limbs of several of the eucalypti in the dry open shadeless forest. These two epiphytes flourish most luxuriantly in an extremely dry atmosphere, and flower usually in the summer season in their native wilds, the high temperature of which is oftentimes greatly increased by the blighting hot winds which not unfrequently prevail at that period from the north-west. The third is *Dendrobium undulatum* of Mr. Brown, a handsome species, originally discovered by Sir Joseph Banks at Bustard Bay, and which has been lately found on barren hills, naturally clear of timber, upon the banks of the Brisbane River at Moreton Bay, where the plant forms tufts on bare rocks exposed to the full heat of the sun, which, during nine months of the year, is very considerable on that part of the coast.'

In many cases a much lower temperature than that hitherto spoken of is natural to these plants, and there are some instances where they are naturally accustomed to rigorous weather. In America, their favourite station, according to Humboldt, is in the gorges of the Andes of Mexico, New Grenada, Quito, and Peru, where the air is mild and humid, and the mean temperature 63°—67° Fahr. (17°—19° Cent.) In these localities they are so abundant, that, according to the authors of the 'Flora Peruviana,' above 1000 species might be found in Tarma, Huanuco, and Xauxa alone. It is therefore not surprising that one species, *Epidendrum conopseum*, should advance as far to the northward as the rice climate of Florida, where it grows on the bark of *Magnolia glauca*, nor that others should be found in the damp maritime parts of the government of Buenos Ayres. But it is more remarkable that an *oncidium nubigenum* should occur at the height of 14,000 feet on the mountains of Peru, and that other

species should, upon the authority of M. Descourtilz, be able to bear without difficulty the cold glacial winds of the high serras of Brazil. The same peculiarities occur in the eastern world. Reinwardt speaks of great quantities of Orchidaceæ in the Storax and Laurel woods of Java, growing along with Nepenthes, Rhododendrons, Magnolias, and Oaks, in a zone of vegetation whose lower limit is 3000 feet above the sea. *Dendrobium nobile*, *Renanthera coccinea*, and some others, bear the periodical cold of Canton, where it occasionally freezes; *Dendrobium catenatum* and moniliforme occur in Japan as far north as 37° or 38°, or the parallel of Lisbon, and are periodically subject to a very low temperature; and Dr. Royle met with the deciduous *Cælogynes* and *Dendrobium alpestre* on the Himalaya Mountains at the height of 7500 ft., where snow sometimes lies in winter for a week or more. To the southward they not only occur in the latitude of Port Jackson, where the mean temperature does not exceed 66° 6', but even in much higher latitudes. The beautiful little *Gunnia australis* grows on the branches of shrubs in Emu bay, in Van Diemen's Land, in about 41° S., and *Earina mucronata* extends to 45° 45' S., in 'the very permanently damp woods which clothe the shores of Dusky Bay in New Zealand,' where it was originally observed by Forster in Cook's second voyage, and where it has since been met with by Mr. Cunningham, whose words we quote.

Such are the more important data that we possess to guide us in the cultivation of orchidaceous epiphytes: the result of which is, that they are kept in this country in stoves the air of which is maintained in a state of constant moisture and at a temperature varying from 56° to 90° or more. The requisite uniformity of their atmosphere is provided for by keeping the houses but little ventilated and the glass of the roof well puttied at the junction of the squares. Shade is secured either by moveable laths or by a screen of netting or coarse canvass, or by some such contrivance; some even grow their plants in a house exposed only to the north: but it does not appear that this plan is a good one; for it is an object not only to exclude excessive light, but also to be able to admit it if requisite, and this cannot happen in a hothouse with a northern aspect.

The soil in which the plants are made to grow is peat or some other kind of decayed vegetable matter, thoroughly drained, and yet so compact as not to be liable to become dry by excessive loss of water. In many cases it is found advantageous to make the plants grow upon the apex of a truncated cone of earth rising several inches above the rim of the pot. Certain kinds are suspended in baskets, or in frames so contrived as to be filled with moss and decayed vegetable mould *rammed in very tight*; and provided that precaution is attended to, the caulescent drooping species, especially *Dendrobiums* and *Vanda*-like plants, thrive admirably; but in general it is found most advisable to plant in earth in common garden-pots. Attempts have been made to grow some species on decayed dead wood, but they are generally abandoned now; nor have the trials to cultivate them on the branches of living trees hitherto proved more successful. The orange tree was employed for this purpose by Mr. Lance with great success in Surinam; but in the hothouse it does not appear to suit them.

By attending to the natural habits of these plants, and observing the precautions just pointed out, the management of orchidaceous epiphytes has been brought quite within the skill of any good gardener. There are however two or three capital points about which cultivators entertain great difference of opinion.

The first is temperature. Some allow the thermometer to rise to 100° and higher in a summer's day, and never suffer it to fall below 65°; the consequence of which is, that their houses are so unpleasant that few persons can visit them to inspect the beautiful objects they contain. Others keep the temperature of even midsummer down to 80° at the most, and permit the minimum heat to be low in proportion: their houses are consequently cool and pleasant at all times. If we must admit that the first practice is eminently successful with some, so is the other most assuredly so with others, and we entertain no doubt that in the end it will be the only method followed.

The second question is the amount of moisture. Some form water tanks in their houses, the evaporation from the surface of which keeps the air continually at the point of saturation; others simply keep the air sensibly moist, by syringing or similar devices; the first is accompanied by a

high, the latter by a moderate, temperature; in this case also we incline to believe that the latter practice is the best. The fact is that it may be reasonably doubted whether it is right always to follow nature literally in what we suppose to be her practice, and whether we ought not rather to adapt the management of our plants to the new and artificial condition under which they are placed. Keeping plants in a state of constant excitement by exposure to an excessive climate is a certain means of weakening them in the long run, and may be compared to keeping an animal always awake. It may be very true that this may seem to happen in nature; but does it really happen? Is it not probable that the long diurnal darkness of a tropical situation may be intended as a compensation for the high excitement of daylight? and are not we, with 18 hours' daylight in summer, in an essentially different position from what orchidaceous epiphytes from equinoctial regions are exposed to in a wild state? Moreover, it can hardly be doubted that a moderate temperature is sufficient for them, even if they can be made to bear an excessive climate.

The third unsettled point is of another nature. In our hothouses we often maintain a high temperature all the year round, keeping our stove-plants growing from January to December. In nature this hardly ever happens. If a country has no winter, it has its dry season, during which plants become more or less torpid. This is quite the case in all the countries inhabited by orchidaceous epiphytes with the exception of some of the temperate parts of Mexico, where the climate is equal and mild. Should we not therefore give such plants, when cultivated, a similar period of repose? About this the opinions of cultivators are so much divided that we cannot say on which side the majority of votes would go. Mr. Bateman calls attention to the fact in his account of Colley's mission to Guiana. 'In consequence,' he says, 'of the unexampled length of the dry season, scarcely an orchidaceous plant was seen in flower, or a pseudo bulb which had not lost its leaves. When, however, the rains had commenced, that is, in the month of July, the Orchidaceæ were pushing rapidly into flower, as were also some of those collected by Mr. Colley, which reached this country in as dry and shrivelled a state as Dutch bulbs usually come over in. This may afford a hint for their cultivation.'

And Henchman, in like manner, urges the circumstance upon the consideration of gardeners:—

'The atmospheric changes,' he says, 'are very great in tropical climates; and, as I consider that Orchidaceæ derive their main support directly from the atmosphere, I think too much attention cannot be paid to the various changes by which they are in their natural state liable to be affected. One of the principal objects kept in view by growers of Orchidaceæ appears to be the keeping up a regular heat in the stove. Nothing can be more contrary to nature; for in the tropics, to a sultry day, with the thermometer standing at from 85° to 95°, succeeds a cool night and a cold morning, the thermometer falling to 60° or 55°; effecting in twenty-four hours a change of temperature of from 20° to 30°. During the dry season, periods of two, three, and often extending to five or six months, the whole nourishment derived by the Orchidaceæ must be communicated through the agency of the tree to which they are attached, or from the atmospheric moisture which is the effect of the action of the sun upon the dew which has fallen during the night and morning; for the situations generally occupied by Orchidaceæ preclude the possibility of the dew reaching them in its descent; and slight though the moisture be which is communicated through these channels to Orchidaceæ, it is nevertheless sufficient to retain the vital principle in the pseudo-bulb, though not sufficient to rouse it into action. The dry season then appears to act upon Orchidaceæ on much the same principle as our winter acts upon our trees, &c. It is for them a period of rest; and the pseudo-bulbs having been well ripened, are ready, when the wet season has given them a sufficient stimulus, to push forth luxuriantly both leaves and flowers.' Nevertheless some of our best gardeners object to the plan of periodical resting; and, it must be added, appear to succeed without attending to it.

So far as the opinion of the writer of this article is of any value, it is rather in favour of the system of resting these plants for three or four months annually, by lowering the temperature to 60°, or thereabouts, and diminishing the moisture very considerably; indeed in regard to *Catasetum*,

Cynoches, *Phaius*, *Bletia*, *Geodorum*, and some others, with deciduous leaves, there is no doubt that the plan is indispensable; and it would probably be equally advantageous with respect to all the kinds with fleshy stems or pseudobulbs; but how far it may suit caulescent species with the habit of *Vanda* and *Aerides* can only be ascertained by direct experiment.

EPÍRUS (Ἠπίρος, mainland), a name given to that district in Northern Greece which extended from the Ceraunian mountains on the north to the Ambracian gulf on the south, and from the Ionian sea to the chain of Pindus, probably to distinguish it from the large, populous, and wealthy island of *Coreyra*, which lay opposite to the coast. It appears that in very ancient times *Acarnania* was also included in the term, and in that case the name was used in opposition to all the islands lying along the coast. (Strabo, p. 453; Homer, *Odys.*, xiv. 100.) The ancient geography of Epirus was attended with great difficulties even in the time of Strabo; the country had not then recovered from the effects of the destruction caused by *Paulus Æmilius* in 167 B.C., who destroyed seventy towns, and reduced to slavery 150,000 of the inhabitants (Polyb. ap. Strab., p. 322; Liv., xlv. c. 34; Plut. *Æmil.*, c. 29), after which the greater part of the country remained in a state of absolute desolation, and where there were any inhabitants they had nothing but villages and ruins to dwell in. (Strabo, p. 327.) The inhabitants of Epirus were scarcely considered Hellenic. The population in early times had been Pelasgic. (Strabo, p. 221.) The oracle at Dodona was always called Pelasgic [DODONA], and many names of places in Epirus were also borne by the Pelasgic cities of the opposite coast of Italy (Niebuhr's *Hist. of Rome*, i. p. 34); but irruptions of Illyrians had barbarized the whole nation; and though Herodotus (ii. 56) speaks of *Theoprotia* as a part of Hellas, he refers rather to its old condition, when it was a celebrated seat of the Pelasgians, rather than to its state at the time when he wrote his History. In their mode of cutting the hair, in their costume, and in their language, the Epirotes resembled the Macedonians, who were an Illyrian tribe. (Strabo, p. 327.) *Theopompus* (apud Strab., p. 323) divided the inhabitants of Epirus into fourteen different tribes, of which the most renowned were the *Chaonians* and *Molossians*, who successively maintained a preponderance in this district. The *Molossians* claimed a descent from *Molossus*, the son of *Neoptolemus* and *Andromache*. *Neoptolemus* is said to have migrated from *Thessaly* into Epirus after the Trojan war, and to have settled there in obedience to the injunctions of an oracle. We hear nothing of his descendants till the time of *Themistocles*, who was hospitably received by *Admetus*, king of the *Molossians*, while flying as a persecuted exile from the reach of his enemies. (Thucydides, i. 136.) The other kings of the *Molossians* are mentioned between this period and the time of Philip of Macedon, when this kingdom rose into importance by the matrimonial connexion of Alexander of Epirus with the king of Macedon. Philip married Alexander's sister, *Olympias*, and gave him his daughter *Cleopatra* in marriage. (Diod. Sic., p. 557.) Alexander was the first of the *Molossian* princes who bore the title of king of Epirus. (Strabo, p. 280.) He invaded Italy to assist the *Tarentines* against the *Brutii* and *Lucani*, and was slain near *Pandosia*. (Liv., viii. 24.) After the death of Alexander, *Æacides* and *Alcetas*, the sons of his predecessor, *Arybas*, successively mounted the throne. *Pyrrhus*, the son of *Æacides*, is the best known of the sovereigns of Epirus. The family of *Pyrrhus* became extinct three generations after his death, and the government was turned into a republic, which subsisted till the year 167 B.C., when the Epirotes were suspected of favouring *Perseus* of Macedon, and utter destruction was, as we have already mentioned, inflicted upon them by the Roman general *P. Æmilius*. Of the other Epirotic nations, the *Thesprotians* were most celebrated. They are mentioned by Homer, who does not name the *Chaonians* and *Molossians* (*Odys.*, xiv. 315), and are considered by Herodotus to have been the progenitors of the *Thessalians*. (vi. 176.) In their territory were the oracle at Dodona, the old city of *Ephyræ*, and the rivers *Acheron* and *Cocytus*, celebrated in the old mythology. It is not possible to draw accurately boundary lines of the district occupied by these three tribes of the Epirotes: it is known that the *Chaonians* occupied the northern district, and the *Molossians* the southern, while the *Thesprotian* territory lay in the middle. The most celebrated cities in *Molossia* were *Ambracia*

P C., No. 591.

and *Nicopolis*. The former was a *Corinthian* colony, founded about 659 B.C. It had a harbour on the Gulf of Arta, and a small naval force. It contributed seven ships to the united fleet at *Salamis* (Herod. viii. 45), and twenty-six to their *Corinthian* expedition against *Coreyra*, just before the *Peloponnesian* war. (Thucyd. i. 46.) *Ambracia* sustained a very severe blow in the defeat upon the *Amphilochians* a short time after (Thucyd. ii. 68), but their losses were in some measure repaired by a new colony from *Corinth*. (Thucyd. iii. 105, &c.) *Pyrrhus* made *Ambracia* his usual place of residence. (Liv. xxxviii. 9.) It sustained a very remarkable siege during the war between the *Romans* and *Ætolians*. (Polyb. xxii. 13.) Under the *Roman* dominion it sunk gradually into insignificance, and its ruin was completed by the transfer of its inhabitants to *Nicopolis*, which was founded by *Augustus* to commemorate his victory at *Actium*. The ruins of this last city are very extensive. (Hughes's *Travels*, ii., p. 412.) The reader will find a minute description of the Gulf of Arta in the *Journal of the Royal Geog. Society*, vol. iii., p. 77.

The modern Albania corresponds in part to Epirus. As the domain of Ali Pacha, it has been a district of great interest in modern history, and *Suli* and *Parga* have become well-known classic names. [ALBANIA.]

Coin of Epirus.

British Museum. Actual size. Silver. Weight, 151½ grains.

EPISCOPACY. [BISHOP.]

EPISCOPIUS, SIMON (whose real Dutch name was *Bisschop*), was one of the most learned men of the seventeenth century, and the chief supporter of the anti-calvinistic doctrines advocated by his contemporary *Arminius*. He was born in the year 1583, at Amsterdam, where he received his school education. In 1600 he went to the then newly-founded university of *Leyden*, of which he became a distinguished member, and entered with zeal and great ability into the predestinarian controversy between the *Arminians* and *Gomarites*, which at that time excited a deep and general interest. He was ordained in 1610, as the minister of the village of *Bleiswyck*, near *Rotterdam*, and in the following year he was deputed to the office of *Arminian* advocate at the conference held at the Hague between the *Remonstrants* and their opponents, the *Calvinists*. It is a proof of the influence and of the acknowledgment of his superior theological learning that he was chosen to fill the chair of professor of divinity in the university of *Leyden*, as the successor of the celebrated Professor *Gomar*, whose doctrinal theory he had powerfully opposed. The predestinarian controversy was carried on shortly after with such virulence and popular excitement that *Episcopus* was not only exposed in the streets and in the pulpit to the greatest abuse and insult, but, on one occasion, barely escaped from being stoned to death. The predominant party of *Calvinists*, or *Gomarites*, treated him with great injustice and tyranny at the synod of *Dort*, to which he went as a deputy from the states of *Holland*. He was refused a hearing in behalf of the less numerous party of *Arminians*. He was told that the synod had met not to discuss but to judge; and it having been decreed that he and the other professors who formed the body of the *Arminian* delegates should neither explain nor maintain any point without being asked to speak, *Episcopus* and his colleagues refused to submit. They were, in consequence, expelled from the synod, and were subsequently deposed from the functions of the ministry and banished from the territory. *Episcopus* retired to France, and continued to write in defence of *Arminianism*, and to console and encourage his unfortunate brethren. In 1626, when sectarian animosity had somewhat subsided, he returned to *Holland*, and became the minister of the church of *Remonstrants* at *Rotterdam*. Finally, he was made rector of the college founded by the *Remonstrant* party at Amsterdam, where he died, in 1643, at the age of 60. His works were published collec-

Vol. IX.—3 Q

tive, in 2 vols. fol., entitled 'Opera Omnia Theologica,' &c., Curcellæi edita. Amsterdam, 1650, 1665, and 1671; and in London in 1678. They consist chiefly of the following treatises: 'Collegium Disputationum Theologicarum in Academia Leydensi,' Dordrecht, 1688; 'Fur Prædestinatus,' Dort., 1642; 'Antidotum adversus Synodi Dortdracensæ Canones,' 'Confession of Faith,' 'Popish Labyrinth, or a Treatise on Infallibility,' &c., English translation, London, 1763. The latter works were written on the occasion of the author's being solicited by Peter Wadingus, a learned Jesuit, to become a Papist.

The highest eulogiums have been bestowed on the abilities of Episcopius by Le Clerc, Mabillon, Grotius, Bishop Bull, and many other eminent scholars of different sects. In England he was closely imitated by Dr. Hammond and Archbishop Tillotson. In his controversial writings he descends occasionally to abusive expressions; but in extenuation of this failing it should be considered that his opponents overwhelmed him with the insulting calumny of a stronger party. It was among the least of their accusations that he was a Socinian, a charge which is not without some degree of evidence to support it, for he strongly maintains that, throughout the first three centuries, the pre-existence of Christ was not an article of faith; and the refutation of this position of Episcopius occasioned Bishop Bull a great expenditure of learning. (*Life of Episcopius*, by Limborch, and by Curellæus; *Life and Death of Arminius and Episcopius*, London, 1672, 12mo.; Moreri's *Dict.*; Chalmers's *Biog. Dict.*)

EPISODE (*ἔπεισος*, *epêisodos*). The Greek word *êisodos*, the principal member of this compound, when applied to the drama, means an entrance of the chorus on the stage; *epêisôdion*, that part of a play which lies between two choral songs; and as these recitations had, in the rude beginning of the Greek drama, no connexion with the choral part, which they were introduced to relieve, the word, with its derivative Latin form, comes to signify a thing connected with, but not essential to, that of which it is part,—which may be taken out and leave a perfect work;—as, for instance, the Catalogue of Ships, in the Iliad, or the War in Heaven, in Paradise Lost. Episodes should grow naturally out of the subject; and when judiciously used, they relieve and diversify the main narration. But they should be sparingly introduced, so as not to create confusion. In the Orlando Furioso, for instance, or the Fairy Queen, the episodes are so many and so long, that the whole resembles a set of detached legends inartificially patched together, rather than a single poem pervaded by one intention. Episodes are commonly the most highly-finished portions, since their shortness warrants a degree of elaboration and ornament which could hardly be maintained through a long composition, and indeed might be wearisome if it could.

EPISPASTICS. [BLISTERS.]

EPISTYLE, the first layer of stone placed on columns to form the architrave. The term is derived from the Greek *epistylum* (*ἐπιστύλιον*), and that from the words *epi* (*ἐπὶ*) 'upon' and *stylos* (*στῦλος*), 'a column.'

EPITAPH (*ἐπιτάφιος*, *epitaphium*), an inscription on a tomb; from *epi*, upon, and *τάφος*, a sepulchre. Inscriptions in honour of the dead are perhaps as old as tombs themselves; the most ancient however with which we are now acquainted are probably those of Simonides upon Megistias the soothsayer of the little army of Leonidas, and on the heroes who fell at Thermopylæ, preserved by Herodotus. (vii. 228.) Another epitaph of very high antiquity may be referred to in the ancient Greek inscription found in the Ceramicus at Athens, upon the warriors who fell at Potidæa 432 years B.C. The original, in a mutilated state, is among the Elgin marbles in the British Museum. (No. 348.) The reader will find examples of Greek and Roman epitaphs in the Elgin and Townley marbles of the British Museum, published under the superintendence of the Society for the Diffusion of Useful Knowledge.

The earliest epitaphs of this country were those of the Romans or Romanized Britons, which usually began with D. M. (*Dis Manibus*), followed by the name, office, and age of the deceased, and a conclusion which informed the reader by whom or through what means the inscription was erected. This seems to have been the ordinary formula of the sepulchral inscriptions of that period.

Whether the Saxons or the Danes used monumental inscriptions among us, either in their own or in the Latin

tongue, has been doubted. The few whom we have for people of the Saxon times are the compositions of a later date. Three or four small slabs, however, bearing crosses and some female names, supposed to be those of nuns, were dug up a few years ago at Hartlepool.

The regular series of English epitaphs begins in the 11th century, when they were still written in the Latin language. One of the most remarkable of this period is that preserved in Sir William Dugdale's Baronage, for William de Warren, earl of Surrey, who died in 1089, copied from the abbey register of St. Pancras Lewes, of which he was the founder, where it is said to have been engraved on white marble.

Hic Guilhelme Comes locus est laudis tibi domes
Hujus fundator, & largus sedis amator.
Iste tuum funus decorat, placuit quia munus
Pauperibus Christi, quod prompta mente dedisti.
Ille tuos cineres servat Pancratius hæres,
Sanctorum castris qui te sociabit in astra.
Optime Pancratie, fer opem te glorificanti;
Daque poli sedem, talem tibi qui dedit ædem.

A mutilated epitaph for Gundreda, daughter of William the Conqueror, and wife of this earl of Surrey, is still remaining in the church of Southover in Kent; she died in child-bed in 1085. The generality, however, of the epitaphs of this period are neither so long nor so laboured as the earl of Surrey's. Vitalis, the twenty-first abbot of Westminster, who died in 1082, had only these lines—

A vita nomen qui traxit, morte vocante,
Abbas Vitalis transit, illoque jacet.

In the 12th century our epitaphs are few. The tomb usually consisted of a single figure; and the inscription added to it was little more than a mere designation of the person: such as that at Hereford, of the year 1148,

Dominus Robertus de Retum episcopus Herefordensis;
or that in the chapter-house at Gloucester, 1176,

Hic jacet Ricardus Strongbow, filius Gilberti Comitis de Pembroke.

Early in the 13th century we begin to find the epitaph in French, occasionally accompanied by promises of absolution to such of those who passed the tomb as might pray for the soul of the deceased. Weaver gives an instance of this in his 'Funeral Monuments,' in an inscription for Robert the third earl of Oxford, who died in 1221.

Sire Robert de Veer le premier Count de
Oxford le tiers gît icy. Dieu de l'ame et loi
Piest face merci. Ki pur l'alme priera x.
Jors de pardon avera. + Pater noster, &c.

At the church of Kingwear in Devonshire we have an epitaph of this kind in rhyme—

Vos qui ici venez
Par l'alme Philip priez.
Trente jours de pardon
Serra vostre gverdon.

Henry the Third's epitaph, in the same language, with a prayer for mercy to him, still remains embossed in old capitals round the ledge of his tomb in Westminster Abbey, A. D. 1272.

The epitaph in French continued till the middle of the 14th century; after which time inscriptions in the vernacular tongue become common. One of the earliest, perhaps, was that upon a stone over one of the Savile family at Thornhill in Yorkshire,—

Bonyz amongg stongs lye ful
stryl, gwylyte the swile wanda
wara were that God wylethe.

Blomfield, in his 'History of Norfolk,' has preserved a curious specimen of the English of the time, in an epitaph from Holm Church in that county, about A. D. 1404:—

Henry Nottingham and his wyff lyn here
That mayden this church, stepull, and quere.
Two vestments and belles they made also,
Christ them save therefore fro wo!
And to bringe ther soules to bles of heven
Saith Pater and Ave with mylde steven.

Gough, in his 'Sepulchral Monuments,' whence much of our information has been obtained, gives the following from the church of St. Peter at St. Albans, 1420:—

In the yere of Christ on thousand and four hundred ful trow with bar and
sirene
I Richard Skipwith gentylman in birth late fellow of New inne.
In my age twent on my sowll partyd from the body in August the 16th day
And now I ly her abyding God's mercy under this ston in clay,
Desyryng yow that this sal see unto the Mayden pray for mee
That bare both God and Man,
Like as ye wold that other for ye shold
When ye ne may not cas.

The clergy and religious, however, still preferred Latin, perhaps, as their more familiar idiom; and one or two in

stances occur, even so late as the middle of the 15th century, where the epitaph is given in Latin rhyme. The last edition of Huthins's Dorsetshire mentions the following as engraved round the arch of the church door at Durweston near Blandford, A. D. 1459 :—

His jacet sub tumulo Downton Willielmus humatus:
Rector erat villæ Durweston; Oxfordie natus.

The generality of the Latin epitaphs of this period were on strips of brass, and began most frequently with *oratio pro anima*, perhaps followed by *miserrimi peccatoris*; an address, says Dr. Johnson, to the last degree striking and solemn, as it flowed naturally from the religion then believed, and awakened in the reader sentiments of benevolence for the deceased, and of concern for his own happiness. There was nothing trifling or ludicrous, nothing that did not tend to the propagation of piety and the increase of devotion.

With the reformation of religion even this ceased. The reign of Elizabeth affords but few instances to the contrary: though it is singular that two occur beginning 'pray for the soul,' upon monuments at Stanton Harcourt in Oxfordshire, one dated 1566, the other 1569.

After this period the diffusion of learning gave a classic turn even to the epitaph, and though the reigns of Elizabeth and James I. can furnish but few of a pure standard, there is one of Ben Jonson's on the Countess of Pembroke which scarcely yields to any in the Anthologia.

Underneath this sable hearse
Lies the subject of all verse:
Sidney's sister, Pembroke's mother.
Death, ere thou canst find another,
Good, and fair, and wise as she,
Time shall throw a dart at thee.

The epitaph on Sir Christopher Wren need hardly be repeated; though it is said to have been borrowed. In real merit it is probably surpassed by the latter part of that in King's College Chapel, Cambridge, over the resting-place of Thomas Crouch,—

Aperiet Deus tumulus; et educet
Nos de sepulchris.
Qualis eram, dies isthæcum
Venerit, ædes.

Wit and humour have also marked the composition of the epitaph in almost all ages. Innumerable instances will be found in all the printed collections. Margaret of Austria composed for herself the following couplet, when in imminent danger of shipwreck :—

Cy gist Margot noble demoiselle,
Deux fois mariée, et morte pucelle.

Collections of epitaphs, ancient and modern, are numerous; there are many of great merit in the Greek Anthologia. A very large collection of epitaphs will be found in 'Theatrum Funebre, exhibens per varias scenas Epitaphia nova, antiqua, seria, jocosa, &c., in quatuor partes distinctum, extractum a Dodone Richea (sen Ottone Aicher),' 4to. Salisburgi, 1675; Hacket's 'Select and Remarkable Epitaphs on illustrious and other Persons,' 2 vols. 8vo., 1757, probably preserves the best English collection.

The funeral orations of the Greeks were called by the name of *Lógos Epitaphios* (λόγος ἐπιτάφιος), or a discourse over the tomb made at the time of interment. It is only necessary to mention this to prevent any confusion of this kind of epitaph with that which is the subject of the present article.

EPITHALAM'IMUM (ἐπιθαλάμιον, from ἐπὶ, 'at' or 'near,' and θάλαμος, 'chamber,' especially that of a new-married couple), a poem composed in honour of a marriage. It was sung by youths and maidens conjointly, at the door of the bridal chamber, after the bride and bridegroom had entered, and also before they rose in the morning. The first Greek epithalamium known to have been written was a poem by Hesiod, now lost, on the marriage of Thetis and Peleus. The most remarkable extant are those of Catullus, who has left three beautiful specimens of this sort of composition. The first, on the marriage of Julia and Torquatus, is the most curious and interesting as an illustration of manners. That on the marriage of Peleus and Thetis, which is probably only a fragment, is one of the most beautiful extant specimens of Latin poetry. Among the Hebrews, as well as the Greeks and Romans, this species of rejoicing was in use. The subject is hardly in accordance with modern manners. Spenser has treated it beautifully and delicately in his Prothalamium and Epithalamium on the marriage of the Ladies Somers. Many other

English specimens may be found, especially among the writers of the seventeenth century: but we know of none remarkable enough to require notice.

EPOCH. (Astronomy.) This term is frequently applied to signify, not a moment of time, but the longitude which a planet has at that moment of time. In order to predict the longitude of a planet at any epoch, some preceding epoch must be taken, at which the longitude is known. This latter is called, *par excellence*, the epoch; and the term longitude at the epoch has been abbreviated into epoch.

EPOCH. (Chronology.) [ÆRA.]
EPODE (in Greek ἐπὶ ὁδῶς, after-song, from ἐπὶ, 'on' or 'upon,' and ὁδῶς, 'song') is one of the three divisions of the Greek ode. [CHORUS.] The performers in singing it stood still; it was not, like the strophe and antistrophe, symmetrical with another member of the ode; so that the poem was unfettered as to its length and as to the choice of measures. The epode, however, is not essential to an ode; many of the Greek choruses have none. Most of Pindar's odes, on the contrary, have an epode interposed between each antistrophe and the following strophe. Epode, according to the grammarians, is also a metrical term given to those measures in which a short verse follows a long one, of which the former is called *proodic*, the latter *epodic*. Hence the fifth book of Horace's Odes is called the Book of Epodes, because nearly all of them are written in that sort of measure: as, for instance,—

• Ibis Liburnis inter alta navium,
Amice, propugnacula.

EPPING. [ESSEX.]

EPSOM. [SURREY.]

EPSOM SALT. [MAGNESIUM.]

EQUAL. Two magnitudes are equal when one of them may be made to coincide with the other. This is the geometrical definition of Euclid, and is placed by him among the axioms, though in reality it is nothing more than the definition of the word equal. Nor is it quite sufficient: a triangle for instance and a parallelogram may be equal in area, and yet neither can, without alteration of form, be made to occupy the same space as the other. The truth is, that the idea of equality is one which will admit no definition: and moreover, it is to the more general notion of the existence of ratio (of which equality is one particular case) that all metaphysical discussion upon this term should be referred.

Some geometers have proposed to use the word equivalent as applied to solids of equal area but different forms: and the distinction is at least harmless. We cannot say more; for when it is once established that the term used by Euclid is to be understood in a wider sense than the words of the axiom will bear, no liability to confusion remains.

EQUATION (in pure mathematics), an assertion of the equality of two magnitudes, represented to the eye by the symbol =. Thus $A=B$ is to be understood as a proposition, declaration, or assertion that the magnitude A is equal to the magnitude B. It is not immaterial to insist upon this definition; for beginners frequently confound the notion of an equation (an *assertion* of equality) with the idea of equality itself, and speak of two *equations* being equal.

To treat of equations is to write on mathematics in general; for when two magnitudes A and B are of the same kind, A must be either greater than, equal to, or less than B. The objects of mathematics generally require that it should be determined (supposing A and B not equal) by how much one exceeds the other: and the assertion that A exceeds B, and exceeds it by M, is equivalent to the equation $A=B+M$. The assertion of inequality is called by continental writers an *inequation*: and one work (we are not aware of any other) has been written on the subject; Carnard's 'Traité des Inéquations,' &c.

An equation may be one of two kinds: necessarily true, whatever may be the value of the symbols employed, and called *identical*; or true only upon the supposition of some particular value being given to certain magnitudes, or of some particular relations existing. The latter species are called equations of *condition*. Thus—

$$a=a, \quad a+a=2a, \quad (a+b)^2=a^2+2ab+b^2$$

are identical equations: while

$$2a+1=13, \quad x^2=5x-7$$

are equations of condition; the first req.

be 6, and the second that x should be either 4 or 1. Again, $a+b=1$ is an equation of condition.

Certain equations being supposed to be true, the determination of all their consequences, that is, of all equations which follow from them, is the great object of mathematical analysis. The difficulties which lie in the way are of various classes, and give rise to various modes of considering equations. These are so widely separated from each other, and diverge into such different subjects, that we can here do no more than point out two or three of the most remarkable species of inquiries. This we shall do in short articles headed by the word EQUATION.

EQUATION. (Astronomy.) The characteristic of all the heavenly motions is, that they nearly follow a simple law, but not quite. The small corrections which must be added to or subtracted from the results of the simple law, in order to secure accurate prediction, are called equations. Thus, the moon moves round the earth with a motion which is not very far from uniform; the average motion is therefore ascertained, and, starting from a given epoch, at which the true place is known, the longitude for that epoch is first increased by the longitude which would have been described by the moon, had she moved with her average motion. The result must then be altered by a number of different equations, some being consequences of the elliptic figure of the moon's orbit, some of the sun's attraction, &c. When all these equations have been annexed, the result is the moon's longitude for the time proposed.

EQUATION OF THE CENTRE. [SUN, MOON, &c.]

EQUATION OF THE EQUINOXES. [PRECESSION.]

EQUATION OF TIME. [SUN.]

EQUATION, ANNUAL. [MOON.]

EQUATION OF PAYMENTS, an arithmetical rule, for the purpose of ascertaining at what time it is equitable that a person should make payment of a whole debt which is due in different parts payable at different times. This rule is now of no practical use, as it rarely, if ever, happens that it is considered necessary to *equate* payments. Sums of money due at future periods are generally secured by bills of exchange or by promissory notes, and when the date of payment is altered, it is usually immediate payment which is contemplated. [INTEREST.]

EQUATIONS, COMMON ALGEBRAICAL. In these the question is to find what number or expression must be substituted for a letter, in order that an equation may be true. Example, what must be the value of x , in order that

$$x^2 = (a+b)x - ab$$

the answer is x is either $= a$ or $= b$: meaning that, if the equation be true, x must be one of the two, a or b . These results are called values of x , roots of the expression $x^2 - (a+b)x + ab$, or solutions of the equation.

We ought in this place to give some account of the history of inquiries, which at one time composed the whole of algebra, and are still considered of fundamental importance. But here, as in some other cases, we are induced to defer the consideration of the subject to as late a period as we can, on account of the rapid progress which is being made on points which have presented difficulty for centuries. The mere mention of the very recent researches of M. Sturm in France, of Mr. Jerrard in England, &c., will be, to those who understand the subject, a sufficient excuse for our referring to THEORY OF EQUATIONS; this being, moreover, the most common title of the subject in question.

EQUATIONS, DIFFERENTIAL, and EQUATIONS OF DIFFERENCES. The difficulty in this case is the inversion of the processes of the Differential Calculus and the Calculus of Differences. We give an example of each case:—

$\frac{d^2y}{dx^2} - \frac{dy}{dx} = x$; is a differential equation. The question

asked is, what is y , that function of x , of which it is the property that the first differential co-efficient subtracted from the second will always leave x .

$\Delta y = y+1$, is an equation of differences. The question asked is, what must y (understood to be a function of x) be, in order that an increase of a unit in the value of x shall increase y by $y+1$. This is in reality a simple functional equation, as follows. Required ϕx , so that

$$\phi(x+1) - \phi(x) = \phi x + 1.$$

The two classes of equations, thus briefly noticed, include in their history that of most of the mathematico-physical sciences. The progress of the theory of gravitation since Newton is contained in successive attempts to solve certain

differential equations. All questions of dynamics, electricity, the theory of light and heat, &c. &c., resolve themselves at last into the solution of differential equations. Works on the differential calculus contain but little on this subject, its utility considered: and it is to the applications themselves that the student must look for further information.

EQUATIONS, FUNCTIONAL. In this case the question is to find the form of a function which will satisfy certain conditions. For instance $\phi(x^2) = \phi x + 1$. Here the question asked is, what is that algebraical expression which will be increased by 1, whatever may be the value of x , by changing x into x^2 . [FUNCTIONS, CALCULUS OF.]

EQUATOR and ECLIPTIC, the two principal circles of the sphere. The first is that circle of the apparent celestial sphere which is in all points equally distant from both poles; the second, the circle through which the sun appears to move. The equator is so called from being the circle on the arrival of the sun at which the day and night become equal. The ecliptic derives its name from being the circle on which (or near which) the moon must be in the case of an eclipse. [SPHERE, DOCTRINE OF THE.]

EQUATORIAL INSTRUMENT. This name is generally given to astronomical instruments having their principal axis of rotation in the direction of the poles of the heavens. When the purpose of a machine of this nature is simply to carry a telescope, it has been called a *machine parallactique* or *parallatique* by the French, and sometimes *polar axis* by English writers; but we shall include both in this article.

The complicated system of circles which formed the astrolabe of Hipparchus, described by Ptolemy (Almagest, lib. v., cap. i.), was made moveable on two pins, which marked the places of the pole in a metallic meridian circle, and thus may be called in some sort an equatorial. There is an excellent plate of the astrolabe in the title-page of Halma's translation, tom. i. This instrument and the copies which were made of it afterwards, according to Ptolemy's description, by the Arabs and by Walther of Nuremberg, were designed for observing the longitude and latitude of a heavenly body directly. The torquetum of Regiomontanus was for the same purpose, using surfaces instead of axes to determine motions, but we know not whether it ever was actually made. Tycho seems first to have seen the immense superiority of the simpler instrument, which sufficed for determining right ascension and declination; and the genuine equatorial is therefore due to him. In his 'Astronomice Instauratæ Mechanica,' Noribergæ, 1602, we find the figures and descriptions of three 'equatorial armillæ' of different sizes and constructions: in one, the diameter of the meridian circle was 7 cubits, or 10½ ft. (For Tycho's equatorials see ASTROLABE.) In the 'Rosa Ursina' of Scheiner, Bracciani, 1626-30, p. 350 et seq., there is a plate and description of an equatorial mounting, invented by Gruenberger, to be used with a lens or telescope, for forming an image of the sun—the mode of observation then in vogue,—or, with a telescope, in the modern manner for viewing the moon, stars, and other phenomena. Gruenberger's equatorial is almost identical with that described and figured by Cassini as his *machine parallactique*, 'Mémoires de l'Académie,' 1721, p. 16, and which is also drawn and described under the same name by Bailly, 'Histoire de l'Astronomie Moderne,' vol. i., p. 601, plate v., fig. 38; and by Lalande, 'Astronomie,' 1792, § 2400, et seq., plate xxiv. In 1674 Hooke published his 'Animadversions' on the first part of the *Machina Cœlestis* of Hevelius. In this remarkable tract he describes, p. 67 et seq., tab. 2, fig. 15, the polar axis, on which he proposes to fix his quadrant for measuring intermutual distances, and 'the watch-work, which is to make it move round in the same time with the diurnal revolution of the earth.*' The regulator of the watch-work is a ball and string, describing a conical surface. When so near an approach had been made to this great desideratum in telescope-mounting, it is somewhat remarkable that nearly 150 years should elapse before it was realized. The astronomical sector with which Flamsteed observed at Greenwich from 1676 to 1689 bears

* Hooke asserts that a clock with a circular pendulum was invented by him in 1666, and complains that Huyghens had published a description of this (in 1674) 'without naming him at all as concerned therein.' Huyghens says that he invented the clock with a circular pendulum about the same time that he applied the oscillating pendulum, i.e., sixteen years before the date of his book, and that several clocks of this description had been made, 'non sine successu,' in the mean time. Both Hooke and Huyghens promise a complete description of this clock at another opportunity.

so strong a resemblance to the quadrant and stand described in Hooke's tract, that we are inclined to attribute the merit of its contrivance to Hooke, particularly as he recommends the artificer Tompion as 'having been employed by him to make that which he had.' Flamsteed's instrument was a sextant mounted upon a polar axis; and a description of the instrument, with a plate, will be found in the '*Historia Cœlestis*,' vol. iii. p. 103.

The next step in constructing the equatorial was made by Roemer, to whom we owe the transit and circle, and whose merits as an astronomical mechanic surpass even his great countryman Tycho. According to Horrebow, *Basis Astronomica*, p. 39, tab. 1, the equatorial of Roemer was erected about 1690. Here we have the second essential to the instrument, a telescope mounted on a cross axis, which is placed at right angles to the polar axis; (this is sometimes called the declination axis, from carrying the declination circle, or transit axis from its analogy to the transit.) In this construction the telescope can be pointed in every direction, and we have heard Roemer's general idea recommended by a very competent judge as that which he would now follow in mounting a 20-foot telescope. Graham's differential sector and Sisson's equatorial are described in Vince's '*Practical Astronomy*,' § 136 and 140, with figures. In both these instruments there is a long polar axis, supported at its upper and lower extremities; the telescope, with its circle or sector, is placed on one side and towards the middle of the axis.

A portable equatorial stand for carrying a reflecting telescope was invented by Short, and is described and figured in the '*Phil. Trans.*' for 1749. This must have been a very rickety affair, judging from the plate. In 1771 Nairne gave a description and figure of a much better instrument in the same work; and in 1772 or 1773 P. and J. Dollond published an account of a 'universal equatorial instrument, or portable observatory,' which in firmness and contrivance is very similar to that of Nairne. This construction, with some slight variations, was followed by Ramsden, in a portable equatorial made for Sir George Shuckburgh in 1779. All these portable equatorials labour under this serious defect; the telescope cannot be pointed on the same star in reversed positions, nor upon any star within 30° or 40° of the pole. Lalande, in his *Astronomie*, § 2413, pl. xxvi., gives an account of an equatorial made by Megnié, for the President de Saron, in which this difficulty is overcome by fixing the telescope at the extremity of the cross axis so as to overhang the hour circle. A very beautiful universal equatorial, in which the same position of the telescope is adopted, was constructed by Troughton, a plate and description of which will be given at the latter end of this article. There are some equatorials by Nairne and Adams which have a telescope at one end of the cross axis, but we are not aware of any plate or description.

A new era in the equatorial commences with the construction by Ramsden for Sir George Shuckburgh in 1791, which is very elaborately described with plates in the *Phil. Trans.*, 1793. In this instrument the telescope and declination circle form a complete and symmetrical transit circle, which is supported at its extremities by two assemblages each of three long parallel brass tubes forming the polar axis. The upper ends of these tubes are set into a circular open frame, from the centre of which the top pivot rises, and their lower ends rest on the base of an inverted cone which has the bottom pivot at its vertex. The polar axis is so long as to allow the telescope to revolve completely, and the object-glass is large enough to give a sight of the pole through the upper circle. The general form of this instrument is followed with some variations in almost every considerable English instrument which has been since made with the view of being used to measure with the circles. All have had a long polar axis supported at the extremities, and divided in the direction of its length into two limbs or cheeks, within which the declination axis is supported as a transit between its piers. Of this kind are the equatorials of Cambridge and Brussels, of Armagh, described in Rees's *Cyclopædia*, and of Camden Hill, described by Troughton, and figured in the *Phil. Trans.* for 1825, in the Preface to Herschel and South's *Observations of Double Stars*.

After Fraunhofer had succeeded in forming larger and better achromatic object-glasses than had hitherto been thought possible, he chose for a stand one which is in principle identical with the Machine Parallatique, only having

the telescope hung on one side exactly as in the portable equatorial of Megnié. To these he applied a very ingenious clock movement, which greatly facilitated the optical use of the instrument, and rendered it a better micrometrical measurer than had existed. To prevent the telescope from bending, Fraunhofer applied a system of balance weights, which were, we believe, invented or brought into extensive use by Reichenbach. It would probably have been better if he had made the telescope stiff, by bracing a form, and had omitted the balance weights for the telescope altogether. It is evident, from their construction, that the least jar or roughness in handling the telescope must set the weights in motion, and consequently ruin the action of the object-glass until they come to rest; and it is not worth while to purchase a little useless accuracy in the measurement with the circles at such a cost. There is a considerable inconvenience in this construction: that in many positions a star cannot be followed from one side of the meridian to the other without bringing the telescope over; that is, turning the polar axis and the telescope each of them half round. This is particularly disagreeable in the measurement of double stars, which ought, if possible, to be observed near the meridian. There is, perhaps, a little more inconvenience in giving small motions to the telescope; but neither this nor the impossibility of using reversed observations in a majority of instances is of much consequence. On the other hand, when the workmanship and material and engineering are good, an instrument of this form may be expected to stand better in adjustment, and to admit of larger dimensions, and to require less room, than any other.

The most celebrated of Fraunhofer's equatorials is one which is erected at Dorpat, and has been described by Professor Struve. (*Beschreibung des grossen Refractors von Fraunhofer*, Dorpat, 1825, folio, with plates.)

Some enormous telescopes have been mounted on this principle: one carrying the largest achromatic telescope we believe in existence, of 14 inches aperture and 25 feet focal length, was erected at Markree Castle, county of Sligo, for E. J. Cooper, Esq., by Mr. Grubb, of Dublin. The tube of the telescope was constructed under the direction of Mr. Cubitt, and is a capital step in the art of applying large telescopes. The form is that of a very long barrel. T bars of wrought iron extend longitudinally from the object to the eye end, the edge bars being directed towards the centre, and these, after they are connected crosswise by strong rings, are covered with iron plate, which is $\frac{1}{4}$ inch thick in the centre and $\frac{1}{8}$ inch at the extremities. The stiffness of this tube is more perfect than would be readily believed without actual examination, and we see no reason to doubt that a telescope, of at least twice these dimensions, may be mounted with success, so far as the tube is concerned, whenever such an object-glass can be procured. In all the other large equatorials which we have seen, the telescope is the weakest part; and as it is the habit of many observers to move their instruments by laying hold of the eye end, it is desirable, for this and for some better reasons, to have it as stiff as possible. In an equatorial to carry a 20-foot telescope now constructing for the observatory of Cambridge, at the expense of his grace the duke of Northumberland, and of Ramsden's form, though with many peculiarities and improvements, Mr. Airy has employed a square wooden tube, which promises to do very well. Mr. Dollond has recently made several equatorials on Sisson's construction, which answer very well. The polar axis in these is square, and composed of four strong slabs of wood, making a sort of tube, a little tapered towards the extremities. This is found to be abundantly stiff and firm, at least up to the dimensions which have been tried, viz., for telescopes of from 10 to 12 ft. focal length.

Though the problem of mounting a large telescope equatorially is not yet fully solved, yet great progress has been made in the last half-dozen years, and we may mention, as the results of recent experience, that it is not expedient to rest the pivots on small superficial bearings, or to relieve the weight by friction rollers, unless the axis of the rollers be made large. It appeared, in Mr. Cooper's equatorial and elsewhere, that when a heavy pressure was laid on a small bearing, the surfaces did not slip freely, but clung as it were, causing small oscillations about the position of rest. Again, great care should be taken in following Sisson's construction, or that which we have described as Ramsden's, to provide against any twisting in the axis; simple flexure is of

little importance. In Sisson's construction, the junction of the telescope and its cross axis should be very firm; in Ramsden's, the union of the two sides of the polar axis with the base should be such as to prevent all wriggling; and in both, the telescope ought to be very stiff, if it is likely to be roughly handled. To Ramsden's we should apply steadying rods. It is also better to rest the pivots of the declination axis in Ys than in collars; but if a collar is preferred, it should be formed of an upper and lower half, which can be adjusted to clasp the pivot close when the collar wears loose. After all possible precautions, accuracy is not to be expected from a large equatorial, when used as an instrument measuring with its circles, compared with those of moderate size. The equatorial by Troughton, at Armagh, which is perhaps the finest instrument existing as a measuring circle, carries a telescope of only 42 inches focal length and $2\frac{1}{2}$ aperture, with an hour circle of 5 feet, and yet the telescope is more powerful than the circles used. Large equatorials are required whenever optical power is wanted, as in the examination of nebulae, noting occultations, &c., where the micrometer is alone required for measurements, as in observations of double stars, or determinations of the diameters and forms and constitutions of planets, and investigation of the systems of those which have rings, satellites, &c.

The adjustments of an equatorial instrument are easy enough to a person tolerably familiar with the management of other astronomical instruments; and the corrections which are to be applied to observations made with an unadjusted equatorial, ought not to present any difficulty to an astronomer acquainted with spherical trigonometry, and with the ordinary rules for determining the value of the coefficients. Still, as there are many persons possessing equatorially-mounted telescopes, who have not the knowledge or even the leisure to understand this subject thoroughly, we shall proceed to give directions which will enable any one to adjust his instruments with more than sufficient accuracy and without trouble.

We suppose the latitude of the place and the direction of the meridian to be approximately known; and we shall always speak as if the instrument showed north polar distance, and the hour circle, when the sun is observed, read as an ordinary clock. Let the polar axis be placed nearly in the direction of the poles of the heavens. The adjustments proceed in the following order:—1st. The polar axis is placed at the altitude of the pole. 2nd. The indices of the declination circle are made to read 0, when the telescope points to the pole; this is sometimes called correcting the collimation in declination or north polar distance. 3rd. The pole of the instrument is brought into the meridian, and as it has already been set at the proper altitude, it now coincides with the pole of the heavens. 4th. The line of sight of the telescope is made perpendicular to the declination axis; this is similar to the collimation adjustment in the transit. 5th. The declination axis is placed exactly at right angles with the polar axis, if the means of adjustment are allowed. 6th. The hour-circle is made to read 0^h, when the telescope is in the meridian of the place.

1st. Observe any known star in north polar distance, and then turning the polar axis half round, observe the same star again; these observations should be as near the meridian as possible; and if the instrument is much out of adjustment, the star should not be very near the pole. Take the mean of the two observations, which is the distance of the star from the pole of the instrument, correct it for refraction, and then compare the result with the true north polar distance given by the Nautical Almanac, or computed from a standard catalogue. If the star be above the pole, and the instrumental north polar distance be *greater* than the true north polar distance, it is clear that the instrumental pole is farther from the star than is the pole of the heavens, or that it is too *low*; but if the instrumental north polar distance be *less* than the true north polar distance, then the pole of the instrument is too *high*. Correct this error by the proper screws for raising or depressing the polar axis, which may be done at once if the thread of the screw and the length of the polar axis be known.

2nd. Take half the difference of the above two observations; this is the index error of the declination verniers or microscopes, and they must be moved just so much in the proper direction by their adjusting screws, and set, if there be more than one, at their proper distances. The polar distance read off will now correspond with the true instru-

mental polar distance in every position of the instrument. Several pairs of observations should be taken, in order to ascertain these two errors with great accuracy before they are finally corrected and considered to be settled.

3rd. Turn the instrument six hours from the meridian either way, and observe the north polar distance of any known star not very near the pole nor yet near the horizon. Correct this for refraction. We will suppose the star observed to the east of the meridian, and that the observed distance exceeds that given by the Nautical Almanac or the standard catalogue; then the pole of the instrument is further from the star than is the pole of the heavens, or is to the west of its proper place; hence the upper pivot must be shifted to the east, or the lower pivot to the west, the proper quantity. In this, as in the former case, several stars should be used for greater accuracy; but there is no necessity for reversed observations, as the index error is already supposed to be corrected, or at least to be known, and therefore easily allowed for. The polar axis is now adjusted both in altitude and azimuth.

4th. Observe the transit of an equatorial star over the middle vertical wire or mean of the wires, note the time, and read off the verniers of the hour-circle. Turn the polar axis half round, and observe the same star a second time exactly as before. Now if the time between the two observations corresponds exactly to the difference between the two readings of the hour circle, all is right; if not, it is evident that one of the transits has been observed too early, and the other too late, on account of the erroneous position of the wires. If the time elapsed be *greater*, by 6^s suppose, than the difference of the hour angles, the first transit has taken place 3^s too early and the second 3^s too late. Set again upon the star and observe how far it appears to travel in 3^s; and then, if the instrument is in the first position, move the wires this quantity in R.A. with the star, and *versâ vice* if the instrument be in the second position. The rule *mutatis mutandis* will apply to any case, and where there are no means of measurement and no mark, the adjustment must be made by repeated trials. With a micrometer in R.A., or with a mark, it may be performed with accuracy at once.

5th. This adjustment may be performed in two ways, either astronomically, or, when there is a level attached to the declination axis, mechanically. In the first case observe the transit of a star, not less than 45° from the equator, in reversed positions of the polar axis, exactly as in determining the collimation. Since an elevation of the west end of the declination axis causes the line of sight to describe a circle to the east of the pole, all the transits observed in that position will be too early, and *versâ vice* all will be too late when the east end is high. Again, if the west end is too high before reversing, the east is too high after reversing; so that an error of inclination has a different effect upon observations in reversed positions, and thus the interval is increased or diminished by twice the error of a single observation. The law of the error is that it varies as the tangent of the star's declination. Suppose the star observed to have 45° declination, and that the interval between the observations is, according to the clock, 3^m 8^s, and according to the hour circle only 3^m. It is evident that the first observation was 4^s too early and the second 4^s too late, and since the tangent of declination = 1, the west end of the declination axis was elevated 1' in the first position and depressed 1' in the second. If the star had had any other declination, as δ , the 4^s should have been divided by the tangent δ before it was converted into an arc. There is a second astronomical method which may perhaps suit some observers better, though less satisfactory, as it depends entirely on the accuracy of the position of the polar axis in azimuth. Having clamped the hour circle very firmly when the instrument is nearly in the meridian, observe the transits of some stars near the equinoctial and others distant from it. If the distant stars agree in giving the same clock error with the stars near the equinoctial, the declination axis is rightly placed in respect of inclination; but if not, then, taking the clock errors from the equatorial stars, it will readily be seen whether the stars between the pole and equator pass too early or too late. If they pass too early, the west end is high, if too late, the east end is high, and the inclination of the axis in arc is equal to $15'' \times \frac{\text{error in time}}{\tan. \delta}$. In both these astronomical modes no error of collimation is supposed to exist.

The mechanical adjustment varies a little according as the level is applied. [LEVEL.] This may rest with its Ys upon the pivots of the declination axis, as in the altitude and azimuth circle [CIRCLE] and transit [TRANSIT], or hang from two cylinders, which, being fixed on the declination axis and parallel to it, project so far as to allow a level suspended from them to swing clear of the axis in all positions of the telescope. Place the declination axis horizontal by the level, and read the hour-circle, turn the polar axis half round, and place the declination axis horizontal again, and again read the hour-circle. If the readings are the same (or where the graduation is to 24^h, differ exactly 12^h) in both positions, the declination axis is adjusted, but if not, place the hour-circle half way between the positions it actually has and that which it ought to have, and make the declination axis horizontal by raising or depressing the screws which adjust it. The swing level requires a preliminary adjustment, that of making the cylinders from which it hangs parallel to the declination axis, which is to be performed thus—By turning round the telescope, bring the level directly below the declination axis; and by turning round the polar axis, bring the bubble into the middle, and clamp the hour-circle. Turn the telescope half round, when the level will be directly above the declination axis. Then, if the bubble run towards one end, bring it half way back by the screws which raise one of its supports, and the other half by the tangent screw of the hour-circle. The process must be repeated till it is satisfactory. The level itself is to be adjusted, as all levels are, by reversing it end for end on its cylinders.

6th. The instrument having been placed in the meridian, and clamped there, the hour-circle verniers, or microscopes, are to be set to mark 0^h. If the observer have the means of getting his time with tolerable accuracy, he may perfect this adjustment thus: Clamp the instrument approximately in the meridian, observe the transit of one or more known stars not far from the equator, and correct the time of observation for the known error of the clock. Then, as the right ascension of the star = true sidereal time of observation \pm true hour angle from the meridian, the true hour angle is known, and the verniers, or microscopes, may be set to mark it. Or the declination axis may be set horizontal by the level, when, if the previous adjustments have been properly performed, the instrument is in the meridian, and the verniers or microscopes set to mark 0^h.

By attending to these rules and repeating the operation (stars near the pole may be safely used the second time), the instrument will be found to be very nearly in adjustment, and it is desirable that it should be so. The computation of instrumental corrections is tedious and perplexing, and most ordinary observers would blunder in the attempt; after all, the results of an equatorial, used as an *independent* instrument, are little to be relied upon. Except for observations of N.P.D. near the meridian, in reversed positions of the polar axis, as described in the first and second adjustment, the best equatorial must always be inferior to an indifferent vertical circle. Out of the meridian the careful observer will always use it as a differential instrument, which is its peculiar destination.

In the rules above given it will be remarked that the observer is directed, in every case but the 3rd, to place the instrument nearly in the meridian. This is the most favourable position of the instrument in its ordinary construction as regards symmetry and strength. Besides this advantage, the computation for refraction in or near the meridian is very simple, being the same in N.P.D. as in zenith distance*, while it is 0 in R.A. For the third adjustment the formula of computation, where great accuracy is not required, is refraction = $57''.77 \times \tan \text{N.P.D. of star}$, or the ordinary formula for refraction in altitude, using the star's polar distance instead of its zenith distance. The formula is more accurate the nearer the star is to the pole, but in these latitudes will be sufficiently correct if the N.P.D. do not exceed 60°. An adjustment within 10'' may be considered to be close enough for all practical purposes.

The equatorial, being thus adjusted, is ready for use, and may be turned upon any star at pleasure. Suppose it is required, at sidereal time 13^h 14^m, to find a star, the R.A.

of which is 17^h 33^m, N.P.D. 67° 28'. As the R.A. of the star is greater than the sidereal time, the star has not yet come to the meridian, or the hour angle is east. Subtracting 13^h 14^m from 17^h 33^m, we have 4^h 19^m for the east hour angle. Turn the telescope to the east, and set to the reading 12^h — 4^h 19^m, or 7^h 41^m of the hour-circle*; then set the declination circle to 67° 28' N.P.D., and the star will be nearly in the centre of the field. With a little habit an observer can make an approximate allowance for refraction by taking away a few seconds from the hour angle, and a minute or two from the N.P.D. If the star be very near the horizon, the usual course is to put on a low power to the telescope, and, having thus found the star, to set the telescope exactly upon it, and then to apply the power best adapted to the observation in view. The telescope being clamped in N.P.D. will follow any star by moving the instrument round in R.A. with an angular velocity equal to the apparent motion of the heavens. This motion is best given by clockwork, which is now coming pretty generally into use; and, indeed, for the measurement of double stars, the observation of occultations, eclipses of Jupiter's satellites, and all optical and micrometrical purposes, is nearly indispensable.

It is not necessary actually to correct each adjustment before proceeding to the next, and the errors in R.A. may be determined at the same time with those in N.P.D. by any person who understands the mysteries of a simple equation and the *law* of the errors. As the subject has not, we believe, been treated very satisfactorily, at least in any English publication, we shall proceed to deduce the errors and corrections of an equatorial every way out of adjustment from observations.

July 8, 1836.

| Star | Face of Dec. Circle. | Sidereal Time. | | | Observed Hour-Circle. | | | Observed N.P. Distance. | | |
|--------------------|----------------------|----------------|----|------|-----------------------|----|------|-------------------------|----|----|
| | | h. | m. | s. | h. | m. | s. | ° | ' | " |
| β Urs. Min | E. | 14 | 53 | 14.5 | 0 | 2 | 56.6 | 15 | 15 | 5 |
| Ditto | W. | 15 | 4 | 53.8 | 0 | 14 | 16.8 | 15 | 8 | 55 |
| α Urs. Maj. | W. | 17 | 1 | 8.0 | 6 | 8 | 45.8 | 27 | 16 | 52 |
| δ Aquilæ | W. | 19 | 18 | 11.8 | 0 | 2 | 15.2 | 87 | 11 | 21 |
| Ditto | E. | 19 | 29 | 41.3 | 0 | 13 | 48.4 | 87 | 17 | 36 |

The sidereal time is corrected for the error of the clock, and the mean readings of the hour-circle and declination circle are corrected for refraction.

The instrumental N.P. distances, instrument east, are larger than those, instrument west, and the difference is

| | |
|--------------------------|-------|
| for β Ursæ Minoris | 6' 20 |
| for δ Aquilæ | 6 15 |

Mean 6 17.5 = double index error.

or the index error is 3' 8.7'' to be subtracted inst. E, and added inst. W.

Again taking the mean of the N.P.D. inst. E. and W.

| | Inst. N.P.D. | N.A. Alm. | Differ. |
|----------------------|--------------|-----------|---------|
| β Ursæ Minoris | 15 12 5.0 | 15 10 17 | 1 48 |
| δ Aquilæ | 87 14 28.5 | 87 12 23 | 2 5.5 |

Mean 1 56.7

and as the instrumental exceeds the true N.P.D. and both stars are above pole, it follows that the pole of the instrument is *below* the pole of the heavens.

α Ursæ Majoris is nearly in the 6 hour meridian west, and therefore in a proper position for determining the azimuthal deviation of the pole: we shall suppose it is exactly at 6 hours from the meridian. Correcting for the index error, we have $27^{\circ} 16' 52'' + 3' 9'' = 27^{\circ} 20' 11''$, for the instrumental N.P.D., whereas the Nautical Almanac gives the true N.P.D. of this star = $27^{\circ} 21' 42''$. The difference is 1' 41'', which is the quantity by which the pole of the instrument is to the west of the pole of the heavens. We have therefore determined the error of the polar axis and the index error of the declination circle, which may be corrected, if necessary, by altering the screws.

* The refraction in N.P.D. may be taken from any of the tables, as the zenith distance is equal to the N.P.D. of the star, after subtracting the colatitude for the upper culmination and adding it for the lower. The correction is to be added to the instrumental N.P.D., when the star is south of the zenith or sub-pole, and to be subtracted when the star is between the pole and zenith.

* The hour angle reckoned from the meridian is always the difference between the sidereal time and the R.A. of the star. When the sidereal time is less than the R.A. of the star, add 12h to the sidereal time, and then, after subtracting the R.A. of the star, you have the reading of the hour-circle, according to the graduation into two twelves. If the graduation is from 0h. to 24h, add 24h instead of 12h to the sidereal time, and subtract the R.A. as before.

the star be above or below pole, which even careful and experienced computers can scarcely at times avoid. In any case the graphical process will afford a very useful check.

The effect of the displacement of the polar axis upon the readings of the hour circle may easily be gathered from the same figure. Suppose the two lines PS and ps to be continued till they meet at the star, and to be produced, if necessary, until they cut the equator in Σ and σ . The reader may imagine or draw the figure. If the star be north of the equinoctial, the lines $PS\Sigma$ and $ps\sigma$ cross at the star, and the hour angle corresponding to p is to the east, and greater than the hour angle corresponding to the true pole P . Hence the reading of the hour circle is too small in the case represented in the figure, or $\Sigma\sigma$ is to be added to the reading of the hour circle. Also, since $\sigma\Sigma : Pk :: \sin. \delta : \cos. \delta \therefore \Sigma\sigma = Pk \times \tan. \delta$. Again,

$$Pk = mv - mw$$

$$= pm \times \sin. mpv - Pm \times \sin. mPw$$

$$= x'' \times \cos. \text{east hour angle} - y'' \times \sin. \text{east hour angle}.$$

The reader will have no difficulty in following out the rules with regard to the signs of the correction in each particular case, but it will be much safer and quite accurate enough to take the value of Pk from the figure and to multiply it by $\frac{1}{2} \tan. \delta$ for the correction. As a practical direction we have found this convenient. Join Pp , and produce it both ways. Then according to this figure, the correction is additive to the hour circle reading for all stars having north declination which are observed on the south side of Pp produced, and *versâ vice* for stars on the north side. The tangent of declination is negative when the star is south of the equinoctial, and the rule is reversed. There is no correction for stars in the direction of Pp , that is for stars having an east hour angle from the south or a west hour

angle from the north, such that its tangent $= \frac{x}{y}$. After this

correction has been applied, the index error of the hour circle may be deduced in the manner pointed out.

It sometimes happens that an observer, from carelessness or want of time or knowledge, does not determine the position of the pole of the instrument by the best means, viz., by observations in the meridian and at 6 hours from it, but that this position is to be deduced from a higgledy piggledy mass of observations made in different parts of the heavens. To form equations such as we have just given for each observation, and to solve them by the method of minimum squares, might possibly be the most accurate mode; but the labour would be very great, and on such an object very much mispent. We have found the graphical process quite sufficient, and it has the further advantage of exhibiting to the eye those observations which, from their extravagance, are probably errors in bisecting the star or in reading off the verniers. Suppose such a set of observations to be given for reduction. Draw WE and NZ , figure 2,

at right angles to each other, and intersecting at P , and then draw from P lines such as PS , PS' for each known star observed, making the angles SPZ , $S'PZ$ equal to the $P.C.$, No. 592.

observed hour angles of the stars. If the instrumental polar distance be less than that of the catalogue, as in S' , take $Pk' =$ the difference; if the instrumental distance be greater, as in S , prolong SP and take $Pk =$ the difference. Through h and h' draw perpendiculars to PS and PS' , and these will intersect at p , the place of the instrumental pole. Repeating this process for each known star, the eye will show pretty nearly where p should be chosen among the various intersections. The place of p being determined, the observations of an unknown star or comet may be corrected as shown above; and by dropping perpendiculars on PW and PN , the azimuthal and vertical errors of the pole of the instrument may be determined.

It seems scarcely necessary to caution any person into whose hands such observations may come, against relying upon intersections which are made at very acute or very obtuse angles. If, for instance, we were to attempt to deduce the place of p as to azimuth by a pair of observations near the meridian, or its place as to altitude by observations near the 6 hour meridian, we should only have our own folly to blame for the inaccuracy of the result. From the nature of the case, the unavoidable errors of observation would be multiplied by the process, and a result of any kind might be obtained, just as by observing the sun near noon for time and near the prime vertical for latitude, a sailor might cause his sextant to be guilty of any assignable error. This is evident from the form of the analytical equation, but any non-algebraist may satisfy himself by drawing lines PS and PS' , making an angle of 5° or 10° , and by finding what the effect of an error of $10''$ in the observations will be on the position of p . If three observations of stars without reversion should be employed, and the index error of the declination circle be deduced at the same time, the blunder will be complete.

Though the errors of an unadjusted equatorial may be detected and the corrections rigorously computed, it would be an abuse of time and calculation to do so. In two of the ordinary constructions of the instrument and probably in the third, the instrumental errors are not and cannot be expected to be accurately the same in all positions of the instrument. In those equatorials of Ramsden's construction which have five feet telescopes and declination circles of three feet diameter, variations of adjustment between the meridian and six hours from it may be expected to amount to $10''$ or $20''$, and in the largest equatorials, which are necessarily more imperfect, discrepancies of $1'$ or even $2'$ may arise. We shall now point out the rational mode of using an equatorial instrument, when the object is to determine the place of any phenomenon in the heavens.

The first thing is to adjust the instrument with great care, and especially to make the pole of the instrument agree with the celestial pole. The permanence of this adjustment depends solely upon the steadiness of the upper and lower supports, which should therefore be fixed very solidly. This being done, suppose a comet is to be determined. Turn the telescope upon it, and having clamped the hour circle very firmly, note the transit of the comet over the vertical wires, bisecting it at the same time in $N.P.D.$ by the horizontal wire. Wait till some other star passes over the field, note its transit, and bisect it in $N.P.D.$ by moving the micrometer screw only. In this case the declination circle is supposed to be firmly clamped between the observations. Then the difference of the times of observation gives the difference of $R.A.$ between the comet and star, and the difference in declination is taken from the micrometer. It is the same thing, of course, whether the star precedes or succeeds the comet. Observations of this kind are amongst the most perfect which can be made, for the errors of the instrument being the same in each case, and the refraction almost the same, no error can creep in except that of noting the phenomenon. The star which is sometimes called the determining star, or the star of comparison, is afterwards observed by meridian instruments, and then the place of the comet is deduced with the greatest accuracy. Frequently, however, there is a dearth of stars of comparison, and the time before a proper star enters the field is too long for the patience of the observer, or he may not have a micrometer. In this case the instrument is kept clamped in $R.A.$, and after observing the comet, the telescope is moved up or down a little, and stars above and below the comet are observed, in

R.A. by noting the clock, and in declination by reading the circle. The instrument should then be turned half round in R.A., and the operation repeated. By combining both sets, as good a place of the comet will be deduced as the division of the declination circle will allow. The stars of comparison are taken above and below, so that the mean of the instrumental errors at the stars may be pretty nearly equal to that at the comet, and as the effect in R.A. of an error of collimation or inclination is changed in sign by reversion, it is therefore eliminated from the mean. The instrument must on no account be moved in R.A. between

the observation of the comet and the stars of comparison. In this way Halley's comet was observed at Greenwich and Cambridge on its late appearance, the stars of comparison were subsequently observed with the meridian instruments, and the apparent places of the comet finally settled. The details will be found in the observations of the respective observatories for the year 1835.

If the utmost accuracy be not required, it is sufficient, after careful adjustment, to note the transit of the comet over the vertical wires, and to read off the declination and hour circle, and then turning the instrument upon one or

Equatorial.

more neighbouring stars, to observe them in like manner. The nearer the stars of comparison are to the comet, the greater probability there is that there is no change, or only a slight change of instrumental error in moving from one to the other. This mode of observation however is only to be tolerated in cases of necessity, when, either from haste or uncertain weather, the observer cannot wait for stars coming to the same meridian with the comet.

Suppose the following observations to have been made of Arcturus and an unknown star or comet, after correcting each for refraction.

| | Time by clock. | Hour Circle. | North Polar Dist. |
|----------|----------------|--------------|-------------------|
| | h. m. s. | h. m. s. | ° ' " |
| Arcturus | 17 17 9.9 | 3 10 15.5 | 69 54 46 |
| Comet | 17 27 11.5 | 2 50 38.1 | 62 11 1 |

To determine the index errors of both circles by Arcturus, we have

| | h. m. s. | | ° ' " |
|-----------------|-----------|----------------|----------|
| Time by clock | 17 17 9.9 | Instl. N.P.D. | 69 54 46 |
| Hour angle west | 3 10 15.5 | Do. Naut. Alm. | 69 57 37 |

| | | | |
|---------------|-------------|---------------|--------|
| Instruml R.A. | 14 6 54.4 | Instl. N.P.D. | } 2 51 |
| R.A. Naut. | } 14 8 10.6 | too small | |
| Alm. | | | |

| | |
|-----------------------|----------|
| Instl. R.A. too small | } 1 16.2 |
| | |

Applying these corrections to the observations of the comet, we have

| | h. m. s. | | ° ' " |
|-------------------|------------|---------------|----------|
| Time by clock | 17 27 11.5 | Instl. N.P.D. | +62 11 1 |
| Instl. hour angle | 2 50 38.1 | Correction | + 2 51. |

| | | | |
|-------------------|------------|--------|-----------|
| Instl. R.A. comet | 14 36 33.4 | N.P.D. | +62 13 52 |
| Correction | + 1 16.2 | | |

True R.A. comet 14 37 49.6

The star of comparison is, in this case, much too distant both in R.A. and N.P.D.; and the index error ought to be determined by stars above and below the comet, and preceding and succeeding it. Also, after the observations have been made in one position of the instrument, it ought to be turned half round and the observations repeated; but the mode of ascertaining and applying the corrections is the same, and needs no further explanation.

The accompanying figure represents the portable universal equatorial as constructed by Troughton: (a drawing and description of a similar instrument, under the title of *Fayrer's Equatorial*, will be found in Rees's *Cyclopædia*, article *Equatorial*). The lower part or stand rests on three foot-screws, and needs no description. The upper part is moveable on a cross axis, A A, on which it is balanced; and when the polar axis is set at the proper inclination by the latitude semicircle B, the clamp C retains it there. The polar axis consists of an outer tube, D D, forming one piece with the horizontal axis above-mentioned, and of an interior axis which turns freely within the tube as in a socket. This latter axis carries the hour circle, E E, the verniers, F F, being fixed to the tube. The clamp and tangent screw of the hour-circle are partially seen at G G. The upper plate H is fixed on the inner axis, and revolves with it. Two pieces, I I, rise from this plate, and carry the collars within which the cross or transit axis, K K, works. The declination circle, L L, and telescope, M M, are fixed to the extremities of the transit axis, the telescope being outside the collar. The declination clamp and tangent screw are seen at N N; the verniers are on the other side. These are attached to the support which rises from the plate H. Two levels are fixed on the lower part of the stand at O O, but they are only to be used for approximate adjustment. A delicate swing level, P, is hung from the transit axis, and a second level, Q, is fixed to the declination circle. The telescope has a micrometer, R, carrying wires for measuring small differences of declination.

It is evident to those who know Fraunhofer's construction, that it is identical with the upper part of this universal equatorial. The suspension and motion of the polar axis and hour circle are the same as in the equatorial made by Troughton for the University of Coimbra. The position of the telescope is that of Meignié and Nairne.

The rules we have already given will enable any one to adjust the universal equatorial; but if the direction of the

meridian be known, it is a simpler plan to adjust the instrument as an altitude and azimuth circle, which it becomes when the polar axis is vertical, and then by inclining the polar axis to the latitude of the place, it becomes an equatorial. There is no provision in the instrument itself for moving the polar axis in azimuth. The whole must be turned bodily, and for this purpose some preparation should be made in the stand on which the foot-screws rest.

The following references will be useful to the reader. A clock for carrying an equatorial, constructed by Messrs. Troughton and Simms, and now in the possession of Charles Holford, Esq., of Hampstead, is described in the *Abstracts of the Proceedings of the Royal Astronomical Society*, vol. iii., No. 6, with a wood-cut. This would probably act somewhat more steadily with a horizontal fly-wheel upon the vertical axis, but its performance is very good. An account of the slipping piece and the wire micrometer to be applied to the equatorial for observing double stars, with directions for their use, is given in the appendix to the *Comparison to the Maps of the Stars published by the Society*, 1836. For the mode of using an equatorial as a measuring circle, see the *Cambridge and Greenwich Observations* for 1835 and 1836 of Halley's Comet, of the Solar Eclipse, and of the elongation of Jupiter's fourth Satellite; and for the corrections for refraction and parallax, *the Introduction to the Greenwich Observations*, 1836, to which the reader should look if he wishes to know the best methods of making and reducing astronomical observations in general. Sir George Shuckburgh's *Memoir* already referred to contains a valuable history of the instrument, though, on consulting the authorities, we have been led occasionally to differ from him. A description of Ramsden's *refraction piece* will be found at page 19 of Shuckburgh's paper, along with a collection of tables for computing the effects of refraction and parallax in R.A. and N.P.D. from the data which this ingenious appendage affords. Pearson's *Practical Astronomy*, vol. ii. p. 517; Littrow, *Memoirs of the Astronomical Society*, vol. ii. p. 45; Kriel, *Mem. Ast. Society*, vol. iv. p. 495. We have committed an oversight by relying on Vince. Graham's astronomical sector is supported as Hooke's quadrant and Flamsteed's sextant: see Smith's *Optics*, § 885, book 3, chap. 9; but in explaining the instrument, Smith uses a figure for illustration, which Vince has copied as the actual instrument. It is now in the transit-room of the Royal Observatory.

EQUERRIES (from the French *écurie*, a stable), the name given to certain officers of the royal household in the department of the master of the horse, the first of whom is styled chief equerry and clerk-marshal. Their duties fall in rotation. When the king or queen ride abroad in state, an equerry goes in the leading coach. They formerly rode on horseback by the coach-side. Officers of the same denomination form a part of the established households of the royal dukes, &c.

EQUIANGULAR, EQUILATERAL, EQUI-CRURAL, EQUI-TANGENTIAL, &c. &c., a class of words beginning with *Equi*, which, in composition forms an adjective expressive of the equality of two things spoken of. Thus equiangular means having equal angles, and so on. There is a certain liability to confusion, arising from mistaking between the application of such terms to different parts of the same figure and to different figures. Thus 'an equilateral triangle' must mean a triangle which has three sides all equal. But 'two triangles which are equilateral' may mean two triangles in which every side of the first has its equal among those of the second: the two not being separately equilateral. To avoid this, it is sometimes said that two triangles, such as have just been mentioned, are *mutually equilateral*.

EQUILIBRIUM (*æqua libra*), a state of rest produced by the mutual counteraction of two or more forces. The science of equilibrium is **STATICS**.

EQUIMULTIPLES, multiples in which equal numbers of times are taken. Thus seven times A and seven times B are equi-multiples of A and B: a league and a yard are equimultiples of a mile and a foot. The student of the fifth book of Euclid should remember that this word has no singular number: 7 A and 7 B are equimultiples, but 7 A is not therefore to be called an equimultiple but one of the equi-multiples. And the same of the word *equal*, whether separately or in composition: A and P may be equal lines, but

A is not *an equal* line. Equality implies comparison of at least two things.

EQUINOCTIAL, a name given to the equator, from the night being equal to the day when the sun is there.

EQUINOXES, the intersections of the equator and ecliptic; the vernal equinox being that in which the sun is when about to rise into the northern hemisphere; the autumnal equinox being that in which the sun is when about to sink into the southern hemisphere. These terms are relative: for the equinox which is vernal in our hemisphere is autumnal in the southern, and *vice versâ*.

EQUISETACEÆ are imperfectly formed plants whose real affinity is uncertain, and the nature of whose parts of fructification is not yet understood. By Linnæus and almost all botanists they are referred to the Cryptogamic class; by a modern English botanist they are regarded as a low rudimentary form of Gymnosperms. Only one genus is known, the stems of which are employed in the shops under the name of Dutch rushes. They are hollow-stemmed leafless plants, with a cuticle composed of pure silex, which gives them the hard surface that makes them useful for the poisher's purpose. In lieu of leaves they have toothed sheaths, each of which has as many series of imperfect spiral vessels passing into fistulæ of the stem as there are toothings. Their fructification grows in terminal cones, consisting of stalked peltate scales, having on their lower side small cases wherein are lodged minute oval or round green bodies, surrounded by four elastic hygrometrical yellowish grey granulated clavate threads. By all botanists the central green body is admitted to be a seed or spore. The nature of the clavate threads is disputed; they are usually called elaters, and are compared to the elastic spiral threads bearing that name in Jungermanniaceæ; but there is no proof of such being their nature, and there is an opinion that they are rudimentary stamens. Be this as it may, the remarkable resemblance between Equisetaceæ and Casuarina, an undoubted flowering plant, the marked similarity of their cones of fructification to those of Cycadaceæ and Coniferae, and the absence of such an evident correspondence between them and any existing or extinct forms of Cryptogamic plants, strongly inclines us to adopt the view of their being a low form of Phanogamous vegetation, bearing the same relation to Cycadaceæ as Lemna to palms and Ceratophyllum to arbores-

cent nettles. Equisetaceæ are in English called horsetails, and are reckoned a sure sign of wet, stiff, springy soil.

EQUISETIC ACID, an acid discovered by Bracconot in the *equisetum fluviatile*, in which it exists combined with magnesia.

This acid may be obtained in small colourless radiating crystals; its taste is sharp, and somewhat analogous to that of tartaric acid: it is unalterable in the air. When heated, it decomposes without subliming, and yields an oily uncrystallizable acid product. It dissolves readily both in alcohol and in water: the solution gives no precipitate either with lime or barytes water, but with acetate of lead and protionate of mercury it gives white curdy precipitates: it precipitates the persalts, but not the protosalts of iron.

With potash and soda it yields deliquescent uncrystallizable salts; with ammonia, a crystallizable salt. With oxide of zinc, with lime, and magnesia, it forms uncrystallizable transparent compounds, which are unalterable in the air.

EQUITES (horsemen), the name of an order in the Roman state. Their origin, according to the old tradition, was this:—Romulus having divided his subjects into three tribes, chose from each one hundred young men whom he destined to serve on horseback and act as his body-guard: this body of cavalry was called the *celeres*, and afterwards the *equites*. (Dionys., ii. 13.) Niebuhr supposes (*Hist. of Rome*, i. p. 325, transl.) that whereas *patres* and *patrii* were titles of honour for individuals, *celeres* was the name of the whole class as distinguished from the rest of the nation. The three centuries of the *celeres* were called by the same names as the three tribes of the patricians, namely Ramnes, Tities, and Luceres. Their tribunes are spoken of as a college of priests (Dionys., ii. 64), and it appears that the tribes of the patricians had also tribunes (Dionys., ii. 7). Moreover, when it is said that Tarquinius Priscus made three new centuries, which he added to the former three, and that the whole went under the name of the Sex Suffragia, or the six equestrian centuries, we cannot doubt that the alteration which he introduced was a constitutional and not merely a military one; that in fact the centuries which he formed were, like the original three, tribes-houses; that his innovation was nothing but an extension of the political division of the inhabitants of Rome and Romulus. (Niebuhr, *Hist. of Rome*, i. p. 391.) When Servius Tullius established the comitia of the centuries, he received the sex suffragia, which included all the patricians into his first class; and to them he added twelve other equestrian centuries, made up of the richest of the plebeian order (Niebuhr, i. p. 427.) The ancient writers appear to have laboured under some great confusion with regard to the arrangement. Livy (i. 43) makes a proper distinction between the twelve equestrian centuries created by Servius and the six which existed before; but when he states (i. 43) that the cavalry in the reign of Tarquinius Priscus amounted to 1800, he appears to be antedating the origin of the eighteen equestrian centuries which formed part of the constitution of Servius. To the establishment of the comitia the creation of a body of equites, as a distinct order, seems to be due. The plan of Servius was, to a certain extent, identical with that of Solon. The object of both legislators was to break down the limits to which the old aristocracy was confined, and to set up an order of wealth by the side of the order of birth: not, however, that when a person could produce his 400,000 sesterces, he became *ipso facto* a knight, as was the case in after times (Hor. *Ep.* i. 1, 57.) According to the Servian constitution good birth or the sanction of the censors was necessary for gaining a place in the equestrian order. (Polyb., vi. 19. Zonaras, vii. 19.) When Cicero says (*De Republica*, ii. 2) that Tarquinius established the equestrian order on the same footing as that on which it stood in his own time, he also attributes to the same king the assigning of money to the equites for the purchase and keep of their horses, which is evidently inconsistent. In Tarquin's time, that is, before there was any plebeian order, it was natural enough that poorer patricians, who were obliged to serve on horseback (just as the *ἵππικὴ* at Athens were a poorer class than the *Πentakosiomedimnoi*, Plut., *Sol.* c. 18.) should be furnished with the means for doing so. But the case was different with the equites after the establishment of an order of wealth. A man might then be of equestrian rank, and have no horse assigned to him; thus, on the one hand, find at the time of the siege of Veii a number of equites serving on horseback at their own expense (Liv., vi.

1, A sterile branch of *Equisetum fluviatile*; 2, a fertile branch of the same in fructification; 3, one of the peltate scales; 4, the same viewed from below; 5, two of the scales very much magnified; 6, an ovule with the four supposed elaters.

and, on the contrary, L. Targuitus, who was a patrician, was obliged to serve on foot from his poverty. (Liv., iii. 27.) From this it appears probable that a certain sum was fixed which it was not necessary for every eque to have, but the possessor of which was obliged to serve on horseback at his own expense if no horse could be given him by the public, and that those whose fortune fell short of this were obliged to serve in the infantry under the same circumstances.

The lieutenant of the dictator was called 'the chief of the equites' (*Magister Equitum*); and although in later times he was appointed to this office by the dictator himself, it is probable, as Niebuhr conjectures (i., p. 559), that he was originally elected by the 12 centuries of Plebeian equites, just as the dictator, or *Magister Populi*, was by the *Sex Suffragia*, in other words, by the *Populus* or Patricians.

With regard to the functions of the equites, besides their military duties, they had to act as judges or jurymen under the Sempronian law: under the Servilian law the judges were chosen from the senate as well as from the equites: by the Glaucian law the equites alone performed the office, and so on by alternate changes till the law of Aurelius Cotta (B.C. 70), by which the judges were chosen from the senators, equites, and *tribuni ærarii*. The equites also farmed the public revenues. Those who were engaged in this business were called the *Publicani*; and though Cicero, who was himself of the equestrian order, speaks of these farmers as 'the flower of the Roman equites, the ornament of the state, the safeguard of the republic' (*Pro Plancio*, 9), it appears that they were a set of detestable oppressors, who made themselves odious in all the provinces by their avarice and rapacity.

The equites, as it may be inferred from what has been already said, gradually lost the marks of their distinctive origin, and became, as they were in the time of Cicero for instance, an *ordo* or class of persons as distinguished from the senate and the plebs. They had particular seats assigned to them in the circus and the theatre. The insignia of their rank, in addition to the horse, were, a golden ring and the *angustus clavus*, or narrow band, on their dress, as distinguished from the *latus clavus* or broad band of the senators: the two last insignia seem to have remained after the former ceased to possess its original and distinctive character.

EQUITY, according to the definition given by Aristotle, is 'the rectification of the law, when, by reason of its universality, it is deficient; for this is the reason that all things are not determined by law, because it is impossible that a law should be enacted concerning some things; so that there is need of a decree or decision; for of the indefinite the rule also is indefinite: as among Lesbian builders the rule is leaden, for the rule is altered to suit the figure of the stone, and is not fixed, and so is a decree or decision to suit the circumstances.' (*Ethics*, b. v. c. x. Oxford trans.) 'Equity,' says Blackstone, 'in its true and genuine meaning, is the soul and spirit of all law; positive law is construed and rational law is made by it. In this respect, equity is synonymous with justice; in that, to the true and sound interpretation of the rule.' According to Grotius, equity is the correction of that wherein the law, by reason of its generality, is deficient.

Until jurisprudence has become really a science based on settled principles, some such jurisdiction as our earlier law writers have attributed to the courts of equity is necessary to the due administration of justice; and it is probable that in England it deserved the humorous description given by Selden in his 'Table Talk.' 'Equity in law is the same that spirit is in religion, what every one pleases to make it; sometimes they go according to conscience, sometimes according to law, sometimes according to the rule of court. Equity is a roguish thing; for law we have a measure, know what to trust to; equity is according to the conscience of him that is chancellor, and as that is larger or narrower, so is equity. It is all one as if they should make the standard for the measure we call a foot a chancellor's foot; what an uncertain measure would this be! One chancellor has a long foot, another a short foot, a third an indifferent foot: it is the same thing in the chancellor's conscience.'

This uncertainty has however long ceased in that branch of our law which is expressed by the term Equity, and, from successive decisions, rules as strict and principles as fixed have been framed and established in our courts of equity as in our courts of law. New cases, it is true, may and do arise, but they are decided upon these ascertained rules and principles, and not from the notions of the judge as to what

may be reasonable or just in the particular case before him. Nothing in fact is more common than to hear the chancellor say, that whatever may be his own opinion, he is bound by the authorities, that is, by the decisions of his predecessors in office and those of the other judges in equity; that he will not shake any settled rule concerning property, &c., it being for the common good that these should be certain and known, however ill-founded the first resolution may have been.

In its enlarged sense, equity answers precisely to the definition of justice, or natural law (as it is called), as given in the 'Pandects' (lib. i. tit. 1, l. 10, 11); and it is remarkable that subsequent writers on this so-called natural law, and also the authors of modern treatises on the doctrine of equity, as administered in the English courts, have, with scarcely any exception, cited the above passage from Aristotle as a definition of equity in our peculiar sense of a separate jurisdiction. But according to this general definition every court is a court of equity, of which a familiar instance occurs in the construction of statutes, which the judges of the courts of common law constantly interpret according to the spirit, or, as it is called, the equity, not the strict letter.

It is hardly possible to define equity as now administered in this country, or to make it intelligible otherwise than by a minute enumeration of the matters cognizable in the courts in which it is administered in its restrained and qualified sense. 'It is no longer,' says Sir James Mackintosh in his life of Sir Thomas More, 'in the acceptance in which the word is used in English jurisprudence, to be confounded with that moral equity which generally corrects the unjust operation of law, and with which it seems to have been synonymous in the days of Selden and Bacon. It is a part of laws formed from usages and determinations which sometimes differ from what is called common law in its subjects, but chiefly varies from it in its mode of proof, of trial, and of relief.'

In this country the remedies for the redress of wrongs and for the enforcement of rights are distinguished into two classes, *those which are administered in courts of law*, and *those which are administered in courts of equity*; the former are called legal rights and wrongs, the latter equitable. Equity jurisdiction may therefore properly be defined as that portion of remedial justice which is administered by a court of equity as distinguished from a court of law, from which a court of equity differs mainly in the subject matters of which it takes cognizance and in its mode of procedure and remedies.

Courts of common law in this country proceed by certain prescribed forms of action alone, and give relief only according to the particular exigency of such actions, by a general and unqualified judgment for the plaintiff or the defendant. There are many cases however in which a simple judgment for either party, without qualifications or conditions, or peculiar arrangements, will not do entire justice. Some modifications of the rights of both parties may be required; some restraints on one side, or the other, or perhaps on both; some qualifications or conditions present or future, temporary or permanent, to be annexed to the exercise of rights, or the redress of injuries. To accomplish such objects the courts of law in this country have no machinery: according to their present constitution they can only adjudicate by a simple judgment between the parties. Such prescribed forms of actions are not confined to our own system of laws; they were known in the civil law, and the party could apply them only to their original purposes. In other cases he had a special remedy. Courts of equity however are not so restrained; they adjudicate by decree pronounced upon a statement of his case by the plaintiff, and the answer of the defendant given in upon oath, and the evidence of witnesses, together, if necessary, with the evidence of all parties, also given upon oath. These decrees are so adjusted as to meet all the exigencies of the particular case, and they vary, qualify, restrain, and model the remedy so as to suit it to mutual and adverse claims, and the real and substantial rights of all the parties so far as such rights are acknowledged by the established rules of equity.

The courts of equity bring before them *all* the parties interested in the subject matter of the suit, and adjust the rights of all however numerous; whereas courts of law in this country are compelled by their constitution to limit their inquiry to the litigating parties, although other persons may be interested, that is, they give a complete

remedy in damages or otherwise for the particular wrong in question as between the parties to the action, though such remedy is obviously in many cases an incomplete adjudication upon the general rights of the parties to the action, and fails altogether as to other persons, not parties to the action, who yet may be interested in the result or in the subject matter in dispute.

Perhaps the most general as well as the most precise description of a court of equity is the outline given by Mr. Justice Story in the 'Encyclopædia Americana,' which he has filled up in his recent Treatise on Equity. It is this—that a court of equity has jurisdiction in cases where a plain, adequate, and complete remedy cannot be had in the common law courts. The remedy must be *plain*, for if it be doubtful and obscure at law, equity will assert a jurisdiction. It must be *adequate*, for if at law it fall short of what the party is entitled to, that founds a jurisdiction in equity; and it must be *complete*, that is, it must attain the full end and justice of the case, it must reach the whole mischief and secure the whole right of the party present and future, otherwise equity will interpose and give relief. The jurisdiction of a court of equity is sometimes concurrent with the jurisdiction of the courts of law; sometimes assistant to it; and sometimes exclusive. It exercises concurrent jurisdiction in cases where the rights are purely of a legal nature, but where other and more efficient aid is required than a court of law can afford. In some of these cases courts of law formerly refused all redress, but now will grant it. For strict law comprehending established rules, and the jurisdiction of equity being called into action when the purposes of justice rendered an exception to those rules necessary, successive exceptions on the same grounds became the foundation of a general principle, and could no longer be considered as a singular interposition. Thus law and equity are in continual progression, and the former is constantly gaining ground upon the latter. Every new and extraordinary interposition is by length of time converted into an old rule; a great part of what is now strict law was formerly considered as equity, and the equitable decisions of this age will unavoidably be ranked under the strict law of the next. (Prof. Millar's *View of the Eng. Govt.*) But the jurisdiction having been once justly acquired at a time when there was no such redress at law, it is not now relinquished by the courts of equity.

The most common exercise of the concurrent jurisdiction is in cases of account, accident, dower, fraud, mistake, partnership, and partition. In many cases which fall under these heads, and especially in some cases of fraud, mistake, and accident, courts of law cannot and do not afford any redress: in others they do, but not in so complete a manner as a court of equity.

A court of equity is also assistant to the jurisdiction of the courts of law in cases where the latter have no like authority. It will remove legal impediments to the fair decision of a question depending at law, as by restraining a party from improperly setting up, at a trial, some title or claim which would prevent the fair decision of the question in dispute; by compelling him to discover, upon his own oath, facts which are material to the right of the other party, but which a court of law cannot compel him to disclose; by perpetuating, that is, by taking and keeping in its custody, the testimony of witnesses, which is in danger of being lost before the matter can be tried; and by providing for the safety of property in dispute pending litigation. It will also counteract and controul fraudulent judgments, by restraining the parties from insisting upon them.

The exclusive jurisdiction of a court of equity is chiefly exercised in cases of merely equitable rights, that is, such rights as are not recognised in courts of law. Most cases of trust and confidence fall under this head. This exclusive jurisdiction is exercised in granting injunctions to prevent waste or irreparable injury; to secure a settled right, or to prevent vexatious litigation; in appointing receivers of property, which is in danger of being misapplied; in compelling the surrender of securities improperly obtained; in preventing a party from leaving the country in order to avoid a suit; in restraining any undue exercise of a legal right; in enforcing specific performance of contracts; in supplying the defective execution of instruments, and reforming, that is, correcting and altering them according to the real intention of the parties, when such intention can be satisfactorily proved; and in granting relief in cases where deeds and securities have been lost.

Much discussion has taken place and various opinions have been expressed upon the question whether it would or would not be best to administer the whole of remedial justice in one court or in one class of courts without any separation or distinction of suits, or of the forms or modes of procedure and relief. Lord Bacon, upon more than one occasion, has expressed his decided opinion that a separation of the administration of equity from that of the common law is wise and convenient. 'All nations,' says he, 'have equity, but some have law and equity mixed in the same court, which is worse, and some have it distinguished in several courts, which is better;' and again, 'In some states, that jurisdiction which decrees according to equity and moral right, and that which decrees according to strict right, is committed to the same court; in others, they are committed to different courts. We entirely opine for the separation of the courts; for the distinction of the cases will not long be attended to if the jurisdictions meet in the same person; and the will of the judge will then master the law.'

Lord Hardwicke held the same opinion. Lord Mansfield, it is to be presumed, thought otherwise, for he endeavoured to introduce equitable doctrines into the courts of law. The old strictness has however been restored. His successor, Lord Kenyon, made use of these expressions: 'If it had fallen to my lot to form a system of jurisprudence, whether or not I should have thought it advisable to establish different courts, with different jurisdictions, and governed by different rules, it is not necessary to say; but influenced as I am by certain prejudices that have become inveterate with those who comply with the systems they find established, I find that in these courts, proceeding by different rules, a certain combined system of jurisprudence has been framed most beneficial to the people of this country, and which I hope I may be indulged in supposing has never yet been equalled in any other country on earth. Our courts of law only consider legal rights; our courts of equity have other rules, by which they sometimes supersede strict legal rules, and in so doing they act most beneficially for the subject.' In this country the principle of separating jurisdictions has been largely acted upon. We have our courts of equity and law; our bankrupt and insolvent courts, and courts of ecclesiastical and admiralty jurisdiction; indeed until lately our several courts of law had, in principle, jurisdiction only over certain specified classes of suits. In countries governed by the civil law, the practice has in general been the other way. But whether the one opinion or the other be most correct in theory, the system adopted by every nation has been mainly influenced by the peculiarities of its own institutions, habits, and circumstances, and the forms of its remedial justice. In all such cases the separation or union of the equitable and legal jurisdiction must be a mixed question of public policy and private convenience.

In some of the American states, the administration of law and equity is perfectly distinct; in others the administration of equity is only partially committed to distinct courts; in a third class the two jurisdictions are vested in one and the same tribunal; and in a fourth there are no courts exercising an equitable jurisdiction.

In most of our colonies the governor is invested with the jurisdiction of chancellor; but in some of the greatest importance where a judicial establishment of some magnitude is maintained, the chief or supreme court is invested with the chancery jurisdiction.

This attempt at the exposition of the general principles of what in this country is called equity seems to the writer of this article to be better suited to a work of this nature than a full description of the practice of, that is, the course of proceeding in a suit in, a court of equity. The practice or procedure of any court can hardly be made intelligible to any person but one who knows something of it by experience; and any technical description of it is useless unless it is minutely and circumstantially exact. It is desirable, however, that in addition to some knowledge of the subjects which belong to the jurisdiction of a court of equity, all persons should have some clear notion of the way in which the matters in dispute between parties to a suit in equity are brought before the court, and by what kind of proof or evidence they are established. It may also be useful that persons should have a general, and so far as it goes, a correct knowledge of the different modes in which such questions of fact are put in issue, and proved in our courts of law and equity. The following short outline

of the course of proceeding in a suit of chancery, taken in connection with other articles in this work, such as CHANCELLOR, CHANCERY, DEPOSITION, EVIDENCE, and PLEADING, may probably, so far as it goes, give somewhat more information on the subject of equity jurisdiction than is found in books not strictly professional.

A suit on the Equity side of the courts of chancery and exchequer is commenced by presenting a petition to the lord chancellor, or the chancellor and barons of the exchequer, containing a statement of the plaintiff's case, and praying for such relief as he may consider himself entitled to receive. This petition is technically called a Bill, and is in the nature of the declaration at common law [DECLARATION]; but if the suit is instituted on behalf of the crown, or a charity, or any of the objects under the peculiar protection of the crown, the petition is in the form of a narrative of the facts by the attorney-general, and is called an information. There is also a petition termed an information and bill, which is where the attorney-general, at the relation (that is, the information) of a third person (thence called the relator), informs the court of the facts which he thinks are a fit subject of inquiry. The practice which governs all these proceedings is the same. It is the practice at the end of the statement in a bill to add what is called the interrogating part, which consists of the statements of the bill thrown into the form of distinct questions, and often expressed in terms of great length and particularity. The statements in the bill are not made upon oath; and further, in order to obtain a full and complete discovery from the defendant, both as regards the complaint and the supposed defence, various allegations are made in many cases from mere conjecture, and this practice, it has been considered after much laboured discussion, tends to the due administration of justice; for though doubtless many frivolous suits are instituted, yet, from the nature of cases of fraud and concealment, the plaintiff is often ignorant of the precise nature of the case, and frames his bill in various forms so as to elicit from the defendant a full discovery of the truth. Bills of this nature are called original bills, and either may be for discovery and relief, or for discovery merely.

When the bill is placed on the records of the court it is said to be *filed*, and the writ of subpoena issues commanding the defendant to appear and answer the allegations of the bill within a certain time.

If, upon the face of the bill, it should appear that the plaintiff is not entitled to the relief prayed for as against the defendant, the defendant may demur, that is, demand the judgment of the court upon the statement made by the plaintiff, whether the suit shall proceed [DEMURRER]; and if any cause, not apparent upon the bill, should exist why the suit should be either dismissed, delayed, or barred, the defendant may put in a plea, stating such matter, and demanding the judgment of the court as in the case of a demurrer. But if neither of these modes of defence are applicable, and the defendant cannot disclaim [DISCLAIMER], he must answer upon oath the interrogatories in the bill according to the best of his *knowledge, remembrance, information, and belief*. This mode of defence is styled an Answer. All or any of these several modes of defence may be used together, if applied to separate and distinct parts of the case made by the plaintiff.

In the successive stages of a suit, references as to the pleadings, and as to facts, may be made to the Masters of the court; as for instance, if any improper statements be made reflecting upon the character of either party, not necessary to the decision of the suit, the pleading may be referred to the master for scandal; if there be long and irrelevant statements, not concerning the matter in question, a reference may be made for impertinence, and the matter so complained of as scandalous or impertinent may be expunged at the expense of the party in fault. Again, if the defendant does not answer the bill with sufficient precision, the plaintiff may except to the answer for insufficiency, and this question is decided by the masters, in suits in chancery, but by the court in the exchequer. If the answer is decided to be insufficient the defendant must answer further.

It frequently happens that during the progress of the suit, from the discovery of new matter, the deaths and marriages of parties, and other causes, the pleadings become defective, and in these cases it is necessary to bring the new matter, or parties becoming interested, before the court. This is done by means of further statements, re-

ferring to the previous proceedings, and being in fact merely a continuation of them, which are called supplemental bills, bills of revivor, or bills of revivor and supplement, according to the nature of the defect which they are intended to supply. These bills are called bills not original.

There is also a third class, called bills in the nature of original bills, which are occasioned by former bills, such as cross bills, which are filed by the defendant to an original bill against the plaintiff to the same bill, touching some matter in litigation in the first bill, as where a discovery is necessary from the plaintiff in order that the defendant may obtain complete justice. There are also bills of review, to examine a decree upon the discovery of new matter, &c., and several others. Upon both these latter descriptions of bills the same pleadings and proceedings may follow as to an original bill.

Pleas and demurrers are at once argued before the court: if allowed, the suit, or so much of it as is covered by the demurrer or plea, is at an end, though the court will generally permit the plaintiff to amend his bill where it is not apparent from his own statement that he cannot make any case against the defendant; otherwise the only object attained by the demurrer or plea would be to drive the plaintiff to file a new bill, omitting or amending the objectionable part. But if the demurrer or plea is overruled, the defendant is compelled to answer fully, just as if he had not demurred or pleaded. When the answer is filed, the plaintiff, if from the disclosures made he deems it advisable, may amend his bill, that is, erase such part of his statements as he no longer considers necessary, and insert other statements which may appear necessary to sustain his case; and the defendant must answer to this new matter.

In cases where the bill is for discovery only, and in some others, the answer puts an end to the suit; and when the object of the bill is to obtain an injunction, which is granted either upon affidavits before answer or in default of an answer, the suit is also ended, unless the defendant desires to dissolve the injunction. But where a decree is necessary, the cause must come on to be heard either upon evidence taken before the examiners of the court or commissioners appointed for the purpose [DEPOSITION, EVIDENCE]; or where the plaintiff considers the disclosures in the answer sufficient, the cause is heard upon bill and answer alone, without further evidence, and this is at the plaintiff's discretion.

The cause is heard in its turn by the master of the rolls or the vice-chancellor, if instituted in the Court of Chancery, for the lord chancellor rarely hears causes in the first instance [CHANCERY]; or if the suit is in the Exchequer, by the chief baron sitting in equity, or by any other of the barons sitting for him, as now authorized by Act of Parliament. If the nature of the suit admits, a final decree is made; or if any further inquiry be necessary or any accounts are to be taken, references are made to the master for those purposes.

The master being attended by the parties or their agents, makes his report; and the cause again comes on in its turn to be heard upon further directions (as it is called), when the like principles prevail as at the hearing.

This is the form of the simplest suit in equity, and is sufficient to point out the successive steps necessary to be taken; but generally suits are of a far more complicated character. Many special applications to the court may become necessary at various stages before the cause is ripe for hearing; and when reference is made to the master, the inquiries to be prosecuted before him may be entangled in the greatest confusion; and even when he has made his report, either party may except to it, and have his exceptions argued before the court. Also when the cause is heard on further directions, other references to the master may be found to be necessary, or may arise out of the circumstances stated in his report; the subject matter of the suit may be such as to prevent an immediate and final decree; a party may be entitled for life to the interest of money, and the persons to take after him may not be born or may be infants. In these and many other cases the court makes such decree as may be necessary, and retains the suit, giving liberty to any parties interested to apply to the court for directions as may become necessary from time to time. It is impossible here to give an adequate notion of the various and complicated operations performed by decrees, by which the interests and rights of all parties are settled, and the most embarrassed affairs are arranged. A very valuable collection of decrees has been published by Mr. Seton.

Those who wish for a more accurate knowledge of the proceedings in a suit in Chancery may consult Lord Redesdale's *Treatise on Pleading*; Beames on *Pleas*; and the various books on Chancery Practice.

The principal English treatises on Equity are those of Mr. Maddock and Mr. Fonblanque: the former treats of his subject under heads devoted to the several subject matters cognizable in courts of equity; the latter considers it with reference to the jurisdiction exercised by courts of law, as concurrent, assistant, exclusive. The American treatise of Mr. Justice Story unites these two modes, and explains the subject in a masterly and scientific manner.

EQUITY OF REDEMPTION. [MORTGAGE.]

EQUIVALENTS, CHEMICAL. [ATOMIC THEORY.]

EQUU'LEUS (the little horse), a constellation of Ptolemy surrounded by Pegasus, Vulpecula, Aquila, and Capricornus.

EQUU'LEUS PICTORIS (the painter's horse, or easel), a constellation of Lacaille, situated close to the principal star of Argo. [CANOPUS.] Its principal star (α) is 583 of Lacaille, and 856 in the catalogue of the Astronomical Society.

EQUUS. [HORSE.]

ERA. [ÆRA.]

ERANTHEMUM, a genus of acanthaceous plants with showy purple flowers, some of whose species are occasionally seen in hot-houses in this country. It has a salver-shaped corolla with a five-cleft nearly equal limb, a four-parted equal calyx, and only two out of its four stamens fertile. *Eranthemum pulchellum* and *bicolor* are the handsomest species in cultivation, and when skilfully managed produce a very striking appearance.

ERANTHIS, a small genus cut off from the old *Helianthus*, in consequence of its having a deciduous calyx, stalked capsules, an involucre to the flowers, and a totally different habit. *E. hyemalis*, or Winter Aconite, is a small stemless, tuberous, herbaceous plant, inhabiting shady places in the midland parts of Europe, and rendering our gardens gay in the earliest spring with its cups of bright yellow. It has peltate, many-cut, pale green, smooth leaves, and a single flowered scape only a few inches high.

Another species, *E. sibirica*, inhabits Siberia, but has not yet found its way into our gardens.

ERASMUS was born October 28, 1467, at Rotterdam, where a fine bronze statue of him, erected in 1622, still stands, and is accounted one of the chief ornaments of the city. He was the illegitimate son of a citizen of Gouda, named Gerrit (Gerard), which, according to a pedantic fashion of the day, he translated doubly into Desiderius Erasmus; and in future years he found time to lament his carelessness in calling himself Erasmus instead of by the more accurate form Erasmus. During his father's life he was well and tenderly educated; but at the age of 14 he fell into the hands of dishonest guardians, who wasted his patrimony, and, to conceal their peculations, drove him, very unwillingly, into a monastery. He took the vows at Stein, in 1486. Fortunately his skill in Latin caused him to be employed as private secretary to the bishop of Cambrai, who, in 1496, at the end of their connection, authorized him to proceed to Paris to continue his studies, instead of returning to the monastic life, which he hated. At Paris Erasmus barely supported himself by taking pupils, in sickness and poverty. For many years he led a

wandering life, relying on the bounty of those patrons who were attracted by his learning and sprightly wit, sometimes in France, sometimes in the Netherlands, sometimes in England, to which he was a frequent visitor. In England he became intimate with More, Colet dean of St. Paul's, and other learned men, of whom he has spoken in high terms of praise: and England, if any permanent establishment had been offered, would have been the home of his choice. For several years he applied himself diligently to the study of Greek, which, after ages of general neglect, was just beginning to be an object of attention. He was *autodidactus*, self-taught, he says: and one of his favourite employments was the translation of sho. Greek treatises into Latin, which answered the double purpose of improving himself, and furnishing him with a number of books to dedicate to his wealthy friends; for in those days the honour of a dedication was generally acknowledged by a handsome present. Careless however of economy, and not averse to pleasure, Erasmus was continually in want; and in one of his letters (xii. 21) he duns Colet for fifteen angels, promised as the price of the dedication of his treatise '*De Copia Verborum*.'

In 1506 Erasmus paid his first visit to Italy, during which he obtained from Pope Julius II. a dispensation from his monastic vows. At Bologna, Venice, and Padua, he improved his knowledge of Greek under the instruction of the best Greek and Italian scholars. At Rome he met with a flattering reception, and promises of high advancement; but having engaged to return to England, he did so in 1510, in the expectation that the recent accession of Henry VIII., with whom he had for some time maintained a correspondence, would ensure to him an honourable provision. During this visit he resided for some time at Cambridge, where he was appointed Lady Margaret professor (in divinity) and also lectured on Greek; his lodging was in Queen's College, in the grounds of which Erasmus' Walk is still shown. But not finding his expectations likely to be fulfilled, he accepted an invitation from the archduke, afterwards Charles V., and went to Brabant in 1514, with the office of counsellor, and a salary of 200 florins. After this we find him resident sometimes in the Netherlands, sometimes at Basle, where the great work, in which he had been many years engaged, the first edition of the New Testament in Greek, was published in 1516, accompanied by a new Latin translation. Some amusing specimens of the objections made to this undertaking by the ignorant clergy will be found in his Letters (vi. 2).

At the dawn of the Reformation, Erasmus, who, in his witty writings had exposed many abuses of the Roman Catholic church, especially those connected with the monastic system, was much embarrassed. It is clear that at heart he went a long way with the reformers, whose tenets he cautiously abstains from censuring, even in letters to dignitaries of the church, where he speaks of Luther himself in no very friendly terms. But he was of a timid temper, disinclined to sacrifice either life or comfort to his opinions, for he says of himself, in a letter to Pace, dean of St. Paul's, 'Even if Luther had spoken everything in the most unobjectionable manner, I had no inclination to die for the sake of truth. Every man has not the courage to make a martyr: and I am afraid, if I were put to the trial, I should imitate St. Peter.' This backwardness brought on him some harsh rebukes from Luther, who nevertheless had an esteem for his person as well as a regard for his talents: and calls him, in a letter written in 1519 (vi. 3) '*Decus nostrum et spes nostra*' ('our glory and our hope'). Neither did the zealots of the other side regard him with more favour. Erasmus, it was said, laid the egg, and Luther hatched it; and no doubt the pungency of his satire had its effect in opening men's eyes, and preparing for the graver warfare of the great reformer.

He removed to Basle in 1521, where, in 1522, his celebrated '*Colloquies*' were published. They were composed ostensibly to supply young persons with an easy school-book in the Latin language, and at the same time to teach them religion and morals. For the purpose of teaching the Latin language this little book seems peculiarly well adapted: it was long used for this purpose in England, in the northern parts of which it was, till very lately, in use, and perhaps still is in some places. In these *Colloquies*, which are generally very amusing, Erasmus has made some of his smartest attacks on various superstitions of the Roman Catholic church. On this account the book was prohibited. In

1529 Erasmus removed to Freiburg, when the reformed party acquired the ascendancy in Basle: for to the last he never threw off an external adherence at least to the ancient faith. But in 1535 he returned to his former place of abode, endeared as it was by the presence of his most valued friends, in hope of renovating his declining health. About this time he received testimonies of high respect from Pope Paul III., who gave him a benefice, and expressed the intention of raising him to the rank of cardinal. But these favours came too late to benefit him. He died at Basle, July 12, 1536, leaving an enduring reputation as the first wit of his age, the man of most general learning, and the most active and serviceable instrument in bringing about the revival of sound learning. Nor were his contributions small towards the success of the Reformation; he was an able sapper, though he wanted energy to storm the breach with Luther and his associates.

His *Encomium Moriae*, 'Praise of Folly,' written in England in 1510, a very witty production, was meant to show that there are fools in all places, however high, even in the court of Rome. It had a great run, and Leo X. is said to have been much amused by it; but at the same time it made its author many enemies among those who loved the abuses or were too fond to see the faults of the church, and did more than any of his works, except the *Colloquies*, to fix the charge of heterodoxy on him. The 'Adagia' (1498), a large collection of proverbs, explained and commented upon with great learning, is another of his most interesting works. 'Enchiridion Militis Christiani' (1503) is a valuable manual of practical religion; the 'Ciceronianus' is an elegant and stinging satire on the folly of those pedants who, with a blind devotion, refused to use in their compositions any words or phrases not to be found in Cicero. Erasmus's own Latin style is clear and elegant: not always strictly classical, but like that of one who spoke and wrote Latin as readily as his mother tongue.

His Letters, comprising those of many learned men to himself, form a most valuable and amusing collection to those who are interested in the manners and literary histories of the age in which they were written; and several of them in particular are highly valuable to Englishmen as containing a picture of the manners of the English of that day.

Of his numerous works, those which we have mentioned are most likely to be read with pleasure in the present day; the rest of them consist chiefly of translations, theology, grammar, and occasional treatises addressed to his friends and patrons.

His greatest work however was the edition of the New Testament, in Greek, from manuscripts, for the first time: for though that portion of Scripture was printed in the Complutensian Polyglot so early as 1514, it was not published till 1522; while the *Editio Princeps* of Erasmus was published in 1516. It is much commended by Michaelis, who says, 'Natural abilities, profound learning, a readiness in detecting errors, with every qualification that is requisite to produce critical sagacity, Erasmus possessed in the highest degree; and perhaps there never existed a more able editor of the New Testament.' As an edition for common use, however, it is of course superseded, in consequence of the accumulated knowledge of later labourers, and the great improvement in biblical criticism.

Erasmus superintended the first Greek edition of the Geography of Ptolemy, which was printed at Basle by Frobenius, 1533, 4to. The edition was founded on good MS., but it contains numerous typographical errors.

There are lives of Erasmus by Knight and by Leclerc, the latter of whom published a complete edition of his works; and there are copious articles in most of the biographical dictionaries. Burigny's 'Vie d'Erasmus,' 1757, 2 vols. 12mo., is strongly recommended, as containing in itself a literary history of Erasmus's time.

At Basle there is a portrait of Erasmus by Holbein (*Biog. Univ.*); there is one also in the hall of Queen's College, Cambridge, but by what artist we have not been able to learn. The last edition of the complete works of Erasmus is that of Leyden, by Leclerc, 1703, 10 vols. fol., often bound in eleven.

ERATO. [MUSES.]

ERATOSTHENES, a distinguished contemporary of Archimedes, is stated to have been born at Cyrene in the year 276 B.C. He possessed a variety of talents seldom united in the same individual, but not all in the same emi-

nent degree; his mathematical, astronomical, and geographical labours, are those which have rescued his name from oblivion.

The Alexandrian school of sciences, which flourished under the first Ptolemies, had already produced Timochares and Aristyllus, whose solstitial observations, made probably by the shadows of a gnomon, and by the armillary circles imitative of those of the celestial vault, retained considerable credit for centuries afterwards, though from these methods of observation they must have been extremely rude and imperfect.

Eratosthenes had not only the advantages arising from the instruments and observations of his predecessors, but the great Alexandrian library, which probably contained all the Phœnician, Chaldaic, Egyptian, and Greek learning of the time, was entrusted to his superintendence by the third Ptolemy (Euergetes), who invited him to Alexandria; and we have proof in the scattered fragments which remain to us of this great man, that these advantages were duly cultivated to his own happiness and the progress of infant astronomy.

The only work attributed to Eratosthenes which has come down to us entire, is entitled 'Catasterismi,' and is merely a catalogue of the names of forty-four constellations, and the situations in each constellation of the principal stars, of which he enumerates nearly five hundred, but without one reference to astronomical measurement: we find Hipparchus quoted in it, and mention made of the motion of the pole, that of the polar star having been recognised by Pytheas. These circumstances, taken in conjunction with the vagueness of the descriptions, render its genuineness extremely doubtful; at all events it is a work of little value. It may be seen in the Oxford edition of 'Aratus,' and was republished by Schaubach, with notes by Heyne (Gött., 1795). A more correct edition of the text was published by F. K. Matthiæ, in his edition of Aratus, Frankfurt, 1817, 8vo.

If Eratosthenes be really the author of the treatise 'Catasterismi,' it must have been composed merely as a 'vade me-cum,' for we find him engaged in astronomical researches far more exact and more worthy of his genius. By his observations he determined that the distance between the tropics, that is, twice the obliquity of the ecliptic, was $\frac{1}{4}$ of an entire circumference, or $47^{\circ} 42' 39''$, which makes the obliquity to be $23^{\circ} 51' 19''.5$, nearly the same as that supposed by Hipparchus and Ptolemy. As the means of observation were at that time very imperfect, the instruments divided only to intervals of $10'$, and corrections for the greater refraction at the winter solstice, for the diameter of the solar disc, &c., then unknown, we must regard this conclusion as highly creditable to Eratosthenes.

His next achievement was to measure the circumference of the earth. He knew that at Syene (now Assouan) the sun was vertical at noon in the summer solstice; while at Alexandria, at the same moment, it was below the zenith by the fiftieth part of a circumference: the two places are nearly on the same meridian (error 2°); neglecting the solar parallax, he concluded that the distance from Alexandria to Syene is the fiftieth part of the circumference of the earth; this distance he estimated at 5000 stadia, which gives 250,000 stadia for the circumference; the following diagram will explain the principle of this admeasurement.

C the centre of the earth, A Alexandria, S Syene, S the sun, \angle ZAS the $\frac{1}{2}$ of four right angles, \angle ASC the sun's parallax, which is very small: $\therefore \angle$ ACS is very nearly = ZAS; therefore distance AC = $\frac{1}{2}$ of circumference of earth.

Thus Eratosthenes has the merit of pointing out a method for finding the circumference of the earth. But his data were not sufficiently exact, nor had he the means of measuring the distance AS with sufficient precision.

Eratosthenes has been called a poet, and Scaliger, in his commentary on Manilius, gives some fragments of a poem attributed to him, entitled 'Hermes, or de Zonis,' one of which is a description of the terrestrial zones: it is not improbable that these are authentic: the chroniclers as well as philosophers of all nations, in a state of incipient civilisation, have called in the aid of metre to popularize their labours. Eratosthenes is therefore entitled to the name of a versifier rather than a poet, like his precursor Manetho, who wrote 'Ἀπορροισματικά' (effects or influences), a mixture of astrology and astronomy; one of whose lines, containing the names of the sun and planets, may be taken as a specimen—

Ζεὺς Ἀφρὴ Παφίη Μῆνη Κρόνος Ἡλῖος Ἑρμῆς.

The wretched doggerel arising from forcing names, scientific terms and reasonings into verse, may be judged by some ridiculous productions of the kind in our own language.

That Eratosthenes was an excellent geometer we cannot doubt, from his still extant solution of the problem of two mean proportionals, preserved by Theon, and a lost treatise quoted by Pappus, 'De Locis ad Medietates,' on which Montucla has offered some conjectures, 'Histoire des Math.,' an. vii., p. 280.

Eratosthenes appears to have been one of the first who attempted to form a system of geography. His work on this subject, intitled 'Geographica' (Γεωγραφικά), was divided into three books. The first book contained a history of geography, a critical notice of the authorities used by him, and the elements of physical geography. The second book treated of mathematical geography, and contained the method above explained, by which he determined the earth's circumference. The third book contained the political or historical geography, arranged according to the three great divisions of the known globe, Europe, Asia, and Libya. The whole work was accompanied with a map of the known world. The geography of Eratosthenes is lost; the fragments which remain have been chiefly preserved by Strabo, who was doubtless much indebted to him.

Eratosthenes also busied himself with chronology. The reader will find some remarks on his Greek chronology in Clinton's *Fasti Hellenici*; and on his list of Theban kings, by R. Rask, in his little work on the antient Egyptian chronology, German translation, Altona, 1830.

The properties of numbers attracted the attention of philosophers from the earliest period, and Eratosthenes also distinguished himself in this branch by a work which he denominated *Κόσμιον, Cribrum, or Sieve*, the object of which is to separate prime from composite numbers, a curious memoir on which was published by Horsley in the 'Philosophical Transactions,' 1772. The principle of the method is to reject all the multiples of the primes, tabulating first all the odd numbers; the multiples of 3 will be found with intervals of two places, those of 5 with intervals of 4, and by placing a mark over each such multiple, none but prime numbers will remain after this sifting. The same method, which is indeed indirect, but comparatively rapid in application, has been employed by Ladislaus Chernac, in forming a table of primes from 1 to 1,020,000, in a treatise published in 1811; the following example will explain the method:—

3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39, 41, 43, 45, 47, 49.

By actually trying this method it will be seen how readily the composite numbers are marked out, and we may terminate the operation when our commencing number exceeds a third of the last number in the table.

Eratosthenes arrived at the age of eighty years, and ultimately becoming weary of life, died by voluntary starvation. (Suidas, *Eratosthenes*.) Montucla, with his usual naïveté, says, it would have been more philosophical to await death 'de pied ferme.'

(Montucla, *Histoire des Math.*, p. 239; Delambre, *Hist. de l'Astronomie Ancienne*, p. 86; Lalande, *Bibl. Astron.* in art.; *Sententiæ Gr. et Lat. in Poetis Mti.*, Radulphi Winterton, Cambridge, 1700; *Fragmenta Gr. et Lat.*, by Shaubach, Göttingen; *Araucan.*, Oxford ed., 1472; Horsley's *Tracts and Memoir in Phil. Trans.*, 1772, *Catasterismi*, Heyne; *Cribrum Arith.*, by L. Chernac; *Geographicorum Fragmenta*, 1787; Eutocius' *Commentary on Archimedes*. The last edition of the *Fragmenta* of Eratosthenes is by Bernhardt, Berlin, 1822, 8vo.: this edition does not contain the *Catasterismi*. See CLEOMEDES.)

ERBIL. [ARBELA.]

ERCILLA Y ZUNIGA, ALONSO, the author of the 'Araucana,' an epic poem, mentioned with high praise by Hayley in his 'Essay on Epic Poetry,' and better known out of Spain than many other Spanish works of greater merit. Alonso was the third son of a celebrated lawyer, Fortun Garcia, lord of the castle of Ercilla, and was born at Madrid in 1533. His mother, Doña Leonor de Zufiga, became a widow the following year, and being appointed *guarda damas* to the wife of Charles V., soon obtained for her son a place among the pages of the prince of Asturias, afterwards Philip II. At the age of fourteen, Ercilla probably had his genius awakened by attending that prince through Italy, Germany, and the Netherlands, in a pompous progress of which the chronicler of Philip II., Calvete de Estrella, has left an account, and in which he has vividly portrayed the manners and pageants of that fierce and romantic age. Following Philip in his subsequent travels, and on the occasion of his marriage with queen Mary, Ercilla came to England in 1554. While in London, he heard of a revolt of the brave Araucanians (*Araucanos*) against the Spaniards in Chile, and his military ardour being excited by the news, he volunteered to go to America in search of that glory which he soon acquired. It was amidst the incessant toils and dangers of a campaign against barbarians, under the canopy of heaven, with nothing to write on but small scraps of waste paper, and often only leather, struggling at once against enemies and surrounding circumstances, that, for the first time, an iron-clad poet

'Tomando ora la espada, ora la pluma.'

attempted to describe in epic strains the exploits in which he himself participated, and which he often directed. Thus did Ercilla write the first part of his 'Araucana,' so named from the war and country of Arauca, or of the *Auca* people, which means free. [ARAUCAINIANS.] After numerous escapes from the dangers of the war, he was ordered to the scaffold (A.D. 1558) by a young and hasty commander, who thought he perceived a premeditated mutiny in a private quarrel which arose in the American city of Imperial, while the people were celebrating the accession of Philip II. to the crown. Ercilla, who on that occasion had to draw his sword in defence of his honour and life, was saved by the timely discovery of the injustice of the sentence which had been passed on him. Much impaired in health, although then only in his twenty-ninth year, the poet-soldier returned to Spain, but only to experience the continued neglect and disdain of that Philip whom he had served all his life, whom he had already invoked as his Augustus, and whom he celebrated in the sequel of his poem. To exalt and propitiate his reluctant patron, he introduced into it the episodic battles of St. Quentin and Lepanto. The indignity which he still experienced induced Ercilla to ramble for some time over different parts of Europe, where the only favour he received was from the emperor Rudolph, who appointed him gentleman of his bed-chamber. At last he settled at Madrid, where he lingered in retirement and penury, writing poetry till his death, the time of which is not ascertained. He was however alive in 1596, for Musquera de Figueroa, in his 'Comentario de Disciplina Militar,' speaks of Ercilla as then engaged in celebrating the victories of Don Alvaro Bazan, marques de Santa Cruz, in a poem which was never published, and perhaps was left incomplete. The 'Parnaso Español' contains also a short erotic poem, written by Ercilla in his youth, and highly commended by Lope de Vega in his 'Laurel de Apolo.' But it is only the 'Araucana' which has recommended Ercilla to posterity. He published the first part alone; then the first and second parts together in 1577; and the whole three parts in 1590, many editions of which have appeared successively in different places. The severe censures passed on this poem by a host of biographers or compilers are in

fact only a long file of repetitions. Voltaire, who, by his 'Essai sur la Poésie Epique,' has made the 'Araucana' more generally known, prefers the character of Colocolo in the second canto to that of Nestor in the Iliad. He shows however, by his sweeping censure of the rest, and by his asserting that Ercilla was at the battle of St. Quentin, that he had not read so far as the seventeenth canto. The writer in the 'Biographie Universelle,' amidst some very fair and proper observations, and after placing the 'Araucana' much above the Henriade, mistakes the xxxvi. and xxxvii., or two last cantos, for its continuation, or the iv. and v. part of the 'Araucana' by Santisteban Osorio, a notion which the most hasty glance at those cantos would have dispelled. The same writer is also unlucky in his refutation of Voltaire, since the elaborate note about the possibility of Ercilla's having fought at St. Quentin contains the anachronism of fixing his return from America in 1554, the precise year in which he sailed for America from London, as above stated. The other note by the same writer about Ercilla's birth proceeds from a misunderstanding of his biographical notice in the second volume of the 'Parnaso Español.'

Bouterwek, after denying to the 'Araucana' the title even of a poem, bestows abruptly sundry high but just commendations on its beauties, and thus revokes, in a great measure, if not totally, his hasty sentence of condemnation. The same writer, in supposing that Ercilla relates Dido's death after Virgil, shows that he had overlooked cantos xxxii. and xxxiii., where the heroine of Carthage is, on the contrary, amply vindicated, on the authority of Justin, from the misrepresentations of the Mantuan bard, who in the words of Ercilla shamefully

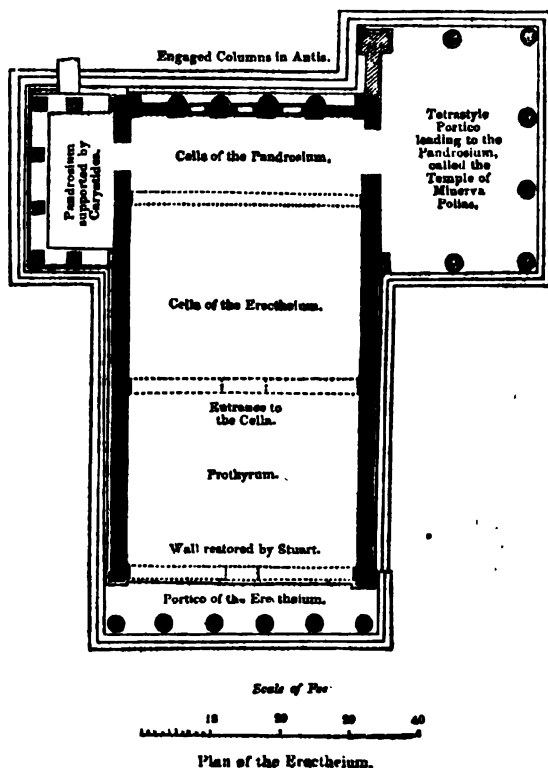

'Falso su historia y castidad preciosa.'

These inaccuracies in great authorities are noticed here in order to put readers on their guard against writers on literature in general; and our remarks on the errors of other critics must stand in the place of a criticism of our own on the poem, which within any reasonable limits would be impracticable. Nothing short of a sketch, however brief, of the 'Araucana,' could give a just idea of its plan and execution. It would however be unfair not to remind those who consider Ercilla as a second Lucan, that he undertook a much harder task than the Cordovan poet, who sung a mighty contest for the mastery of the world; while Ercilla had to contend against two features in his subject, the most unfavourable to an epic—a conquest not yet accomplished over a narrow, rocky, and unknown spot, and a brave and injured enemy struggling for their freedom. Still he succeeded in infusing an Homeric spirit into his long narration, which, independently of its other merits, is a real historical record.

ERECTHEIUM, a beautiful Ionic temple dedicated to Erectheus, built near the western brow of the Acropolis at Athens, and at the time when Stuart visited the place forming part of the modern fortress of the Acropolis. Connected with this building, and placed on one side of it at the end of the cella, is a tetrastyle pseudo-dipteral Ionic portico, in the same style as the portico of the Erechtheum; and on the opposite side is a small roofed building supported by caryatides, placed on an elevated basement. [CARYATIDES.] The back wall of the cella of the Temple of Erectheus is decorated with four semi-columns in antis engaged in the wall, and of the same order as the portico, which is hexastyle, and raised on three steps, forming a basement which runs round the entire building with its adjuncts. In Stuart's 'Athens,' the prothyrum is restored, and forms a closed chamber, for which there does not appear to be sufficient authority. It is more probable that the prothyrum was open, like some other Greek temples, because, as shown on Stuart's plan, the portico from its shallowness would be of little use as a covering, and would also produce little architectural effect. In the side portico, called Minerva Polias, which was most probably constructed after the Erechtheum, there was no opportunity of producing a depth of shadow by the deep recess of an open prothyrum, and the architect accordingly appears to have adopted the pseudo-dipteral portico to produce a somewhat similar effect, as well as to gain a covered space for those who officiated. It would appear from the regularity of the plan of the Temple of Erectheus, that it was constructed before the other, and of that regular parallelopipedal figure most commonly employed in these buildings; and that at a later period the Pandrosium was

constructed, with the portico on the opposite side forming the entrance or vestibule to the cella of the temple, which was formed from a part of the cella of the Temple of Erectheus, cut off from the end of that cella, which was either at that time or previously lighted with windows.

The length of the Temple of Erectheus is 73 ft. 2 in. 18 from the columns of the portico to those at the back of the cella; the width is 36 ft. 6.67 in. The depth of the portico of Minerva Polias is 21 ft. 1.75 in., and the width 33 ft. 1.30 in. The Pandrosium is 18 ft. 4.45 in. wide, and 11 ft. 9.57 in. deep. (See Stuart's *Antiquities of Athens*, edited by W. Kinnard, architect.) The columns of the Erechtheum are 2 ft. 3.8 in. in diameter at the base, and 1 ft. 11.2 in. at the upper diameter; and those of the Minerva Polias 2 ft. 6.9 in., and the upper 2 ft. 3.5 in.; while the intercolumniations are respectively—Erechtheum 4 ft. 7.95 in., Minerva Polias 7 ft. 8.19 in., although there is a slight variation in the intercolumns, which may be the effect of time and inaccuracy in setting them out originally. The columns of the Minerva Polias are on a much lower level than those of the Erechtheum. The capitals of the order of these two temples are very richly carved. If anything, the capitals of the Minerva Polias are a little richer than the Erechtheum. The volutes are very graceful [COLUMN], and the spiral lines are elaborately arranged. The angular volute is ingeniously contrived. The necking of the capital is enriched with leaves, as well as with an enriched ovolo and astragals, and the volutes are connected by an enriched twisted band or guilloche ornament. The shafts are fluted. But with regard to many peculiarities in the detail, we must refer to the plates in Stuart's 'Athens.' The entablatures have several of their members enriched, and are similar in design; the bases of the columns however vary. The height of the columns of the Erechtheum is 27 ft. 7.5 in., and of the Minerva Polias 25 ft. 0.85 in. The pilaster of the Erechtheum is elegantly decorated, and the mouldings and decorations are continued under the architraves. The height of the entablature of the Erechtheum is 4 ft. 11.3 in.; and the height of the Minerva Polias is 5 ft. 5.34 in. The rise in the pediment of the portico of the latter is 3 ft. 4.33 in. The entablature of the Pandrosium is heavy: it is decorated with dentils, and also with pateræ on the upper face of the architrave. The windows and doors diminish at the top, and the friezes of the porticos appear to have been formerly decorated, if we may judge from the remains of cramps and cramp-holes on their faces. Some details respecting this building, not published in Stuart, are

given in the 'Erectheion,' a work on this edifice by H. W. Inwood, architect, who has imitated the Eretheion and Pandrosium in the external design of part of the New St. Pancrass Church, London. Stuart's Athens, vol. ii., contains the plans, elevations, sections, and details of this building.

ERETRIA. [EUBŒA.]

EREWASH. [TRENT.]

ERFURT, a province or administrative circle in Prussian Saxony, consisting of the former principalities of Erfurt, the former Imperial free towns of Mühlhausen and Nordhausen, the earldom of Hohnstein, together with the bailiwicks of Langensalza and Weissensee, and several adjacent districts, as settled by the congress of Vienna. Its area is 1296 English square miles, and its population, which was 234,427 souls in 1816, and 285,874 in 1831, is at present estimated at about 298,000. About one fourth part of this population are Roman Catholics, and the remainder, with the exception of about 900 Jews, are Protestants. It is bounded on the north by Hanover and Brunswick, and on the south by Saxe Weimar, Gotha, and Schwarzburg, with the exception of the isolated districts of Henneberg, Neustadt, and parts of the Voigtland. The soil of this province is favourable for the cultivation of grain, and rather more than one half of its surface is arable land. About one-fifth of it is appropriated to meadows or pastures, and rather more than one-fourth is occupied by woods and forests. It is not watered by any streams of magnitude: the largest are the Unstrut, the Gera, Werra, Salza, Erlau, Heide, Wipper, and Saale. There are a number of mineral springs in the hilly districts. The stock of cattle in 1831 was as follows: horses 17,694, horned cattle 62,399, sheep 189,797, goats 13,242, and swine 31,909.

This province is divided into the nine circles of Erfurt, Nordhausen, Heiligenstadt, Mühlhausen, Worbis, Schleusingen, Langensalza, Weissensee, and Ziegenrück, and contains 1 fortress (Erfurt), 22 towns, among which are Erfurt, Heiligenstadt on the Leine, 3500 inhabitants, Langensalza, on the Salza, 6500; Tannstädt, on the Schambach, 3000; Mühlhausen, on the Unstrut, with ramparts and ditches, 11,000; Nordhausen, on the Zorge, at the southern extremity of the Harz mountains, 10,900; Benneckenstein, on the Harz, 3000; Ellrich, 2800; Bleichrode, on the Bode, 2500; Schleusingen, at the confluence of the Erlau and Nahe, 2660; Suhl, on the Aue or Lauter, 6500; Weissensee, on the Holbe, 2250; Gross-Sömmerdu, on the Unstrut, 2300; Worbis, near the source of the Wipper, 1600; and Ziegenrück, on the Saale, 820. The chief products of the province of Erfurt are grain, flax, safflower, tobacco, hops, oil, and salt; large flocks and herds of cattle and swine are reared; and in the circles of Weissensee and Schleusingen there are mines of iron, lead, and copper. Marble and gypsum, as well as sulphur, are also among its mineral productions. Erfurt is likewise distinguished for its manufactures of iron and steelware, tin plates, seed oil, woollen yarns, cloths, flannels, and carpets, linens, silks, cottons, stockings, paper, porcelain, glass, brandy, wooden clocks, &c. It has government establishments for the manufacture of gunpowder and fire-arms. There are mineral springs near Schleusingen and in other parts.

ERFURT, the capital of the minor circle of that name, as well as of the province, is situated on the Gera, a tributary of the Unstrut, in a richly cultivated plain in 50° 58' N. lat., and 11° 3' E. long. It was the ancient capital of Thuringia, and is a fortress of the second order, possessing among its defences, which have been entirely renewed and much strengthened in recent times, two citadels, one the Petersburg, within the walls, and the other, Cyriaxburg, on Mount Cyriax, outside of the town. Erfurt, which has a number of gardens among its six suburbs, has six gates, five public squares, or open spaces, the largest of which is the market-place (with an obelisk of stone fifty feet high, erected by the citizens in 1802, to Charles, elector of Mentz, their then sovereign), several broad and well-built streets, and 19 churches, 11 being Roman Catholic, and 8 Protestant, of which the collegiate church of St. Mary is a fine Gothic structure: in this church there is a bell called the Maria Clara Susanna, cast in 1492, and weighing thirteen tons and upwards. There are 2 chapels, and there were several monasteries and convents, but all have been suppressed with the exception of the Ursuline nunnery, to which a female school is attached. In 1832 Erfurt contained 5 palaces, or princely residences, 73 buildings for government purposes, 47 ma-

nufacturing establishments, and 2743 dwelling-houses, with 22,000 inhabitants, exclusive of the military: in 1816 they amounted to 13,097, but in the sixteenth century they were not less than 58,000. About one fourth of the present population is of the Roman Catholic persuasion; the remainder, with the exception of about 200 Jews, are Protestants. What was once an Augustine monastery, where Luther resided from 1501 to 1508, in a cell which is still shown to visitors, is at present appropriated to the Lutheran Orphan Asylum. In this cell are a portrait of the reformer, his travelling pocket-case, and some of his books; and the following inscription stands over the doorway:—

'Cellula divino magnoque habitata Luthero
Salve, vix tanto callula digna viro.'

The suppressed Scots' monastery contains the cabinet of physics, once the property of the university of Erfurt, which was founded in 1392, and closed in 1816. The scholastic institutions in the town are—a Lutheran high school, with which a seminary for teachers is connected, a Roman Catholic gymnasium, a mechanics' school, a deaf and dumb school, a school of surgery, another of design, and a third for arts and architecture, a Sunday-school for apprentices, and 16 schools of an inferior class. Among other institutions there are one of pharmacy and chemistry, a society of the useful arts, a botanical garden, a library of about 50,000 volumes, formerly belonging to the university, an ophthalmic and blind hospital, a general hospital, and a Bible society. Erfurt is the seat of provincial administration and of the provincial tribunals. It has considerable manufactures of cottons and woollens, besides less extensive ones of linens, ribbons, leather, soap, earthenware, meal, oil extracted from seed, stockings, gloves, tobacco, &c., and it carries on a brisk trade in fruits, seeds, grocery and drugs, grain, &c. It was, between the fourteenth and sixteenth centuries, the centre of the commercial intercourse between the north and south of Germany, and belonged to the Hanseatic league. At the foot of Mount Cyriax there are three mineral springs called the 'Dreibrunnen,' in the midst of shrubberies and gardens. Erfurt and the adjacent lands, to the extent of about 294 square miles, was a domain of the electors of Mentz from 1664 to 1802, when it was transferred to Prussia by way of indemnity for certain losses; in 1807 it was annexed to the French empire under the treaty of Tilsit; in 1808 it was the place of conference between Napoleon, the emperor of Russia, the kings of Saxony and Bavaria, and other sovereign princes; and in 1815 the congress of Vienna restored it to the crown of Prussia.

ERGOT, a name bestowed upon a peculiar state of the seed of several cereal grains, but most frequently of the rye, which resembles a spur, or horn; hence, likewise, termed *secale cornutum*, or *spurred* rye. Whether this state of the grain be merely an altered condition of the pistil, or the result of the puncture of insects, or of the development of a fungus, is doubtful; but the best authorities incline to the opinion that it is a fungus. This last view is rendered probable by the investigations of Wiggers, who found by analysis that the basis of the structure of the spur is almost identical in chemical properties with the principle called *fungin*, and that the white dust sometimes found on the surface of the spurs will produce it in any plant, if sprinkled in the soil at its roots, and therefore appears to be analogous to the sporidia or spawn of the admitted fungi. (See Mr. Bauer's paper on the *Uredo fetida*, *Supplement to Penny Magazine*, March, 1833.) De Candolle considers the fungus to be the *Sclerotium clavus*. The spur is of variable length, from a few lines to two inches, and is from two to four lines in thickness; when large, only a few grains in each ear are affected; when small, in general, all of them are diseased. In colour the exterior or husk is of a bluish-black or violet hue, with two or three streaks of dotted gray; the interior is of a dull whitish or gray tint. It is specifically lighter than water, which affords a criterion for distinguishing sound from tainted grain. When fresh it is tough and flexible, but brittle and easily pulverized when dry. The powder is apt to attract moisture, which impairs its properties. Time also completely dissipates its peculiar qualities. It has a disagreeable heavy smell (which, being analogous to that of many fungi, strengthens the opinion that it belongs to that class of vegetable substances), a nauseous, slightly acid taste, and imparts both its taste and smell to water and alcohol. Bread which contains it is defective in firmness, liable to become moist, and cracks

and crumbles soon after being taken from the oven.' The most recent chemical analysis is that of Wiggers, who found it to contain a heavy-smelling fixed oil, fungin, albumen, osmazone, waxy matter, and an extractive substance of a strong peculiar taste and smell, in which, from experiments on animals, he was led to infer that its active properties reside. To this he gave the name of *ergotine*. Dr. Christison found Wiggers's statements to be correct in most points, except that what he procured as ergotine was destitute of marked taste or smell. Willdenow is of opinion that there are two varieties of the spur, and that only one of them is possessed of active properties.

Spurred rye occurs more frequently in some countries and districts than in others, and more abundantly in some seasons than in others. Rye raised in poor soil, and in a humid close air, such as that of the district of Sologne in France, is most liable to be infected; but, according to the experiments of Willdenow, it may be brought on at any time, by sowing the rye in a rich damp soil, and watering the plants freely in warm weather. A very rainy season, such as was that of 1816, is apt to produce it.

Bread prepared from grain which has a large admixture of the spur, occasions very distressing and often fatal effects, which are shown more or less rapidly according to the quantity present in the food, and the circumstances in which those who use it are placed. They have been observed to be most serious in seasons of scarcity, when various causes concur to produce disease. The symptoms which result from spurred grain, when used for a considerable time, are of two distinct kinds, one of a nervous nature characterized by violent spasmodic convulsions, the other a disordered state of the constitution, which terminates in the peculiar disease called gangræna ustilaginea, or dry gangrene. A single dose of the spur, not diluted by admixture with sound flour, excites effects which vary according to the quantity taken and the state of the person, and are chiefly limited to the stomach and intestinal canal, if the dose be small; but if so much as two drachms be taken, it causes giddiness, headache, flushed face, pain and spasms in the stomach, nausea and vomiting, with colic, purging, and a sense of weariness and weight in the limbs. In the case of parturient females, when given at a certain stage of the labour, it is admitted by most practitioners and writers to produce specific effects, and to expedite the labour in a very marked manner. It is by some persons alleged to produce hurtful effects upon the child; but such consequences probably occur only when it has been used at an improper stage of the labour; or when it ought not to have been employed under any circumstances. The rules for its employment are given in works devoted to obstetrics, to which we refer. It has likewise been recommended in menorrhagia and in leucorrhæa, but its utility rests upon less decisive evidence than in the case already stated.

The nervous symptoms arising from the use of bread formed of spurred rye may in general be cured by emetics, laxatives, and frequent small doses of opium, provided this treatment be adopted in reasonable time, and the unwholesome food completely withdrawn.

The tendency to dry gangrene is to be combated by the use of cinchona and cordials, with local applications to the part threatened. The noxious food must be completely relinquished. (Christison on Poisons.)

ERGOT, botanically considered, is a fungus belonging to the Gymnomycetous division, and constituting one of two species of *Spermoëdia* admitted by Fries. He calls it *S. clavus*, and separates it from the genus *Sclerotium*, to which it had previously been referred, on account of its growing in the inside of other plants, and having no proper fructification. He defines the genus *Spermoëdia* as follows: 'Variable, rounded, entophthal, rootless, of a fleshy mealy homogeneous texture, with a rind concrete, scaly, or somewhat pruinose. Proper fructification none.' And then he adds 'that it is only a morbid condition of the grain of corn, not propagated by seed, but generated by a particular combination of external influences (*cosmica momenta*).' Endlicher takes the same view of the nature of ergot, only with more consistency he does not admit it as a real fungus, but only enumerates it as a diseased state of the seed of grasses, swelling into a fungoid body, and covered externally with powder. The same opinion is also very generally entertained. Nevertheless, we regard the question as being far from settled. The definite form assumed by ergot is unfavourable to the idea of its being a mere disease; the powdery

efflorescence proceeding from its surface requires to be more particularly examined; and the microscopical anatomy of the production in different states must be far more exactly studied than it has yet been before the true nature of ergot can be positively determined. De Candolle is clearly of opinion that it is a peculiar fungus which attacks the ovary of grasses, destroying them when young, and protruding from them in a lengthened form, in rye and other European grasses: and Fontana asserts that it may be propagated by contact; the latter statement has however been contradicted.

The ergot of rye is not confined to that kind of grass, but attacks many other species. Fries distinguishes it by the lengthened form and white interior from *Spermoëdia Paspali*, a Carolina ergot, which is globose and somewhat compressed, scaly and rough externally, pale brown and yellowish inside. A third species, not yet registered by botanists, attacks Indian corn in Columbia, and has a pear-shaped figure.

ERGYNE. [ISOPODA.]

ERICA, one of the most extensive and beautiful genera known in the vegetable kingdom, belonging to the natural order that bears its name [ERICACEÆ], and therein distinguished by its calyx being four-leaved, its corolla four-toothed, and its fruit a dry, four or eight-celled, many-seeded capsule, opening into valves with the dissepiments projecting from their middle.

Under this character is included a great variety of species having very narrow linear leaves arranged in whorls, and so little different in their vegetation in most cases, that when out of flower they are often not easily distinguished from each other; but exhibiting a surprising diversity in their flowers, in which their great beauty resides. The richness of colour, the elegance and variety of form, the delicacy of texture, or the minute microscopic perfection of their corolla, are such as no words can describe. Lovely as even our wild moorland heaths are, they rank among the lowest in point of beauty in this extraordinary genus, in which all the hues of red, pink, and purple, vie with each other in the most brilliant manner, assuming every tint but blue, and fading into the purest and most transparent white. Some of the species have the corolla as much as two inches long, in others it is not bigger than a pepper-corn; in some it is long and slender, in others inflated like a flask, or dilated like a vase of the purest form, or as round as an air-bubble; and there are many in which it is split almost to its base, and immersed in a calyx whose texture and colours are even more brilliant than its own. Here we have a species the surface of whose corolla rivals in evenness and polish the finest porcelain; there another appears covered all over with hairs, exuding a glutinous secretion, which glitters upon its sides like solid crystals; and some again have their colours so dimmed by a loose shaggy coat, that their real tint can hardly be ascertained. There are even some in which the corolla assumes the very colour of the leaves, only clearer, brighter, and richer. This great difference in the structure of the flowers of different species is accompanied by distinctions in their anthers, which are either *muticous* (destitute of appendages), *cristate* (furnished with two little broad projecting membranes), or *aristate* (that is having a couple of bristle-shaped processes proceeding from their base). It has lately been proposed to take advantage of these and similar differences for breaking up the genus *Erica*, now consisting of between 300 and 400 supposed species, into a number of new genera; and accordingly in Don's 'General System of Gardening and Botany,' we find no fewer than twenty new groups formed at the expense of *Erica*. There can however be no reasonable doubt of this having been an injudicious measure, and that the greater part of these new genera are little better than fresh contributions to the confusion that already reigns in the nomenclature of garden plants. Dr. Klotzsch in particular, the present conservator of the Royal Herbarium at Berlin, by whom the order Ericaceæ has been made a subject of special study, objects to them in unmeasured terms; and it must be admitted that he possesses a much more correct acquaintance with *Erica* than any other author. For his views concerning the real importance of the differences observable in the organization of heaths, and the commencement of his still unfinished but very careful revision and reconstruction of the genus, the reader is referred to the 'Linnaea,' vol. ix., p. 612. The best arrangement in any work published in this country is to be found

in the second edition of the 'Hortus Kewensis,' an enumeration with brief characters of 304 species, illustrated with a considerable number of good wood-cuts, is published in Loudon's 'Encyclopædia of Plants;' the 'Botanical Cabinet,' 'Botanical Repository,' and 'Botanical Magazine,' contain coloured figures of numerous species; and there are separate works upon the subject, also with coloured plates, one by Mr. Andrews, and the other by the gardener to the duke of Bedford.

The genus is confined to the old world. A few species occur in the north of Europe, and others in the countries bordering on the Mediterranean. In Great Britain, heather (*Erica* or *Calluna vulgaris*) covers large tracts of waste land and is used to thatch houses, to make brooms, and even beds, in the northern parts of the island. There is a double variety of this species which is extremely beautiful. All our British heaths are improved by cultivation, and are general favourites where the climate and soil are suited to them. They will not however thrive in hot dry places and in any common soil, but require sandy peat earth, and a situation where they are moderately shaded from the sun. *Erica carnea*, one of the few plants whose flowers bid defiance to the rigour of winter, and appear as the earliest harbingers of spring, is found wild in Germany and generally on the mountains of middle Europe. *E. Australia, arborea, Mediterranea*, and *odonodes*, adorn the rocks of the south of Europe.

But it is at the Cape of Good Hope that the principal part of the species is found; indeed the whole of those which are cultivated in greenhouses. In their native country they are by no means so handsome as when cultivated, but form scraggy shrubby bushes, with so little beauty, that the colonist bores have not vouchsafed to give them even a name.

On account of the great beauty of Cape heaths and the property which so few plants possess in common with them of producing their blossoms the whole year round, they have become universal favourites with all those who have a greenhouse at command. But an impression that there is great difficulty in cultivating them, and in fact the want of success that often attends their management, has deterred so many from attempting to grow them, and thus has robbed our gardens to such a degree of their very greatest exotic ornament, that we shall take this opportunity of stating at some length what precautions are really requisite in cultivating heaths, and of pointing out to what causes failure is generally to be attributed. We are the more induced to do so because the taste for this tribe of plants is reviving in this country, and because the supposed difficulty of keeping them in health has no foundation; for with a little care, and less expense than is required to grow pelargoniums, they may be brought to the highest state of perfection.

No man has ever given such excellent practical directions for the whole management of heaths from their first stage of a seedling or a cutting to their last of a noble full grown bush, as Mr. M'Nab of Edinburgh, of whose experience we of course avail ourselves in the succeeding statement; referring our readers to it for further information as one of the very best practical horticultural papers in any language. (*Treatise on the Propagation, Cultivation, and general Treatment of Cape Heaths*, by Wm. M'Nab, Edinburgh, 1832.)

If new varieties are wanted, the only way is to raise them from seed, but when this is not the object, by far the best method of propagating is from cuttings. Much of the success which attends the striking of cuttings depends upon the state they are in when taken from the plant; for example, if they are too young they are liable to damp off, and on the other hand, if they are too old, they do not emit roots freely; therefore the best is a middle course, which is not liable to either of these objections.

The leaves of the cutting must be stripped off to about one-half of its length, and its end cut with a sharp knife: in this state it is fit for the cutting-pot. In preparing the pot, it is necessary to be particular about the draining, and for that purpose it should be filled to within about two inches of its top with broken pots, rough ashes, or something of this description; the remainder must be filled with sand, which should be procured as free from ferruginous matter as possible. Between the sand and draining, it is a good plan to have a thin layer of decayed turf or rough peat soil, otherwise the water will carry down the particles of sand, and render the drainage of little or no use.

Some cultivators press the sand very hard, water it well, and then put in the cuttings; others do not press it at all, nor give it any water until the cuttings are introduced; the last method is perhaps the best, at least the intended effect is best produced by it; for while the water which is given afterwards, in the former case renders the cuttings more loose, in the latter they always become more firm; and it will be found, that those which have not been pressed at all, in a few days will be more firmly fixed than those which have been treated in a different manner.

Bell-glasses are frequently put over heath cuttings, but these are in most cases unnecessary, unless where the cuttings are exposed to a current of air, and where evaporation goes on rapidly. If bell-glasses are used at all, it is of the greatest importance to look over and wipe them occasionally, otherwise the moisture which is deposited upon the glass will prove very injurious to the young cuttings.

Heaths may be propagated at any season of the year when the young wood can be obtained in a firm but not hardened state, but the spring is the best time for performing this operation, because the young plants get rooted before the commencement of the dull and damp winter season, in which heaths are apt to suffer, if injudiciously treated.

If it is winter when the cuttings are put in they will require a little artificial heat, and may be placed in a stove; but, if in the end of spring or summer when the weather is warm, a cool greenhouse or frame is quite sufficient to insure their growth.

After the cuttings are sufficiently well rooted, which is easily known by their beginning to grow freely, they must then be potted off, in pots of the smallest size, and regularly shifted into larger as they require it.

With regard to the soil in which it is most advisable to grow them, as very different statements are to be found in books, we quote Mr. M'Nab's words.

'The soil,' he says, 'for the first potting should be one half peat and one half sand, always taking care to drain the pots well with small pieces of broken pots or cinders.' 'The soil for the second potting should be about two-thirds peat and one-third sand, and in all the after-pottings the soil should be the same as will hereafter be recommended.'

In the same part of his work he says, 'The soil which I have found Cape heaths thrive best in is a black peat soil taken from a dry heath or common which is never overflowed with water. In general it should not be taken off more than five or six inches deep. This, however, must partly depend upon the subsoil: for, in some cases, I have seen at twelve or fourteen inches deep the soil quite as good as at the surface. Whatever heath or other vegetable production is on the surface, should be taken along with the peat earth to the compost ground, and there laid up in a heap till wanted. It frequently happens that peat earth taken from such situations as I have mentioned has sand intermixed with it in its original state; but when this is not the case a quantity of coarse white sand should be procured and mixed with the earth in the compost ground. This should be at least to the extent of one-fourth or one-fifth of the whole, and although a little excess of sand is used, it will never be found injurious to the health of the plant.'

Mr. M'Nab, in shifting his heaths, has always at hand some fragments of soft freestone, which he introduces amongst the soil around the ball of the plant; the size of these stones is regulated by the width of the pots or tubs into which they are put. His reason for introducing stone shows how far his mode of cultivation is from quackery, and that he recommends nothing for adoption for which a sound physiological reason cannot be assigned.

'When stones are introduced among the earth in the way I have recommended, heaths will never suffer so much in the summer from occasional neglect to water them as they would do if the stones were not introduced; because these stones retain the moisture longer than the earth, and in winter they allow a freer circulation through the mass of any superabundant moisture which may be given.'

The same successful cultivator recommends the plants to be raised a little higher in the pot at each shifting than they were before; and after several shiftings the old ball around the stem will be raised two or three inches above the level of the edge of the pot or tub; always taking care, however, to leave sufficient room to hold enough of water

between the base of the cone of earth and the rim of the pot

This is an excellent plan, and one which cannot be too highly recommended, for there is scarcely a chance of the plant suffering from too much water being given it, even in winter; and if by chance it should receive too much, it can only be round the sides of the pot or tub, and at the extremity of the roots, whence it is carried off by the quantity of draining below. Moreover, and this is a most essential point, the water percolating through the earth next the sides of the pot ensures the tips of the roots being always kept damp and cool, a precaution absolutely indispensable to preserving heaths alive. It will generally be found that the sudden death so common among these plants is owing to the sides of the pot having become accidentally dried and heated. On this account a low pit, in which the pots can be so arranged that their sides are always in the shade, will be found a convenient place to grow them in during summer.

By treating Cape heaths in this way, they may be brought to a state of perfection quite unknown in their native country. From a list of some of the larger specimens grown in the Royal Botanic Garden, Edinburgh, it appears that they have attained the height of six, seven, and eight feet, and from ten to twenty-six feet in circumference. (*Arboretum et Fruticetum Britannicum.*)

The degree of cold which these plants will bear without injury is much greater than is generally imagined; at the same time experience shows that some are far more hardy than others. We learn from Mr. M'Nab that 'many of them will be much injured when the thermometer (Fahrenheit) falls eight or ten degrees below freezing; many others will require ten or twelve degrees below freezing to produce the same effect.' 'On the 30th of January, 1829, we had twenty-nine species of heaths planted out, which remained without injury till the 21st and 22nd of January the same season. The thermometer then fell fourteen degrees one night, and seventeen degrees the other below the freezing point, when they were all totally destroyed. The frost before had never been more than nine degrees below freezing.'

As the means of cultivating these beautiful plants are extremely different in different places, the following lists will be found useful to those who are only able to give a few of them room in their collections. They are borrowed from Mr. M'Nab, and therefore may be implicitly relied upon.

1. List of Cape heaths which will stand in the open air in autumn or middle of winter without protection, with the thermometer seven or eight degrees below freezing, without suffering in any way from such a degree of cold:—

| <i>Erica acuminata</i> | <i>Erica longiflora</i> |
|------------------------|-------------------------|
| aggregata | longipedunculata |
| campanulata | lucida |
| cerinthoides superba | mammosa |
| comosa alba | margaritacea |
| conferta | montana |
| congesta | nigrita |
| coridifolia | pendula |
| cruenta | perlata |
| — superba | physodes |
| curviflora | pubescens-minor |
| cupressina | ramentacea |
| Ewerana pilosa | rosea |
| expansa | serpyllifolia |
| exudans | setacea |
| ferruginea | Spermannia |
| fiaccida | splendens |
| globosa | tenella |
| glomerata | tenuiflora |
| gracilis | tetragona |
| grandiflora | transparens |
| hispidula | triflora |
| hyacinthoides | ventricosa |
| igneocens | viridescens |
| intertexta | verticillata |
| leucanthera | |

2. Heaths which are tenderer than those mentioned in the preceding list, and which, when exposed to the same degree of cold, will be injured by it, but will not suffer although fully exposed to a temperature four or five degrees below freezing:—

| <i>Erica abietina</i> | <i>Erica Linneana-superba</i> |
|-----------------------|-------------------------------|
| albans | Linneoides |
| articularis | mollissima |
| assurgens | nudiflora |
| baccans | mundula |
| barbata | pellucida |
| Blasria | persoluta |
| Bonplandia | perspicua |
| cafra | prægnans |
| calycina | propendens |
| cerinthoides-alba | pubescens-major |
| comosa-rubra | quadriflora |
| colorans | radiata |
| concinna | reflexa-ruora |
| Coventryana | rubens |
| cubica-minor | Sebana |
| cylindrica | — aurantiaca |
| daphnæflora | simpliciflora |
| decora | sessiliflora |
| depressa | spicata |
| discolor | spuria |
| divaricata | triceps |
| elata | trivialis |
| Ewerana | tubiflora |
| gelida | urceolaris |
| halicacaba | vestita-rosea |
| incarnata | viscaria |
| Linneana | |

3. A list of the most ornamental heaths which will flower in succession at all times of the year.

| | Time of flowering. | | Time of flowering |
|-----------------------|-----------------------|------------------------|----------------------|
| <i>Erica abietina</i> | Sept.—Mar. | <i>Erica melastoma</i> | April—July |
| <i>acuminata</i> | Mar.—June | <i>metulæflora</i> | April—Sep. |

Those who have not the convenience of a green-house or heath-house to grow Cape heaths in may nevertheless form beautiful clumps in their flower gardens by a judicious selection of hardy sorts (some of which have been already named), and by attending to the principles which have been laid down, namely, draining the ground, removing the soil where it is not suitable for their growth, and filling the space with a mixture of peat soil and sand, and at the same time introducing a quantity of freestone to equalize the moisture of the soil.

ERICA'CEÆ, a natural order of exogens, deriving their name from the extensive genus that forms the subject of the last article. It is readily known from all other orders by its anthers bursting by pores at their apex, the stamens being hypogynous, the corolla monopetalous, and the ovary containing more cells than two. By this character are combined with the genus *Erica* the fragrant richly-coloured *Azalea*, the shady evergreen *Rhododendron*, and the delicate irritable *Kalmia*, together with *Arbutus*, *Andromedas*, *Gaultherias*, and many others equally beautiful; in fact it is probable that if it were necessary for a botanist to name some one natural order as pre-eminent for beauty, this would be the one selected. It is therefore not a little curious that it should also be an order of poisonous plants; for one would hardly expect danger to lurk beneath forms so fair. Nevertheless *Rhododendron ponticum*, *Azalea pontica*, and various *Kalmias* and *Andromedas* are notoriously deleterious, and even the *Arbutus* berries are in no inconsiderable degree narcotic.

The order is unknown in very hot countries, except at considerable elevations; it appears generally to love exposed situations, and, with the exception of *Erica* itself, to follow mountain chains, as it advances from the cool plains of the temperate zone to equinoctial regions. Hence, although we find *Befarias*, *Gaylussaccias*, *Andromedas*, and others in Peru, Brazil, Ceylon, Java, Madagascar, and elsewhere, it is only upon the tops of lofty mountains or upon their sides.

Ericaceæ are frequently polypetalous, and give rise, along with other similar cases, to a suspicion that the usual division of exogens into polypetalous, monopetalous, and incomplete sub-classes, is essentially bad. [EXOGENÆ.]

Erica longiflora.

1, Stamens and pistil; 2, calyx; 3, ovary; 4, anther; 5, section of seed, showing the embryo.

ERICHTHUS, Latreille's name for a genus of deep-sea crustaceans, and placed by M. Milne Edwards between the genera *Squilla* and *Alima*. The last-named author makes the tribe *Erichthians* (*Erichthiens*) belong to the family of Unicuirsatiated Stomapods (*Stomapodes Unicuirsatiés*), the general characters of the tribe being an undivided carapace and a styliform rostrum; no moveable rostral plate; and branchiæ, in general, rudimentary.

The tribe, according to M. Milne Edwards, is composed of a certain number of small crustaceans approximating to the *Squilla*, but which have in general only rudimentary branchiæ, and are often completely deprived of them. They

are easily distinguished by their carapace, which is large, lamellar, generally transparent, without longitudinal furrows or distinct lobes, and always armed with a styliform rostrum, which advances above the ophthalmic and antennular rings. These two first rings of the head are less distinct than they are in *Squilla*, but have very nearly the same conformation, and move upon the succeeding cephalic segment. The *Internal antennæ* are inserted below and behind the ocular peduncles; they are rather distant from each other, and their slender and cylindrical peduncles are composed of three joints, and carry at their extremity three multiarticulate filaments. The *External antennæ* are inserted at some distance behind the preceding, and are directed outwards; their peduncle is large and formed of two joints, of which the first gives origin, by the anterior border of its extremity, to a slender and short stem (tige), composed of two peduncular joints and a multiarticulate filament, the second carrying at its extremity a large oval-shaped blade or lamina with ciliated edges. The *Epistome* is not projecting and swollen as in *Squilla*, and the mouth resembles a pear-shaped tubercle, situated near the middle or towards the posterior third of the lower surface of the carapace. The *Upper Lip* has the form of a triangle, with a rounded base which is directed backwards. The *Mandibles* are vertical, swollen at their base, and armed with two branches with denticulated borders, the upper of which raises itself into the interior of the pharynx; their palpiform stem (tige) is either rudimentary or null. The *Lower Lip* is large and composed of two swollen lobes. The *Jaws* are small and of the same conformation as those of *Squilla*, excepting that those of the second pair are narrower. The members which represent the anterior jaw-feet, the prehensile feet (*pates ravisseuses*), the three pairs of subcheliform feet applied against the mouth, and the three pairs of natatory feet, which terminate the series of thoracic members, are formed and disposed in the same manner as they are in *Squilla*. It is only to be remarked that often the three pairs of subcheliform feet are less approximated to the mouth than they are in the *Squilla*, and that those of the three last pairs are sometimes rudimentary. The carapace is prolonged more or less far beyond the last rings of the thorax, or even beyond the first segments of the abdomen, but without adhering thereto. The abdomen is elongated; its last segment is very large, and entirely covers the appendages of the preceding ring, which are short, but formed like those of the *Squilla*. Finally, the false feet suspended from the five first rings of the abdomen are more slender and more elongated than in the other division of the family, and, as has already been noticed, present in general only the vestiges of branchiæ.

Geographical Distribution.—The *Erichthians* have as yet occurred hardly any where else than in the ocean (haute mer), and have hitherto been found only in tropical regions

Genera: Squillerichthus.

Carapace armed with spiniform prolongations and covering the base of the internal antennæ, but posteriorly it does not overpass (not comprising the spines) the last ring of the thorax. The rostrum is styliform and very long. The eyes are large, pear-shaped, and articulated on a very slender and rather long cylindrical peduncle. The ophthalmic ring is not distinct from the antennular ring, as in the *Squillidae*, but the mode of insertion of the antennæ is the same as in those animals, and in the *Erichthi*. The antennæ of the first pair are directed forwards, and present nothing remarkable. The external antennæ are directed outwards, as in the *Erichthi*, and present also a large peduncle, carrying at its extremity a large oval-shaped lamina ciliated all round, and giving insertion, by its anterior border, to a very short stemlet (tigelle), composed of two peduncular joints and a terminal filament. The mouth is little distant from the base of the antennæ, and situated towards the middle of the carapace. The upper lip is large, demicircular, and projecting. The mandibles are directed downwards as in the *Squilla*, and there is a large denticulated tooth and a prolongation equally denticulated on its edge, which mounts towards the stomach, but the palpiform stem is null or rudimentary. Behind the mandibles are found a large inferior bilobed lip; and then two pairs of jaws, the form of which is the same as in the *Squillidae*. The appendages that correspond to the jaw-feet of the first pair present nothing remarkable; they have the form of a long and slender stem, and, as in the

other crustaceans of this family, do not seem to form a part of the buccal apparatus. The members of the following pair are very large and constitute *prehensile feet* (pates ravisseuses), exactly similar to those of the *Squilla*; their penultimate articulation is enlarged and spinous towards the base, and their terminal claw is short and armed with spiniform teeth on the prehensile edge. The feet of the three following pairs are inserted on a transverse curved line immediately behind the prehensile feet, and are habitually applied against the mouth exactly as in the *Squillidae*; each of these carries at its base a flattened disk-like vesicle, and is terminated by an oval cheliferous *manus*. The three last thoracic rings are complete, and free below the carapace, which covers the two first. The three pairs of corresponding feet are of moderate size, and formed as they are in the *Squillidae*, only their last joint is not setiferous. The abdomen is large, and much resembles that of the *Squilla*, except that the last segment is much larger and habitually covers the members of the penultimate ring. These last organs are composed, as in the *Squilla*, of a peduncular joint, which prolongs itself inferiorly into a great lamina, and carries two appendages inserted on its edges near its base. The internal appendage consists of a great ciliated lamina, and the external one is composed of two joints, of which the last is oval, and the penultimate joint armed with spines on the external border. The *false feet* suspended from the five first rings of the abdomen are large and formed of a nearly square peduncular joint and of two great oval laminae with ciliated edges; the internal lamina bears on its internal edge a small rudimentary appendage, and the external gives insertion, near its base, to a large ramose *branchia*.

Place in the series.—M. Milne Edwards, who founded this genus, and whose description we have above given, considers that *Squillerichthys* forms the passage between the *Squilla* and the *Erichthi*.

Locality.—The form has only been found as yet in the Asiatic seas.

The species (two only are recorded) are small. Example, *Squillerichthys typus*.

Description.—Rostrum advancing beyond the peduncle of the internal antennae; a great horizontal spine on the middle of the posterior border of the carapace; and, on each side, another and longer spiniform elongation, springing from the angle of the carapace; finally, a rather strong point towards the middle of the lateral border of the carapace, and another above the base of the external antennae. Claws of the prehensile feet, armed with four teeth (including the terminal point). The last thoracic ring is not covered with the carapace, and the abdomen is very large. Its last segment is much longer than it is wide, and armed with three pair of marginal teeth. Length about 16 lines. Found in the seas of Asia. (Milne Edwards.) The other species recorded by M. Milne Edwards, *S. spinosus*, was taken by M. Dussumier in the gulf of Bengal.

Erichthus.

Carapace very large, convex, and armed with spiniform elongations. It entirely covers the base of the ocular peduncles, as well as of the antennae, and extends backwards more or less far beyond and above the abdomen, which is short and large. The *eyes* are large, pear-shaped, and are not carried on a slender and elongated stem, as in the *Squillerichthi* and *Alima*. The *antennae* present nothing remarkable, except that the stemlet (tigelle) of those of the second pair is often rudimentary, and that those of the first pair are rather short. The mouth is formed in the same manner as it is in the *Squillerichthi*, only the external jaws are extremely small and narrower. The *jaw-feet* of the first pair are extremely slender and of moderate length; they are slightly enlarged towards the extremity and have a rudimentary nail or claw at the end. The *prehensile feet* are but little developed: their claw is nearly straight and without dentilations, and the penultimate joint is slender, elongated, straight, and devoid of spines. The feet of the three following pairs are formed in the same manner as they are in *Squillerichthys*, but they are inserted one after the other; the flattened vesicle fixed at the base of each of these organs, as well as of the members of the two preceding pairs, is very large. The thoracic feet of the three last pairs are formed in the same manner as in *Squilla* and *Squillerichthys*, but are little developed, and sometimes want the styliform append-

P. C., No. 594.

age; at other times they are entirely rudimentary, and are only composed of a small peduncle, terminated by two articulations, nearly like the false abdominal feet, but much smaller. The *abdomen* is wide and short; the caudal fin which terminates it is disposed as in *Squillerichthys*, and the false feet of the first pair are large and terminated by two great oval laminae, on one of which is a rudimentary *branchia*.

M. Milne Edwards, who gives the above characters, divides the nine species into the following sections:—

^a
Species whose rostrum is very long and passes sensibly beyond the internal antennae.

Example, *Erichthus vitreus* (*Smerdis vulgaris*, Leach). Locality, the Southern Atlantic Ocean.

Erichthus vitreus.

^β
Species whose rostrum is of moderate length, and passes beyond the peduncle of the internal antennae without attaining to the extremity of those appendages.

Example, *Erichthus armatus* (*Smerdis armata*, Leach) Locality, Coasts of Africa.

^γ
Species having the rostrum extremely short (not passing beyond the peduncle of the internal antennae).

Example, *Erichthus Duvaucellii*. Locality, Gulf of Bengal.

Erichthus Duvaucellii.

Alima.

Carapace narrow, straight above, if not altogether so behind, where it often presents a sudden roof-like elevation; *rostrum* straight and styliform. The anterior angles of the carapace constitute two acute spines directed forwards; the posterior angles are also prolonged into the form of points directed backwards on each side of the abdomen. Finally, the lateral borders of the carapace are nearly straight. The ophthalmic and antennular rings are not hidden under the carapace as in *Erichthus*, but are seen uncovered under the rostrum. The *eyes* are carried on slender, long, cylindrical peduncles directed outwards. There is nothing particular about the *antennae*. The *mouth* is situated very far from the front, towards the posterior third of the lower surface of the carapace; the *upper-lip*, the *mandibles*, the *lower-lip*, and the two pairs of *jaws* have the same form as in *Erichthus* and *Squillerichthys*. The thoracic feet are formed also in the same manner as in *Erichthus*, but the three pairs of members which follow the prehensile feet are more approximated to the mouth, as in the *Squilla*. The posterior border of the carapace is ordinarily notched, so as to leave uncovered the two

VOL. IX.—3 T

last thoracic rings, and the *abdomen* is narrow and elongated. The false feet are large, but are, in general, completely devoid of branchiæ: sometimes vestiges of these organs are found upon the abdominal members of the first pair, and at other times they are represented by a small pediculated tubercle fixed to the external blade of these appendages. Finally, the conformation of the species of caudal fin formed by the last abdominal segment and the false feet of the sixth ring are entirely the same as in *Erichthus*. M. Milne Edwards, whose description we have given, states that the *Alima* bear an extremely strong resemblance to the *Erichthi*, but always have the body more elongated. Their manners, he adds, are not known, and he divides the five species into the following sections:—

a

Species which have the hand of the prehensile feet unarmed with spines.

Example, *Alima hyalina* (Leach). Locality, Cape Verd.

Alima hyalina. a. Natatory ventral appendage magnified.

b

Species which have the hand of the prehensile feet armed with teeth or spines on the prehensile border.

Example, *Alima laticauda*. Locality, New Guinea. (Quoy and Gaimard.)

M. Milne Edwards observes that the species figured by M. Guérin under the name of *Alima triacanthura*, belongs to this division, and seems to be distinguished from the other species by the brevity of the rostrum, the shortness of the lateral blades of the caudal fin, &c.

Alima longirostris of the same naturalist has not, according to M. Edwards, been described, but seems to approach very nearly to the preceding species.

ERICHT, LOCH. [INVERNESS-SHIRE.]

ERICK, in Swedish, is synonymous with the German Heinrich, and the English Henry, and is the name of many kings of Sweden and of Denmark. Of the earlier kings of this name little is known, for the history of the Scandinavian nations previous to the ninth or tenth centuries of our æra is very confused. Messenius, in his 'Scandia Illustrata,' ridicules the accounts given by Johannes Magnus and other Swedish historians, who, he says, have striven to outdo the Danish chronicler, Saxo Grammaticus, in his fabulous legends. Another respectable authority, Puffendorf, expresses himself as follows: 'The names and deeds of the early kings of Sweden and the periods of their reigns cannot be easily determined, as the lists which have been published are by no means authenticated, and the traditions of those times have been derived chiefly from the ancient songs and fabulous legends, or out of the allegorical traditions of the ancient Scalds or poets, which have been perhaps wrongly interpreted.' (*Introduction to the History of Sweden*.) In the earlier centuries of our æra the country now called Sweden was divided into several kingdoms or states, of which Sweden Proper and Gothia were the two principal. Sweden Proper comprised the central part of present Sweden, and included the provinces of Upland, Sudermanland, Westmanland, Nerike, and part of Dalecarlia. The kingdom of Gothia comprised the southern part of the great Scandinavian peninsula, including the provinces of Ostrogothia and Westrogothia, divided by the Wetter Lake, Småland, Bohusland, Skåne, and Blekingen, with the isles of Gothland and Oeland. But the most southern provinces, especially Skåne, were for a long time a subject of contention with the Danes, who frequently occupied them.

There was also the kingdom of Wärmeland, north and west of the great Wener Lake, extending to the borders of Norway, and the kingdom of Hälsingland, north of

Sweden Proper, which included the provinces of Angermanland, Jämtland, East and West Bothnia, up to the wilderness of Lapland. Most of these provinces had each its separate chief or king, something like the earlier Saxon kingdoms in England; but the king of Sweden Proper, or of Upsal, as he was also called, was considered in ordinary times as the head of the whole, like the Bretwalda of the Saxon Hephtharchy. Odin or Wodin, the conqueror of Scandinavia in the century previous to our æra, is said to have kept Sweden for himself, allowing his relatives or companions to settle in the rest of Scandinavia as his vassals; and this superiority of Sweden was acknowledged for several centuries after, so that at the great general meetings of the Scandinavian nations the king of Denmark used to hold the bridle and the king of Norway the stirrup of the king of Sweden's horse. (Puffendorf.)

Among the earlier kings of Sweden, in the fifth and sixth centuries, we find several Ericks, of whom little or nothing is known. One of these reigned together with his brother Alrick as kings of Upsal, from about A.D. 465 to A.D. 485. Another Erick and his brother Jorund, being the sons of Yngus Alrickson, were following the then common profession of sea-kings, or pirates, when a vacancy on the throne of Sweden, to which they had some family claim, recalled them home about A.D. 525. They were opposed by the usurper Haco, when Erick was killed, and Jorund was obliged to escape. In the ninth century we find Erick Björnson reigning together with his father Björn Järnsida, about A.D. 864. Björn died in 870, and Erick reigned alone till 874, when he died abroad in some expedition. He was succeeded by his son Björn and his nephew Erick, the son of Refil the Sea King, who reigned together for a time. The two kings went with a host to join their Norman friends at the siege of Paris, A.D. 886, when Charles the Fat was obliged to conclude a dishonourable peace. Björn appears to have died at the siege, and Erick Refilson returned home and died some years after. He was succeeded by Erick, son of the late Björn, who reigned together with his brother Björn, called of Höga, from the place of his residence. After his death, Erick Emundson, a grandson of Erick Refilson, was proclaimed king about A.D. 910, under the guardianship of his great uncle Björn of Höga. Björn died in 925, and Erick remained sole king of Upsal. He sustained a war against Harald Harfager, king of Norway, and at his death was succeeded by his son, Björn IV.

Erick Segersäll or 'the victorious' reigned from 970 to 994. He retook Skåne and Halland from the Danes, and at last drove away their king, Sweno, from Denmark itself. He also defeated the Norwegians and Finlanders, and conquered Livonia, Esthonia, and Courland. Erick was succeeded by his son Olaf, or Olaus, who is mentioned as the first Christian king of Sweden.

In the year 1155, after the death of Swerker Kolson, the Othogothians chose his son Charles for their king, but the Swedes at their general assembly at Upsal elected Erick Jadwardson, a nobleman connected by alliance with both the royal families of Sweden and Denmark. He is styled Erick IX. by most chronologists, and he is also called Erick the Pious, or St. Erick. After some demur the Gothians agreed that he should reign over both kingdoms, but that after his death Charles Swerkerson should succeed him. Erick brought back the Hälsingers and the Jämtlanders to Swedish allegiance. In 1157 he proceeded with troops to Finland, in order to subdue the natives and convert them to the Christian faith, and the bishop of Upsal accompanied him on this expedition. The Finlanders were defeated, many of them were slain, and the rest were baptized. Christian churches were founded by the bishop, who remained in the country, while Erick returned to Sweden, where he employed himself in compiling a code of laws out of the ancient constitutions of the kingdom. This compilation is known by the name of St. Erick's law. Erick is remembered in history as a good king. In 1161, on the 11th May, as he was in the neighbourhood of Upsal, a party of Danes who had landed on the coast under Prince Magnus, surprised and killed him after a brave defence on his part. Magnus had his head cut off, and afterwards proclaimed himself king; but the Swedes and Gothians uniting under Charles Swerkerson fell upon the Danes and killed them all, together with their prince, and out of the spoil they built a church on the spot. Charles was then ac-

knowledge as king of the Swedes and the Goths, the title which the kings of Sweden bear to this day.

Charles was killed by Knut, St. Erick's son, about 1168, who succeeded him, but after Knut's death, A.D. 1192, the crown was again disputed between Erick Knutson and Swerker the son of Charles, who was supported by the Gothians. After a long war, Swerker was killed in battle A.D. 1210, and left Erick Knutson in quiet possession of the throne. St. Erick's convention was then renewed, and John, the son of Swerker, was constituted heir to the throne, which was afterwards to return to Erick's descendants. Erick died in 1219 at Wisingöe, which was the usual place of residence of the Swedish kings in those days.

Erick Erickson, son of the preceding, succeeded John in 1222 according to the convention, and reigned till 1250. His reign was at first distracted by civil war. The powerful family of Tolekunger, who were allied to the king by marriage, revolted against him; but they were defeated, and two of the leaders were put to death. Under this king Gulielmus Sabinensis, the Pope's Legate, first forbade marriage to the Swedish priests. Erick made war upon the Finlanders, who had revolted, and built several fortresses on their frontiers. He died at Wisingöe without issue, and was succeeded by Waldemar I, his sister's son.

Erick, son of king Magnus, and of Blanche, daughter of the Flemish Earl of Namur, was made colleague to his father by a powerful party of the nobility in 1344. A war broke out between father and son in 1357, and at last the kingdom was divided between them, Erick having the whole southern part, including Skane, East Gothia, Småland, &c. Erick was shortly after poisoned at an interview with his father, and, it was reported, by the agency of his own mother.

Erick, styled XIII., Duke of Pomerania and nephew to Queen Margaret of Waldemar, who had united Sweden, Norway, and Denmark under her sceptre, was appointed by the General States of the three kingdoms assembled at Calmar in 1396 to be her successor. He married in 1410 Philippa, daughter of Henry IV. of England, and in 1412, after Margaret's death, he assumed the reins of government. But he soon gave proofs of incapacity, and his capricious and tyrannical sway disgusted the Swedes, to whom he preferred his Danish subjects. Becoming entangled in a tedious war with the Dukes of Holstein and Mecklenburg and the Hanse Towns, in order to carry it on he loaded his subjects with taxes, while their commerce was ruined. He violated the articles of the Calmar union, stripped Sweden of its archives, which he took with him to Denmark, and filled most military and civil offices in Sweden with Danes and other foreigners. The Dalecarlians were the first to revolt, being led by a nobleman of the name of Englebrecht. They were joined by the North Hallanders and others, and at last they obliged the senate of the kingdom assembled at Wadstena to renounce its allegiance to Erick. Erick made a hasty peace with the Hanse Towns, collected a fleet with troops on board, and sailed for Stockholm. After repeated attempts, he was obliged to make a convention with the insurgents, by which the king retained garrisons in the three castles of Stockholm, Calmar, and Nyköping; all other situations in the kingdom being filled by Swedish natives. At the same time he promised to respect the articles of the Calmar union, and returned to Denmark. But his bad faith kept alive the discontent, and in 1438 the leaders of the Swedes entered into secret negotiations with the chief men in Denmark, who were likewise dissatisfied with Erick, and a general revolt ensued. Erick had already withdrawn from Denmark into the island of Gothland with his treasures. The Danes chose for their king Christopher, Duke of Bavaria, king Erick's sister's son, and the Swedish Diet assembled at Arboga offered him likewise their crown under the stipulations of the Calmar union. Erick was allowed by Christopher to retain possession of the island of Gothland; but after Christopher's death in 1448 Charles Knutson, who succeeded to the throne of Sweden, besieged Erick in the town of Wisby. Erick escaped into Pomerania, with the assistance of Christian, king of Denmark, who sent him to the island of Rugen, where he ended his days. (Dalin's *Svea Rikes Historia*, Stockholm, 1747; Puffendorf's *Introduction to the History of Sweden*; and Geijer *Svea Rikes Häfder*, 1825.)

ERICK XIV. of Sweden, the son of Gustavus Vasa,

was acknowledged, by a diet held at Westeraas in 1544, as heir to the throne, while he was in his eleventh year: he succeeded his father in 1559. He began by showing a considerable degree of jealousy towards his brothers John, Magnus, and Charles, whom their father had made dukes of Finland, East Gothia, and Sudermanland, as feudatories of the crown. He was also engaged in war with the Liffanders or Livonians, who had placed themselves under the protection of Denmark and of Poland; but the Esthlanders remaining attached to Sweden, Erick sent an army to Revel for their protection, and successfully defended that place against the Poles. Erick had at one time, before he was king, asked the hand of Elizabeth of England, who gave no positive answer, and after his accession to the throne he embarked to pursue his addresses in person. A violent temper however having driven him back to Sweden, Erick, who was superstitious and a believer in astrology, gave up all thoughts of the match, and turned his attentions to Mary, queen of Scotland, but with no better result. His brother John having married Catharine, daughter of Sigismund, king of Poland, without Erick's consent, Erick besieged him in the castle of Abo, made him prisoner, and kept him and his wife in close confinement, until the remonstrances of the people obliged him to release them. At the same time a war broke out between Denmark and Sweden, in which the Swedes had the advantage in several sea-fights. Meantime King Erick gave himself up entirely to his mistresses, and entrusted the care of the kingdom to his favourite Joram Peerson, an unprincipled man, by whose advice and that of Dionysius Burræus, a Frenchman by birth and his former tutor, he put to death several noblemen, among others the Stures, father and son, who belonged to a powerful Swedish family of Nils Sture: one of them was stabbed by the king with his own hand. Erick even went so far as to concert a scheme to put to death his brothers at a great festival to be given at Stockholm, but having been apprized of it, they conspired against him, seized upon several castles, collected a force, and marched upon the capital. Erick, after some defence, was obliged to surrender; the assembly of the states deposed him in 1568, and he was kept a close prisoner in the castle of Gripsholm, where he was treated very severely. His brother John was proclaimed king of Sweden. After nine years' confinement, Erick was put to death by poison, by order of his brother in 1577. (Celsius, *Könung Erick den Fiortondes Historia*, 1795.)

ERICK I. of Denmark reigned about the ninth century. He is commonly reckoned as the first Christian king of Denmark, and it was under his reign that Ansgarius, bishop of Bremen, preached Christianity both in Denmark and in Sweden.

ERICK II. succeeded his brother Olaf or Olaus IV. about the year 1095. He made war in Pomerania, and took Jutin, then a considerable town of that country. He greatly favoured the Christian religion, and obtained of the pope the establishment of the archbishopric of Laud in Scania, which then belonged to Denmark. Erick visited Rome, and died in the island of Cyprus about 1103, while on a pilgrimage to the Holy Land.

ERICK III., son of the preceding, made war against the Wendes or Vandals, who were carrying on piracy in the Baltic. He died about 1138, and was succeeded by

ERICK IV., his son, called 'the Lamb,' who turned monk at Odensee, in 1147.

ERICK V. succeeded his father Waldemar II. in 1241, and was murdered by his brother Abel, in 1250, who succeeded him on the throne.

ERICK VI. succeeded his father Christopher I. in 1259, was engaged in war against the king of Norway, and was involved in disputes with his own nobles, who, at a Diet held at Wyborg in 1282, obliged him to sign an act defining their privileges and the limits of the royal authority. He was taken prisoner in battle by Erick, duke of Holstein, and cruelly murdered in 1286.

ERICK VII. succeeded his father Erick VI., and continued the war against the king of Norway. He reigned till 1319, and was succeeded by his brother Christopher II.

ERICK VIII., styled by some VII., is the same as Erick XIII. of Sweden, the nephew and successor of Margaret of Waldemar. [Erick XIII.]

ERI'DANUS. [Po.]

ERI'DANUS (the river Eridanus), a constellation first mentioned by Aratus, who calls it Eridanus. Hyginus

states it to have been named from the Nile, and assigns a reason [CANOPUS]; but the scholiast on Aratus states this to have been peculiar to the Egyptians. In the heavens it is a winding stream, not very well marked by stars, extending from a bright star (α) of the first magnitude, called Achernes, and situated near the southern part of Phoenix, past the feet of Cetus, and ending at the star Rigel in Orion. Its principal stars are as follows:—

ERIE, LAKE. [CANADA.]

ERIGENA, JOANNES SCOTUS, a native of Ireland, from whence his appellation of Erigena is derived, that of Scotus being synonymous with it, as the Irish were still called in foreign countries Scots in those times, flourished about the middle of the ninth century, and was a celebrated scholar of that age. He resided chiefly in France, at the court of Charles the Bald, who seems to have been very partial to him. His writings on theological matters were considered as heterodox, and his treatise on the Eucharist was condemned to be burnt by the council of Rome A.D. 1059. [BERENGER.] His treatise on predestination is found in the *Vindiciae Prædestinationis et Gratia*, 2 vols., 4to., 1650. In his work 'Dialogus de Divisione Naturæ' he displays a wonderful information for the times he lived in, and an intimate acquaintance with the Greek language. He gives large extracts from the Greek fathers, and also

* Mr. Bally marks this ϵ^2 . ** ϵ^2 in Mr. Bally's work.
† So marked by Mr. Bally. †† Mr. Bally marks this ϵ^2 .

quotes Aristotle, Plato, Cicero, Pliny, and other ancient philosophers, and he gives the opinions of Pythagoras and Eratosthenes on some astronomical topics. In another part he inserts a very elaborate discussion on arithmetic, which, he says, he had learnt from his infancy. Turner, in his history of the Anglo-Saxons, has given an account of this singular work of this writer. Erigena also translated from the Greek certain theological works attributed to Dionysius Areopagita. To the writings and translations of Erigena is attributed by some the introduction of the later Platonism of the Alexandrian school into the theology and metaphysics of Europe. Erigena is believed to have died in France about the year 875. He must not be confounded with Joannes Duns Scotus, who lived in the thirteenth century. [DUNS SCOTUS.]

ERINACEUS. [HEDGEHOG.]

ERINNA, a poetess and the friend of Sappho, flourished about the year 595 B.C. All that is known of her is contained in the following words of Eustathius (ad Iliad. ii., p. 327.) 'Erinna was born in Lesbos, or in Rhodes, or in Teos, or in Telos, the little island near Cnidos. She was a poetess, and wrote a poem called 'The Distaff,' in the Æolic and Doric dialect: it consisted of 300 hexameter lines. She was the friend of Sappho, and died unmarried. It was thought that her verses rivalled those of Homer. She was only 19 years old when she died.' Another poetess of this name is mentioned by Eusebius under the year 354 B.C. This appears to be the same person who is mentioned by Pliny (*Hist. Nat.* xxxiv. 8) as having celebrated Myro in her poems. We possess no fragments of either of these poetesses.

ERIOCAULO'NEÆ, a group of endogenous plants subordinate to Restiaceæ, for the most part inhabiting swampy or marshy places, or the bottom of lakes, and having the flowers collected into dense heads. The sexes are separated; the perianth consists of from two to six divisions immersed in soft bracts; there are from two to six stamens; the styles are two or three; the cells of the ovary are the same number, and the seeds solitary, with lines of hairs upon their surface. The embryo is placed on the outside of the albumen at the apex of the seed. The flowers are always very small, and difficult to examine on account of the thinness and delicacy of their texture. Eriocaulon itself is the principal genus, consisting of about one hundred and twenty known species, ninety-four or ninety-five of which are met with in the equinoctial parts of America, and one solitary instance, *E. septangulare*, in the Isle of Skye. Mr. Bongard, who has written a monograph of the South American species, states, that in that part of the world, although they prefer marshy and inundated places, yet some are found upon damp sand, others among grass, and some in dry and stony places; they

Eriocaulon dendroideum.

1. A female flower with six segments to its perianth, the three outermost of which are broadest and fringed with long hairs. The ovary has three stigmas, exterior to which are three horn-like appendages. 2. A male flower; a bract at the base, the three outer divisions of the perianth separate, the three inner united into a three-toothed cup, and three stamens within its border.

are also frequently met with in alpine situations, some as high as 5590 feet above the sea on the summit of Mount Iambé. The preceding figure of *Eriocaulon dendroideum* gives a correct notion of the appearance of these plants.

ERIOPHORUM, the systematic name of the sedge-like plant which is called in this country wild cotton, or cotton-grass, in consequence of the long cottony tufts which wave upon its stalks in marshy and sedgy heaths and wastes in all parts of this country. The appearance is owing to the hypogynous scales, which, in this glutinous genus, represent the calyx, being extended into long numerous white hairs, which project far beyond the scales of the flower head. It is not a little curious that while, in most of the species, these hairs are indefinitely numerous, they should in one, *E. alpinum*, be reduced to the regular number, six, which is the general proportion of floral envelopes belonging to endogens. Professor Kunth enumerates twelve species, all inhabiting the colder parts of the northern hemisphere.

ERIPHIA, Latreille's name for a genus of Brachyurous or short-tailed Crustaceans.

Carapace less wide, and more quadrilateral than in the other Cancrarians; length two-thirds more than the breadth; the fronto-orbital border occupies more than one-half, and sometimes more than three-fourths of its breadth; and the latero-anterior borders, directed nearly right backwards, only describe a slight curvature, and prolong themselves but little. *Orbits*, as in the genus *Ruppellia*; but the space which separates their edges from the basilar joint of the external antennæ is very considerable; this joint is but little developed, and does not occupy a fourth of the space comprised between the antennary fossette and the internal canthus of the eyes; on the contrary, the moveable stem of the external antennæ is much more developed than in the *Ruppellia*, and is inserted at a small distance from the antennary fossette. For the rest, not differing from the other Cancrarians.

M. Milne Edwards, whose description we have given, says, that the *Eriphia*, which he places among the Quadrilateral Crustaceans, approach the *Ruppellia* nearly, but that the general form of the body of *Eriphia* tends to establish a passage towards the *Thelphusa*. He divides the species into the following sections.

a.

Species having the hands (manus) tuberculous.

*

Front armed with spines.

Example. — *Eriphia spinifrons* (*Cancer spinifrons*, Herbst).

Locality. — Inhabits all seas (Milne Edwards).

Eriphia spinifrons.

* *

Front devoid of spines.

Example. — *Eriphia gonagra* (*Cancer gonagra*, Fabricius).

Locality. — Coasts of South America.

Eriphia gonagra.

β.

Species having the hands (manus) smooth, not tuberculous.

Example. — *Eriphia levimana*.

Locality. — Isle of France.

Eriphia levimana.

M. Milne Edwards observes, that the *Eriphia* figured by Savigny (*Egypt*, pl. 5, fig. 1), and referred with doubt by M. Audouin to *E. spinifrons*, appears to him (Edwards) to be a distinct species; and that *Eriphia prismatica* of Risso has not been described with sufficient details to justify its reference to this genus with certainty. *Cancer euryrhone* (Herbst) appears to M. Edwards to be an *Eriphia*.

ERIVAN is a town in the Russian government of Georgia, or Grusia, situated about 40° N. lat., and 44° 30' E. long., at no great distance from the place where the boundary lines of Russia, Persia, and Turkey meet. The country in which it lies once belonged to the kingdom of Armenia, and in later times to the Persian province of Azerbaijan, but was given to Russia by the peace of Turkmanchai in 1828. The town is situated on the banks of a considerable river, named Zanga, or Zengin, which flows from the lake of Erivan, or Gouksha, and falls into the river Aras; the river is crossed at the town by a handsome stone bridge of several arches. The town is built partly on a hill and fortified, besides being defended by a fort, which is of an elliptical form, upwards of 6000 yards in circuit, and surrounded by two strong walls flanked with towers. The town is of considerable extent, but probably does not contain more than 10,000 or 12,000 inhabitants, the greatest part of its area being occupied by gardens. The base of Mount Ararat is only about six or eight miles from the town.

ERLANGEN, or **CHRISTIAN'S ERLANGEN**, the principal town of the bailiwick of Erlangen, in the Bavarian circle of the Retzat, and the only Protestant university in the kingdom of Bavaria, is situated in a sandy but well cultivated plain, in 49° 35' N. lat., and 11° 4' E. long., within a short distance of the confluence of the Regnitz and Schwabach. It is divided into the Old and New Town, the latter of which was founded by Christian, Markgrave of Bayreuth, in the year 1686, and first inhabited by some French colonists: from that prince it takes the name of Christian's Erlangen. It is surrounded by walls, has seven gates, and its population is about 10,000, of whom about 600 are Roman Catholics. The New Town is handsome, and regularly built. Erlangen has three Lutheran and two Reformed Lutheran churches, a Roman Catholic place of

worship, an orphan asylum, and infirmary, and a military hospital. The palace, which was partially destroyed by fire in 1814, has been fitted up for the use of the university, which was founded by Frederic, Markgrave of Bayreuth, in 1743. The establishments now connected with it are—an equestrian academy, a gymnasium, an ecclesiastical seminary, a polytechnic school, an academy of morals and the fine arts, a fine chemical laboratory, a botanical garden, a philological seminary, an anatomical school, museums of natural history, the fine arts, and experimental philosophy, a library of upwards of 100,000 volumes, and a clinical institute. The average yearly number of students attending this university is about 350. The Leopold-Caroline academy of naturalists, which was established in the year 1666 simultaneously with the Parisian academy of sciences, has its seat here, and is the first learned society that was instituted in Germany. There are also a society of medicine and natural philosophy, and a general society for domestic and rural economy. The town has factories for weaving and printing cotton goods, and also manufactures stockings and hats on a large scale, gloves, leather, tobacco, looking glasses, linen, toys, &c. Erlangen, together with the principality of Bayreuth, became an appendage of the Bavarian crown by the treaty of 1809.

ERLAU (in Hungarian EGER, and in antient records AGRIA) is the chief town of the county of Heves, in Upper Hungary. It is situated in a beautiful valley in the midst of richly cultivated lands, skirted by mountains crowned by woods and vineyards; in 47° 53' N. lat., and 20° 23' E. long. The Erlaubach divides it into two parts, which are surrounded by fortifications about seven miles in circuit, through which there are six gates; the number of houses is about 2900, and of inhabitants about 18,400, but the majority dwell in the suburbs outside the walls. Erlau was founded by Stephen, king of Hungary, who resided in it about 800 years ago, and made it the seat of a bishop; of late years it has become that of an archbishop. It contains four Roman Catholic churches, two monasteries, and a Greek and a Protestant church. The houses in the town are large, and built in a neat style; the principal ornament is the Lyceum, a very handsome and spacious edifice, begun by Count Charles Eszterházy in 1760, and finished in 1775, at a cost of upwards of 160,000*l.*; there is an observatory 172 feet high, a handsome chapel, and a very spacious examination hall and library attached to the institution. The Lyceum has two faculties, philosophy and jurisprudence, conducted by sixteen professors, and is very numerously attended. Opposite the Lyceum stands the cathedral church, which has nothing remarkable about it; but the neighbouring church of the Minorites is a splendid structure. The archbishop's palace is a fine building situated on a hill. Erlau has a county hall, a high school, an ecclesiastical seminary, an asylum for decayed clergymen, a school for educating teachers, several libraries, an hospital, and two mineral springs much used by invalids. The town has an extensive traffic in red wines, the produce of the vineyards in the vicinity, which is estimated at 1,197,000 gallons per annum. The manufactures consist of linens, woollens, hats, &c.

ERMINE, or ERMIN, one of the furs in heraldry, so called from the *mustela erminia*, whose skin furnishes it.

It is represented white, with black spots or tufts. The black spots in ermine are not of any determinate number, but are left to the discretion of the herald-painter.

ERMINE. [MUSTELA.]

ERNE, LOUGH, lies almost entirely in the county of Fermanagh, which it traverses from one end to the other. The limits are considered to extend from Beleek on the north-west to Belturbet on the south-east, a length of forty English miles; but for some distance within these two towns, as well as about Enniskillen, it is so narrow as to form more properly part of the river Erne. It offers the greatest extent of inland navigation, though somewhat obstructed by shallows, of any of the Irish lakes; but Lough Neagh, from being more free from islands, contains a greater surface of water. The waters of Lough Erne do not possess the petrifying qualities of that lake, but they have a harsh and unpleasant taste, and are unwholesome to drink, particularly at the season for gathering the flax, which is laid to soak along its shores.

The lake abounds in fish—such as trout, salmon, pike, perch, bream, eels, and smaller fish: there are also great quantities of wild duck, and during the winter it is visited by flocks of geese and various marine birds. There is not one village immediately on its shores along the whole extent, and the country is but thinly populated. There are several ruins of antient castles along the shores, and on the island of Devenish is a round tower in excellent preservation. Several large rivers empty themselves into the lake, which are navigable for boats from two to three miles up. On account of the numerous shoals and fords that occur in the narrow parts, the boats employed on the lake are chiefly flat-bottomed, and of a very rude construction: they are called 'cots,' and are principally used in supplying the town of Enniskillen with turf.

Lough Erne is usually considered as divided into two, the Upper and Lower Lakes, with a distance of six or seven miles between them, consisting of a narrow channel, which may more properly be called part of the river Erne. The Lower Lake is by far the larger and deeper, having in some places from 200 to 230 feet of water, but the depth is very irregular, and its surface is thickly studded with islands. Although within four miles of the sea, it stands at an elevation of 148 feet above low-water spring-tides in the dry season, and rises from 6 to 8 feet in the winter, according to the season. The first fall occurs at the village of Beleek, from which point to Ballyshannon there is a constant succession of falls. There is in this lake an expanse of water, about ten miles in length and five in breadth, tolerably clear of islands.

In the Upper Lake the most open part is not above a mile and a half in each direction, and in this space are several small islands. Its depth seldom exceeds 20 feet, the greatest that occurs being 75. Its level ranges from 11 inches to 2 feet 10 inches above the Lower Lake, the mean difference being about 20 inches.

The general features of the shores around the lake are rounded isolated limestone hills of moderate height, rarely rising to 600 feet above its surface, except towards the western extreme, where the Poola Fooka range of table-land reaches 1000 feet. The prevailing nature of the bottom is a bluish clay.

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

E R N

ERNESTI, JOHN AUGUSTUS, was born at Tennstadt, in the Thüringer Wald, on the 4th August, 1707. He was educated at Wittenberg and Leipzig, and became corrector of the school of St. Thomas, in the latter city, in the year 1731. He succeeded J. M. Gessner as rector in 1734. While engaged in this situation he acquired a great reputation as a classical scholar; so much so, that in 1742 the University of Leipzig violated its own rule of never electing to any professorship the master of a school, and appointed him professor extraordinary of antient literature. He was made professor of eloquence in 1756, and professor of theology, with the degree of Dr., in 1758: he held the two last named professorships together till 1770, when he gave up the former to his nephew, Augustus William. He died on the 11th September, 1781. Ernesti was a man of considerable abilities, and especially of a very methodical mind, to which are due the great improvements in the system of teaching introduced by him, and still, to a certain extent, adopted in the German universities. He was well acquainted with the classics, and no mean proficient in theological learning. His Latin style is very elegant for a German, little inferior indeed to that of Ruhnken, and fully equal to that of Wyttenbach: a good specimen of his Latinity may be seen in A. Matthiæ's *Eloquentia Latina*. His knowledge of Greek, though less accurate, was still very respectable. The work for which he is best known is his edition of Cicero, which has been made the basis of all subsequent ones. The third and last edition of this author published by him was printed at Halle in 1775. His *Clavis Ciceroniana*, or Index of words and subjects to Cicero's works, is still in general use. Besides his Cicero, Ernesti's *Initia Doctrinæ Solidioris et Institutio Interpretis Novi Testamenti* are much esteemed by students at the present day; the latter has been recently translated into English. The edition of Homer which Ernesti published in 1759-65 is merely an improved reprint of the hackneyed edition by Dr. Clark. It was republished by Dindorf in 1824. His edition of Callimachus, which appeared in 1761, is suspected to have owed a good deal of what is valuable in it to the contributions of Ruhnken. An account of it is given in the 'Museum Criticum,' vol. ii., p. 151. Ernesti's editions of Polybius, Tacitus, and Suetonius, have been quite superseded by those of Schweighäuser, Bekker, and F. A. Wolf.

ERNESTI, AUGUSTUS WILLIAM, nephew of the preceding, was born at Frohndorf, near Tennstadt, the 26th November, 1733. He was a pupil of his uncle at Leipzig. was made professor of philosophy there in 1765, and, as has been mentioned, succeeded, on his uncle's resignation, to the professorship of eloquence (in 1770). He died of apoplexy on the 29th July, 1801. He was principally distinguished as a very good Latin scholar. His best known work is an edition of Livy, with a very copious glossary, which was reprinted twice in his lifetime; the third edition P. C., No. 595.

E R P

was in the press when he died, and was completed by Schäfer.

ERNESTI, JOHN CHRISTIAN THEOPHILUS, also a nephew of John Augustus, was born at Arnstadt, in the Thüringer Wald, in 1756. He was professor of philosophy in the University of Leipzig from 1782 to 1801, when he succeeded his cousin, Augustus William, as professor of eloquence. He died on the 5th June in the following year. This scholar published editions of Silius Italicus and Æsop; *Lexicon Technologiæ Græcæ Rhetoricæ*, Lips. 1795; *Lex. Techn. Romanorum Rhetoricæ*, Lips., 1797 (both very useful works); *Hesychii Glossa Sacra*, 1785; *Suidæ et Phavorini Glossæ Sacra*, 1786; a translation into German of Dumesnil's Latin Synonyms, and a German version of the principal works of Cicero. (Cicero's *Geist* and *Kern*, 1799-1802.)

ERPE'NIUS. The celebrated orientalist, Thomas Erpenius, or Thomas van Erpen, was born at Gorcum, on the 7th of September, 1584. At the age of ten years he was sent to Leyden, where he received his education; and in 1608 he took the degree of Master of Arts in the university of that town. He had studied chiefly theology and oriental literature, and after the termination of his academic education, he undertook a tour to England, France, Italy, and Germany, for the farther prosecution of his favourite pursuits. At Paris he became acquainted with Isaac Casaubonus, and availed himself of the Arabic instructions of a learned Maronite, Joseph Barbatius, then a resident in the French capital. Erpenius returned to his native country in 1612, and was in the following year appointed professor of Oriental languages in the university of Leyden, an office to which was added subsequently that of Arabic interpreter to the Netherlands. On two occasions, in 1620 and 1621, he was sent to Paris on business of the university of Leyden. With these interruptions he seems to have devoted himself exclusively to the cultivation of Oriental literature. He established an Arabic press at his own house, and employed himself in editing a number of works, which have been of the greatest utility in promoting the cause of Oriental learning. He died of a contagious disease at the age of forty, November 13th, 1624. The work which has contributed most to give celebrity to the name of Erpenius is his 'Grammatica Arabica, quinque Libris methodice explicata,' published at Leyden in 1613, 4to. It has often been re-edited with additions and alterations, and has become the foundation of nearly every subsequent Arabic grammar printed in Europe down to that of Silvestre de Sacy. The most remarkable of Erpenius's other publications are the following: 'Proverborum Arabicorum centuriæ duæ,' Leyden, 1614 and 1623, 8vo.; 'Locmani Sapientis Fabulæ et selecta quædam Arabum Adagia,' Leyden, 1615, 8vo.; an edition of an Arabic version of the New Testament and of the Pentateuch, the former published in 1616, the latter in 1622; an edition of the chronicle of Elmakin, with a

Vol. X.—B

Latin translation, published after his death, under the title of 'Historia Saracenicæ,' Leyden, 1625, fol.; two original treatises on Arabic grammar, bearing the title, 'Grammatica Arabica, dicta Giarumia, et libellus centum Regentium,' Leyden, 1617, 4to.; and a Hebrew Grammar, 'Grammatica Ebraea generalis,' Leyden, 1621, 8vo.

HERPETOLOGY. [HERPETOLOGY.]

HERPETON, Lacépède's name for a genus of serpents placed by Cuvier next to *Eryx*. The name should be written *Herpeton*.

The genus is furnished with two soft prominences, covered with scales, on the muzzle. The head is protected by large plates; those beneath the belly are not large, and those beneath the tail scarcely differ from the other scales. The tail however is very long and pointed. Cuvier, who speaks of the priority of Lacépède, who first described the genus under the name of *Erpeton*, remarks that Merrem has changed the name to *Rhinopirus*.

Herpeton tentaculatus.

ERRATIC BLOCKS are those weather-worn and more or less rounded fragments of the harder rocks which are found very widely scattered over the surface of the earth, and at great distances from the places whence they are supposed to be derived.

In size they vary from ten thousand cubical feet and upwards to a few inches. M. Brongniart has proposed to designate the several sizes by particular names, as gigantic, metric, cephalary, pugillary, &c. But in England we generally confine the term erratic blocks to the larger masses, calling those of middling size boulders, and arranging the smaller along with gravel: this is, however, too vague. The nature of erratic blocks is not less various than their size. Every species of rock seems to have contributed a portion of its substance towards the mass, though the harder, being better capable of resisting the disintegrating and corroding influence of atmospheric causes, are found in the greatest abundance, such as quartz, petrosilex, greenstone, granite, porphyry, syenite, gneiss, primitive and transition limestone, dolomite, serpentine, siliceous pudding-stones, siliceous sandstones, &c.

The distribution and situation of these blocks are also very different. Seldom isolated, they are generally found in patches or groups, as in the environs of Geneva, the plains of Westphalia, in Sweden, &c.; or in long bands or trains, as in the north of Mecklenberg Strelitz, where they run in a direction west-north-west and east-south-east; or widely spread over considerable tracts, as between Warsaw and Grodno, between St. Petersburg and Moscow, in East Prussia, &c. Sometimes they cover horizontal plains, as in the north of Germany; sometimes they rest on the sloping sides of mountains, as in the Alps and the Jura, and occasionally on the very tops of lofty eminences, as on the summits of the calcareous mountains of Rettwick, of Rødsberg, and of Osmund, about 6000 feet above the level of the sea. Sometimes they are seen in greatest abundance at the

bottom of valleys where they open into the plains, and in other instances they are found collected in the largest quantity in the high and narrow parts of the valleys, as is observed at Detmold and east of Lemgo. At times they are so abundant as to be accumulated into hills of a particular form, as is the case in Smaland, in Sweden; and sometimes they form even mountains of considerable height, as may be seen near Quedlie, in Norway; and what is remarkable, the larger blocks are at the top, the others diminishing gradually towards the bottom.

Though generally superficially disposed, erratic blocks are however in some places found imbedded in a fine sand which has nothing in common with their nature or origin, as in the plains of Westphalia. Some blocks (and this may depend either on their own particular nature, or the greater or less friction to which they have been subjected, the length of time they have been exposed to atmospheric influence, or the nature of the climate,) have their angles and edges as sharp as though they were just detached from their native mountains, as is the case in the neighbourhood of Groningen.

When the erratic blocks are not at any great distance from the spots whence they come, they may be easily traced up to their origin. Thus those which are in the basin of the Rhine come from the Grisons; those of the valley of the lake of Zürich and of the Limmat have been detached from the mountains of Glaris; those of the basin of the Reuss come from the rocks at the source of this river; and those of the Aar and the Jura from the lofty mountains in the canton of Berna. Even those which cover the widely extended tract from Holland on the west, to St. Petersburg and Tver on the east, are supposed by Von Buch, Hausmann, Brongniart, Alex. Brongniart, &c., to be traceable to Scandinavia. It is however remarkable that, contrary to what is generally observed of transported debris, the blocks are frequently largest as they are farthest removed from the place whence they came, diminishing gradually in size as they approach the parent rock; thus the blocks found in Mecklenberg and Seeland, which are ascertained to be derived from the Scandinavian peninsula, are larger than the blocks of the same rocks in Scania and East Gothland, and they disappear altogether close to the primordial mountains whence they were derived.

In certain places the blocks are almost exclusively of a particular kind, while in others they vary greatly in their mineral character, proving, together with the ascertained situation of the same rocks in situ, that they must have been assembled from various quarters. This is the case with the erratic blocks of Yorkshire, and with those of Lithuania, for though the greater part, perhaps, of those in the latter locality may be similar to the rocks in Sweden and Norway, there are many evidently derived from other places.

As for the direction in which the bands of erratic blocks seem to lie, and the quarter whence they seem to have come, they are very various. We have just seen that in the north of Mecklenberg the trains are in a line west-north-west and east-south-east. Count Rasmussen observes that, when many blocks are accumulated they form parallel lines with a direction from north-east to south-west. Brongniart says they have a general direction north and south. Sir James Hall speaks of those in the neighbourhood of Edinburgh as coming from the west. We have said that those on the north of the Alps come from the south.

If any thing further were necessary to complicate the problem of erratic blocks, it is the immense distance at which they are sometimes found from the nearest rocks of similar composition; thus blocks of granite are found on the mountains of Potosi, while the nearest granite rocks are in Tucuman, about four hundred leagues off. Nor is distance all; the detached blocks are found separated from their parent rocks by intervening hills, broad and deep valleys, as that of the Aar, and even by straits and seas: thus in the north of Cumberland there are boulders which have been transported across the Solway Frith from Dumfries, and the blocks on the low plains of Germany are separated from their parent rocks by the Baltic.

England, as well as the continent of Europe, has many spots covered with erratic rocks, some of which seem to be derived from Norway, while others are evidently the debris of our own mountains. For details we refer the reader to the observations and works of Sedgwick, Conybeare, Lyell, Buckland, Phillips, Hibbert, &c.

Erratic blocks are also common in America and other parts of the world.

From what has been already said, and from the circumstance of erratic blocks lying on some of the most modern formations, it will be easily conceived that they present one of the most inexplicable of geological phenomena. The blocks on the Jura, and from the Alps generally, having first attracted notice, have given rise to a great variety of hypotheses, the most remarkable of which are the following:—1. De Luc was of opinion that these blocks had been projected into the air by the same force which upheaved the Alps, and that they had fallen at greater or lesser distances, according to the strength and direction of that force. 2. Von Buch, Escher, &c., attribute their existence to an immense débris which swept down the blocks from the Alps to the foot of the Jura, up the slope of which they were forced by the impulse they had received, in the same way as a ball rolled along with force rises up a hillock. 3. Others, as Daubuisson, have thought that these blocks, which are almost wholly of transition rocks, were the remains of a mantle of these rocks, of later formation than the limestone of the Jura, and consequently much more recent than is generally admitted, and which, having been destroyed, left nothing but these testimonials of their former existence. 4. Dolomieu supposed that the summits of the Alps were formerly connected with those of the Jura by an inclined plane, which has been destroyed by the same revolution that precipitated the blocks from the summit of the Alps to the plateau, and into the valleys of the Jura. 5. Venturi has attempted to explain the passage of the blocks from the Alps into the basin of the Po, by floating them down on rafts of ice. 6. Others have upheaved the Jura, which they suppose to have been formerly on a level with the base of the Alps, and with it the blocks which had rolled down upon this calcareous plain. 7. Finally, Von Buch, extending his general theory to the particular phenomenon, thinks that the dispersion of the blocks is the result of an uprising of the Alps posterior to the formation of the tertiary rocks.

M. Brongniart very justly observes that these hypotheses leave many difficulties unexplained: he conceives that as the phenomenon of erratic blocks is a very general one, it is presumable that the cause also is general. Certain it is that even if it were possible satisfactorily to assign a cause for the erratic blocks found upon the Jura, the same reasoning would hardly be applicable to other cases; and in the utter impossibility of discovering any single cause competent to the production of such different effects, we must have recourse to the more probable conjecture of M. Lavière, that the dispersion and disposition of erratic blocks have been effected in different ways. The more powerful cause however he conceives to be the transporting power of ice-mass and icebergs, in which opinion he is followed by Mr. Lyell and others.

Erratic blocks, like other phenomena, are attended with their peculiar advantages: thus on hot and dry soils, and when not in too great abundance, they keep the soil cool and moist, sheltering it from the direct rays of the sun in the day, and thus diminishing the evaporation of its moisture. On cold soils they tend to maintain an equable warmth by diminishing radiation at night. In some countries they are the only building-stones, as in East Friesland and the neighbourhood of Groningen. In others they supply the necessary lime, as at Königsberg, Revel, &c. Those of a convenient size are used in Russia and Poland for paving the towns: when broken they are exceedingly well adapted for the repairs of roads.

ERRHINES (from *en* (iv), and *rhin* (ptv), 'the nose'), medicines which are applied to the nostrils, and which cause an increased flow of the secretion of the membrane which lines them, and often of the contiguous cavities and sinuses; frequently also occasioning sneezing, and an unusual secretion of tears. Snuffs of different kinds are familiar examples of this class of substances, and these generally cause sneezing, at least when first employed; but others, such as the turpeth mineral, merely produce increased secretion of the membrane. Where sneezing ensues, a considerable shock is felt over the whole frame, and of this effect advantage is sometimes taken to change the action of the system, or to remove morbid impressions, as when certain fits are impending, or for more limited purposes, such as dislodging any foreign body from the nose. The secondary effect of errhines is more frequently desired

to give relief to the loaded vessels, by exciting them to an increased secretion. Hence they are used in various diseased conditions of the organ of smell, and even of the neighbouring organs, being supposed to influence the vessels of the eye, and even of the brain. Some affections of the eye, and also of the head, are certainly relieved by such means, and their occasional use may be permitted; but the habitual use of errhines is in most cases objectionable, and followed by hurtful consequences. The membrane of the nose becomes thickened, its sensibility impaired, and the power of discriminating odours greatly lessened; while, if the substance be possessed at the same time of narcotic qualities, such as snuff procured from tobacco, the palate, the stomach, and other organs concerned in digestion likewise suffer, and loss of appetite with other symptoms of indigestion result.

ERRINA. [MILLERIANA.]

ERROR (in law), a fault in the pleadings or in the process, or in the judgment, upon which a writ, called a writ of error (*breve de errore corrigendo*), is brought. It is the ordinary mode of appeal from a court of record, and is in the nature of a commission to the judges of a court superior to that in which the judgment was given, by which they are authorized to examine the record, and on such examination to affirm or reverse the judgment according to law. For the cases in which this writ is issued, and the courts to which it is directed, see *Bac. Abr. tit. Error*.

ERSKINE, THOMAS LORD, was the third and youngest son of David earl of Buchan. He was born, according to some authorities, in January, 1746, and received the rudiments of his education partly in the high-school of Edinburgh, and partly at the University of St. Andrews. In 1764 he entered the navy as a midshipman, but not thinking his prospects of promotion in that service sufficiently good, he accepted a commission in the first regiment of foot in 1768. In 1770 he married Frances, daughter of Daniel Moore, M.P. for Marlow, and soon after went with his regiment to Minorca. Upon his return to England, in 1779, he appears to have become remarkable for the brilliancy of his conversational talents. (*Wrexall's Memoirs*, vol. i. p. 159, and *Boswell's Life of Johnson*, vol. ii. p. 170, ed. 1799.) In 1775, at the pressing solicitation of his mother, but it is said against his own judgment, he commenced the study of the law, and entered himself a student of Lincoln's Inn, and also as a fellow commoner of Trinity College, Cambridge, but only for the purpose of obtaining a degree, and thereby saving the additional term of two years, during which his name must otherwise have remained on the books of Lincoln's Inn. He became the pupil of Mr. Buller, and afterwards of Mr. Wood, both of whom were subsequently raised to the Bench. In Trinity term, 1778, Mr. Erskine was called to the bar, where his success was as rapid as it was brilliant. In the same term he was employed as one of the counsel for Capt. Baillie, lieutenant-governor of Greenwich Hospital, who was prosecuted for an alleged libel on the other officers of that establishment. The prosecution was in fact instituted by Lord Sandwich, then at the head of the admiralty, who, it appeared, had abused the charity by appointing landmen as pensioners to serve his own electioneering purposes. Mr. Erskine's eloquent and indignant speech at once established his reputation; such indeed was its instantaneous effect, that thirty retainers were presented to him before he left the court. His practice and reputation increased so rapidly, that in 1783, when he had been scarcely five years at the bar, he received a patent of precedence at the suggestion of Lord Mansfield, who then presided in the court of King's Bench. In the same year Mr. Erskine was returned member for Portsmouth, through the interest of Mr. Fox, with the immediate view of supporting that minister's famous India Bill. In the House of Commons however his success by no means equalled the expectations which his friends had formed, though his parliamentary speeches would appear to have been far above mediocrity. In the same year also he was made attorney-general to the prince of Wales, an appointment which, to the disgrace of the advisers of the crown, he was called upon to resign in 1792, in consequence of his refusing to abandon the defence of Thos. Paine when he was prosecuted for his publication 'The Rights of Man.' In 1802 he was made chancellor of the Duchy of Cornwall; and in 1806, on the formation of the Grenville ministry, he was appointed lord chancellor.

and raised to the peerage by the title of Baron Erskine, of Restormel Castle, in Cornwall. His tenure of office was however brief, for on the dissolution of the ministry in 1807, he retired from public life. After this period Lord Erskine seldom appeared in his place in the House of Lords, but in 1820 he took a prominent part on the occasion of the trial of Queen Caroline.

In the later years of his life he was harassed by pecuniary embarrassments, arising from the loss of his large professional income, and an unfortunate investment of the fruits of his industry in land. His first wife died in 1805, and an ill-assorted second marriage increased his domestic disquietudes, injured his reputation, and gave pain to his friends. He died Nov. 17, 1823.

Lord Erskine's talents were peculiarly those of an accomplished and dexterous advocate: his eloquence formed an era at the bar, and his addresses to juries captivated their understandings, their imaginations, and their passions; they were not marked by beauty of diction, richness of ornament, or felicity of illustration, but by strength, vigour, and simplicity, and a perfect freedom from colloquial vulgarisms. A remarkable feature in his speeches is an exact and sedulous adherence to some one great principle which he laid down, and to which all his efforts were referrible and subsidiary. As the principle thus proposed was founded on truth and justice, whatever might be his ingenuity in applying it to the particular case, it naturally gave to his address an air of honesty and sincerity which had great influence with the jury.

His extraordinary talent was developed by the times in which he lived; his indignant eloquence was called forth in defence of those individuals in whose persons the court and the government attacked the liberty of the press and constitutional freedom. The public mind was in a state of ferment from the recent events of the French revolution; and the government, in their hatred of the great principles of liberty then being established, forgot that actions, not principles, are the proper subjects for prosecution. As counsel for the defendants in these political prosecutions, Lord Erskine made his noblest and most successful efforts; fearless and zealous in the cause of his client, he spoke home truths without using unnecessary violence or low invective.

Lord Erskine has left few productions in writing; the principal are the Preface to Fox's Speeches, the political romance called 'Armata,' and a pamphlet entitled 'View of the Causes and Consequences of the War with France,' which passed through 48 editions. His speeches have been published in 5 vols. 8vo. Lord Erskine is not to be considered as a literary man; but it is one of the many singularities in his history, that with a scanty stock of what is usually called literature, he should have been one of our purest classical speakers and writers. His study was confined to a few of the greatest models, and these he almost knew by heart. He greatly admired the writings of Burke, and frequently quoted them in his speeches.

Scanty notices of the life of Lord Erskine are published in Lardner's *Cyclopædia* ('Lives of British Lawyers') and the 3rd vol. of the *Gallery of Portraits*, from which this account has been taken. There are some remarks upon the style of his eloquence in Butler's *Reminiscences*, vol. i. p. 70. His statue is in Lincoln's Inn Hall.

ERUCIVORA. (Zoology.) [LANIADÆ.]

ERUPTION. [VOLCANO.]

ERWIN. [STRASBURG.]

ERYCINA. [VENERIDÆ.]

ERYON, Desmarest's name for a macrourous crustacean, only known in a fossil state.

External *antennæ* short (one-eighth of the total length of the body including the tail), setaceous, provided at their base with a rather large scale, which is ovoid and strongly notched on the internal side; *intermediate antennæ* setaceous, bifid, much shorter than the external ones, and having their filaments equal. *Feet* of the first pair nearly as long as the body, slender, linear, not spinous, terminated by very long and narrow chelæ, with fingers little bent, but slightly inflected inwards; *carpus* short; feet of the other pairs also slender, and those of the second and third pair terminated with pincers, like the feet of the crawfishes (écrevisses). *Carapace* very much depressed, wide, nearly square, but little advanced anteriorly, profoundly notched on its latero-anterior borders. *Abdomen* rather short, formed of six articulations, of which the four intermediate

ones have their lateral borders prolonged in angles, well detached, as in the crawfishes. Caudal-fin formed of five pieces, of which the two lateral are entire, rather large, a little rounded on the internal side, and the three middle ones triangular and elongated, especially the intermediate one.

Locality.—Lithographic limestone of Pappenheim and Aichtedt in the Margraviat of Anspach. (Desmarest.)

M. Desmarest observes that this genus is entirely anomalous, and ought, in a natural classification, to form a section by itself. According to the method of Dr. Leach, it would belong, 1st, to the order *Macroura*; 2nd, to the second section, which includes those *Macroura* which are provided with a caudal flabelliform fin; 3rd, to the subsection B, which have the peduncles of the internal antennæ moderately elongated; 4th to the 5th division, which have the natatory blades of the extremity of the tail formed of a single piece, the second articulation of the abdomen not dilated, and rounded anteriorly and posteriorly on each side; and finally, feet to the number of ten.

M. Desmarest goes on to say that it is to the *Callinassæ*, the *Thalassinæ*, the *Gebiæ*, and the *Axiæ*, that *Eryon* bears relation. Nevertheless it has not, he observes, the habit of any of them. Its short depressed carapace, and its little elongated abdomen approximate it to *Scyllarus*, but its internal antennæ with short peduncles, its external setaceous antennæ and its great anterior didactylous feet, widely separate it from that genus. It cannot be confounded with *Palinurus*, which has the external antennæ and the peduncles of the internal ones so long, and whose feet are all monodactylous; and, finally, it cannot be referred to the crawfishes or lobsters (*Asiacus*), whose shell is differently formed, and which have the external natatory blades of the tail composed of two pieces; but Desmarest thinks that it is to the last-named genus that *Eryon* most approximates, taking into consideration its general character. He regrets that he has not been able to satisfy himself whether the four antennæ are inserted on the same horizontal line or not, a fact which would have assisted him in his comparison with other genera.

Example.—*Eryon Cuvieri*. Carapace finely granulated above, marked by two deep and narrow notches on the two latero-anterior borders, and finely crenilated on the latero-posterior borders. Length, four to five inches French.

Eryon Cuvieri.

The fossil was noticed by Richter, Knorr, and others, before M. Desmarest, as, indeed, he states.

ERYSIPELAS (*Ignis Sacer*, the *Rose*, *St. Anthony's Fire*), an inflammation of the skin, occasioning a spreading redness, which occupies a broad surface, on which are formed vesicles or blisters, preceded by and accompanied with fever. The whole of the inflamed surface is painful, but the pain is not acute; it is rather a sensation of burning or stinging than of severe pain. The redness is not intense like that produced by phlegmon or boil, but is of a pale rose colour. There is always considerable tumefaction; the tumor is not surrounded by a definite boundary, but is diffuse, irregularly circumscribed, and unattended with a sensation of throbbing. The tumor is often soft and boggy. It is characterized by the vesications which form upon it.

The proper seat of erysipelas is the skin, but the appearance of the disease is somewhat modified according to the

part of the skin which is more especially inflamed. If the rete mucosum, or the part of the skin which is placed immediately beneath the cuticle [SKIN] be the principal seat of the inflammation, the vesication is remarkable; there is commonly a considerable discharge from the vesicles, and a free exfoliation of the cuticle: if, on the contrary, the inflammation be chiefly seated in the cutis vera, or the true skin, namely, that portion of the skin which lies immediately beneath the rete mucosum, the cellular tissue beneath the skin is always more or less involved in the inflammation, and then the tumefaction is considerable on account of the infiltration of the cellular tissue with serum poured out from the blood by the inflamed cuticle.

Erysipelatous inflammation is characterized by its tendency to spread, and thereby to cover a considerable portion of the external surface of the body. It creeps on in succession from one part of the skin to another until it extends to a great distance from the part originally attacked, the inflammation often disappearing from the former as it becomes established in the latter. Sometimes the inflammation appears to pass from the external surface to the internal organs, and occasionally the disease quits the surface as it attacks the internal organs, although more commonly the external and internal inflammation go on simultaneously, greatly increasing the severity and danger of the attack.

Erysipelas most commonly attacks the face, but it sometimes seizes on one of the extremities: the disease is always more severe when it attacks the head than when it is seated in any other part of the body.

The inflammation which appears on the external surface of the body in erysipelas is not the primary and essential part of the disease, but a remote event depending on a preceding state of disease affecting the whole system. This is proved by the fact that constitutional disturbance always precedes, commonly for the space of two or three days, the appearance of the local affection.

An attack of erysipelas comes on either with chills or a distinct cold shivering, attended with a sense of lassitude, aching in the limbs, restlessness, and that disordered state of the skin which has been expressively termed febrile uneasiness. There is from the beginning uneasiness or confusion in the head, which soon amounts to decided pain. This is accompanied with such a degree of drowsiness, that the attack may sometimes be predicted long before there is any appearance of redness or swelling in the face, from the inability of the patient to keep himself awake. The chilliness is soon succeeded by heat of skin; the appetite fails, the bowels are constipated, the tongue is dry and parched, there is sometimes nausea and vomiting; the pulse is always frequent, sometimes full, soft, and compressible, but occasionally hard and tense.

After these symptoms have continued some time, always one, generally two, and sometimes three days, there appears on some part of the face a redness, attended with burning heat and tingling. Commonly a red spot appears on one cheek; after a short time a similar spot appears on the other cheek; often the redness spreads successively from one cheek to the other across the nose, which is completely involved in the affection: from the nose it extends to the forehead, and thence over the whole scalp. Soon after the redness appears the face begins to swell; and by the second night, or the morning of the third day from the commencement of the fever, the eyes are completely closed, the eyelids exceedingly prominent, the nose distended, and the ears tumid, red, shining, and burning. On the fourth or fifth day the vesications appear on the inflamed surface, which break on the fifth or sixth, when the redness changes to a yellowish hue. The whole face is now so turgid that the form and expression of the features are completely lost, and the patient could not possibly be recognized by his most intimate friend.

The surface of the skin in the blistered places becomes covered with a brownish or dark coloured scab, which often gives a livid or blackish appearance to the part; but this livid colour seldom goes deeper than the surface, and does not proceed from any degree of gangrene affecting the skin. On the parts of the face not affected with blisters the cuticle is destroyed, and desquamates, a new cuticle being formed beneath it. Though the face, in general, however intensely inflamed, seldom goes into suppuration, yet it is by no means uncommon for matter to form in the tumid eyelids.

Occasionally, though not often, when erysipelas attacks the face, it extends to the mouth and fauces, and even to the pharynx and larynx, at the same time that it covers the neck and chest externally. Dr. Copland mentions a case in which the enormous tumefaction of the neck and throat with the affection of the larynx and trachea, increased by the constriction produced by the integuments surrounding the neck and throat, caused suffocation in a few hours. When the inflammation extends to the fauces, throat, and larynx, it sometimes produces a species of croup.

On whatever part of the body the inflammation appears in erysipelas, even when it is strictly confined to the skin, its appearance is not attended with any remission of the fever which preceded it: on the contrary, the fever generally increases with the augmentation and extension of the inflammation.

The progress of the disease is more or less rapid, and its duration longer or shorter, according to the age, the temperament, and the vigour of the individual. In the young, the sanguine, and the robust, the tumefaction is sometimes fully formed on the second day, and the whole terminates on the sixth or seventh, while in the aged and the less vigorous it may be protracted to the tenth or twelfth, and the disquamation may not be completed before the fourteenth day. The average duration of the disease may be stated to be from eight to ten days.

When the fever and inflammation are intense, delirium comes on, which sometimes rapidly passes into coma. These are most alarming symptoms, indicating a severe and too often a mortal inflammation of the brain. In such cases death frequently takes place, with many of the symptoms of apoplexy on the seventh, ninth, or eleventh day of the disease. 'In such cases,' says Dr. Cullen, 'it has been commonly supposed that the disease is translated from the external to the internal parts. But I have not seen any instance in which it did not appear to me that the affection of the brain was merely a communication of the external affection, as this continued increasing at the same time with the internal.'

When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and perhaps the other external parts of the head, ceases. With the inflammation the fever also ceases; and, without any evident crisis, the patient returns to his ordinary state of health.

In the cases which prove fatal, on the examination of the body after death, the inflamed skin is found infiltrated with serum, which is sometimes mixed with pus, and occasionally portions of the skin are found disorganized, and in a state of gangrene. It is remarkable that the blood in the large vessels and in the cavities of the heart is semifluid, and that the veins which proceed from the inflamed parts are in a state of inflammation, and contain pus, more especially when the inflammation has extended from the skin to the cellular tissue and has passed into suppuration. In the cases attended with delirium and coma the membranes of the brain, and especially the arachnoid, are thickened and opaque with the effusion of serum between the membranes and into the ventricles. If the disease has been complicated with inflammation of the fauces, pharynx, œsophagus, trachea, and bronchi, these organs present the ordinary signs of inflammation; and the same is true with regard to the mucous membrane of the stomach and intestines; but in all these cases the signs of inflammation are much more closely allied to those which occur in fever than to those which are proper to pure inflammation.

There is a peculiar condition of the skin which seems to predispose to erysipelas connected with the irritable or bilious temperament, and a plethoric habit of the body. The occurrence of the disease once renders the skin peculiarly susceptible to its recurrence. Unwholesome and indigestible food, the excessive use of spirituous liquors, the suppression of the excretions, and more especially the suppression of the perspiration, of the bile, and of the catamenial discharge, predispose to erysipelas.

The exciting causes are exposure to cold and moist air after the body has been previously heated; exposure to sudden and great alternations of temperature; exposure to great heat however produced, whether by the direct rays of the sun or by a fire; intemperance; unwholesome articles of diet, as shell-fish, or stale and rancid fish; rich, oily, fat, or smoked meats; impure states of the atmosphere; an impure state of the body, arising from a morbid condition of

the blood, in consequence of the suppression of its depurating processes, whence the frequent occurrence of the disease in the advanced stages of fever, greatly complicating the state of fever and exhausting the little remaining strength of the patient. Violent emotion of mind has also been observed to be an exciting cause of erysipelas in those powerfully predisposed to the disease; in whom also local irritants often induce it, as wounds or punctures in the skin, the bites of leeches, the stings of insects, inoculation with variolous or vaccine matter. Instances are on record in which both variolous and vaccine matter have produced in children of irritable habits, two or three days after inoculation, an erysipelatous inflammation which has proved fatal.

It is a point much disputed whether erysipelas be capable of being propagated by contagion. 'The disease,' says Dr. Bateman, 'has been noticed in several hospitals to prevail in certain wards, among patients admitted with different complaints; but has seldom been known to spread in private houses. Dr. Wells, indeed, has collected several examples of the apparent communication of erysipelas by contagion, which occurred in private families. But such are at all events extremely rare, and perhaps never happened in well ventilated and cleanly houses. From the Royal Infirmary, at Edinburgh, this disease, like the puerperal fever, was banished by ventilation, white-washing, and other means of purification; and it has not occurred in any hospital of late years, since a better system has been adopted in these respects. Other diseases, not infectious in themselves, appear to become united with typhus, or contagious fever, under similar circumstances, and thus to be propagated in their double form; the dysentery, for example, the peritonitis of women in child-bed, ulcerated sore throat, &c. The simple phlegmonous erysipelas, at all events, was never seen to spread like an infectious disease.'

The danger of erysipelas is in proportion to the intensity of the inflammation, and the severity of the affection of the brain. The danger is also imminent when there is great tumefaction of the throat, or when the inflammation spreads to the respiratory passages and the respiratory organs. As long as the inflammation is confined to the external surface, and the fever remains moderate, the brain not much affected, and the heart's action not inordinate, a favourable termination of the malady may be expected. The different varieties or species of the disease are also attended with very different degrees of danger. Authors usually describe four species, namely, the phlegmonous, the œdematous, the gangrenous, and the erratic. The phlegmonous is that form of the disease in which the inflammatory state of the system is the most distinctly marked. In the œdematous the fever and inflammation are less intense; but the tumefaction is so great that the appearance of the face resembles that of a bladder distended with water. This form of the malady most commonly affects persons of debilitated constitutions, who have been previously attacked or are simultaneously affected with dropsy, or some other chronic disease, incident to a cachectic state of the system, and induced commonly by habitual intemperance. It is always attended with considerable danger, for the disorder of some internal function increases with the advancement of the external disease. Very frequently delirium and coma come on at the height of the disease, and terminate fatally on the seventh or eighth day; or, in other cases, the symptoms continue undiminished, and death occurs at a later period. When this form of the disease attacks one of the extremities, it is attended with but little danger.

In the gangrenous form of the disease the colour of the affected part is of a dark red, and scattered vesicles with a livid base appear upon the surface, which frequently terminate in gangrenous ulcerations. Suppuration and gangrene of the muscles, tendons, and cellular tissue often take place, producing little caverns and sinuses, which contain an ill-conditioned pus, together with sloughs of the mortified parts, which are ultimately evacuated from the ulcers. It is accompanied with symptoms of low fever, in the progress of which delirium comes on, soon followed by coma. It is always a tedious and precarious and often a fatal form of the disease.

In the erratic species the inflamed patches appear one after another in different parts of the body, thus travelling in succession from the face to the neck and trunk, and from the trunk to the extremities. It often happens that each accession of the complaint is less and less severe as it re-

cedes to a greater distance from the part first affected, and this form of the disease commonly terminates favourably in a week or ten days.

In the phlegmonous species, characterized by the presence of inflammatory fever, the method of treatment must be widely different from that proper to the œdematous and gangrenous, in which there is the very opposite state of the system. In the young, the plethoric, the sanguine, and the robust, at the commencement of the attack, when there is much pain in the head, when the heat of the skin is intense, and the pulse is full and strong, the remedies proper in any other case of inflammatory fever are required; namely, bleeding to the extent of the subdual of the inflammatory condition of the system. In such a case there is danger that the disease will terminate in fatal inflammation of the brain, unless there be a free abstraction of blood. But it must be borne in mind that erysipelas does not ordinarily occur in the youthful and vigorous constitution; that it is not often accompanied with the signs of acute inflammation; that blood-letting is required only when acute inflammation is present, and that the extent of the bleeding must be strictly regulated by the degree of the inflammatory action. In an ordinary attack of phlegmonoid erysipelas, general bleeding is not necessary, at least in the constitutions commonly found in a crowded city. Moderate purging, diaphoretic and saline medicines, strict confinement to bed in a cool apartment, with the diet appropriate to febrile diseases, are all the remedies required. If local bleeding and blistering appear to be indicated, care must be taken not to apply the leeches or the blister near the inflamed surface. Various applications to the inflamed surface have been recommended, the most common of which is flour, or some other absorbent powder, to imbibe the fluid which oozes from the vesications. The utility of such applications is doubtful. 'The application of powdery substances,' says Dr. Bateman, 'has commonly, according to my own observation, augmented the heat and irritation in the commencement; and afterwards, when the fluid of the vesications oozes out, such substances produce additional irritation, by forming, with the concreting fluid, hard crusts upon the tender surface. In order to allay the irritation produced by the acrid discharge from the broken vesications, Dr. Willan recommends us to foment or wash the parts affected, from time to time, with milk, bran, and water, thin gruel, or a decoction of elder-flowers and poppy-heads. In the early state of the inflammation, when the local heat and redness are great, moderate tepid washing, or the application of a cool but slightly stimulant lotion, such as the diluted liquor ammoniæ acetatis, has appeared to me to afford considerable relief.'

In the œdematous species, when it occurs in broken-down constitutions, the result of habitual intemperance, even purgatives must be very cautiously administered; the strength must be sustained by mild nutritive diet, and tonics, as cinchona or quinine, and even stimulants, as camphor, wine, or the beverage to which the patient has been habituated, are required. The aperients employed should be mild alterative mercurials, with equal parts of castor-oil and the spirit of turpentine administered perhaps every alternate morning.

In the gangrenous species, quinine in considerable doses through the whole course of the disease, opium, camphor, the mineral acids, wine, brandy, and the general regimen adapted to gangrenous affections occurring under other circumstances, must be freely employed. The remedies indispensable in the phlegmonoid species would be fatal in this form of the disease, while the remedies which afford the only chance of saving life in the latter would produce fatal inflammation of the brain if administered in the former.

ERYTHACA (Zoology). [BLUZ BRAD, vol. v. p. 17; SYLVIADE.]

ERYTHE'MA, a superficial redness of some portion of the skin, varying in extent and form, attended with disorder of the constitution, without vesications, and uninfected. It is distinguished from erysipelas by the slight degree of constitutional disorder, by the slight degree of local pain, by the more uniformly favourable termination of the disease, and by the absence of tumefaction and vesication.

Authors describe several species of this affection, namely 1. The fugacious (*Erythema fugax*), consisting of red patches of an irregular form, resembling the redness produced by pressure. These patches appear successively on the arms, neck, breast, and face. This affection is gene-

rally indicative of, and produced by, some disorder of the digestive organs.

2. The shining (*Erythema leve*), exhibits a uniformly smooth shining surface, and chiefly appears on the lower extremities in confluent patches. It is sometimes symptomatic of disorder of the digestive organs; occasionally attends the catamenia in delicate and irritable females, but most commonly accompanies anasarca or oedematous swellings. Under whatever circumstances anasarca occurs, as greatly to stretch the skin, this Erythema is liable to be produced, and is often checkered with patches and streaks of a dark red and purple hue. It commonly terminates in extensive disquamation of the skin, and may be considered as merely a modification of oedematous erysipelas.

3. Marginated (*Erythema marginatum*) occurs in patches which are bounded on one side by a hard elevated tortuous red border, in some places obscurely papulated; but the redness has no regular boundary on the open side. The patches appear on the extremities and loins in old people, and remain for an uncertain time, without producing any irritation in the skin. They are connected with some internal disorder, and may be considered as indicative of serious and dangerous diseases.

4. Papulated (*Erythema papulatum*) appears chiefly on the arms, neck, and breast, in irregular extensive patches, and most frequently in females and young persons. The patches are of a bright red hue, often slightly elevated; and for a day or two before the colour becomes vivid they are rough or imperfectly papulated. The redness afterwards continues for several days; and, as it declines, assumes, in the central parts, a bluish or pale purple tinge. This variety is generally attended by a tingling sensation, passing to soreness as the colour changes; and sometimes with much constitutional disturbance,—with a frequent small pulse, loss of appetite, depression of strength and spirits, watchfulness, and pains or tenderness of the limbs, but the general disorder is trifling.

5. Tuberculated (*Erythema tuberculatum*) is merely a slight modification of the advanced stage of the papulated.

6. Nodose (*Erythema nodosum*) consists of large oval patches on the fore part of the legs; the long diameter of the patch is parallel with the tibia; these patches slowly rise into hard and painful protuberances, and as regularly soften and subside in the course of nine or ten days. The red colour turns bluish on the eighth or ninth day, as if the leg had been bruised. It chiefly affects children, and particularly females, and is very seldom observed in boys. It is preceded by slight febrile symptoms for a week or more, which generally abate when the erythema appears. It is sometimes connected with the approach of the catamenia, and its premature disappearance is not unfrequently succeeded by dangerous internal disease, as inflammation of the lungs.

The primary causes of erythema are the friction of contiguous parts, especially in fat persons; the accumulation of morbid secretions and excretions on the skin, as the matter of the perspiration, of the leucorrhœal discharge, of the catamenia, and of the alvine and urinary evacuations, in the adult in the course of other diseases, and in the infant in consequence of a want of proper ablution. It is also constantly produced by irritating articles of food and drink, and is the sign and the result of a disordered state of the digestive organs.

In most cases the affection disappears soon after the removal of the cause which produces it—by free ablution where it is the result of irritating matters on the skin, and its disappearance is assisted sometimes by the application of an absorbent powder to the inflamed surface, and at other times by the use of a gently stimulating lotion, as the spirit wash. When the disease is dependent on a disorder of the digestive organs, it can be removed only by the remedies proper for the removal of the stomachic, the hepatic, or the intestinal derangement. For the restoration of these organs to their sound condition, the most appropriate remedies are light diet, diaphoretics, the mercurial alteratives in combination with gentle aperients, and the mineral acids as tonics. (Bateman's *Practical Synopsis of Cutaneous Diseases*; Copland's *Dictionary of Practical Medicine*.)

ERYTHRÆA, a pretty genus of annual plants, belonging to the natural order Gentianaceæ, and inhabiting dry sandy places in Great Britain and other parts of Europe, especially near the sea. The species have small oval sessile

ribbed radical leaves, diminishing in breadth as they ascend the stem; a corymbose stem, a five-cleft calyx, pink funnel-shaped flowers, with a short five-lobed limb, five stamens, spiral anthers, two roundish stigmas, and a linear capsule. They are all extremely bitter, and are collected by country people, under the name of centaury, as a substitute for gentian, in domestic medicine. English botanists reckon four supposed species.

ERYTHRÆA CENTAURIUM, Lesser Centaury, an indigenous plant, common by way-sides and edges of fields, flowering in August, at which time it is to be collected. The whole plant is taken up; it has a square stem, with opposite entire three-nerved leaves. It is devoid of odour; the taste is strongly bitter, but not unpleasant: 100 parts of the fresh herb dry into 47; 10 pounds of the dry herb yield by a single decoction 3 pounds of extract.

It contains a principle called Centaurin, which at present is known only as a dark brown extract-like mass; but which, united with hydrochloric acid, furnishes an excellent febrifuge medicine. As a bitter, it suits irritable systems better than any article of that class of medicines, and is therefore to be preferred. In other respects it has the general properties of bitter tonics.

ERYTHRIC ACID, a substance obtained by Bragnatelli from the mutual action of nitric and uric acids; by spontaneous evaporation rhombic crystals are obtained, which have first a sharp and afterwards a sweetish taste, redden litmus, become of a rose colour, and effloresce in the air. Instead of being a peculiar acid, Dr. Prout regards it as a compound of nitric and purpuric acid and ammonia.

ERYTHRINA, a leguminous genus of tropical trees and tuberous herbs, with ternate leaves, and clusters of very large long flowers, which are usually of the brightest red; whence the species have gained the name of coral-trees. Frequently their stem is defended by stiff prickles. They occur in the warmer parts of the Old and New World. An Indian species, *E. monosperma*, is said to yield gum-lac. De Candolle mentions thirty-two species; of which *E. crista galli* is commonly cultivated in greenhouses for the sake of its splendid blossoms.

ERYTHROGEN, a neutral crystalline fatty matter found by M. Bizio in bile altered by disease.

ERYTHRONIUM (*Dens Canis*), a pretty little bulbous plant, whose name, Englished dog's-tooth violet, is derived from the form of its long slender white bulbs, is a native of woody subalpine places among bushes and stones, in Croatia, Idria, and about Laybach; it also occurs in Switzerland, but more seldom, and is also met with in the north of Italy. It is not mentioned in the Floras of the south of Europe. Two or three varieties are known in gardens as gay hardy flowers appearing early in the spring; one with purple, a second with white flowers, and a third, elevated by some into a species, with a somewhat stronger habit of growth.

ERYTHROXYLÆ, a group of exogenous plants, con-

Erythroxylon laurifolium.

1. A calyx with the monadelphous stamens; 2. a petal with its appendage; 3. the ovary, with the three styles; 4. a half-ripe fruit; 5, a transverse section of the same, showing that one only of the seeds comes to perfection, the two others being abortive.

sidered by some as a distinct natural order; by others as a subordinate division of Malpighiaceæ. They have alternate stipulate leaves, and small pallid flowers. The calyx is five-lobed; the petals are five, with a remarkable appendage at their base, which afford one of the marks of distinction between Erythroxylæ and Malpighiaceæ; the stamens are ten, slightly monadelphous. The ovary is superior, three-celled, with three styles, and solitary pendulous ovules. The fruit is drupaceous. Some of the species of Erythroxylon, the only genus, have a bright red wood, occasionally used for dyeing; but the most extraordinary species is the Erythroxylon coca, of whose inebriating effects a full account has already been given. [Coca.]

ERYX or ERIX, a genus of serpents separated by Daudin from *Boa*, and differing from it in having a very short obtuse tail, and the ventral plates narrower. The head of *Eryx* is short, and the characters generally would approximate the form to *Tortrix*, did not the conformation of the jaws place it at a distance from the last-named genus. The head, besides, is covered with small scales only. *Eryx* has no hooks at the vent.

Eryx Bengalensis.

ERZERUM, ERZ-RU'M, or ARZRU'M, a town in Turkish Armenia, in 39° 57' N. lat., and about 41° 15' E. long., towards the eastern extremity of an extensive and fertile plain between 30 and 40 miles in length and from 15 to 20 miles in its greatest breadth. This plain is watered by the Karâ Sû, or western branch of the Euphrates, which rises at its eastern extremity, and from whose banks the town is three or four miles distant. The town is very large, and is partly surrounded by an old castellated wall, with a ditch, and on its southern skirts stands a citadel encircled by a double wall flanked with towers very close to each other, and with a ditch: it has four gates, and incloses the palace of the pacha and nearly the whole of the Turkish population. But a large portion of Erzerum is unwall'd, and contains the principal bazaars and khans. The houses for the most part are low, and built of wood, but the bazaars are extensive, and well supplied with provisions. Erzerum has nearly forty mosques, a Greek church, and a large Armenian chapel. In the beginning of this century the population was estimated at 100,000 individuals; and in 1827 at 130,000. But being soon afterwards occupied by the Russians, the greatest part of the inhabitants abandoned the town, the Armenians emigrating to Russia, and the Turks retiring to the adjacent parts of Asia Minor. Since its restoration to the Turks by the peace of Adrianople the place is slowly rising from its state of decay, but in 1835 its population did not exceed 15,000. We do not know if any of its numerous manufactures have been revived. Before the Russian invasion considerable quantities of silk and cotton cloth were made here, and much leather tanned; there were also some manufactures of copper vessels.

Erzerum is important as a commercial town. Besides the produce of its manufactures it exports the excellent grain which is grown in the plain. But it derives other commercial advantages from its being situated on one of the most frequented caravan roads of Western Asia, which leads from Persia and Georgia to the great commercial towns of Asia Minor. This renders Erzerum an important place also in a political and military point of view. It is the seat of a pasha, and the pashalik yields only in rank and extent to that of Bagdad. (Kinneir; Brant, in *London Geogr. Journal*, vi.)

ERZGEBIRGISCHE-KREIS (circle of the Ore Mountains), a large province of the kingdom of Saxony, which takes its name from the mountains which bound it on the south and separate it from the kingdom of Bohemia. On the north it is bounded by the circle of Leipzig and by the duchy of Saxe-Altenburg; on the west by the grand duchy of Saxe-Weimar, the principality of Reuss, and the circle of Voigtland; and on the east by the circle of Meissen. It is the largest and most populous province in the kingdom, and contains an area of about 1747 square miles, on which there are 58 towns, 13 market villages, and above 700 villages and hamlets. In 1829 the population was 488,863, and it is at present estimated at about 506,000. The surface rises gradually from the borders of the Leipzig and Meissen circles, until it reaches the southern frontier and the lofty summits of the Ore Mountains. The province is intersected in all directions by offsets from those mountains, and presents a constant succession of hills and valleys. The loftiest heights in it are the Fichtelberg, at the southernmost extremity of the province, which is 3968 feet, and the Auersberg, about eleven miles north-west of the Fichtelberg, which is 3132 feet above the level of the sea. The Freiberg or Eastern Mulde, the largest river in the province, flows through its eastern districts, and the Schneeberg or Western Mulde through the western districts; the centre is irrigated by the Zschoppau, Flöhe, Pöhl, Sehm, Bockau, Chemnitz, and other streams; the Weiseritz or Westritz partially traverses the most easterly part, and the Pleisse the most westerly. There are no inland waters deserving the name of lakes, but there are a number of mineral springs, chiefly used for bathing, at Wolkenstein, Wiesa, near Annaberg, &c. The province is full of woods and forests, particularly its most elevated parts, such as the vicinity of Schwarzenberg. The average height of the Erzgebirgische Kreis above the level of the sea is estimated at 1200 feet.

In consequence of the rugged character of the surface, the hard, stony soil, and the rawness of the climate, neither agriculture nor horticulture are pursued on a scale of sufficient extent to supply the wants of the province. Oats, rye, linseed, potatoes, and a small quantity of wheat, are cultivated; these articles are also imported from Bohemia and the adjoining circle of Leipzig. There are fine and extensive pastures, particularly in the vicinity of Zwickau, Chemnitz, Augustusberg, Freiberg, and Nossen, where large flocks of sheep are kept; but cattle-breeding, on the whole, is not so actively carried on as it might be. The province is well known for its large trout, its salmon, carp, and other fresh water fish.

The very name of this part of Saxony, 'the circle of the Ore Mountains,' indicates the peculiar character of its natural riches. It abounds in mines of silver, tin, lead, iron, cobalt, &c., the first working of which is said to have taken place in the middle of the twelfth century. Their most flourishing state was in the fifteenth, when the silver mines of Schneeberg and Annaberg and the tin mines of Altenberg were discovered and opened. At the present day they afford employment, either directly or indirectly, to upwards of 200,000 persons. The largest silver mines are in the neighbourhood of Freiberg, of which the Erbsdorf alone produced 3,048,500 ounces of silver between 1769 and 1818: their number is about 200, with 540 pits (zechen); they occupy 4800 hands, and their present produce is from 375,000 to 450,000 ounces annually. The other silver mines are at Schneeberg, Schwarzenberg, Annaberg, Marienberg, &c. The most considerable tin mines are at Altenberg and Geier; others at Schneeberg, &c. No mines in Saxony produce so much iron as those of Johann-Georgenstadt: this metal is also obtained at Schneeberg, Altenberg, &c. Near Aue and Bockau, to the south of Schneeberg, in what is called the 'Saxon Siberia,' lie the largest

cobalt mines, and smalts, or blue-colour works in Germany; of these smalts the yearly produce is between 9000 and 10,000 cwt., besides large quantities of arsenic, &c. The white porcelain-earth used in the royal china manufactory at Meissen is procured and prepared in this district. Much sulphur and vitriol are made at and near Beierfeld and Geier: magnesia and porcelain earth are obtained at Elterlein; and there are coal mines of importance at Planitz, and other spots near Zwickau. The value of all the silver sold in 1833 was 862,764 dollars (122,200*l.*); and in 1834 about 1,000,000 dollars (141,600*l.*). The cobalt and blue colour (smalts) produced 321,724 dollars, or about 45,500*l.* The lead mines yield annually about 500 tons; the tin about 3000 cwt.; the copper about 18 tons; and the iron between 4000 and 4500 tons.

Besides considerable manufactures of iron, tin, and copper ware, the largest of which are at Freiberg, Schwarzenberg, Wiesenenthal, and Elterlein, there are extensive manufactures of thread, twist, linens, cotton goods, woollen cloths, flannel, woollen stockings, &c., at Chemnitz, Zwickau, Zschoppau, Oederan, &c. Laces and bobbinet are made at Altenberg, as well as Annaberg, where nearly a thousand hands are engaged in making tapes and ribands. Much serpentine stone is worked from the quarries of Zöblitz, and steel is made at Schedewitz near Zwickau. In the upland districts various articles in wood are manufactured.

This province also includes the independent earldom of Solm-Wildenfels, with an area of 31 square miles, the 6200 inhabitants of which are principally employed in making linen, coarse cottons, and stockings; and the possessions of the princes and counts of Schönburg, in the north-western part of the province, comprising an area of 252 square miles and a population of about 84,000, who are engaged in agriculture as well as manufactures. The chief town is Glauchau, on the Western Mulde, with 5000 inhabitants, and manufactures of woollens.

The province is divided into the 'Amtshauptmannschaftliche Bezirke' or bailiwicks of Chemnitz, Zwickau, Walkenstein, and Freiberg. Chemnitz, in the north-west, contains the towns of CHEMNITZ (see vol. vii. p. 38), Frankenberg on the Zschoppau, 5200 inhabitants; Oederan, 3800; Zschoppau, on the river of that name, 3300; and in the Schönburg possessions, Lösnitz, 3450; Glauchau; Hohnstein, 3600; Waldenburger, on the western Mulde, 3000; Penig, on the same river, 3100; and St. Merane, 2300. The bailiwick of Zwickau, in the west and south-west, contains Zwickau, on the western Mulde, with 5400 inhabitants and large woollen manufactures; Werdan, on the Pleisse, 3600; Wildenfels; Schwarzenberg, on the Schwarzwasser, 1400; Wiesenenthal, 1600; Johann-Georgenstadt, on the Schwarzwasser, 2700; and Schneeberg on the Schleierbach, 5800. The bailiwick of Walkenstein, in the south, contains the towns of ANNABERG (vol. ii. p. 40); Walkenstein on the Zschoppau, 1600 inhabitants; Geyer on the Pleisse, 1800; Zöblitz, 1100; Elterlein, 1200; and Stollberg, 3050; and the bailiwick of Freiberg, in the east, contains Freiberg, on the eastern Mulde, the chief town of the Erzgebirge circle, 11500 [FREIBERG]; Haynichen, on the Striegis, 3000; Nossen, on the eastern Mulde, 1200; Rosswein, on the same river, 3500, with woollen manufactures; Fraunstein, 800; and Altenberg, 1600.

ERZGEBIRGE (the Ore Mountains) is a mountain-range in Germany, extending along the boundary line of the kingdoms of Bohemia and Saxony. It begins about 25 miles south-east of Dresden, on the very banks of the river Elbe, and extends in a west-south-west direction to the sources of the river called the White Elster (Weisse Elster), about 12° 30' E. long., where it is connected with the Fichtel Gebirge. The river Elbe divides its eastern extremity from the Winterberg, the most western of the mountains of Lausitz, or Lusatia. The Ore Mountains extend in length about a hundred miles, and their mean width is estimated to be more than thirty miles.

The highest part of the range, which is towards its southern border, forms partly the boundary-line between Bohemia and Saxony, but is mostly within the former kingdom. Its southern declivity, which is steep and intersected by narrow valleys, terminates in the valley of the river Eger, about 10 or 15 miles from the upper range. The valley of the Eger lowers gradually from west to east, from 1100 feet to 400 feet above the sea. The northern de-

clivity of the range descends in more gentle slopes towards the great plain of Northern Germany; and these slopes are divided from one another by wide and open valleys. A line drawn from Pirna on the Elbe to Tharand, Freiberg, Chemnitz, Zwickau, and Reichenbach, indicates with tolerable correctness where the range on this side ceases. The undulating plain which lies contiguous to it may be from 500 to 600 feet above the level of the sea.

The highest portion of the range occurs on both sides of 13° E. long., but rather to the west of it. Here are the Keilberg, 4212 feet, the Fichtelberg, 3968 feet, the Schwarzenberg, 3988 feet, and the Hainsberg, 3248 feet above the sea. Farther east and farther west the range gradually sinks lower, the Great Chirnstein, on the banks of the Elbe, rising only to 1824 feet above the sea.

This range belongs to the primitive formation, granite and gneiss being everywhere prevalent, except along the banks of the Elbe, where sandstone almost exclusively occurs. It is rich in metals of almost every kind, from which circumstance indeed its name is derived, though it is less productive than it was some centuries ago. The working of the mines is pursued with great activity and skill, and it is stated that more than 10,000 families are dependent on them for their livelihood. Gold occurs in a few places, but is not so abundant as to pay for the labour of getting it. The silver-mines are considerable, and their annual produce amounts to 60,000 marks, at 12 ounces to the marc; that of the iron-mines amounts to 3500 or 4000 tons. The tin-mines of Saxony are the most valuable on the European continent, and produce annually 140 tons. Copper is not abundant, and the annual produce does not exceed 30 tons; but from the lead-mines 400 or 500 tons are annually obtained; and of cobalt 600 tons and upwards. Arsenic, brimstone, and vitriol, are likewise abundant; and there is also quicksilver, antimony, calamine, bismuth, and manganese. Coal abounds in the neighbourhood of Dresden and Zwickau. One of the most remarkable mineral productions is the kaolin, or porcelain clay, which occurs in layers six feet thick at Aue, about 12 miles south-east of Zwickau, whence it is carried to Meissen, and there used in the manufacture of the fine china-ware. Several kinds of precious stones are found, as garnets, topazes, tourmalins, amethysts, beryls, jaspers, and chalcidones.

The upper parts of the range are covered with extensive forests, which furnish fuel for the great smelting-works. The lower slopes and valleys are well cultivated, but the produce is not sufficient for the maintenance of the great population which is employed in the mines and in the numerous manufactures of cotton, silk, and linen. Great quantities of corn are annually brought from the plain which lies to the north of the range.

Six great roads pass over this range. By the two most eastern Dresden communicates with Prague. The more eastern of these two runs from the last-mentioned place to Lowositz and Aussig, passes near Porterswalde through the pass of Zehist, and hence descends to Giesshübel and Pirna. The more western goes from Lowositz to Töplitz, passes the range near Zinnwald, and descends through Altenberg and Dippoldiswalde to Dresden. The third road leads from Prague to Laun on the Eger, hence to Komotau, passes the range by the pass of Bäsberg, and descends to Chemnitz. The fourth road runs along the Eger from Saatz to Kaaden, traverses the range by the pass of Pressnitz, and thence leads to Annaberg and Chemnitz. The fifth road leaves the valley of the Eger near Kaaden, passes the range near Gottesgab, and leads through Schneeberg to Zwickau. The sixth and most western road runs from Carlsbad to Joachimsthal, and thence over the range through Johann-Georgenstadt and Schneeberg to Zwickau.

ESCALLONIA/CEÆ, a small natural order of exogenous plants, related to the genus Ribes, in the opinion of some, but to that of Saxifraga, according to other botanists. It consists of shrubs with evergreen leaves, which often emit a powerful odour like that of melilot; their flowers are red or white, and often are quassimonopetalous, in consequence of the approximation of their petals. They have an inferior many-seeded ovary, with two large placentæ in the axis, a definite number of epigynous stamens, a single style, and minute chaffy seeds with a very small embryo lying in oily albumen. All the species inhabit South America, on the mountains, especially in alpine regions. Escallonia rubra, montevidensis, illinita, and others, have now become common in warm sheltered gardens in this country.

Escallonia serrata.

1, A flower magnified, without the petals; 2, a transverse section of the ovary.

ESCAPEMENT. [HOROLOGY.]

ESCARP, or **SCARP**, in fortification, is that side of the ditch surrounding or in front of a work, and forming the exterior of the rampart. In field-works the escarp is usually formed by cutting the earth at such an inclination as will permit it to support itself, which may be at 45 degrees with the horizon or more, according to the tenacity of the soil; and, to impede the enemy in attempting an assault, fraises or inclined palisades are frequently planted on the slope. In large fortresses the escarp is the exterior surface of the revetment wall which supports the rampart, and it is frequently formed at such an inclination that its base, measured in front of a vertical plane passing through the top of the wall and in the direction of its length, is one-sixth of the height of the wall; but engineers at present recommend both the escarps and counterscarps to be vertical, from an opinion that the action of the weather upon the brick-work will thereby be diminished. [REVERMENT.]

ESCARPMENT, a precipitous side of any hill or rock. In military operations ground is frequently scarped, as it is called, or cut away nearly vertically about a position, in order to prevent an enemy from arriving at the latter. Part of the rock of Gibraltar has been rendered inaccessible in this manner; and, in the execution of the intrenchments about Lisbon, in 1810, the British troops formed an escarpment from 15 to 20 feet high, and about two miles long, on the brow of a ridge of heights extending from Alhandra to the valley of Calandrix, in order to secure the line against an attack at that part. A similar work was executed along a ridge of hills between Mafra and the mouth of the S. Lorenzo.

E'SCHARA. [POLYPARIA MEMBRANACEA.]

ESCHAROTICS (*τοξαιμικά*, from *τοξάω*, to form a crust, or scab), are agents applied to the surface of the body, which destroy the vitality of the part which they touch and produce an eschar. This effect they occasion either by combining chemically with the animal matter, or by destroying the old affinities, and causing the elements of the part to enter into new combinations. Their action is more energetic in proportion to the degree of vitality of the part to which they are applied. They are classed under two heads, the *potential* cauterants, and the *actual* cautery: the former are chiefly chemical agents, and form new compounds with the elements of the part with which they come in contact; but some merely cause irritation and augmented absorption, and are distinguished as *erodents*. The actual cauterants are substances of an elevated temperature, which decompose the part which they touch, and completely destroy its organization.

The chief potential cauterants are strong mineral acids, such as the sulphuric or nitric, pure alkalies, and some metallic salts, especially nitrate of silver, or lunar caustic. These are used either to produce counter-irritation, or to remove fungous or morbid growths. Lunar caustic seems

to possess peculiar properties, and is unquestionably the most powerful *direct* antiphlogistic agent known. If applied in the solid state to many inflamed parts it speedily checks the morbid action, and is decidedly the best application to chilblains, and in leucorrhœa. The actual cauterants are used either for their primary action, viz., the immediate destruction of the part, or for their secondary effects. The former object is rarely attempted, except to prevent the absorption of any poisonous or contagious matter, such as the venom of a snake, or bite of a mad dog. The secondary effects are more important, and more varied according to the degree of heat of the substance applied. The first effect is pain more or less severe, a flow of blood towards the part, and more rapid performance of the process of interstitial deposition and absorption, terminating in inflammation, extending to a greater or less depth, according to the intensity of the heat, or form of the body employed. This increased action has often a salutary effect, which is frequently felt through the whole frame. Torpor and paralysis of the nervous system often disappear, and neuralgia both of the neighbouring and even distant parts is removed. Atony and laxity of the muscular system vanish, and every part displays more energy and power.

The actual cautery may be applied in a variety of ways, viz., hot water, hot vapour, moxa, and heated iron. The first of these is a very ready means of causing vesications in some diseases. In phthisis pulmonalis, or consumption, where pain is often more relieved by vesication than any other means, placing a sponge in a wine-glass, and pouring boiling water on it, then suddenly inverting the glass over the part of the chest where the pain is felt, will cause immediate vesication, followed by speedy relief. The vapour of boiling water, as it issues from the spout of a kettle, is also a convenient method of applying heat in inflammations of the joints, as in gout, morbus coxarius, and other deep-seated diseases of the bones. As the red-hot iron is now seldom used, being confined to veterinary medicine, moxa affords the best substitute, and it is very convenient, as any degree of intensity or rapidity of action can be given to it. [MOXA.]

The eschar which follows the application of the potential or actual cautery generally separates in a few days. The ulcer is then to be treated with different agents, according as it is wished to heal it or keep it open, as a farther means of counter-irritation.

ESCHEAT, from the Norman French word *eschet* or *echet*, chance or accident (a word derived from *escheoir*, the old French form of the verb *échoir*, 'to fall'), is defined by Sir William Blackstone as an obstruction to the course of descent by some unforeseen contingency which consequently determines the tenure. In this case the land reverts back by a kind of reversion to the original grantor or lord of whom it is held.

Escheat takes place when the tenant of lands dies intestate and without an heir: in such case the lands, if freehold, escheat to the king, or other lord of the fee; if copyhold, to the lord of the manor. Lands which have descended to the last tenant from a paternal or maternal ancestor, escheat, if there are no heirs on the part of that ancestor from whom the lands descended. Since the 1st day of January, 1834, there can be no escheat on failure of the whole blood, wherever there are persons of the half-blood capable of inheriting under 3 & 4 Will. IV., c. 106.

If a bastard dies intestate and without issue, his lands escheat to the lord of whom they are held.

Escheat also takes place upon attainder for treason and murder, by means of which the blood is in law considered to be corrupted, and the attainted owner of lands rendered incapable of holding them himself, or transferring them by descent. In consequence of this extinction of heritable blood, the lands of such felons revert in the lord, except in cases of treason, when a superior law intervenes, and they become forfeited to the crown. Previously to a recent act (3 & 4 William IV., c. 106), a person could not trace his descent through another person who had been attainted; but this may now be done, provided that other person shall have died before such descent shall have taken place. [ATTAINDER.] And by the 4 & 5 William IV., c. 23, no property vested in any trustee or mortgagee shall escheat or be forfeited by reason of the attainder or conviction for any offence of such trustee or mortgagee, except so far as such trustee or mortgagee may have a beneficial interest in such property

This doctrine of escheat consequent upon the commission of certain crimes is derived from the feudal law, by which a vassal was only permitted to hold real property upon condition of well demeaning himself.

The doctrine of escheats, with regard to extinct successions, seems to have been adopted in every civilized country to avoid the confusion which would otherwise arise from the circumstance of any property becoming common; and the sovereign power, or those who claim under it, are consequently the ultimate heirs to every inheritance to which no other title can be found.

ESCHEATOR, an ancient officer appointed by the lord treasurer, and so called because his office was to look after escheats, wardships, and other casualties belonging to the crown.

There were at first only two escheators throughout England, one on this side and the other beyond the Trent; but in the reign of King Edward III. there was one appointed for every county, who was to continue in office for one year only. This office has now ceased to exist. (Blackstone's *Commentaries*; Wooddesson's *Lectures*.)

ESCHSCHOLTZIA, a genus of beautiful yellow-flowered papaveraceous plants, inhabiting California and the north-western coast of North America, and now become extremely common in the gardens of Great Britain. They are known by the base of their calyx remaining at the base of the silique fruit in the form of a firm fleshy rim, by their calyx being thrown off like a calyptra when the petals unfold, and by the stamens being inserted into the edge of the permanent rim of the calyx. Otherwise they are very near our sea-shore *Glaucium*. Two certain species only, *E. Californica* and *E. crocea*, have yet been introduced; a third, *E. compacta*, is figured in the 'Botanical Register,' but it is probably a mule between the two first. It has been recently proposed to alter this name, which has a barbarous sound and appearance, for the more harmonious one of *Chryseis*, and it is hardly to be doubted that the latter will be adopted. (*Botanical Register*, t. 1948.)

ESCHWEGE. [HESSE, LOWER.]

ESCUAGE, or SCUTAGE, a pecuniary payment, by way of commutation for knight-service, whereby the tenant was bound to follow his lord into the wars at his own charge. The term escuage or scutage is from the old French *escu*, and that from the Latin *scutum*, 'a shield;' a name also given to coins on which there was the shield or escutcheon of the sovereign.

The personal attendance in knight-service growing troublesome and inconvenient in many respects, the tenants found means of compounding for it, by first sending others in their stead, and in process of time by making a pecuniary satisfaction to the lords in lieu of it. This pecuniary satisfaction at last came to be levied by assessments, at so much for every knight's fee; and therefore this kind of tenure was called *scutagium* in Latin, or *servitium scuti*; as being a pecuniary substitute for personal service. The first time this appears to have been taken was in the 5th Hen. II., on account of his expedition to Toulouse; but it soon came to be so universal, that personal attendance fell into disuse. Hence we find in our ancient histories that, from this period, when our kings went to war, they levied scutages on their tenants, that is, on all the landholders of the kingdom, to defray their expenses, and to hire troops. and these assessments, in the time of Henry II., seem to have been made arbitrarily and at the king's pleasure. This prerogative being greatly abused by his successors, it became matter of national complaint, and King John was obliged to consent, by his *magna charta* (c. 12), that no scutage should be imposed without consent of parliament. But this clause was omitted in his son Henry III.'s charter; where we only find (c. 37) that scutages or escuage should be taken as they were used to be taken in the time of Henry II.; that is, in a reasonable and moderate manner. Yet afterwards, by statute 25 Edw. I. c. 5 and 6, and many subsequent statutes, it was enacted, that the king should take no aids or tasks but by the common assent of the realm. Hence it is held in our old books, that escuage or scutage could not be levied but by consent of parliament (*Old Ten. tit. Escuage*), such scutages being indeed the groundwork of all succeeding subsidies, and of the land-tax of later times. (Jacob's *Law Dictionary*, in voce; Blackstone's *Comment.* vol. ii. pp. 74, 75.)

ESCULA'PIUS. [ÆSCULAPIUS.]

ESCULIC ACID, a peculiar acid procured from horse-chestnuts. This acid is colourless, insoluble in water, but

dissolved by alcohol, and is deposited from it in crystalline grains. It forms with bases salts termed *esculates*, but they are quite unimportant. Esculic acid consists of 8.34 hydrogen, 57.26 carbon, and 34.39 oxygen, in 100 parts.

ESCURIAL, or ESCORIAL, a vast edifice in the kingdom of Toledo, situated seven leagues from Madrid in a north-west direction. The term escorial is considered by some to be Arabic, meaning a place full of rocks, but by others is derived from *scoria ferri*, iron dross, from the circumstance of there having been antiently great iron works near this place. The situation is rocky and barren, devoid of all vegetable matter, except what has been conveyed there by man; and it appears to have been chosen for the advantage of procuring stone. The edifice was begun by Philip II., five years after the battle of St. Quintin, fought on the anniversary of St. Lawrence (both of which circumstances it was intended to commemorate) and was finished in twenty-two years. This extensive building is laid out, on its ground plan, in the form of a gridiron, a part (which forms the royal residence) advancing to form the handle, attached to a long rectangle forming several courts and quadrangles. This part is 640 by 580 feet, and the average height to the roof is 60 feet. At each angle is a square tower 200 feet high. The plan is divided so as to form a convent with cloisters, two colleges, one for the clergy and one for seculars, the royal palace, three chapter houses, three libraries with about 30,000 volumes and some valuable MSS., five great halls, six dormitories, three halls in the hospital, with twenty-seven other halls for various purposes, nine refectories, and five infirmaries, with apartments for artisans and mechanics. There are no less than eighty staircases. The gardens and parks, formed by art, are decorated with fountains.

The monks of the order of St. Jerome were 200 in number, and had a revenue of 12,000*l.* per annum.

The stone of which the building is constructed is white, with dark grey spots. The windows on the outside are 1110 and within 1578; of the former 200 are placed in the west front and 366 in the east. Including the out-offices, there are not less than 4000 windows. There are fourteen entrances or gateways, which have pretensions to architectural decoration, and 86 fountains.

The church is 374 feet long and 230 broad, and is divided into seven aisles. It is crowned with a dome 330 feet high from the ground, and is paved with black marble. In the church are forty chapels with their altars. In the palace and in the church there is a profusion of gilded bronze work and incrustation of marbles. There are numerous paintings by the great masters in the Escorial. It is possible however that these may have been removed to the Royal Museum at Madrid, formed by the late King Ferdinand. (*Spain Revisited*, cap. 13, vol. i.) The sculpture is said not to have any great merit. Philip IV. added a beautiful mausoleum 36 feet in diameter and incrustated with marbles: the design is in imitation of the Pantheon at Rome. The cost of the Escorial was six millions of piastres. For some curious details of the Escorial see 'The Escorial, or that wonder of the world for architecture and magnificence of structure, &c., translated into English by a servant of the earl of Sandwich in his extraordinary embassy thither,' Lond., 1671. From the title-page it appears that there was a report in 1671 that the Escorial had been destroyed by fire. There was a similar report a few years since.

ESCUTCHEON or ESCOCHEON, the heraldic term for the shield, on which, under every variety of shape, arms are emblazoned. The word is derived from the French *écusson*, and that from the Latin *scutum*. The first representation of arms was, no doubt, as an ornament to the shield. The shield afterwards became the appropriate and legitimate instrument for displaying them; hence in sculpture and painting they were never separated; and when shields ceased to be employed, their form remained, and still continues to be the field on which coat-armour is invariably depicted. An *escutcheon of pretence* is the small shield in the centre of his own, on which a man carries the coat of his wife, if she is an heiress and he has issue by her. In this case the surviving issue will bear both coats quarterly.

ESNE. [EGYPT, p. 312.]

ESOTERIC. [EXOTERIC.]

ESPALIER, a trellis for training fruit trees or bushes upon, instead of nailing them to walls.

In certain situations this kind of training is not only extremely neat but possesses peculiar advantages: the trees are more fully exposed to the influence of light, less liable

to be broken by high winds, and in small gardens in particular, where room is of great importance, and where a collection of the finer sorts of fruit is always desirable, it is found highly useful, both on account of the small space which the trees occupy, and because they will bear fruit much sooner than when allowed to grow in their natural form.

In France and other parts of the Continent this kind of training is very much practised, and in the northern parts of England and in Scotland, where the borders of the kitchen-garden are frequently planted with flowers, in order to combine pleasure with utility, espaliers are trained along the back of the flower borders to prevent the vegetables being seen from the walks.

When the espalier is fastened to a wall, as is very common on the Continent, peach and nectarine trees are frequently trained upon it; but where it is detached, as it is most commonly in Britain, apples and pears, and sometimes gooseberries, are the only fruits which are successfully cultivated in this way. Plums and cherries are occasionally so managed, but not so advantageously as the others.

When a common espalier is to be covered, the trees should be planted from 20 to 24 feet apart, which will allow the branches to grow 10 or 12 feet on each side: but as a considerable time would elapse before they would fill this space, a duplicate tree may be planted between each, and cut away as the others grow. Gooseberries of course require a small space; three or four feet from plant to plant is sufficient.

The training on espalier is very simple, and easily performed. When the trees are young, one shoot must be trained perpendicularly, and two others horizontally, one from each side; the two last must not be shortened, but the perpendicular shoot is to be shortened in the following year to three good buds, two of which are to form new side branches, and the other a leader as before; and so on every year until the trees have attained the desired size. The proper distance between the horizontal branches must depend upon the peculiar growth of the tree, but from six to nine inches is what is generally allowed. Trees are sometimes trained upon a double espalier which has the advantage of giving two surfaces to train upon. It consists of two trellises instead of one, about two feet apart at the bottom, and approaching at the top.

The only kind of espalier worth notice, which differs from those now mentioned is a table-rail: this, the management of which is called table training, consists of rails resembling tables, up the centre of which the tree is trained and regularly spread over the surface. It is rarely employed, and has the essential fault of exposing the blossom so much to the effect of nocturnal radiation that in this country a crop is rarely obtained from such espaliers.

The stakes which form the espalier are made of different materials, some of wood, others of wire and wood, and some of cast iron. The first of these is by far the most simple, and is composed of stakes, five or six feet in height, driven into the ground from one to two feet apart; along the top a bar, which is nailed to each, connects the whole together. It is of no use to have the stakes either so strong or so high when the trees are first planted, because they are not required, are unsightly, and will have to be renewed before the trees have attained their intended height; for this reason, stakes of a much weaker kind will at first answer quite as well. The wire and wood rail is formed by strong vertical wires, strained from two wooden horizontal rails, which are connected and held fast by wooden posts let into the ground. The iron rail is constructed upon the same plan as a common street railing.

The objection to all iron trellises is, that they cut and canker the trees; and when the cheapness of the wooden one is considered, besides the more natural appearance which it presents, it must undoubtedly have the preference.

The best wood for this purpose is young larch, the thinning of plantations.

ESPALION, a town in the department of Aveyron, in France. It is on the left or south bank of the river Lot, 17 miles from Rhodéz, the capital of the department, and 339 from Paris by Fontainebleau, Briare, Nevers, Moulins, Riom, Clermont, and St. Flour. The principal street of the town is broad, and lined with well-built houses: it leads down to the bridge over the Lot. The population in 1832 was 2260 for the town, or 3545 for the whole commune. The inhabitants manufacture light woollen stuffs, and there

are several tan-yards: morocco leather is manufactured. Good wine is produced in the country round Espalion. The town has a subordinate court of justice (*tribunal de première instance*), a high-school, and a drawing-school.

The *arrondissement* of Espalion is subdivided into nine cantons or districts, under the jurisdiction of a justice of the peace, and 101 communes: it had in 1832 a population of 65,086.

ESPIRITU SANTO. [BRAZIL, p. 336; CUBA, p. 205.]

ESPRIT. SAINT, a suburb of Bayonne. [BAYONNE.]

ESPLANADE, the ground between the fortifications of a citadel and those of the town to which it belongs. It is recommended by writers on fortification that this space should be about 300 fathoms broad, reckoning from the covered way of the citadel, that in the event of an attack on the latter the enemy may not construct batteries within breaching distance under the cover afforded by the buildings of the town.

ESQUILINE HILL. [ROME.]

ESQUIMAUX, a nation inhabiting the most northern countries of America, and, if the extent of country be considered, one of the most widely-spread nations on the globe. On the eastern coast of America they are met with as far south as 50° N. lat. on the shores of the Strait of Belle Isle, which separates Newfoundland from the mainland of America. They occupy the whole of the great peninsula of Labrador and the whole eastern coast of Hudson's Bay up to East Main River. On the western side of Hudson's Bay they inhabit the coast north of Churchill River, whence they extend northwards over the Barren Lands to the Great Fish River, or Thleweschodezeth, on both banks of which river they are found east of 100° E. long. The whole country between this river, the Great Bear Lake, the Mackenzie River, and the Arctic Ocean, is exclusively inhabited by them. The coast lying to the west of Mackenzie River is also in their possession; and they seem to be spread as far as Kotzebue Sound, on Behring's Straits. They also occupy Greenland and all the other islands between the northern coast of America and the pole, as far as they are habitable.

In stature the Esquimaux are inferior to the generality of Europeans. A person is rarely seen who exceeds 5 feet in height. Their faces are broad, and approach more to the rounded form than those of Europeans; their cheekbones are high, their cheeks round and plump, mouth large, and lips thick. The nose is small, and, according to some authors, flat, which, however, is denied by others. Their eyes are in general of a deep black; but some are of a dark chestnut colour: they appear very small and deeply seated, owing to the eye-lids being much encumbered with fat. The hair is uniformly long, lank, and of a jet black colour. The ears are situated far back on the head. Their bodies are large, square, and robust, the chest high, and shoulders very broad. Their hands and feet are remarkably small; there is, however, no sudden diminution, both extremities appearing to taper from above downwards in a wedge-like shape. Graah, in his 'Voyage to Greenland,' observes that the inhabitants of the eastern coast have disproportionately large hands and feet. They are of a deep tawny or rather copper-coloured complexion. They are not without beard, as it has been asserted, but they pluck it out as soon as it appears. Some of them even wear long beards. They show a good deal of ingenuity in making their dresses and instruments; and some of them have attracted the attention of our travellers by their display of mental powers.

Their language is different from that spoken by the other savage nations who inhabit North America; but it seems that the same language is spoken by all the different tribes of the Esquimaux, though of course each of them has expressions which are peculiar. (Parry; Mac Keevor; Graah's *Voyage to Greenland*.)

ESQUIRE (from the French, *écuyer*, or shield bearer) is the next title of dignity to that of knight. The esquire was the second in rank of the aspirants to chivalry, or knighthood, and had his name from carrying the shield of the knight, whose bachelor, or apprentice in arms, he was. The gradations of this service, or apprenticeship to arms, were, page, esquire or bachelor, and knight, who, in his turn, after the formation of degrees of knighthood, was called a knight bachelor, as aspiring to the higher honours of chivalry. The esquire was a gentleman, and had the right of bearing arms on his escutcheon or shield; he had

also the right of bearing a sword, which denoted nobility or chivalry, though it was not girded by the knightly belt; he had also a particular species of defensive armour which was distinguished from the full panoply of the knight. So much for the esquire of chivalry, which order is only preserved in the almost obsolete esquires for the king's body, whom antiquaries have pronounced to be the king's esquires in chivalry (that is, his esquires, as being a knight), and in the esquires of knights of the Bath.

There was also another class, who may be called feudal esquires, and consisted of those tenants by knight's service who had a right to claim knighthood, but had never been dubbed. They were in Germany called *ritters*, or knights, but were distinguished from the actual knights, who were called dubbed knights, or *Ritter Geschlagen*, and had many of the privileges of knighthood. This distinction still exists in many of the countries which formed part of the German empire. In Hainault, Brabant, and other provinces of what was Austrian Flanders, the antient untitled nobility, or gentry as they are called in England, to this day are styled collectively the *Ordre Equestre*, or knightly order. It also existed in England until James the First had prostituted the honour of knighthood, for Camden frequently speaks of knightly families (*familias equestres*, or *familias ordinis equestris*), where the heads of them were not, at the time, actual knights. Writers on precedence make mention of esquires by creation, with investiture of a silver collar or chain of *ss*, and silver spurs: but these seem to have been only the insignia of the esquires for the king's body, which being preserved in a family as heir looms, descended with the title of esquire to the eldest sons in succession. The sons of younger sons of dukes and marquesses, the younger sons of earls, viscounts, and barons, and their eldest sons, with the eldest sons of baronets, and of knights of all the orders, are all said to be esquires by birth, though their precedence, which differs widely, is regulated by the rank of their respective ancestors. Officers of the king's court and household, and of his navy and army, down to the captain inclusive, doctors of law, barristers, and physicians, are reputed esquires. A justice of the peace is only an esquire during the time that he is in the commission of the peace, but a sheriff of a county is an esquire for life. The general assumption of this title by those who are not, in strictness, entitled to it, has virtually destroyed it as a distinct title or dignity. The heads of many old families are, however, still deemed esquires by prescription.

ESSAYISTS, BRITISH. This title is customarily confined to a certain class of periodical writers upon subjects of general interest, as morals, criticism, manners, &c. The notion of a series of papers fit for general circulation, and not including news or politics, was originated by Steele and Addison in the 'Tatler.' [ADDISON.] The 'Freeholder,' 'Craftsman,' 'Freethinker,' &c., now almost forgotten, were rather political pamphlets than essays in this sense of the word; and an interval of thirty-five years elapsed from the end of the 'Spectator' to the successful revival of this style of writing by Dr. Johnson, in the 'Rambler,' in 1750. Its great popularity led to the establishment of a number of similar periodicals during the latter half of the eighteenth century, since which time they have again gone out of fashion. We give a list of those contained in Alexander Chalmers's collective edition of British Essayists, which includes some that have little claim to a place among the standard works of our language; with the names of the principal and most celebrated contributors to each.

- 'Tatler'—Steele, Addison.
- 'Spectator'—Addison, Steele, Budgell, Pope, &c.
- 'Guardian'—Steele, Addison, Berkeley, Pope, Tickell, Gay, &c.
- 'Rambler'—Johnson, almost entirely.
- 'Adventurer'—Hawkesworth, Johnson, Jos. Warton, &c.
- 'World'—Moore, Lord Chesterfield, Horace Walpole, J. Warton, &c.
- 'Connoisseur'—G. Colman and Bonnel Thornton chiefly; Cowper a few.
- 'Idler'—Johnson; a few by Warton and others.
- 'Mirror'—Henry Mackenzie and others.
- 'Lounger'—The same.
- 'Observer'—Richard Cumberland, almost entirely.
- 'Olla Podrida'—Moore, &c.
- 'Microcosm'—Canning, Frere, Smith, &c.

ESSEK, ESZEK, ESSEG, or OSZEK, the chief town of the circle of Esseck, and the capital of Austrian Slavonia, is a

royal free town situated in a level and marshy district on the right bank of the Drave, a little to the west of its efflux into the Danube. It lies in 45° 34' N. lat., and 18° 42' E. long. Its site is that of the Mursia, or Mursa of the Romans, which was founded in the year 125 by the emperor Hadrian, and afterwards became the residence of the Roman governors of Lower Pannonia. Constantine made it the seat of a bishopric in the year 335. It now consists of four quarters; the present fortress, begun under the emperor Leopold I. in 1712, and finished in 1719, is well built, contains 147 handsome and lofty houses, an arsenal and barrack, and is regularly fortified: an esplanade runs round it, and to the north-west of it stands the Felso-Varos (Upper Town), which is approached by an avenue 1100 paces long, is the residence of the merchants and dealers, and has well-attended fairs. South-east of the fortress lies the Alsó-Varos, or Lower Town, the site of the antient Mursa, which consists of broad and handsome streets, and has some fine churches; and in the east is the New Town, composed rather of farms and gardens than of lines of streets. The fortress and suburbs contain altogether about 1800 houses, 5 Roman Catholic churches, 4 chapels, and a church for those of the Greek persuasion, and 11,200 inhabitants. There are several handsome buildings, such as the town-hall, the house of assembly for the states of Veróca, the county in which Esseck is situated, the barracks, engineers' house, officers' pavilion, and arsenal. Esseck has a Roman Catholic high-school, a gymnasium, a Greek school, a military cadet academy, and a Franciscan and a Capuchin monastery. A causeway or bridge about two miles and a half in length, 55 feet in breadth, and 9 feet in height, constructed in the year 1712, leads across the Drave and the swamps on its northern bank into the Hungarian county of Baranya. With the exception of some silk-spinning there is little mechanical industry in the town. There is a considerable trade in grain, cattle, and raw hides.

ESSEN, a township in the Prussian administrative circle of Düsseldorf, consisting of the town of Essen only, which lies on the Berne, in 51° 27' N. lat., and 7° 2' E. long. It was the spot where the foreign princes of the Rhine and of Westphalia formerly held their diets, or 'Fürstentage.' Essen is surrounded by walls, has about 830 houses, and the population, which was 4706 in the year 1817, is now about 5700. It is the seat of mining and crown-domain boards, and has 2 Protestant and 2 Roman Catholic churches, a gymnasium, a Capuchin monastery, a Protestant orphan asylum, and a hospital. The chapel of St. Quirinus is supposed to be the first place of Christian worship erected in these parts. The manufactures consist of woollens, linens, vitriol, leather, arms, iron and steel ware, &c. The town has some trade, and there are coal-mines in the vicinity, as well as a number of iron works.

ESSENCE is derived from the Latin *essentia*, a word which is used by Cicero and Quintilian, and formed, not as stated in Mr. Richardson's Dictionary, from *existentia*, but from *essens*, the analogous but obsolete participle of the verb *esse*, to be. The English word essence consequently signifies that which constitutes the being of a thing, or, in the words of Locke, that which makes it to be what it is. This term was the subject of many very subtle disquisitions and disputes among the scholastic logicians of the fourteenth, fifteenth, and sixteenth centuries; and the metaphysical notions of essence entertained by these logical doctors cannot be understood without reference to their discussions respecting the nature of universal ideas, as real or nominal, of abstraction, genus, species, differentia, substance, properties, accidents, &c., of all which particulars may be found in Smigleci Logic. Disputat.; Burgersdicii Logica; Eustachii Logica; Le Grand, Institut. Logic.; Wallisii Logica; and in many other logical and philosophical treatises cited in Johnson's *Quæstiones Philosophicæ*, p. 168, &c. Some amusing instances of metaphysical sagacity concerning logical essence are exhibited in the scholastic work of Louis de Lesclache, 'La Philosophie, divisée en cinq Parties,' 1548. 'Il n'y a rien dans la substance qui ait moins d'essence que la substance; aussi il n'y a rien dans la substance qui soit moins substance que la substance,' &c. In the Oxford Manual of Scholastic Logic, by Dr. Aldrich, as expounded by Mr. Huyshe, it is taught, in accordance with the theory of the Nominalists, that essence is not really existent, but is merely a figment of imagination, and that the notion of it is resolvable into two parts; that which is common to other

essences being called the *genus*, and that which is peculiar to one particular essence, distinguishing it from all others and constituting it what it is, being called the *differentia*. The whole essence is called the *species*; that is, genus + *differentia* = *species*. The qualities joined to essence are also of two kinds; those which are joined necessarily are called *properties*, and those which are joined only contingently are called *accidents*. Hence the five predicables, or only possible parts of a thing which can be the objects of assertion:—1. Species or whole essence. 2. Genus, the common or material part of the essence. 3. Differentia, the peculiar or formal part of the essence. 4. Property or quality, necessarily joined to the essence. 5. Accident, or quality contingently joined to the essence. The following statements, collected from Locke (*Essay*, book iii., c. 3 and 6), exhibit the principal points of his doctrine of essence. He considers essence to be of two kinds: 1. The real essence, which constitutes the insensible parts of a thing, and is wholly unknown to us. 2. The nominal essence, which depends on that which is real, and is the complex idea, for instance, of the properties of colour, weight, malleability, fixedness, fusibility, &c., expressed by the word gold; for nothing can be gold which has not the qualities conceived in the abstract idea to which this name is applied. In simple ideas (see book ii. c. 2), the real and nominal essence are identical, but in substances they are always different. Each of the distinct abstract ideas which men make and settle in their minds by giving them names is a distinct essence; and the names which stand for such distinct ideas are the names of things essentially different. Thus, a circle is as essentially different from an oval as a sheep from a goat; the abstract idea which is the essence of one being impossible to be communicated to the other. As essences are nothing but the abstract complex ideas to each of which has been annexed a distinct and general name, and as of such ideas there are some which correspond to no reality in nature—for instance, those of mermaids, unicorns, &c.—it is evident that there are essences of things which have no existence. In considering essence with regard to the scholastic theory of genus and species, Locke observes that we classify things by their nominal essences, having no other measure of essence and species but our abstract general ideas or mental archetypes, without reference to which we cannot intelligibly speak of essential and specific difference. The doctrine of the immutability and ingenerable incorruptible nature of essences can be founded, says Locke, only on the relation between abstract ideas and the sounds by which they are signified; that is, on the fact that the same name retains the same signification, and also on the fact that, whatever may become of individuals, as Alexander and Bucephalus, the ideas of man and horse remain unaltered. Some of these positions, as that real essences are unknown, and that species are distinguished by essences merely nominal, are disputed in Green's *Philosophy* and Lee's work against Locke. (See also many of the earlier scholastics; and for an exposition of the doctrine of essence, according to the transcendental theory, see Kant's 'Kritik der reinen Vernunft' and Wiegman's *Logic and Metaphysics*, in the 'Encyclopædia Londinensis.') Substance, as distinguished from essence, is understood to mean all the essential, with the accidental qualities; and essence (genus and differentia, or common and proper) the essential qualities alone, that is, the pure substance, or metaphysical substratum. The Greek word *ousia* (*οὐσία*) has many significations applicable to the individual, genus, species, and subject (Aristotle, *Metaphys.* i. 6, c. 3); on which it is remarked by Roy Collard (*Essai sur la Psychologie*, 1826, p. 149. 246), that while the Latin and all modern languages have two distinct expressions for essence and substance, it is surprising that the Greek, which is otherwise so rich, had only one name (*ousia*) for these two ideas. The word *hypostasis*, *ὑπόστασις* (substance), was subsequently employed, but with similar duplicity and confusion. Hence arose many of the Trinitarian controversies, or rather logomachies, which embroiled the first ages of the church; for Athanasius, Epiphanius, and most of the other Greek fathers understood *πρόσωπον*, person or mode of being, as meaning the same thing as *ὑπόστασις*, substance; and Sabellius, Arius, Nestorius, and Eutyches understood *ὑπόστασις* as signifying the same thing as *οὐσία*, that is, essence or nature. So that Sabellius said, there is one essence or nature in God, *therefore* one substance or person. These are three substances or persons in God,

said Arius, *therefore* three essences or natures. There are two essences or natures in Christ, said Nestorius, *therefore* two substances or persons. There is but one substance or person in Christ, said Eutyches, *therefore* but one essence or nature. The essay on the difference between *οὐσία* and *ὑπόστασις*, essence and substance, which is often attributed to St. Gregory, appears to belong rather to St. Basil: at least it is contained in his 43rd epistle. The epithet *essential* denotes those indispensable qualities in a thing, without which it could not be what it is; and the name *essentials*, as the essentials of logic, signifies those parts alone which are valid for general or particular uses.

ESSENES. [HESSENES.]

ESSEXQUIBO. [GUIANA, BRITISH.]

ESSEX, an English county, situated on the eastern coast of the island of Great Britain. It is of irregular form, approximating to the quadrant of a circle, of which the north-western point of the county may be considered as the centre; the southern, south-eastern, and eastern sides a portion of the circumference; and the northern and western sides the circumscribing radii. It is bounded on the north by the county of Suffolk (from which it is separated by the river Stour) and by the county of Cambridge (from which it is separated for a very short distance by the river Cam); on the west by the county of Herts (from which it is separated, along a part of the boundary-line, by the river Stort, a feeder of the Lea, and by the river Lea); and by the county of Middlesex (from which it is separated throughout by the Lea, which joins the Thames at the south-western extremity of the county); on the south side and on a portion of the south-east side it is bounded by the gradually widening estuary of the Thames, by which it is separated from the county of Kent; and on the remainder of the south-east side and on the east side by the German Ocean. The length of a straight line drawn from the north-western to the north-eastern extremity of the county, is 53 miles; but the northern boundary of the county, following its turnings, is about 75 miles; the length of a line joining the north-western with the south-western extremity, is 37 miles; but the boundary-line, from its many windings, extends to 53 miles. The length of a line joining the south-western to the north-eastern extremity of the county (which would be the chord of the circumscribing arc of the quadrant) is 63 miles; but the boundary along the bank of the Thames and the coast of the ocean is about 85 miles. The area of the county is estimated at 1533 square miles; or, taking the estimated areas of the several parishes, 979,000 acres. The population, according to the return of 1831, was 317,507, giving 207 to a square mile. In magnitude it is the tenth of the English counties, being a little smaller than Kent, and a little larger than Suffolk. In absolute population it is the thirteenth, and in relative population the eighteenth, of the English counties. Chelmsford, the county-town, is on the river Chelmer, 29 miles from St. Paul's, London, in a straight line north-east by east; and the same distance from Whitechapel Church, London, by the road through Romford, Brentwood, and Ingatestone. (*Ordnance Survey*.)

Coast, Islands, &c.—The bank of the Thames and the sea-coast of Essex are marshy almost throughout. From the junction of the Lea with the Thames to Purfleet, 11 or 12 miles, the marshes extend from a mile to a mile and a half or even two miles inland, and the river is confined to its bed by an embankment. At Purfleet the hills come down to the river; and from Purfleet to Grays Thurrock, 5 miles, the marshes consist only of a very narrow strip along the river-bank; the embankment is, however, carried on, except just at Purfleet. West and East Tilbury marshes, on each side of Tilbury Fort, extend 6 miles along the river, and from one to two miles inland; but below them the breadth of the marsh land is again contracted, along that bend of the river called The Hope, 3 miles long, from the lower end of which they again widen, and extend above 9 miles along the river, and nearly 4 miles inland, being intersected by an inlet called Hole Haven, the branches of which cut off from the mainland the low marshy Isle of Canvey. The embankment of the river is carried round the inlet of Hole Haven, along the bank of the creek which separates Canvey Island from the main, and round the whole of Canvey Island; those portions of the marsh-land which are not comprehended within the embankment are, below Tilbury Fort, salt marshes. From the eastern end of Canvey Island the marshes cease; and about Leigh

and Southend the coast rises into low cliffs. At Shoebury Ness, a low point of land at the mouth of the Thames, 6 miles from the east end of Canvey Island, where the coast turns to the north-east, the marshes reappear; and with an interval of about a mile just beyond Shoebury, they continue along the coast 11 miles, to the mouth of the river Crouch. Nearly 4 miles from Shoebury a narrow creek, with many ramifications, penetrates inland into the channel of the river Crouch, and with that river cuts off from the mainland several low flat islands, Russels, Haven Gore, New England, Potten, Wallasea, and Foulness. The edge of this creek and its various ramifications, as well as of the Broomhill and Crouch rivers, which unite with it, are embanked, and the islands are embanked all round. The marshy tract, including the islands and the adjacent part of the mainland, is from 3 to nearly 6 miles broad; and the sand (Foulness Sand), dry at low water, which at Shoebury Ness was a mile and a quarter broad (having widened from a quarter of a mile at Hole Haven), is off Foulness Island 4 miles broad; there is a road along this sand from Kennet's Head, near Shoebury, almost to the north-eastern end of Foulness Island. From the mouth of the Crouch the coast runs nearly north and south 8 miles to the mouth of the Blackwater river. In this part of the coast the sea encroaches upon the land. The marshes (Burnham Marsh, Southminster Marsh, Dengy Marsh, Tillingham Marsh, and Bradwell Marsh) extend in the southern parts nearly 5 miles inland, but gradually become narrow to the northward to St. Peter's Chapel, where they are interrupted by the higher ground running down to the coast; the sand, which is dry at low water, has a breadth of from two miles to two miles and a half. Between the estuaries of the Blackwater and the Colne, in the inlet formed by their junction, the mouth of which inlet, from St. Peter's Chapel to St. Osyth Point, is above 5 miles over, is the island of Mersey, separated from the main by a marshy tract and an intervening narrow channel. The outer or seaward shore of this island is skirted by a very narrow tract of marsh-land; but the marshes about St. Osyth Point are from three-quarters of a mile to a mile broad. The marshes, however, terminate 4 miles beyond St. Osyth's Point, and (with a slight interruption of a mile of marsh-land near the mouth of Holland Creek) a high broken coast extends between 9 and 10 miles to the Naze, the most eastern point of the county. This point formerly extended much farther toward the east. The ruins of buildings have been found at considerable distances from land; and a shoal called West Rock is 5 miles from shore. From the Naze to Harwich, between 5 and 6 miles in a direct line north and south, the coast forms an inlet lined by salt marshes, and occupied by Horsey Island, Holmes Island, Pewit Island, and one or two smaller islands. The sea-coast terminates at Harwich; but the estuary of the Stour, which is in most parts more than a mile wide at high water, extends up to Catawade Bridge, above Manningtree. (*Ordnance Survey.*)

The islands have been named in the course of the foregoing description of the coast we subjoin a few particulars of the chief of them.

Canvey Island is bounded on the south-west and west by Hole Haven, and on the north by a narrow creek, which separates it from the mainland. It is entirely marsh-land, banked in all round. Its extreme length from east to west is 6 miles; its greatest breadth from north to south 2½. Its area is estimated at more than 2600 acres (*Lib. of Useful Knowledge: Geography*), chiefly appropriated to grazing sheep and cattle; or 3600 acres (*Morant's Hist. of Essex*). It is connected with the mainland by a causeway leading to the village of South Benfleet. It does not form a distinct parish, but pays tithes and rates to several parishes. From its being comprehended in so many parishes, its population cannot be ascertained from the population returns; but the 'Clerical Guide' (A.D. 1836) assigns to it a population of 216. Morant, in his 'History of Essex,' states that there were then (A.D. 1788) fifty dwellings in the island. In 1622, the land being subject to be overflowed at high water in the spring tides, the owners of lands in it entered into an agreement with Joas Croppenburgh, a Dutchman, for 'inuing and recovering the island,' as Morant terms it. A timber chapel was built for the use of the Dutchmen employed in the work. This chapel has been twice rebuilt: the present chapel will hold 106 persons. The value of the perpetual curacy, to which several endowments are attached, is 58*l.*: it is in the gift of the bishop of London. There is a yearly fair on the island.

Foulness Island (so called from the Saxon *Fugel*, a fowl, and *nepe*, a promontory, 'the Promontory of Fowls') is bounded on the north by the river Crouch, on the east and south-east by the German Ocean, on the west by the Broomhill river, which separates it from Wallasea Island, and on the south-west by a creek which communicates between this river and the sea and separates Foulness from Potten and New England Islands. Its extreme length, from north-east to south-west, is almost 6 miles; its greatest breadth 2½. Its area is given by Morant at 4500 acres, and in the 'Lib. of Useful Knowledge' at 5000; but in the Population Returns, Foulness parish, which does not, so far as we know, comprehend more than the island, is given at 8060 acres, with a population of 630, almost entirely agricultural. The soil is good, the upper part producing corn of every kind, and the lower part pasturage; the only fences are ditches, which are filled at every tide. Fruit-trees thrive ill. The water is brackish; the only fresh water is rain-water. The houses are scattered over the island, upon the different farms; they are all of wood—a material which, from some cause or other, is here liable to rapid decay. The church, also of wood, is situated near the centre of the island; it will hold 300 persons. The living is a rectory, exempt from the archdeacon's jurisdiction, of the yearly value of 300*l.*, with a glebe-house. There is a yearly fair in the island. Beds of oyster and cockle-shells have been found beneath the surface of this island, which renders it probable that it was originally formed by deposits from the sea.

Wallasea, otherwise Wallet or Wallia, so named from the sea-walls which surround it, is bounded on the north by the river Crouch, on the east and south by the Broomhill river, which separates it from Foulness and Potten Islands, and on the west and south-west by Paglesham Creek, which separates it from the mainland. There is a causeway over Paglesham Creek. Its greatest length is, from east to west, 3½ miles; its greatest breadth is 1½ miles. The water is too salt to be fit for kitchen use, and the inhabitants have to fetch fresh water from the mainland; that in the ponds is so brackish that horses do not thrive till they have been inured to it. The whole island is marsh-land; it is included in several parishes.

Potten Island, Haven Gore, New England, and Russels or Rushley, belong to the same group as the two foregoing; they are to the south-west of Foulness and to the south of Wallasea. The whole group is in Rochford hundred. In the creeks which surround or separate these islands are fed the small oysters called Wallfleet oysters.

Mersey Island is in an inlet formed by the estuaries of the Blackwater and the Colne. The name is derived from the Saxon *Mepe*, the sea or a marsh, and *ig*, an island. It is bounded on the south by the estuary of the Blackwater river, on the south-east by the German Ocean, on the east by the estuary of the Colne, and on all other sides by a creek, which, running through the marshes on its north-west side, under the names of Mersey Channel or Pyefleet Channel, separates it from the mainland; a portion of the marsh on the north side of the island is separated from the rest by a channel called Passfleet. The greatest length of the island is, from east-north-east to west-south-west, nearly 5 miles; the breadth varies from one to two miles. The island is divided into the two parishes of East and West Mersey or Mersea, of which the former comprehends an area of 1810 acres, with a population, in 1831, of 300; the latter an area of 3020 acres, with a population of 847; together, 4830 acres and 1147 inhabitants. There is a passage from the island to the mainland over the Mersey Channel, dry at low water, called 'the Strode' or 'Stroude,' i. e., a bank along the side of a creek, river, or sea. The history and antiquities of this island will be noticed with those of the county at large.

Horsey Island is in that inlet which occurs between the Naze and Harwich. Its greatest length is from north-west to south-east about two miles: its greatest breadth rather more than a mile. It consists almost entirely of salt marshes: a spot rather more elevated than the rest, about one-fourth of the whole, on the south-west side of the island, is banked in. In the marshes there is a decoy for wild fowl.

Pewit Island and Holmes Island, with one or two others are near Horsey: all these islands are separated from each other and from the main by narrow channels.

Surface, Hydrography, Communications. This county has few hills of any considerable elevation: its general slope, as determined by the watershed, is towards the south and

east; the coast and the banks of the Thames present a succession of unhealthy marshes commonly known as the hundreds of Essex. High Beach, on the north-west side of Epping Forest, near Waltham Abbey (390 feet high), Langdon hill, south of Billericay (620 feet high), Danbury hill, between Chelmsford and Maldon, of nearly the same height, and Tiptrey Heath near Witham, are probably the highest parts of the county. The Chalk downs which form the continuation of the Chiltern hills just cross the north-western part of the county in their extension towards the north-east.

The rivers of Essex are—the Thames with its affluents, the Lea (into which flows the Stort), the Roding, the Bourne Brook, the Ingerburn, and some smaller streams; the Crouch with its affluent the Broom-hill; the Blackwater with its affluents the Pods Brook or Witham river; and the Chelmer (into which flow the Sandon Brook, the Ter, and some other streams); the Colne with its affluent the Roman; the Stour; and the Granta or Cam.

The Thames bounds the county on the south side. Its course, though winding, is on the whole nearly from west to east. It is a tide river, and navigable for the largest merchant ships (that is, for East Indiamen of the first class, 1400 tons burden), and for frigates and other smaller ships of war throughout that part of its course which belongs to this county. The mouth of the Thames contains numerous shoals.

The Lea bounds the county on part of its west side. It more properly belongs to Hertfordshire, in which it has a considerable part of its course. It meets the border of Essex at the point where it receives the Stort, along which the boundary previously runs and flows south past Broxbourn (Herts), Waltham Abbey, Chingford, Layton, and Stratford (all in Essex), 20 miles, into the Thames. The banks of this river are marshy; and the marshes are from half a mile to a mile wide. The stream is frequently divided and flows in several channels, and in some places cuts have been made in order to improve or shorten the navigation, which comprehends all that part of the river connected with this county. Some of the acts of parliament relating to the navigation of this river are above 400 years old.

The Stort rises in Hertfordshire, but soon enters Essex, through which it flows for some miles, and then touches the border again, and flows sometimes on the border, sometimes in Hertfordshire, into the Lea. Its whole course is about 24 miles, for about 10 miles of which it has been made navigable. The navigation of the Stort and the Lea serves for the conveyance of corn, malt, wool, and other agricultural produce to London; and for the conveyance in return of coals, timber, deals, bricks, paving stones, groceries, cloth, and other articles of daily consumption.

The Roding rises in the western part of the county, near Easton Park, a short distance north-west of Dunmow: it flows southward about 15 miles to the neighbourhood of Chipping Ongar, where it receives the Cripsey Brook (about 9 miles long) from the north-west. From the junction of the Cripsey Brook, the Roding flows south-west in a very winding channel 14 miles past Kelvedon Hatch, Navestock, Abidge, Loughton, and Chigwell, to Woodford bridge: and from Woodford bridge it flows about 7 or 8 miles south and south by east past Ilford and Barking into the Thames. Its whole course is about 36 or 37 miles. The banks are low and marshy from the neighbourhood of Ongar. The west bank, from Ilford, and both banks from below Barking, are protected by embankments. It is navigable under the name of Barking Creek up to Ilford bridge, and serves to convey coals and other articles for the supply of Romford and the neighbourhood.

The Bourne Brook rises between the villages of Navestock and Havering-atte-Bower, and flows in a winding channel past Romford (below which it receives a small brook from Hornchurch), and between Dagenham and Hornchurch Marshes into the Thames. Its length is about 12 miles. In the lower part of its course the Bourne Brook is connected with the pool formed by Dagenham Breach. This breach was occasioned in 1707 by the blowing up of a small sluice that had been made for the drainage of the land waters: an opening was formed by the rushing in of the Thames, 300 feet wide, and in some places 20 feet deep: 1000 acres of rich land in the adjacent levels were overflowed, and the surface of nearly 120 acres was washed into the Thames, where a bank was formed nearly a mile in length, and extending halfway across the river. After

various ineffectual attempts, the breach (which in course of time had been, by the force of the reflux every turn of the tide, worn into several channels like the arms of a river) was stopped, by driving dove-tailed piles and other expedients, under the direction of Captain Perry, who commenced his works in 1718. Within the embankment there is yet a pool of between 40 and 50 acres, where the soil was carried away by the tide. [BARKING.] Through the upper part of this pool the Bourne Brook flows.

The Ingerburn rises near Havering-atte-Bower, not far from the source of the Bourne Brook, and flows southward, past Upminster, into the Thames. It is about 12 miles long. A stream of about the same length, which rises close to Thorndon Park near Brentwood, falls into the Thames near Purfleet.

The Crouch rises on the slope of the hills, south of Billericay, and flows east by north about 25 miles into the sea, passing the villages of Ramsden Cray, Wickford, Runwell, and much lower down, the village of Burnham. The tide flows about 13 miles up the river and is kept from overflowing the low lands on its banks by mounds. In the tideway there are many arms; and the various channels by which the river communicates with the sea form the group of Foulness, Wallasea, and the adjacent islands. Just above its mouth it receives the Broom-hill river (10 miles long), which is navigable for seven miles nearly up to Rochford.

The Blackwater, which in the upper part of its course is called the Pant, rises near the village of Wimbish, three or four miles from Saffron Walden, in the north-western part of the county. It flows first south-east and then south about 30 miles, past Redwint, Great Sampford, Little Sampford, Great Bardfield, Weathersfield, Shalford, Panfield, Bocking, Stisted, Coggeshall, Kelvedon, Great Braxted, and Little Braxted, to the neighbourhood of Witham. Here it is joined by the Pods Brook, a stream 14 or 15 miles long, which rises near Great Bardfield and flows past Rayne, Braintree, Black Notley, White Notley, Faulkbourne, and Witham. From the junction of this stream the Blackwater flows south about 4 miles to the junction of the Chelmer; after which it flows east about 12 miles into the sea, having a course of about 46 miles. From Maldon, which is below the junction of the Chelmer, it is a tide river; and its estuary, which is at high-water from 14 to 24 miles wide, contains the islands of Northey, Osey, Ramsey, and Pewit. Lawling Creek and Goldhanger Creek are channels in the ooze or strand of this tideway.

The Chelmer rises near Debden, two or three miles south of the sources of the Blackwater, and flows south-south-east about 23 or 24 miles to the town of Chelmsford, passing Thaxted, Tilty, Great Easton, Dunmow, Great Waltham, and Little Waltham. At Chelmsford it is joined by a stream which rises near Thorndon Park and flows northward between Billericay and Ingatstone to Widford and Writtle, and then turns east and runs into the Chelmer after a course of about 14 miles. From Chelmsford the Chelmer flows east about 10 miles till it falls into the Blackwater near Maldon. Its whole course is about 34 miles. The Sandon Brook, which rises near Stock, two miles north-east of Billericay, and has a course of about 10 miles, joins the Chelmer between Chelmsford and Maldon. The Ter rises between Felsted on the Chelmer and Rayne on the Pods Brook, and flows south-east 13 or 14 miles into the Chelmer, which it joins about two miles below the junction of the Sandon Brook. It passes Little Leighs, Great Leighs, Terling, and Hatfield Peverel.

The Colne rises in the north-western part of the county, between Great Sampford on the Pant, and Steeple Bumpstead on the Stour. It flows east about 7 miles to the neighbourhood of Great Yeldham, where it is joined by another stream of nearly the same length. From this junction it flows south-east 6 miles past Castle Hedingham and Sible Hedingham to Halsted; and from thence east-south-east about 13 miles to Colchester. Below Colchester it becomes a tidewater and flows 8 or 9 miles south-east into the sea at the north-east end of Mersey Island. Its whole course is about 35 miles.

The Roman rises about 2 miles north of Coggeshall on the Blackwater, and flows east by south about 13 miles into the tideway of the Colne, which it joins midway between Colchester and the sea. A brook eight or nine miles long from Layer Marney and Layer Breton joins the Roman about three miles above its junction with the Colne.

The Stour may be considered as equally belonging to Suffolk and Essex. Of the three springs which may claim to be its sources, one which flows past the village of Kedington is in Suffolk; a second in Cambridgeshire, and from it a stream flows by the town of Haveril in Suffolk; the third spring is in Essex, and the stream from it passes Steeple Bumpstead. From the junction of these three streams, which takes place about 6 or 8 miles from their respective sources, the river to its outfall divides the counties of Essex and Suffolk. Its course is first east about 10 miles past Wixoe, Stoke, Clare, and Cavendish in Suffolk, to the neighbourhood of Long Melford, above which it receives two small tributaries on the Suffolk bank; from thence its course is south by east about 8 miles past Sudbury in Suffolk to Bures; and from thence east 13 miles past Neyland, in Suffolk (below which it receives two considerable affluents), and Dedham in Essex to Catawade bridge, just above Manningtree. Below Catawade bridge the stream widens into a considerable estuary, 11 or 12 miles long, and for the most part above a mile wide, which unites with the estuary of the Orwell, a Suffolk river, and passes into the open sea between Harwich and Langard Fort. Its whole course is about 50 miles. Manningtree, Mistley, Wrabness, and Harwich are on the Essex bank of this estuary.

The Cam rises near Debden, 4 miles from Saffron Walden, and flows first south-west for 2 miles, and then turns north and flows 8 or 9 miles past Newport, Audley Park, Littlebury, and Little and Great Chesterford, into Cambridgeshire, to which the principal part of its course belongs.

The Thames and the Lea are navigable throughout that part of their course which belongs to this county; the Stort is navigable from Bishop Stortford to its junction with the Lea; and it has been projected and acts of parliament obtained (A.D. 1812 and 1814) to make a navigable canal from Bishop Stortford along the valley of the Cam to the navigable part of that river below Cambridge, thus uniting the Thames and the Lea with the Cam and the Ouse. The tideway of the Crouch is navigable, and serves for the importation of groceries and fuel, and the exportation of agricultural produce. Near Burnham this river is a quarter of a mile wide (not three quarters of a mile, as Mr. Young states in his 'Agricultural Survey'), and has depth of water sufficient for a 98-gun ship: a 74 might go almost up to Hull bridge at the head of the tideway. The Blackwater does not appear to be navigable above the junction of the Chelmer. Vessels of considerable burden can get up to Maldon at spring tides. The Chelmer is navigable to Chelmsford. This navigation supplies Chelmsford and other places in the interior of the county with coal, deals, timber, and groceries, and serves for the exportation of agricultural produce. The navigation of the Colne, which extends to Colchester, answers the same purposes for that town and neighbourhood. The river Stour is navigable up to Sudbury, about 30 miles above Harwich. Essex has no navigable canals.

The principal roads in the county are the three roads from London to Norwich, by Ipswich, by Bury, and by Newmarket. The road by Ipswich enters the county at Bow bridge, about three miles from Whitechapel church, London, and crosses the county in nearly its greatest extent from south-west to north-east, passing through the market towns of Romford (12 miles from London), Chelmsford (29 miles), Witham (38 miles), and Colchester (51 miles), 7½ miles beyond which the road crosses the Stour at Stratford bridge and enters Suffolk. The road through Bury branches off from the Ipswich road at Chelmsford, and passes through the towns of Braintree (40½ miles from London) and Halsted (46½ miles), 8 miles beyond which the road crosses the Stour into the town of Sudbury in Suffolk. A branch from this road passes through the villages of Sible Hedingham, and Castle Hedingham, instead of through Halsted, and reunites with the main road about 2 miles before it quits the county: this branch is rather longer than the principal line. The road by Newmarket branches off from the Ipswich road a little beyond Bow bridge, crosses part of Epping Forest, and runs through the town of Epping (17 miles from London), about 7 miles beyond which it crosses the Stort into Hertfordshire: between 29 and 30 miles from London it re-crosses the same river into Essex, runs northward near but not through Saffron Walden, and finally quits the county at the village of Great Chesterford, 45 miles from London.

P. C., No. 597.

A road which quits London by Shoreditch church enters the county at Lea bridge, and falls into this road at Snarebrook, about 7 miles from London.

From the road by Colchester and Ipswich several roads branch off to different places on or near the bank of the Thames, or on the south and east coasts, as to Billericay (23 miles from town); to Tilbury Fort (25 or 29 miles by different roads); Southend (42 miles); and Maldon (37½ miles), from which place are roads to the villages of Bradwell (51 miles), Southminster (48 miles), and Burnham (48½ miles), in the marshes of the south-east coast. From Colchester there are roads to Harwich (71½ miles from London), at the north-east extremity of the county, and to Neyland, in Suffolk (57 miles), on the border of Essex. From the Colchester road, near Bow bridge, a road runs by Chipping Ongar (21 miles) to Dunmow (40½ miles). From the Bury road, between Braintree and Halsted, there is a road by Sible Hedingham to Haverill, in Suffolk (59 miles), on the borders of Essex. The towns in the northern part of the county are connected by a road which runs from Bishop Stortford, in Herts, on the border of Essex, through Dunmow, Braintree, and Coggeshall to Colchester. A road from Saffron Walden runs through Thaxted and Dunmow to Chelmsford; and short branches from the Colchester and Harwich roads lead respectively to Coggeshall and Manningtree.

Geological Character.—A considerable tract in the northern part of the county, stretching along the river Stour from the village of Kedington to between Sudbury and Neyland, and extending into the interior of the county bounded by a line drawn from Kedington to the village of Hempstead, six miles east of Saffron Walden, from thence to Thaxted and the village of Great Easton on the road from Thaxted to Dunmow, and from thence by the neighbourhood of Halsted (a mile or two north of that town) to the Stour, is occupied by diluvial beds, consisting of loam with fragments of chalk. The coast of the north-east part of the county is covered with the sand or gravel of the upper marine formation, which occupies a considerable part of the counties of Norfolk and Suffolk, and is locally designated 'crag.' At the headland of the Naze it constitutes about 30 feet of the upper part of the cliffs (which are about 45 feet high) resting upon the London clay south of the Naze its thickness appears to vary from 10 to 40 feet. In the projecting cliff of Harwich it includes friable masses of ferruginous sand, somewhat cemented together, and inclosing shells. The shells of this formation are in excellent preservation, commonly in a confused mixture, but at other times in patches of particular genera; and for the most part they do not appear to differ specifically from those of the neighbouring seas. Fragments of fossil bones washed out of the strata of this formation, in which they had been imbedded, are found on the beach at Walton, but occur in much greater quantities at Harwich. It is not known to what animal these belong, but a large fossil tooth, probably of the mammoth, was found, within the last few years, on the beach at Harwich. (Phillips and Conybeare, *Outlines of the Geology of England and Wales*.) In Mr. Greenough's Geological Map of England and Wales the cliffs south of the Naze are said to consist of loam, which contains the bones of the elephant, deer, horse, pig, aurochs or wild bull, and hippopotamus; and the strata along the south bank of the estuary of the Stour are said to contain elephants' teeth.

The greater part of the county, including Epping and Hainault or Henhault Forests, is occupied by the London clay. This formation extends on the south and east to the banks of the Thames, to the coast, and to the tract occupied by the Crag: it is bounded on the inland side by a line drawn from the banks of the Stour about Boxted near Neyland to the junction of the Stort with the Lea. These may at least be taken as its approximate limits, for some of the beds of the plastic clay formation, which immediately underlies the London clay, are so similar to it, that it is difficult to trace exactly the line of demarcation. The London clay of the cliffs near Harwich contains beds of stratified limestone: the same cliffs are very productive in the fossils with which this formation abounds. South of Walton, near the Naze, abundance of septaria are found which are sent by sea to Harwich, where they are manufactured by government into a cement. The principal elevations in the county, High Beach, Langdon and Danbury Hills, and Tiptrey Heath, are formed of London clay. The

Vol. X.—D

surface of the vegetable mould does not commonly rest immediately on the London clay, but on alluvial beds of rich marl and loam, which often alternate with gravel and sand, and sometimes have a thickness of 30 or 40 feet.

The sands and clays of the plastic clay formation skirt the district of the London clay on the north-west. Halsted and Coggeshall, with the intermediate tract, are both on the plastic clay. The border of Essex, near Hadleigh, is the most northerly point at which this formation has been found.

The north-western extremity of the county, about Saffron Walden, consists of chalk: the great chalk district, in its extension from south-west to north-east, just crosses that part of the county. The chalk appears also at Purfleet and Gray's Thurrock, on the banks of the Thames. At the former place is an extensive chalk-pit belonging to Mr. Whitbread. Gun-flints are made at or near Purfleet. A subterranean forest underlies the marshes on the banks of the Thames.

Agriculture The climate of Essex is favourable to vegetation: the sea and the numerous æstuaries which bound it on the south and east soften the rigour of winter, and keep up a certain degree of moisture in summer. The same cause, however, produces cold fogs and exhalations in spring and autumn, which are very prejudicial to the health of those who are not inured to the climate. In consequence of this the most fertile portions of the county, which lie along the Thames and the sea coast, towards the Colne river, and which are usually called the hundreds of Essex, contain few seats of men of fortune; and notwithstanding the richness of the soil, and the great advantage of the marshes for feeding cattle, few men from other counties venture to take farms in this part of Essex. This reproach to the climate of the hundreds of Essex is rapidly diminishing, since the marshes have been better drained and the woods, which prevented the free circulation of the air and the dispersion of the fogs, have been gradually cut down, and the land brought into cultivation. The soil all along the coast, and 10 or 12 miles inland, is of a very excellent quality, being a friable loam of greater or less tenacity in different parts, but peculiarly adapted to the cultivation of wheat, beans, and oats. The Isle of Mersey, which lies at the mouth of the Colne river, has been long noted for the fertility of its soil, which is a fine alluvial loam composed of the various earths deposited from the river and the sea, like the warp lands along the Humber, or the polders in the Netherlands. The whole island is protected by a sea-wall, and produces every kind of grain which is usually cultivated; wheat, barley, oats, beans, and rape seed are the principal produce. Sir Humphry Davy found that the soil taken from Mersey Island and dried recovered its moisture from the atmosphere in less time than any other on which the experiment was tried; and this gives perhaps a better measure of fertility than any chemical analysis of its constituent parts. The best soils of Essex lie low, and require to be protected from the sea by embankments. Many marshes which formerly produced nothing but herbage, and were subject to inundations, are now converted into arable fields; and a great tract of land all along the coast, which used to be covered by the sea at high tides, is now laid dry by proper deep and broad ditches, here called fleets, and protected by high and well-constructed sea-walls, the repairs of which are a great expense to the proprietors. In some of these marshes the want of fresh water in summer was often felt severely. But lately recourse has been had to boring, which has been attended with great success, especially in the marshes at St. Osyth, where the finest springs of water have been found, which flow over the surface, and keep ample reservoirs continually full. The depth at which the water was found did not exceed fifty feet. This discovery greatly increases the value of these marshes in dry summers, such as that of 1836. The soil in the uplands along the coast consists chiefly of good loams varying in tenacity from a strong clay to a light gravel; most of it is of such a nature as to bear both turnips and beans. The stiffest soils, as well as the lightest, which form the two extremes, are more inland. The whole county has an undulating surface, which is very pleasing when fields and woods are interspersed, as is very generally the case in this county. The only level tract is that along the Thames, which extends to its mouth and along part of the south-eastern coast. The remainder consists of gentle elevations just sufficient to

give a great variety of soil and aspect. The clay soils, on the whole, prevail in most parts of the county, and from this circumstance arises the modes of cultivation and the rotations of crops which are most commonly adopted. There are very few such light soils in Essex as there are in Norfolk and in Lincolnshire, and except on the borders of Hertfordshire and Cambridgeshire, chalk and marl are rare.

The cold wet clays have given rise to a mode of tillage which is minutely described by Arthur Young in his 'View of the Agriculture of this County, and held out as a pattern for the cultivation of cold wet clays. It consists of repeated ploughings in spring and summer, and exposure to frost in winter; two things, no doubt, highly beneficial to stiff land. But since the introduction of extensive under-draining and high manuring, much of the labour of the horses in ploughing and harrowing has been saved. The peculiarity of the Essex method, on stiff clays, was to work the fallows two winters for barley, during which period the land was ploughed in all directions eight or nine times, and even more, until it was sufficiently pulverized. The rotation was fallow; barley; fallow; wheat; beans: that is, two fallows in five years. The beans were frequently omitted: so that the land was alternately cropped and fallowed. No stock was kept on the farm, but a few cows for the use of the farmer, and the horses required to plough the ground; and the soil not being favourable for artificial grass, very little manure could be made except upon those farms which have marshes attached to them, which is not generally the case where the soil is the stiffest. There was consequently no sufficient manure for the land, and fallows were unavoidable to keep the soil in a moderate state of fertility. From sixteen to twenty bushels of wheat per acre, and from twenty-four to thirty of barley, was a common average produce on very good clays, which, with under-draining and proper manuring, now produce thirty-two of wheat and forty-eight of barley. The fallows at the same time are now removed to every fifth or sixth year.

The present mode of ploughing in Essex is similar to that of Norfolk and Suffolk; the ploughs most commonly in use are Suffolk wheel-ploughs, or swing-ploughs without wheels. The great manufactory of these instruments is that of Messrs. Ransom, at Ipswich, which chiefly supplies the three eastern counties. In good loams, not too stiff, two horses are driven abreast with reins, whether the plough has wheels or not. In the very heavy wet clays three horses are used, who walk one before the other in the furrow. The object is that they may tread the land less; but some very judicious agriculturists maintain that three horses treading the bottom of the furrow render it quite impervious to water, and do more harm than if they had walked abreast over the land already ploughed, where they would only have trod in small cavities. This is rather a new mode of viewing the subject, but it is worth considering, and making trials to ascertain the real effect.

After harvest the stubble is generally ploughed in, and before winter the field is laid in narrow ridges which are formed by two turns of the plough, and sometimes by four turns, or two bouts, as they are called. The ploughmen are expert in this, and lay the ridges very regularly, sometimes diagonally across the field, which has a good effect in dividing the soil more completely. In this form a greater surface is exposed to the frost and air, and in spring it is mellow and crumbling, where in autumn it rose in an unbroken furrow. If a fallow is intended to clean the land, it is ploughed at intervals, and the roots of weeds gathered and burnt; if it is not very clear of these by wheat-sowing time, it is put in ridges again till the next spring, by which time it is quite pulverized, and fit to be manured for barley and clover. If wheat is sown in autumn, the manure is put on before the last ploughing.

The most common rotation on the stiffest clays which will not bear turnips is now 1, fallow; 2, wheat or barley; 3, clover; 4, oats or wheat; 5, beans; and where manure is abundant, a second crop of wheat is taken in the sixth year before the course begins again. On the rich soils which bear turnips the usual rotation is turnips, barley, clover, wheat, beans, oats, or wheat. The manure is put on for the turnips and the beans: pease and tares are taken on part of the land, which otherwise would have had clover, and on that where the clover has failed. The mole plough has been used with good effect in many stiff soils, but the treading of the horses when the ground is soft, the only

time when the mole plough can be used with effect, does a great deal of harm on such land, so that this instrument is not so generally used as it might be. The method of draining introduced of late is so superior in its effects to the mole plough, that this instrument will soon be laid aside, except in old pastures, where it may sometimes save the expense of draining. The subsoil plough is not yet generally introduced, but will, no doubt, soon be found an admirable instrument. The feeding of oxen in winter is now extensively practised by all good farmers in Essex, whether of strong or light loams. In sandy and gravelly soils sheep may be more profitable; but where turnips, especially the Swedish, or mangel wurzel can be raised, on heavy soils, the only practical plan is to draw them and give them to the cattle in yards or stalls, together with straw and oil-cake. When the soil will not allow the carts to go over the fields where the turnips are without doing harm in winter, asses with panniers are used to bring the turnips to a cart on the hard road, or at once to the yard, if it is near at hand. Asses and boys may be employed in this manner with advantage in many situations, and the expense will not exceed that of horses and carts, although they bring but a small load at a time.

In those farms which have marshes attached to them a great number of cattle is constantly kept, and all the straw is converted into manure, by which the arable land is kept in a high state of fertility. Along the Thames the salt marshes are extensive, and are profitable from the number of horses which are sent to feed there from London, after they have been over worked and require rest, or when they have met with some accident. Where there is not a sufficient number of horses taken in to stock the marshes, oxen and sheep are bought to complete the number, but the profit on these is seldom equal to that on horses agisted.

Besides the common crops usually cultivated, a considerable quantity of cole or rape seed is raised on the richer alluvial soils of the hundreds. It is a profitable crop, owing to the abundant supply of manure brought from London by the Thames. In other situations it has been found to deteriorate the succeeding crops too much, and the cultivation has been abandoned. Flax is not cultivated anywhere in the county, at least to any extent, and very little hemp is sown. A few hops are raised in the western part of the county, towards Cambridgeshire. The cultivation of this plant is spreading rapidly, and every year some new hop gardens are formed. The extent of hop ground is however inconsiderable, when compared with that in the hop-growing counties of Kent, Surrey, Hertfordshire, &c. The cultivation of caraway, coriander, and teasles, which is peculiar to this county, is described under CARAWAY.

In that part of Essex which lies within a few miles of London the cultivation of the soil partakes more of the garden culture. Vegetables, especially cabbages, are raised in great quantities, and very extensive fields are almost entirely devoted to the raising of potatoes. The ground is ploughed, and very highly manured with stable dung from London. The potatoes are usually set by hand, and moulded up with the plough. They are taken up with the common three-pronged fork, and wheat is immediately sown after the principal crop is taken up. Those which are of an early kind, and taken up in June or July, are followed by cabbages. Mangel wurzel for the London cowmen are also raised in considerable quantities. The meadows within fifteen miles of London regularly supply the Whitechapel market with hay, and every cart brings back a load of dung.

The cows and horses in Essex are chiefly reared in Suffolk, and Scotland supplies the oxen to fatten. There are a few considerable dairies about Epsom; but in general the number of cows kept on a farm is not considerable. Many calves are fatted, which are killed in the country, or go to Romford to be sold to London butchers.

Sheep are now kept in greater flocks by the Essex farmers than they used to be, and with considerable advantage. By means of draining, the land has been made capable of being folded over even in winter. It is not a sheep-breeding county, although many fine lambs are reared; but they are generally bought from the breeders in Wiltshire or Sussex in autumn, and sold fat to the butcher in the succeeding spring. The South-down breed is preferred in general; but there are also many improved Leicesters, and lately the Norfolk sheep have come into favour with some farmers, who think them hardy and profitable, and

whose fences are in such a state as to repress their rambling propensities. There is no peculiar breed of horses. The Suffolk punches seem to be in general use for farm work, and it is scarcely possible to find a breed better adapted for every kind of work. When crossed with a half-bred horse of some substance and action, a Suffolk mare produces admirable carriage horses. In the marshes a good many horses are bred of various kinds, chiefly for draught. Essex has been long noted for a superior breed of pigs, which has been produced and improved by crosses with foreign breeds, chiefly the Neapolitan, which has very little hair, and the Chinese. The common Essex pigs have long ears standing upright, and thin in their texture. The best breeds are quite black, and have *wattles*, which are small appendages of skin like a long teat, hanging from the neck under the jaws. The most common Essex pigs, which are brought in great quantities to Smithfield market, are black and white, the head and rump being generally black, and the back and belly white. They fatten early, and make excellent small pork when fed on the refuse of the dairy. Lord Western's breed is in great repute, not only in Essex, but all over England.

The principal fairs in Essex are:—Billericay, August 2; October 7. Bishop Stortford, Holy Thursday; Trinity Thursday; October 10. Barking, October 22. Braintree, May 8; October 2 and 3. Chelmsford, May 12; October 12. Coggeshall, Whit Tuesday and Wednesday. Colchester, July 5, 23; October 20. Dunmow, May 6; November 8. Epping, Whit Tuesday; November 13. Grays, May 23; October 20. Halsted, May 6; October 29. Harlow, May 13; September 9; November 28. Lachinden, near Maldon, August 27. Maldon, May 1, 2; September 13, 14. Romford, June 24. Saffron Walden, day before Mid-lent Sunday; November 1. Stansted, May 12. Stebbing, July 9. Thaxted, Monday before Whit Monday. Waltham Abbey, May 14; September 25.

Divisions, Towns, &c.—Essex is divided into twenty parts, of which fourteen are called hundreds, five half hundreds, and one royal liberty. We subjoin a table of these divisions, with their situation, their respective areas, and population in 1831. We have distinguished by the letters (h) and (l) the half hundreds and the liberty.

| | Ares. | Inhabitants. |
|--|---------|--------------|
| Barstable, S. | 73,290 | 13,181 |
| Becontree (h), S. W. | 35,950 | 34,924 |

There is no city in Essex. There are nineteen market-towns: three of these are parliamentary boroughs; Colchester, on the Colne, population of the borough and liberty in 1831, 16,167; Harwich, at the mouth of the Stour, population in 1831, 4297; and Maldon, on the Pant or Blackwater, population in 1831, 3831. Chelmsford, the county town, is on the Chelmer; population in 1831, 5435. Of these places, as well as of Barking, a market-town on the Roding (population of the town ward in 1831, 3404; of the whole parish, which includes Ilford, 8036), an account is

given under their respective names. Of the other towns we subjoin an account.

Billericay is in the hundred of Barstable: it appears in one antient record, under the name Beleuca, which is probably a variation of the old word Baleuga or Banleuga (in French Banlieu), the territory or precinct round a manor or borough. The town stands on an eminence on the road leading from London, through Brentwood, to Rochford and Southend. In Camden's time the market was considerable, but for a long time past it has been much decayed. The town has been much improved of late years by a number of good houses, and from its situation commands a beautiful prospect over the valley which extends southward to the Thames. It is in the parish of Great Burghsted or Bursted, the church of which is about a mile and a half or two miles south of the town. There is a chapel in Billericay, supposed to have been founded in the fourteenth century: the tower, which is surmounted by a leaden spire, may be of that date, but the body of the chapel is of more modern origin. There are places of worship for Baptists, Independents, and Quakers.

The inhabitants of the parish of Great Bursted, in 1831, were 1977, of which about two-fifths were engaged in agriculture. There is a weekly market on Tuesday. There are scarcely any manufactures. The living is a vicarage, with the chapel of Billericay annexed. By the Education Returns of 1833, there were in the parish twelve day and five boarding-schools with 260 children, and two Sunday-schools with 171 children. One of the day-schools, with 49 scholars, has a small endowment. There is a parish almshouse for poor women.

At Blunts-walls, near Billericay, are some earth works, the remains of a ditch and rampart, enclosing an area of about four acres: within the area were some artificial mounds, now chiefly levelled. Some remains of Roman pottery, several Roman copper coins and two silver coins, one of Trajan and one of Adrian, have been found in the neighbourhood.

Braintree is in the hundred of Hinckford, and on the north bank of Pod's Brook; it is on the high road from London to Norwich, through Bury, 40½ miles from London and 11½ from Chelmsford, the county town. Antiently the name of Braintree, or, as it is termed in Domesday, Raines, comprehended the neighbouring parish of Rayne as well as that of Braintree: part of the lands in it belonged to the bishops of London; it was alienated by Bishop Ridley at the time of the Reformation: the manor-house (long since destroyed) was an episcopal palace. The parish was dismembered from that of Rayne, of which it was previously a hamlet, about the time of John or Henry III., the former of whom constituted it a market-town. The growth of the place is to be ascribed to its situation on one of the high roads from London into Norfolk and Suffolk, and to the building of inns and lodging-houses for the reception of the numerous pilgrims to the shrines of St. Edmund at Bury, and our lady of Walsingham in Norfolk. At the Reformation this source of its prosperity failed; but the town, and the adjacent village of Bocking, obtained consequence by the settlement of the Flemings who fled from the tyranny of the duke of Alba and established here the manufacture of baize and other light woollens, which for some time constituted the staple manufacture of the place, and is still carried on, though not to so great an extent as formerly.

It will be desirable to consider, in connection with Braintree, the adjacent village of Bocking; for although Bocking Church and Church Street are a mile and a half from Braintree, and on the north-east bank of the Pant or Blackwater, what is termed Bocking Street is contiguous to Braintree, and the two form one continuous place, the main street of which covers two-thirds of the extent between Pod's Brook and the river Pant, and stretches about a mile. Braintree consists of this street and of some others, formed by the intersection of the road from Bishop's Stortford and Dunmow to Coggeshall and Colchester, with the Norwich road, and by the convergence at this point of bye-roads from the surrounding villages: there are some back streets or lanes. The streets are inconveniently narrow; and many of the houses are of wood, and of considerable antiquity. The church is on the right at the entrance of the town from London; it is large, built chiefly of flint, and mostly in the perpendicular style of English architecture: the tower, at the west end, is of early English, and is surmounted by a lofty shingled spire of much later date. This

church was enlarged in the time of Henry VIII., the expense of the alteration being partly defrayed by the profits of three mysteries or plays performed in the church. There are places of worship for Independents, Baptists, Quakers, and Methodists. Bocking Church is remote from the town: it is spacious and handsome, and chiefly in the perpendicular style; the tower is lofty and well designed. In the neighbourhood of Braintree are the remains of an antient church, formerly the parish church. Some coins, sepulchral urns, and other Roman antiquities, have been found.

The parliamentary returns for 1831 assign to the parish of Braintree an area of 2500 acres, 708 inhabited houses, and a population of 3422, about one-sixth agricultural: to that of Bocking an area of 3800 acres, 647 inhabited houses, and a population of 3128, about one-fourth agricultural, giving an aggregate of 6300 acres, 1355 houses, and 6550 inhabitants. The woollen manufacture has been in a great degree superseded by that of silk and crape, which is carried on to a considerable extent. The market is on Wednesday for corn, eggs, poultry, and occasionally cattle and live-stock of all kinds. There are several fulling and corn mills on the Pant.

The living of Braintree is a vicarage, of the yearly value of 212*l.*, with a glebe-house, in the archdeaconry of Middlesex: that of Bocking is a rectory, of the yearly value of 923*l.*, with a glebe-house, in the peculiar jurisdiction of the archbishop of Canterbury, being subject only to his jurisdiction, or that of his commissary, who is called Dean of Bocking.

There is at Bocking an almshouse or hospital, originally for seven poor people, but now divided into nine tenements, with an endowment from the benefactions of several individuals. The returns made to parliament show that there were in the two parishes in 1833 twelve day or boarding and day-schools (two of them with 255 to 275 scholars, endowed, and three others with 340 scholars, supported by subscription), containing 813 to 833 scholars; one dame or infant school, with 60 or 70 scholars; and four Sunday-schools with 540 scholars.

Coggeshall is in Lenden hundred, on the northern bank of the river Blackwater, 44 miles from London by Chelmsford, Witham, and Kelvedon, where the Coggeshall road turns off from the Ipswich and Norwich road. It is sometimes called Great Coggeshall, to distinguish it from the adjacent hamlet of Little Coggeshall. This town has by some antiquaries been considered to be the Canonium of Antoninus; and several Roman remains have been found in and about the town, but these are not deemed by others sufficient to prove anything more than that a Romish villa existed here. Morant, the historian of Essex, ascribes the origin of Coggeshall to an abbey, founded here in 1142 by King Stephen and Maud, his queen, for Cistercian monks. To this abbey succeeding princes granted various privileges, among which was that of holding a market weekly. The yearly revenue of the abbey at the dissolution was 298*l.* 8*s.* gross, or 251*l.* 2*s.* clear. The town was formerly much engaged in the clothing trade, and was particularly famous for a white baize of superior fabric, called Coggeshall Whites. The clothing trade has much declined for many years past.

The town is irregularly laid out, and the streets are narrow and ill paved. The church, at the north-eastern end of the town, is a spacious and handsome building in the Perpendicular style of English architecture: the windows, especially the east window, are large and handsome: there is a large square tower at the west end. A small part of the abbey is yet remaining; and near it is a bridge of three arches, originally built by King Stephen over a cut made to convey the water of the river nearer to the abbey. The abbey has some good plain lancet windows, and the interior has some good groining and windows, with shafts; it is occupied as a farm-house. At Little Coggeshall, a hamlet of the town, half a mile south of it, said to have been once a distinct parish, were formerly two churches, one of them built by the monks of the abbey for their own use, the other the parish church: the former has been long demolished; the latter, or what remains of it, is now used as a barn. There are meeting-houses for Independents, Baptists, Quakers, and Methodists.

By the returns of 1831, the parish comprehended an area of 2770 acres, and had 624 inhabited houses, with a population of 3227, about two-sevenths agricultural. The

silk manufacture has been introduced here, and constitutes the principal manufacture of the place; that of woollens has declined. Some of the inhabitants are engaged in toy making. The market is on Saturday for corn, butter, eggs, and poultry, and occasionally live stock.

The living is a vicarage, of the yearly value of 215*l.* with a glebe house, in the archdeaconry of Colchester.

There are three unendowed almshouses near the church, and there is an endowed school. The parliamentary returns for 1833 assign to Coggeshall eleven day, or boarding and day, or evening schools, one endowed and one Lancastrian, with 294 scholars; thirteen dame or infant schools with 189 scholars; and six Sunday-schools with 490 scholars.

Dunmow, or Great Dunmow, is in Dunmow hundred, on the south-west bank of the river Chelmer, 38 miles from London by Epping, Harlow, and Hatfield Broad Oak; 40½ by Chigwell, Abridge, and Ongar; and 42 by Chelmsford, Great Waltham, and Barnston. Great Dunmow is considered by some antiquaries to have been the Roman station *Cesaromagus*, which others fix near Widford, two miles south-west of Chelmsford. A number of Roman coins, of different emperors, have been found here. It is on a Roman road, crossing the county from west to east from Hertford to Colchester.

Dunmow is pleasantly situated on an eminence, and consists principally of two streets. The market-cross in the centre of the town was erected in 1578, and repaired in 1761. The church stands a considerable distance from the main portion of the town: the houses adjacent to it form a group called Church End. It is a spacious building, with an embattled tower at the west end; it has some portions in the Decorated English, and some in the Perpendicular style. The east window, which is very fine, is of Decorated character. There are meeting-houses for Independents, Baptists, and Quakers.

The area of the parish is 7910 acres; there were in 1831, 499 inhabited houses, and 2462 inhabitants: nearly one-half of the population is agricultural. The manufacture of baize and blankets, formerly carried on, has been given up; some sacking and coarse cloth are made. The market, which according to one of our latest authorities has been discontinued, was on Saturday.

The living is a vicarage of the yearly value of 421*l.*, with a glebe-house, in the archdeaconry of Middlesex. There is an almshouse for six poor persons.

About two miles east of Great Dunmow is the village of Little Dunmow (population in 1831, 378), where was a priory of Augustine canons, founded in 1104 by the Lady Juga, sister of Ralph Baynard, the then lord of the manor. Its yearly value at the dissolution was 173*l.* 2*s.* 4*d.* gross, or 150*l.* 3*s.* 4*d.* clear. The monastic buildings are now razed, and the site partly occupied by the manor house. The priory church was a large and stately fabric, partly in the decorated English, partly in an earlier style of architecture: the roof was sustained by pillars, having capitals ornamented with oak leaves elegantly carved. Some of these remain in the part now used as the parish church. The well-known custom of the 'fitch of bacon' was connected with the manor of Little Dunmow. [DUNMOW BACON.]

Easton Lodge, the seat of Viscount Maynard, is situated on high ground in a spacious park about two miles north-west from Great Dunmow. It is a venerable pile of the Elizabethan period and style. In the returns of schools made to parliament for 1833, no account is given of those at Great Dunmow, except that there was a national school for girls, containing 103 scholars; and that a national school for boys, suspended from various causes at Christmas, 1832, had at the time of the suspension an average attendance of 75.

Epping is in the half hundred of Waltham, and on the high road from London to Norwich by Newmarket, 17 miles from London. The principal part of the town, called Epping Street, consists of a street extending more than half a mile in length, lined with irregularly built houses, and having in the centre a row of decayed mean-looking shambles. The church is situated two miles north-west of the street, and with the houses grouped round it constitutes what is distinguished as Epping Upland. The church is pleasantly situated on a rising ground: it is dedicated to All Saints, and is not distinguished by its architecture. In the 'Street' is a chapel of ease originally belonging to the abbot and monks of Waltham, to whom the great tithes had been granted, and who kept the parish in

their own hands as a curacy. The chapel is now vested in trustees for the benefit of the inhabitants. It stands at the London entrance to the town, and has lately been rebuilt. There are places of worship in Epping for Quakers and Independents; but that for the Quakers, though close to the town and virtually belonging to it, is in an adjacent parish. There are many inns in the place.

The parliamentary returns for 1831 assign to Epping an area of 5250 acres, 429 inhabited houses, and 2313 inhabitants, of which 83 houses and 427 inhabitants are in Epping Upland and the hamlet of Rybill, the last in Harlow hundred. In Epping Upland four-fifths of the population is agricultural, in the whole parish about two-fifths. The neighbourhood of Epping is celebrated for butter, pork, and sausages, of which articles it furnishes a considerable supply to the metropolis. The market is on Friday. In the spring great numbers of suckling calves are brought to Epping market from Suffolk, and those parts of Essex where dairy farms are numerous.

The living of Epping is a vicarage 'in the peculiar jurisdiction of the Court of the Commissary of London, concurrently with the Consistorial Episcopal Court.' (Lewis's *Top. Dictionary*.) Its yearly value is 729*l.*, with a glebe-house: the chapelry is of the yearly value of 120*l.*, arising from endowments.

The returns made to parliament in 1833 assign to the parish of Epping four infant or dame schools, with 50 children, eight boarding or day schools (one of them a charity school), with 343 scholars, and one Sunday school, with 70 boys. About 70 girls from this parish attend the national school of Theydon Garnon or Theydon Gernon (two miles south-east of Epping Street), to which the parishioners of Epping contribute largely.

In the parish of Epping is Copped Hall, a mansion erected near the site of an older structure raised by the monks of Waltham Abbey when they had possession of the manor; it was built near a century ago, and has since been much improved. It is one of the finest seats in the county. Near it are the remains of an antient camp, probably British, now overgrown with trees, called Ambreys, or Ambersbury banks.

Epping gives title to Epping Forest, a considerable tract of waste land in the south-west part of the county. This forest was formerly called the forest of Essex, being the only forest in that county, the whole of which was antiently comprehended in it. By a charter of king John, dated 25th of March, in the fifth year of his reign, and confirmed in the eighth of Edward IV., all that part of the forest which lay to the north of the highway from Stortford to Colchester (very distant from the present boundaries) was disafforested. The forest was further reduced by a commutation made in the twenty-ninth of Edward I., in pursuance of the *Charta de Foresta*; but the metes and bounds of it were finally determined by an inquisition and perambulation taken on the 8th of September, 1640, by virtue of a commission under the great seal of England, in pursuance of an act of the 16th of Charles I., for settling the bounds of the forests. The boundaries as thus settled include the whole of the eleven parishes of Wansted, Leyton, Walthamstow, Woodford, Loughton, Chigwell, Lambourne, Stapleford Abbots, Waltham Holy Cross, Epping, and Nazing, and parts of the ten parishes of Chingford, Stratford, East Ham, West Ham, Little Ilford, Great Ilford, Barking, Dagenham, Haverstock, and Theydon Bois. The extent of the forest is estimated at 60,000 acres, of which 48,000 acres are estimated to be enclosed and private property; the remaining 12,000 acres are the unenclosed wastes and woods. What is called Henhault, or Hainault forest, is a part of this waste. (*Fifteenth Report of the Commissioners of Land Revenue*, quoted in Young's *Agriculture of Essex*.) Tending hundred had been disafforested by king Stephen before the grant of John mentioned above. (Morant's *History of Essex*.) Epping forest is much resorted to by Londoners in what are termed 'gipsy parties'; and on the first Friday in July a kind of fair is held round the spot once occupied by an enormous oak called Fairlop oak. The fair retains the title of Fairlop Fair. On Easter Monday there is a stag-hunt much patronized by the inhabitants of London. The kennel for the hounds and the building belonging to the hunt were rebuilt several years ago at an expense of many thousand pounds.

Grays Thurrock is in the hundred of Chafford; it is on the bank of the Thames, 24 miles from London through

Romford, Upminster, and Stifford. This little town consists chiefly of one irregular street on a creek of the Thames, accessible to boats and other small vessels. The church, near the north end of the town, is built in the form of a cross, with a tower on the north side.

The area of the parish is 1570 acres; the number of inhabited houses by the census of 1831 was 243, the population (including that of the liberty of Lee, in East Tilbury parish, Barstable hundred), 1248. The population had greatly increased before the census, owing to the number of labourers employed in brick-making. The market is on Thursday, and is chiefly for the sale of corn; it is much frequented: there is one yearly fair.

The living is a vicarage of the yearly value of 160*l.*, with a glebe-house: it is in the archdeaconry of Essex.

There were in 1833 eight day-schools, with 138 scholars, 20 of whom (boys) were educated from the proceeds of an endowment; and two Sunday-schools, with 202 children.

There are two villages near this town which also bear the name of Thurrock: Little Thurrock, to the east of the town (population 302), and West Thurrock, to the west of the town (population 804). The chalk-quarries of Purfleet are in the parish of West Thurrock. In Little Thurrock parish, and in Chadwell parish, which adjoins it, are some remarkable caverns or holes in the chalk, to which tradition has assigned the name of 'Cunobelin's gold-mines.' It has been conjectured that they were granaries of the antient Britons. They are also called 'Dane holes,' from having been used by those invaders as lurking-places or receptacles for plunder.

Halsted is in Hinckford hundred, on the north-east bank of the river Colne, and on the road from London by Bury to Norwich, 46½ miles from London, and 17½ from Chelmsford. It is supposed that a market was established here in the Saxon times: a hill at the upper end of the town, on which for several centuries it was held, retains the name of Cheping hill.

The town stands on the slope of a gravelly eminence, rising from the river, and consists of the main street along the Norwich road, and some other streets. The church is near the centre of the town. It is a large edifice, capable of accommodating 1200 persons, and consisting of a nave, chancel, and side-aisles, chiefly in the Perpendicular English style: the chancel is in the Decorated style, with a good window of five lights, and others of two lights. There is a tower at the west end surmounted by a wooden spire, the third that has been erected on the same tower, two previous ones having been destroyed by lightning. There are places of worship for Independents, Baptists, and Quakers. There is a house of correction at Halsted.

The parish comprehends an area of 6230 acres; and had, in 1831, 989 inhabited houses, and 4637 inhabitants: about three-eighths of the population was agricultural. The silk manufacture is carried on to a considerable extent: the manufacture of baize and other light woollens has been discontinued. There is a market on Friday, one of the principal in the county for corn and occasionally for cattle and other live stock. Some hops are grown round the town.

The living is a vicarage, of the yearly value of 390*l.*, with a glebe-house, in the gift of the bishop of London: the minor canons of St. Paul's are the impropiators. There was a college of priests at Halsted before the Reformation; the foundation was for eight, but it is doubtful there was ever the full number. The revenue at the dissolution was 26*l.* 5*s.* 8*d.* per annum gross, or 23*l.* 16*s.* 5*d.* clear.

There were in Halsted, according to the returns made to parliament for 1833, ten infant or dame schools, with 150 scholars; four day-schools, one supported by voluntary contributions, containing 40 children, and three others with 100 children; and four Sunday-schools, with 695 scholars. There is a grammar-school, founded by Dame Mary Ramsey, for 40 poor children of Halsted and Colne Engaine (a neighbouring parish), which is not distinctly mentioned in the return.

'At a house in this parish is a Greek inscription, brought from a village near Smyrna, where it was erected one hundred and fifty years before Christ, to the honour of Crato, a musician.' (*Beauties of England and Wales*, 1803.)

Near Halsted are the remains of the antient manor-house of Stansted Hall.

Manningtree is in the hundred of Tendring, on the estuary of the Stour, 60 miles from London, through

Chelmsford and Colchester. This place was antiently known by the name of Sciddinchou; the origin of its present appellation, formerly written Many-Tree, is not known. It is a small place, irregularly laid out. The church, a chapel, built out of the ruins of a more antient one, which stood on a site not far removed from that of the present building, was formerly very small, but has been lately enlarged. There are meeting-houses for Independents, Quakers, and Methodists.

The parish, or rather the chapelry, by the return of 1831, comprehended only 30 acres, and had 241 inhabited houses, and a population of 1237, a very small proportion of which was agricultural. Manningtree appears to be the residence of an unusual proportion of genteel families. A considerable trade in malt is carried on; and corn, coal, deals, iron, and fish are imported. The market is on Thursday.

The living is a perpetual curacy, united with the rectory of Mistley (of which parish the chapelry of Manningtree is a dependency) and the vicarage of Bradfield. The whole are of the yearly value of 698*l.*, with a glebe-house. They are in the archdeaconry of Colchester.

The chapelry contained, in 1833, one national school, containing 223 children; and one Sunday-school, with 60 children.

Mistley is adjacent to Harwich. Mistley Hall, the seat of the Rigby family, is on a pleasant eminence in the midst of gardens and plantations elegantly laid out. On the bank of the Stour is a quay with warehouses, at which considerable trade in corn, malt, and coal is carried on. These belong to the proprietor of the mansion.

Ongar, distinguished as Chipping Ongar from another parish of the same name (High Ongar), is in Ongar hundred, near the right or west bank of the Roding, and the left or east bank of the Cripsey brook, just above the junction of these two streams: it is 21 miles from London by Woodford bridge, Chigwell, and Abridge; or 24 miles by Epping.

A castle was built here by Richard de Lucy, one of the principal nobles of the time of Henry II.: the keep stood on the summit of a lofty artificial mound. The castle having become very ruinous, was, in the time of Queen Elizabeth, pulled down, and a brick house was built by the then owner of the place on the site of the keep. This house was demolished in 1744, and a large summer-house, of castellated architecture, built in its room. The moat which surrounded the keep, and other earthworks of the castle, still remain. The sides of the mound are planted with trees and shrubs.

The town chiefly consists of one long and wide street, extending from the bridge over the Cripsey brook, up the slope and along the brow of a hill. The church, which is in a central situation, is a small neat structure: the windows are remarkably small, so as to resemble the loop-holes of a castle. The church contains a monument of Jane, one of the daughters of Oliver Cromwell. Many Roman bricks have been worked into the building, and the foundations of Roman buildings are said to have been dug up in the churchyard. The principal road from Londinium (London) to Camulodunum (Colchester) is supposed by some to have passed this way, though others make it pass near or through Romford and Chelmsford. The town is within the area of an antient entrenchment, which may still be traced on its different sides. It was antiently called Ongar ad Castrum, perhaps with reference to this entrenchment. There is an independent meeting-house.

The area of the parish is 480 acres: the number of inhabited houses in 1831 was 134, and the population 798, of which a small proportion is agricultural. The market is on Saturday.

The living is a rectory in the archdeaconry of Essex, of the yearly value of 127*l.*, with a glebe-house.

There were in 1833 nine boarding or day-schools, with 140 scholars; and two Sunday-schools, containing 95 children. One of the day-schools is endowed.

High Ongar, which is on the other side of the Roding, is a much larger parish than Chipping Ongar, and had, in 1831, a population of 1205, chiefly agricultural.

Rochford is in Rochford hundred, on the Broomhill river, which is navigable to within about a mile of the town, 40 miles from London through Romford, Brentwood, and Bille Ricay. The town consists principally of two streets running one into the other in the form of the letter T: the houses are all built the market-house, which is of timber, stands

near the centre of the town, and has on it the date 1707: it is not used as a market-house now. There are two bridges over the river, which close to the town is an inconsiderable brook. The church, which is a little removed from the town, is a good-sized building, consisting of nave, chancel, and side aisles, with a lofty brick tower at the west end. There is an Independent meeting-house. At the lower end of the town are a row of brick almshouses for six poor people, founded and endowed by Robert Rich, earl of Warwick, in the early part of the seventeenth century.

The parish comprehends an area of 1240 acres: it had, in 1831, 271 inhabited houses, and a population of 1526, of which more than a third was agricultural. The chief trade is in corn. The market is on Thursday.

The living is a rectory, in the archdeaconry of Essex, of the yearly value of 570*l.*, with a glebe-house.

There were in the parish, in 1833, a Lancasterian school, with 70 boys; a national school, with 64 children (rather more on Sunday); seven other day-schools, with 158 scholars; and one Sunday-school, with 100 children: to the Sunday-school a lending library is attached.

Romford is in the liberty of Havering atte Bower, on the Bourne brook: it is a great thoroughfare, being on the high road from London to Chelmsford, Colchester, Ipswich, Bury, Norwich, Yarmouth, and other large towns in Essex, Suffolk, and Norfolk; between 11 and 12 miles from London. The derivation of the name has been much disputed, some contending that it is derived from Roman *ford*, others from two Saxon words signifying 'broad ford.' This place, or some spot in the neighbourhood, is supposed to be the site of the Duroplitum of the Itinerary of Antoninus.

The town consists almost entirely of one long wide street, near the centre of which is the market-house and town-hall, which was repaired in 1768 at the expense of the crown. The houses are tolerably good, and the street is paved and lighted. The chapel, situated at the entrance to the town from London, on the left hand, is a tolerably large building, erected in the early part of the fifteenth century: it is dedicated to the Virgin Mary and St. Edward the Confessor, and consists of a chancel, nave, and north aisle, with a square tower at the west end. In the east window is a figure of Edward the Confessor in stained glass, the arms of that king, and another coat of arms. The Independents have a meeting-house at Collier's Row, a hamlet of the parochial chapelry of Romford, about two miles north-west of the town; a house for the pastor and a small endowment are connected with it. There is also a Methodist meeting. An almshouse for five poor men was founded and well endowed by Roger Reed near the end of the fifteenth century. There were formerly cavalry barracks at the London entrance to the town: they were of wood, and have since been pulled down.

The parish comprehends an area of 3340 acres, and had, in 1831, 766 inhabited houses, and a population of 4294, of which less than one-third is agricultural. The general market is on Wednesday: there is a market on Monday for calves, and on Tuesday for hogs. In spring and summer great numbers of suckling calves are brought to market from Suffolk and the dairy districts of Essex.

This parish, with those of Hornchurch and Havering, form the liberty of Havering atte Bower, the quarter sessions for which are held at Romford. Commissions for trying felons within this liberty may be obtained by a small payment to the crown, but no commission has been applied for for many years. (*Lysons' Environs of London.*)

The living is a chapelry originally included in the parish of Hornchurch, the limits of which were once coextensive with those of Havering liberty, but separated from it by act of parliament, A.D. 1658. The living is of the annual value of 800*l.*, with a glebe-house, in the patronage of New College, at Oxford: it is in the archdeaconry of Essex. There were, before the Reformation, a chantry and a small guild attached to Romford chapel, the lands of which were valued at 4*l.* 10*s.* 2*d.* per annum.

There were, in 1833, in the parish, one endowed day-school with 121 scholars, six other day-schools with 172 scholars, and two Sunday-schools with 143 scholars.

Walden or Saffron Walden is in the hundred of Uttlesford, which occupies the north-western extremity of the county: it is near the Cam, and a little to the right of the road from London to Newmarket and Norwich, 42 miles from London. It was conjectured by Doctor Stukely, but

without sufficient authority, that this was a Roman station. Its name is derived from two Saxon words, *Weald*, a wood, and *den*, a valley: its epithet 'Saffron' is derived from the great quantity of that plant formerly cultivated in the neighbourhood: this cultivation has been long abandoned. At the period of the Domesday survey the lordship of Walden was possessed by a Norman, Geoffrey de Magnaville, one of the companions of the Conqueror. This nobleman erected at Walden a castle, which, judging from the remains of it, must have been of great strength. The remains occupy the highest part of the town, and consist of some parts of the walls and towers, built with flint bound together by a very hard cement. Geoffrey, the grandson of the founder of the castle, having deserted the party of Stephen for that of the Empress Maud, obtained of her permission to remove the market from the neighbouring town of Newport (now a village) to Walden. Having been however seized by Stephen, he could only obtain his freedom by the delivery of his castles, Walden being one of them, to the king. The same nobleman founded here in 1136 a Benedictine priory, which was some years later raised to the rank of an abbey: this abbey obtained several valuable benefactions, and had, at the time of the dissolution, a yearly revenue of 406*l.* 15*s.* 11*d.* gross, or 372*l.* 18*s.* 1*d.* clear. The site was granted to Sir Thomas Audley, lord chancellor, and the title of Lord Audley of Walden was conferred upon him. On the site and grounds of the monastery, enlarged by a subsequent addition of 200 acres, stand the present mansion and park of Audley End.

The town is irregularly laid out, and the houses are many of them of considerable antiquity. The church is 'a large and very elegant specimen of the late Perpendicular style. It has a nave and aisles, large south porch, and chancel and aisles. The clerestory windows of the nave are very large and of six lights; those of the chancel, which has a lower roof, are much smaller, and two in each arch. The eastern end of the nave is finished by two octagonal turrets with crocketed ogee heads. The windows of the aisles are very large, filling up the spaces close to the buttresses, and they are mostly square-headed. The tower has bold buttresses, crowned with octagonal turrets, and very long plain pinnacles. These pinnacles and the spire, which is of wood covered with lead, appear to be of later date than the church. The interior of this church is very fine, the piers being remarkably light and elegant.' *Rickman's Essay on Gothic Architecture.* Since the above extracted account was written the wooden spire has been replaced by one of stone more in character with the rest of the building. There are two places of worship for Calvinistic or Particular Baptists, and one for Arminian or General Baptists, and one each for Independents, Quakers, and Wesleyan Methodists. The town-hall is a neat building in the market-place, which is spacious. There are a cattle-market and a handsome range of almshouses lately built in the place of a former range founded and endowed by Edward VI. for 16 decayed housekeepers of each sex. There is also a neat building lately erected near the ruins of the castle for a museum, and for the meetings of a literary society established in the town. Audley House, or as it is usually termed, Audley End, the seat of Lord Braybrooke, is a noble mansion erected by the Earl of Suffolk, who in the time of James I., had inherited the estate of the Lord Chancellor Audley. The grounds are beautiful, and the Cam, which flows through them, though here an inconsiderable stream, expands so as to form a considerable sheet of water in front of the house. The mansion, originally more extensive than at present, is still one of the finest in the county; it is said to have cost at its erection 190,000*l.* The house contains some interesting portraits and other pictures. On a green near the town is a singular remain of antiquity called the Maze. It consists of a series of concentric circles with four outworks cut in the chalk, which here rises to the surface. Its origin and use are unknown: Dr. Stukely conjectures that it was a British cursus or place of exercise for the soldiery. A short distance from the town are the remains of an ancient encampment of an oblong form called Pell Ditches or Repe Ditches. The south bank is 730 feet long, 20 high, and 50 broad at the base, and 6 or 8 wide at the top: the west bank is 588 feet long: both banks and ditches are extremely bold and well preserved.

The parish of Saffron Walden contains 7380 acres, and had in 1831 941 inhabited houses and a population of 4762, of which about one-fourth was agricultural: there are

many genteel families in the town. The chief trade is in barley and malt: the market is on Saturday. Walden is a municipal though not a parliamentary borough. By the Municipal Reform Act the corporation consists of a mayor, four aldermen, and twelve councillors. The borough is co-extensive with the parish.

The living is a vicarage in the archdeaconry of Colchester, of the annual value of 237*l.*, with a glebe-house. Lord Braybrooke is patron and impropriator.

There were in Walden in 1833 one infant school with 70 children: two national schools, containing 124 boys and 106 girls (with the addition of 10 boys on Sundays); a school for 25 boys and as many girls, chiefly supported by Lord Braybrooke; and six other day-schools with 212 children; and two Sunday-schools with 289 children.

Waltham Abbey, or Holy Cross, is in the half-hundred of Waltham, 12½ miles from London, a little to the right of the road to Ware, Royston, and Huntingdon. It is on the river Lea (which is here separated into several channels, some of which flow through the town) near the junction of the Cobbin brook, which flows a short distance from the town on the east and south.

The first notice of Waltham occurs in the reign of Canute, whose standard-bearer, Tovi, founded here a religious house with two priests, probably secular canons of St. Augustine. The place derived sanctity and name (Holy Cross) from a cross with the figure of Christ upon it found at Montacute and transferred here, to which miraculous powers were ascribed. Harold, afterwards king of England, enlarged the foundation of Tovi, A.D. 1062, furnished it with ample endowments, increased the number of canons to 12, one of whom had the rank of dean, rebuilt the church, and established such a school of learning as the state of the age admitted. When the unfortunate Harold fell in the battle of Hastings, A.D. 1066, his body, which had been given up to his mother, was brought to Waltham for interment and his tomb erected. William the Conqueror treated the religious of Waltham harshly, and deprived them of their moveable valuables, but left their lands untouched or nearly so. In the reign of Henry II. (A.D. 1177) regular canons were substituted for seculars, the number enlarged to 16, the endowments of the establishment augmented, and the dignity of abbot conferred upon the head of it. Subsequent monarchs favoured the establishment: Henry III. frequently resided in the abbey, and granted to the inhabitants of the village the privilege of a market and a fair. Some accounts make the market more antient. In the reign of this king, A.D. 1242, the conventual church was again solemnly dedicated, the king and several of his nobles being present. The yearly revenues of the abbey at the dissolution were 1079*l.* 12*s.* 1*d.* gross, or 900*l.* 4*s.* 3*d.* clear.

The town consists principally of one main street, running nearly east and west. The church, formerly part of the conventual church, is on the north side of the main street, near the centre of the town. As the conventual church it was very extensive, consisting of nave, transept, choir, and chapels. At the intersection of the transept, which may still be traced, rose the great tower, which contained a ring of five bells. Part of this tower having fallen in, the remainder was blown up by underminers, and the whole choir, tower, transept, and east chapel demolished. The nave and some adjacent chapels alone remained: the nave, with its side-aisles, forms the body of the present church. The extent of the original fabric may be estimated by the fact, that Harold's tomb, which was in the choir or in a chapel beyond it, stood about 120 feet eastward from the termination of the present building. The church is about 90 feet in length, and in breadth, including the side-aisles, 48 feet: it is in the Norman style, with round massive piers (some of which have indents of wave and zig-zag lines), dividing the nave from the side-aisles; semicircular arches, and zig-zag enrichments. The great arch of the cross, now walled up, is a very fine one. Above the arches dividing the nave from the side-aisles are two other ranges or tiers of arches: those of the second tier correspond in width to those of the lower, but are not of equal height; the arches of the third tier are three to each arch of the lower tiers, with a window pierced in the middle arch of the three. The roof is modern, and little ornamented. The side-aisles are surmounted with galleries, erected about half a century ago. At the west end of the church is a heavy square embattled stone tower, 86 feet high, bearing the date 1558. From the south side of the church projects the Lady Chapel, now used as a

vestry and school-room, under which is a fine crypt. Another little chapel, at the south-east end of the church, is now a repository for rubbish. These chapels have some beautiful and well-executed portions in the Decorated English style. There are in the church various inserted windows of different dates. The font is apparently very antient, and there is a fine wooden screen. The building has been much injured and its beauty deformed by dilapidation and alterations, but it is still well worthy of attention.

Exclusive of the nave of the abbey church, the remains of the abbey are but few. They consist of an entrance-gateway, and bridge across an arm of the Lea, which bounds the enclosure of the abbey on the west side; some walls, and a few vaulted arches in a garden belonging to the abbey farm. The refectory is reported to have stood eastward of the church; and what is now the abbey farm is said to have been antiently the stables. The gateway is in a much later style of architecture than the church. In the gardens formerly belonging to the abbey, now occupied as a nursery-ground, is a tulip tree, reported to be the largest in England. There are at Waltham Abbey meeting-houses for Baptists and Wesleyan Methodists.

The parish of Waltham Abbey is extensive, comprehending 11,870 acres: it had, in 1831, 760 inhabited houses, and a population of 4104; but of these 344 houses and 1902 inhabitants were in the three hamlets of Holyfield, Sewardstone, and Upshire; leaving for that part of the parish which contains the town 416 houses and 2202 inhabitants: only a small proportion of the population of the town division is agricultural; but the greater part of the population of the hamlets is so. The powder-mills belonging to government employ many hands: many are engaged in the printing of silk handkerchiefs, and some in the manufacture of pins: some also, though not in the town division, are engaged in throwing and spinning silk. The market is on Tuesday.

The living is a donative curacy, in the peculiar jurisdiction of the bishop of London: it is of the annual value of 237*l.* There is an almshouse for eight poor widows.

There were in the year 1833 one infant school, with 135 children: three day-schools, viz., one endowed for 20 boys and 20 girls, one national school for 60 girls, and a school with 24 boys at High Beach, besides many small private day-schools; one evening-school, supported by voluntary contributions, with 42 boys; and four Sunday-schools, with 310 children.

Witham is in the hundred of Witham, and on the high road from London to Norwich by Ipswich, 38 miles from London. It is on Pod's Brook, just above the junction of that stream with the Blackwater.

This town is generally reputed to have been built by Edward the Elder, but it is questionable if that prince did more than restore a place that bears marks of having been a Roman station. On Cheping Hill or Chipping Hill are the remains of a circular camp, with a double vallum. A quantity of Roman bricks are worked up in the tower and body of the church, and one or two Roman coins were discovered in levelling the fortifications of the above-mentioned camp. From these indications it has been supposed that Witham was the Canonium of Antoninus, which is placed by others near Kelvedon.

The town consists of two portions: the larger portion consists of one main street along the high road and a short street or two branching from it: the other portion, in which is the church, is situated half a mile to the north of the principal part, on Cheping Hill, mentioned above. There is no kind of manufacture carried on; but the trade of the place arises from the wants of the neighbourhood, and its situation on a great public thoroughfare. Several genteel families reside in the town; and a mineral spring, Witham Spa, attracted some years since, and perhaps still attracts, visitors in the summer. The church is a tolerably large building, containing some antient monuments. There are places of worship for Independents, Baptists, Quakers, and Catholics; and several almshouses, but none very extensive or richly endowed.

The parish comprehends an area of 3280 acres; and had, in 1831, 552 inhabited houses, and a population of 2735, of which less than a fifth was agricultural. The market is on Tuesday.

The living is a vicarage, in the archdeaconry of Colchester, of the yearly value of 473*l.*, with a glebe-house, in the gift of the bishop of London.

There were, in 1833, fifteen day-schools with 361 children; two boarding-schools with 40 girls; and one Sunday-school with 200 children, and a lending library attached. Of the day-schools, one (for 100 boys and 50 girls) is partly supported by an endowment; another (for 70 girls) partly by voluntary contributions.

Faulkbourne hall, not far from Witham, is an antient manor-house, different parts of which have been erected at very different periods. A tower gateway of curious architecture is supposed to be as old as the time of Stephen.

Beside the above market-towns, there are several villages which are of sufficient importance to call for notice. The following were formerly market-towns, and some of them still retain their place as market-towns in many of our common maps:—Great Bardfield, Brentwood, Dedham, Harlow, Hatfield, Horndon, Ingatestone, Leigh, Thaxted, and Rayleigh.

Great Bardfield is in the half hundred of Froshwell or Freshwell, on the south bank of the Pant or Blackwater, over which it has a strong brick bridge. In the south aisle of the church are some coats of mail, &c., said to have belonged to the Lumley family. The population, in 1831, was 1029, about half of them agricultural. The market has been long given up.

Brentwood is on the road to Chelmsford and Colchester, 18 miles from London and 11 from Chelmsford. Some Roman antiquities have been found in the neighbourhood. The assizes for the county were formerly held here. The place consists chiefly of one main street along the high road, with irregular and mean houses: from its situation on a great thoroughfare, it has many public-houses and inns. There are the remains of the old prison and town-hall, the tenants of which are bound to put them in repair if ever the assizes should be held in the place again. There is an antient chapel in the town (for Brentwood is only a chapelry in the parish of South Weald, and the living a perpetual curacy, worth 124*l.* a year, with a glebe-house, in the archdeaconry of Essex), founded about the year 1227, by the prior of the monastery of St. Osyth, for the tenants of a manor belonging to that monastery: this chapel is a small building, dedicated to St. Thomas à Becket, of whom it contains a rude image carved in wood. There is an endowed school: races are held in the neighbourhood; and at Warley, not far off, are cavalry barracks. The area of the chapelry is 730 acres: the population, in 1831, was 1642. The market has not been discontinued many years. There are two yearly fairs, at which a great number of cattle are usually sold: it is one of the fairs from which the farmers of 'the hundreds' obtain their live stock.

Dedham is in Lexden hundred, on the south bank of the river Stour, just on the right hand of the road to Ipswich and Norwich, about 58 miles from London. In the reign of Richard II. this place was famous as one of the seats of the clothing trade. It is situated in a picturesque valley, and is a small place, consisting chiefly of one street. The church is a large building in the Perpendicular style of English architecture; it has a fine tower at the west end with octagonal turrets crowned with rich pinnacles. There is a bridge over the Stour. The population of the parish, in 1831, was 1770, about half agricultural: many genteel families reside in the place. There is an endowed free grammar school for 40 boys; and an English school, partly endowed, with more than 60 scholars; and a number of private schools. The living is a vicarage worth 170*l.* per annum, with a glebe-house: the rectorial tithes form the foundation of a lectureship connected with the church. The Rev. W. Burkitt, author of a well-known commentary on the New Testament, was lecturer here.

Harlow is in the half hundred of Harlow, just beside the road by Newmarket to Norwich, rather more than 23 miles from town. The village is about a mile from the river Stort. It was formerly the seat of a large woollen manufacture and of a considerable trade. The church is in a central situation, and is of tolerable size: it was originally in the form of a cross, with a central tower rising from the intersection of the transepts: this church was much injured by fire in 1711, and upon its restoration a cupola was substituted for the tower: the church is adorned with much painted glass. There is a place of worship for Baptists, several almshouses, and a charity school.

At Harlow Bury, a mile north of the village, is a large antient chapel, used as a barn or farm-office. It has a fine
P. C., No. 598.

semicircular-headed door, the shafts of which have small capitals like those of the Galilee at Durham. There are some small windows with round heads and others with pointed heads.

The parish of Harlow contains 4490 acres, and had in 1831 a population of 2101, above half agricultural. There are three considerable fairs in the year for horses and cattle; the second, held on Harlowbush Common, two or three miles south of the village, is the most frequented; horses for all purposes, black cattle and other live stock, and wool, are brought for sale, and the fair attracts a concourse of people for fifteen or twenty miles round, and even from the metropolis. The living is a vicarage, of the yearly value of 383*l.*, with a glebe-house, in the archdeaconry of London.

A large sum of money (8000*l.*), bequeathed by Mr. Geo. Fawbert, has been vested in trustees for the establishment of a day school and library at Harlow, and for apprenticing or otherwise advancing in the world those educated at the school.

Hatfield is in the half hundred of Harlow, on the road from London by Harlow to Dunmow, 30 miles from town: it is on the Pincey brook, which flows into the Stort. This place was formerly part of the royal demesne, from which circumstance it obtained one of its distinguishing epithets, Hatfield Regis: its other designation of Hatfield Broad Oak it obtained from a large oak supposed to have flourished here in the Saxon times. A portion of this tree (if we may trust the accuracy of Mr. Arthur Young's statement) was yet remaining in Hatfield Forest, a mile or two north of the town, when that gentleman published his agricultural survey of Essex, in which an engraving of this venerable tree is given. Aubrey de Vere founded, A.D. 1135, a Benedictine priory at Hatfield, supposed to have been at first a cell of the abbey of St. Melanious Redonensis, at Rennes or Rêdon, in Bretagne, but subsequently rendered independent. The possessions of this priory at the suppression were estimated at the yearly value of 157*l.* 3*s.* 2*d.* gross, or 122*l.* 13*s.* 2*d.* clear. The parish, which is very large, had in 1831 a population of 1825, chiefly agricultural. The church has a western tower and a large porch in the Perpendicular style, and other parts are of a character betokening a more antient date. The Methodists have a place of worship. The living is a vicarage, worth 210*l.* a year, with a glebe-house, in the archdeaconry of Middlesex.

Horndon, distinguished from two other parishes of the same name by the epithet 'on the hill,' is in Barstable hundred, and is situated, as its name imports, on an eminence, from whence there is a fine view. The church is in the middle of the town; it has a stone tower, embattled. The parish had in 1831 a population of 511, chiefly agricultural. The market, when Morant published his history of Essex (1768), was very small; it has been since given up. There is one fair in the year, chiefly for wool. It is 27*½* miles from London through Brentwood.

Ingatestone is in the hundred of Chelmsford, and on the road from London to Chelmsford, 23 miles from London. It is supposed to have derived its name from a Roman military stone, and from the Saxon word Ing, a meadow; thus, Ing-atte-stone. The village, which extends into the adjoining parish of Fryerning, consists of a long street along the high road, and a smaller street running out of this to the south-east. From its situation on so great a thoroughfare it abounds with inns. It had formerly a large cattle market, but this is now discontinued: there is a large cattle fair. The church is in the middle of the town, and contains several monuments of the Petre family. There is an almshouse and an Independent meeting-house. Ingatestone Hall, a little way south of the town, was once the seat of the Petre family: it is a very antient and irregular pile. The grounds are well stored with fish-ponds, and the whole was formerly surrounded by a park. The population of the parish, which is small, was in 1831 789, chiefly agricultural; to these we may add perhaps 300 for that part of the village which is in Fryerning parish. It may be observed that the syllable Ing (or Ging, which appears to be a variety of it), which enters into the name Ingatestone, is found in the names of several other parishes or manors in this neighbourhood, as Fryern-ing, Margaret-ing, Mountneys-ing, Ginges-joiberd (commonly called Buttsbury), Ingrave or Ging-ralph, and Trestl-ing or Thrustl-ing; to which we may add Bark-ing.

Raleigh or Rayleigh is in Rochford hundred, 34 miles from London. It was, at the time of the Domesday survey, one of the numerous lordships of Suene, who, having joined the Conqueror at an early period, was allowed to retain his possessions. He built a castle here, of which some earthworks yet remain, consisting of a mound with an oval base, surrounded by a double ditch and embankments. The village stands on an eminence, and has, at the upper end, the church, an edifice principally in the Perpendicular style, with some portions of an earlier date: the tower has a short spire and a staircase turret battlemented. The Baptists have a place of worship here. When Morant wrote, a weekly market was held at Rayleigh: it is now given up. There is a cattle fair. The population of the parish in 1831 was 1339, chiefly agricultural. The living is a rectory of the yearly value of 774*l.*, with a glebe-house, in the archdeaconry of Essex.

Thaxted is in the hundred of Dunmow, 44 miles from London by Harlow, Hatfield Broad Oak, and Dunmow. This is a very antient place, and probably existed in the time of the Saxons. It was incorporated by charter of Philip and Mary, and its government vested in a mayor, bailiffs, and chief burgesses; but the corporation became extinct in the time of James II., the corporate officers having retired from their offices on being served with a *Quo Warranto*. The town is irregularly laid out; its chief ornament is the church, which is in the centre of the town, and is one of the finest in the county. It is mostly in the Perpendicular English style, and consists of a nave and chancel with side aisles, transept, and tower at the west end. The nave is not so wide as either of the side aisles, from which it is separated by eight clustered pillars on each side with pointed arches. The windows are mostly large, and many of them are ornamented with tracery and painted glass, but the latter is much broken and otherwise defaced. The north and south porches are richly ornamented with sculpture. The tower is sustained by buttresses, and is embattled, and terminated with a very rich crocketed spire, supported by flying buttresses. Most of the buttresses of the aisles have fine pinnacles, and are enriched with paneling. The height of the tower and spire is 183 feet, which is also the length of the church: the breadth of the church is 87 feet. It is supposed to have been built in the fourteenth century. There are at Thaxted meeting-houses for Quakers, Independents, and Baptists. There is a free grammar-school, which contained, in 1833, 30 boys on the foundation and 30 others whose education was paid for by their parents. Upon the same foundation 20 girls were educated at another school.

The population of Thaxted parish (which comprehends 5890 acres) was, in 1831, 2293, more than half agricultural. The living is a vicarage, in the archdeaconry of Middlesex, of the yearly value of 450*l.*, with a glebe-house. The market, which had been long disused, was revived about the close of the last century, but was not much attended, and has since been again discontinued. There are two fairs in the year. There are several almshouses in the place, and the benefactions to the poor have been very considerable. Near Thaxted is the antient hall, Horeham-hall, the seat of Sir William Smith: it is a castellated gothic mansion partly covered with ivy.

Beside the above, which have been market towns, there are several other villages which, from their importance, call for notice.

Ashdon, the parish of which, including the hamlet of Bartlow End, had, in 1831, a population of 1103, is in the half hundred of Freshwell, three miles from Saffron Walden. It is supposed by some to have been the scene of a dreadful battle fought between Edmund Ironside and Canute; but the battle was more probably fought at Assingdon in the hundred of Rochford. At Bartlow hills, in the parish of Bartlow, Cambridgeshire, two miles north of Bartlow church, four contiguous barrows have been regarded as the tumuli raised over those who were slain in this battle, but this rests on tradition only.

Brightlingsey (population in 1831 1784) is on the estuary of the Colne, in Tendring hundred. The inhabitants are engaged in the oyster fishery. The parish forms a peninsula, surrounded by the marshes of the Colne and its inlets, except on the north-east side, where is the only entrance to the parish, except by a ford. The church is near this entrance, the village is a mile distant nearer the sea.

Morant speaks of an establishment for preparing copperas here, and the 'copperas house' is marked in the Ordnance Survey. Brightlingsey is a member of Sandwich in Kent, one of the Cinque Ports. The population has nearly doubled within the present century.

Burnham is in Dengie hundred, on the north bank of the estuary of the Crouch, which has here a depth of water sufficient for a ninety-gun ship. It had a good street to wards the river and a commodious quay. The church is nearly a mile from the village. The population, in 1831, was 1393: the inhabitants are engaged in the oyster fishery.

Chigwell lies between Epping and Henhault forests: from Chigwell Row, on the border of the latter, a most extensive view is obtained over the south of Essex and the Thames into Kent. There is an endowed grammar-school which, in 1833, had six scholars, and another endowed school with sixty boys. Population in 1831, 1815.

The Hams are in Becontree hundred, and in the immediate neighbourhood of London. West Ham parish occupies the south-west corner of the county, and is bounded by the Thames and the Lea, by which it is respectively separated from the counties of Kent and Middlesex. It is divided into four wards: All Saints, Church Street, Plaistow, and Stratford. West Ham had formerly a market, the charter for which was procured in the thirteenth century. There was formerly at Stratford Langthorn, in this parish, an abbey for Cistercian monks. The abbey having become dilapidated from the flooding of the marshes, amid which it was built, the monks were removed to Burgestede (now Burstead), near Billericay, until 'one of the Richards, kings of England,' (probably Richard II.) repaired the abbey and brought the monks into it again. In 1307 the abbot was summoned to parliament. At the dissolution the yearly revenues of this house were estimated at 573*l.* 15*s.* 6*d.* gross, or 511*l.* 16*s.* 3*d.* clear. The chief remains now existing of the conventual buildings are a brick gateway, the entrance to the precincts, and an ornamented arch in the Early English style, which appears to have been the entrance to the chapel: they are nearly half a mile south-west of the church. The site of the precincts was moated and contained about sixteen acres. West Ham church consists of a nave and chancel, and side aisles to both: it is large, but not distinguished for its architecture.

Stratford, which is one of the wards of this parish, lies along the road to Romford, Chelmsford, &c., and may be regarded as a prolongation of the suburbs of the metropolis, being joined to it by an almost continuous line of buildings, constituting the village of Bow, and the hamlet of Mile End in Middlesex. A new church has been lately erected here. The Newmarket road branches off from the Chelmsford and Colchester road at Stratford.

The population of West Ham parish was in 1831 11,580, of which less than one-sixth was agricultural. A considerable number of the inhabitants are labourers, employed in the East and West India docks at Poplar and Blackwall. Calico and silk dyeing and printing are extensively carried on: chemicals are manufactured, and porter is brewed. The West Ham water-works supply the eastern suburbs of the metropolis with water. Several of the wealthier inhabitants of London have residences at West Ham.

The living of West Ham is a vicarage, in the archdeaconry of Essex, and in the gift of the crown: its yearly value is 875*l.* There are several dissenting meeting-houses.

There were in this parish in 1833 two infant schools, partly supported by contributions, with 150 children; three endowed day-schools, with 257 children, some of whom were clothed; a national school, partly supported by endowment and subscription, with 50 boys; a school with 40 children, supported by contribution by Roman Catholics; another of 10 children, supported by Dissenters; and another school of 120 children, partly supported by contributions; and four Sunday-schools, with 390 children. There were also many private boarding and day schools, containing 488 children.

East Ham parish joins that of West Ham. The church consists of a nave with two chancels; the upper chancel, which forms the eastern extremity of the church, is semi-circular at the east end, and has narrow pointed windows. Part of the walls of the nave and lower chancel are in the Norman style, as is the lower part of the tower; but the

windows of the nave are of later date, and some of them modern. In the church is a monument of Edmund Nevill, Lord Latimer. Dr. Stukely, the antiquary, is buried in the churchyard, but, at his own desire, without any monument. At Green Street, a hamlet of this parish, is an antient mansion, supposed to have been the residence of the Nevill family. The population of East Ham in 1831 was 1543, chiefly agricultural. There is an almshouse for three poor men, and a place of worship for Wesleyan Methodists.

The Hedinghams are in Hinckford hundred, and on a road branching off from the Bury and Norwich road at High Garrett, two or three miles beyond Braintree, and reuniting with it at Bulmer Tye, a little before it quits this county for Suffolk. They formerly constituted one parish: from the time of Henry III. they appear as two; Sible Hedingham, on the south-west bank of the Colne, 48 miles from town; and Castle Hedingham, on the north-east bank of the river, one mile farther. We subjoin the following particulars respecting them.

Sible Hedingham, area 5490 acres. Population in 1831 2194. Living, a rectory in the jurisdiction of the Commissary of Essex and Herts, concurrently with the consistorial court of the bishop of London, of the yearly value of 905*l.*, with a glebe-house. Castle Hedingham, area 2600 acres. Population in 1831 1220. Living, a donative in the archdeaconry of Middlesex, of the yearly value of 129*l.* The population of these places is more than half agricultural.

Sible Hedingham church is a neat and tolerably spacious building, supposed to have been erected in the reign of Edward III. There was formerly a chantry here, founded by the executors of Sir John Hawkwood, whose monument, now demolished, stood in the church: the house of the chantry priest is still standing; it had been originally built for the reception and entertainment of devout pilgrims, and still retains the name of the hostage. The castle, which gives name to the parish in which it stands, was built by the De Veres, to which family the lordship of Hedingham was given by the Conqueror. Its architecture, which is very similar to that of Rochester Castle, leads to the supposition that it was erected about the same time as that fortress, viz., towards the close of the eleventh or the beginning of the twelfth century. Maud, wife of king Stephen, is said to have died here. In the civil wars of the reign of John, it was held by Robert de Vere, earl of Oxford, for the barons, and was taken A.D. 1216 by the king: it was retaken in the beginning of the reign of Henry III. by Louis, dauphin of France, but recovered by the earl of Pembroke, governor to the young king. In the reign of Henry VII. that prince was sumptuously entertained here by John de Vere, earl of Oxford, who had suffered severely for his attachment to the Lancastrian cause, and had been one of the chief instruments in placing the crown on Henry's head. As the king was departing, he observed that the earl, to do him honour, had put liveries on his retainers, and in return for his hospitality compelled him to compound by a fine of 15,000 marks for breaking a statute, recently passed, forbidding such a practice. The De Veres retained the castle until A.D. 1625. It has since passed through various hands. The keep is the only part remaining; it is one of the finest and best preserved Norman keeps in the kingdom. The walls are above 100 feet high, and from 11½ to 12½ feet thick at the bottom, and from 9½ to 10 feet thick at the top: the eastern wall is at least a foot thicker than the others, having been so built, it is conjectured, in order to withstand the violent easterly winds. The building is a parallelogram, of 55 feet on the east and west sides, and 62 feet on the north and south. At each angle on the top there was formerly an embattled turret; two of the turrets are remaining: the parapet, now destroyed, was also embattled. The castle is built with irregular flints or stones, imbedded in grouting or fluid mortar, and is cased on the outside with squared stone very neatly and regularly put together. It has five stories, including the ground-floor and platform: the principal entrance is on the first story, and on the west side, with a flight of stairs leading up to it: entrances to the ground-floor were made with great labour in 1720 by the proprietor, who wished to convert that floor into an out-house. The whole building is worthy of attention; it has some fine Norman emplacements in the interior. Castle Hedingham church is an antient fabric of stone with brick

battlements, partly in the Norman and partly in the Early English style: the tower is of much later date. In the chancel is a superb, but somewhat mutilated monument of John de Vere, earl of Oxford, who died A.D. 1539. A Benedictine nunnery was founded here by the first earl of Oxford and his wife, A.D. 1190. Its revenues at the dissolution were valued at 29*l.* 12*s.* 10*d.* The nunnery, long since converted into a farm-house, and part of the chapel belonging to it, are yet standing. There was also an hospital for the sick and decrepit poor at Hedingham, attached to which were two or three chaplains with a clerk and servant. This hospital has long been destroyed: it was on the south-east side of the castle.

Leigh is in the hundred of Rochford, about 36 miles from London. The houses are principally arranged in one street running along the foot of an eminence and on the bank of the Thames. The summit of the eminence commands a fine prospect, and is crowned by the church with its ivy-mantled tower, and the manor-house. The population (1254 in 1831) consists chiefly of fishermen. The place has some trade, and there is a small custom-house here. The Wesleyan Methodists have a meeting-house. Some Roman coins have been discovered at Leigh.

Leyton, or Low Leyton, derives its name from the river Lea, near to which it is situated; it is in Becontree hundred, about 5 miles from London. It had in 1831 a population of 3323, of which less than one-third was agricultural. The village contains several residences of London merchants and tradesmen. The church is pleasantly situated, overlooking the marshy valley of the Lea, but possesses no beauty of architecture. Among the tombs in the chancel is that of the historian and antiquary John Strype, who was vicar of the parish for nearly seventy years. Leytonstone is a hamlet of this parish. It was supposed by Camden that Leyton was a Roman station, the Durolitum of Antoninus; but though the name as interpreted by some (according to whom Durolitum signifies 'the water of Ley') gives countenance to the supposition, it does not accord with the distances of the *Itinerary*. Roman and other antiquities have been however found at Leyton in considerable number: such as the foundations of buildings; Roman intermingled with other bricks; a subterranean arched gateway, and steps leading down to it; urns with bones and ashes; wells; a quantity of oak timber mortised together like a floor, grown very hard and black, and of uncertain extent; Roman silver and brass coins, consular and imperial, and some silver coins with Saxon characters. At Ruckholts, or Rockholts, a manor in this parish, are some remains of antient entrenchments, a square double embankment, with an intervening ditch, enclosing a circular embankment, thirty-three yards in diameter, surrounded by a moat; both are much obscured by trees.

St. Osyth is in the hundred of Tendring, 62 miles from London and 11 from Colchester, on the marshy coast at the north-eastern side of the mouth of the Colne. A small creek, or arm of that river is navigable for small boats up to the quays in this parish. The population in 1831 was 1583, chiefly engaged in agriculture. The original name of the place was Chich, and it took its name of St. Osyth from a virgin said to be of royal blood, but whose history involves too glaring an anachronism to be worthy of credit, who founded here a nunnery, afterwards destroyed by the Danes. An abbey for the canons of St. Augustin was subsequently founded here in or before the year 1118, in honour of St. Peter, St. Paul, and the above-mentioned St. Osyth. The yearly value of the revenues of this abbey at the dissolution was 758*l.* 5*s.* 8*d.* gross, or 677*l.* 1*s.* 2*d.* clear. The quadrangle of the antient monastic buildings is almost entire, excepting on part of the north side, where it has been replaced by modern apartments; the entrance is by a beautiful gateway of hewn stone mixed with flint, having two towers and two posterns: the stables and offices on the east and west sides of the court bear marks of great antiquity, and among the ivy-grown ruins of the garden is a pier with a Latin inscription describing the antient magnificence of the place. There are a battery, or martello tower, on the coast in this parish, and a signal station. The church contains several monuments of the D'Arcy family.

Prittlewell is in Rochford hundred, 39 miles from London, on the northern shore of the estuary of the Thames. Milton, now a hamlet of this parish, is said to have been antiently a distinct parish; part of it has been

swallowed up by the sea gaining on the land. Morant, writing near the middle of the last century, says, 'it had a church, or chapel of ease, the remains of which were visible not long ago at low-water mark.' The village consists of two streets, on the slope of a hill, forming a right angle with each other, and having the church at the vertex on the summit of the hill. The church has a nave and chancel, a side aisle running the whole length of the building, and of nearly equal breadth with the nave. There is a fine western tower (in the Perpendicular English style) embattled, with strong buttresses and rich pinnacles: from its height and lofty situation it is a good sea-mark. There was once a priory of Cluniac monks here, cell to an alien priory of the same order at Lewes, in Sussex, but afterwards made independent: its yearly revenue at the dissolution was 194*l.* 14*s.* 3*d.* gross, or 155*l.* 11*s.* 2*d.* clear.

Southend is a hamlet of Prittlewell. It is pleasantly situated on the side of a wooded hill, and is in some repute as a bathing-place. The terrace, in what is commonly called New Southend, or the upper town, is a handsome range of buildings. There are a good hotel, an assembly-room (beside one at the hotel), a theatre, and a library, the last somewhat in the Gothic style. There is an Independent meeting-house. The population of the whole parish of Prittlewell was, in 1831, 2266; nearly half agricultural.

Stansted Montfichet is 32½ miles from London, on the Newmarket road, partly in Clavering half hundred, and partly in Uttlesford hundred. It consists mainly of a long straggling street. The name, Stansted, is supposed to be corrupted from Stone Street, the name of a Roman way, on or near which it stood; the epithet Montfichet was the surname of William Gernon, to whose father the lordship had been given by the Conqueror, and who built a castle here; the artificial mound on which the keep was built yet remains. It may be doubted whether the place took its name from the builder of the castle, or *vice versa*: population in 1831, 1560.

The Sokens, including Kirby le Soken, Thorpe le Soken, and Walton le Soken, are in Tendring hundred: these parishes are for ecclesiastical purposes consolidated, and form a benefice in the diocese of London (exempt from the archdeacon's jurisdiction), of the annual value of 513*l.*, with a glebe-house. The word Soken is derived from the Saxon Soc, or Soca, signifying a peculiar power to administer justice within itself, and likewise the circuit within which such power was exercised. These villages possess some peculiar immunities, to which they owe their designation. They comprehend the promontory of the Naze, which formerly extended much farther to the west, but has been contracted by the encroachment of the sea. Ruins of buildings have been discovered under the water, particularly on a shoal called the West Rocks, nearly five miles from the shore, which is left dry at great ebbs. The spot where the ruins are found is distinguished by the name of The Town. The wall thrown up to keep out the sea gave name to Walton parish. There is a church in each parish; that at Thorpe is the largest. There is also a Baptist meeting at Thorpe, and a customary market is held there on Wednesday evening. Walton having the recommendation of a firm and extensive beach, has been resorted to for bathing by invalids from the eastern parts of Essex. The population of the three parishes in 1831 was as follows:—Kirby 972, Thorpe 1173, Walton 469; total 2614.

Walthamstow, is in Becontree hundred, a little to the left of the Newmarket road, about 6 miles from London, between the marshes of the Lea and Epping Forest. It contains a number of good houses usually occupied by persons engaged in business in London; but Walthamstow is not so much resorted to by these as formerly: its population has therefore diminished. The population in 1831 was 4258; above a third were employed in agriculture. The church possesses no architectural beauty. There are copper and oil mills in the parish. Wanstead, in the same neighbourhood, is a village occupied, like Walthamstow, by persons doing business in London; it is much smaller however, containing in 1831 only 1403 inhabitants. Wanstead House, formerly the seat of Earl Tynney, was one of the finest residences in the county of Essex. It was pulled down a few years since, and the materials sold. The park is let out in portions for grazing of cattle. A tessellated pavement of considerable dimensions, and several other Roman antiquities, were dug up in the year 1735.

Wivenhoe is in Lexden hundred, 4 miles from Col-

chester and 55 from London. It is on the north-east bank of the river Colne, just at the junction of the Roman. The village is on the slope of a hill, and commands a pleasant prospect down the river. Wivenhoe has a commodious quay and a custom-house; it may be considered as the port of Colchester. The population of the parish in 1831 was 1714, of which about one-fourth was agricultural. The living is a rectory, of the yearly value of 371*l.*, with a glebe-house.

Woodford is in Becontree hundred, 8 miles from London on the Newmarket road. It is a long straggling place with a number of good houses, inhabited by merchants and tradesmen from London. The population in 1831 was 2548, of which about one-fourth was agricultural; the number of inhabitants had materially diminished since the previous census. The church is a modern erection, but in the ancient English style. A group of houses about a mile north from the main part of the village takes the name of Woodford Wells, from a mineral spring, now in little repute.

Writtle is a large village, in Chelmsford hundred, about 3 miles west from the town of Chelmsford. It was formerly a market-town, but dwindled as Chelmsford rose into importance. Morant was inclined to place the *Cæsaromagus* of the *Itineraries* here; but there is no proof of its having ever been a Roman station. King John is said to have had a palace here, and a square plot of ground, with a moat round it, in which the foundations of a building were dug up about the middle of the last century, is thought to have been the site of it. The church contains a number of monuments, some of them elaborate and elegant. There was, before the Reformation, a hermitage in this parish, attached to St. John's Abbey, Colchester. The population in 1831 was 2348, nearly two-thirds agricultural.

There are several large villages in Essex beside those already noticed. Four (Dagenham, Finchfield, Hornchurch, and Great Waltham) had, in 1831, above 2000 inhabitants; five others had above 1500; and nineteen others had more than 1000.

Divisions for Ecclesiastical and Legal Purposes.—Essex constitutes the largest part of the diocese of London, which is in the ecclesiastical province of Canterbury; and is divided between the three archdeaconries of Colchester, Essex, and Middlesex. The office of rural dean has been disused for many years; the county is, however, still divided into deaneries, which are thus arranged.

The deaneries of Colchester, Lexden, Tendring, Newport, and Sandford constitute the archdeaconry of Colchester. The deaneries of Barstable, Barking, Chafford, Chelmsford, Dengie, Ongar, and Rochford constitute the archdeaconry of Essex. The deaneries of Dunmow, Harlow, and Heddingham constitute part of the archdeaconry of Middlesex, which extends beyond this county.

The number of benefices we cannot exactly give. The Population Returns for 1831 contain the names of 409 parishes and 4 district chapelries (Basildon, Brentwood, Canvey Island, and Epping), together 413 benefices; but of these three (Bures, Haverhill, and Keddington or Kitton) are mostly in Suffolk; and Ballingdon or Brundon (antiently Berington) is for ecclesiastical purposes united to the parish of All Saints, in Sudbury. The parishes of Bocking, Stisted, Latchingdon-with-Lawling, and Southchurch are in the peculiar jurisdiction of the archbishop of Canterbury. Of the above parishes, 16 are in the borough and liberties of Colchester, 2 in the borough of Harwich, and 3 in that of Maldon.

Morant, in his History of Essex, gives the following as the number of churches and chapels. In the archdeaconry of Colchester, 161; in that of Essex, 175; in that of Middlesex, 83; peculiars 4; total, 423; but this, no doubt, includes chapels of ease, or non-parochial chapels. In Gorton's Dictionary the number of parishes is given at 405, which agrees with the number in the Population Returns, deducting the three which are mostly in Suffolk, and that of Ballingdon, which is ecclesiastically united to a Suffolk parish. Lewis's Dictionary gives the number of parishes at 400, of which 250 are rectories, 134 vicarages, and the remainder perpetual curacies.

Dissenters are numerous in Essex, especially the Independents; nearly all the towns and many of the villages have congregations of this persuasion, and some of the congregations are very large. The Baptists have also many meeting-houses; the Wesleyans, we believe, not so many,

the Quakers have places of worship in several of the large towns.

Essex is in the home circuit. The assizes and quarter-sessions are held at Chelmsford, where is the shire-hall, an elegant structure, and the old county-gaol and house of correction. The new county-gaol is at Springfield, a village about a mile from Chelmsford, on the road to Colchester.

For the election of members of parliament the county was, by the Reform and Boundary Acts, divided into two parts, each returning two members. The northern division comprehends the hundreds or half hundreds of Clavering, Dunmow, Freshwell, Hinckford, Lexden, Tendring, Thurstable, Uttlesford, Winstree, and Witham. Braintree is the chief place of election, and the polling-stations are Braintree, Colchester, Saffron Walden, and Thorpe-le-Soken. The southern division comprehends the hundreds or half hundreds of Barstable, Becontree, Chafford, Chelmsford, Dengie, Harlow, Ongar, Rochford, Waltham, and the liberty of Havering. The chief place of election is Chelmsford, and the polling-places are Chelmsford, Billericay, Romford, Epping, Rochford, and Maldon. The boroughs of Colchester, Harwich, and Maldon continue to return two members each, as before the Reform Act. By the Boundary Act an addition (the parish of Heybridge) was added to Maldon. The boundaries of the other boroughs remain as before. None of the old parliamentary boroughs disfranchised or the new ones created by the Reform Act are in this county. The only change in the number of representatives made by that act was by the division of the county and the consequent addition of two representatives.

History and Antiquities.—In the earliest dawn of the authentic history of our island, Essex was inhabited by the Trinobantes (*Τρινοβαντες*), a powerful tribe whose dominions perhaps extended across the Stort and the Lea into Hertfordshire and Middlesex. At the time of Julius Cæsar's invasion (B.C. 55 and 54), Imanuentius, as he is called in Latin, prince of the Trinobantes, had been slain by Cassivellaunus, the predominating chieftain of a neighbouring tribe, and his son, Mandubratius, had been driven into exile, and had gone as a suppliant to Cæsar in Gaul. Cæsar's success induced the Trinobantes to implore of him the restoration of their native prince; and Cæsar, acting upon the usual policy of the Romans, which was to secure allies in or near the countries which were the objects of their attack, complied with their request. Mandubratius was restored, and afterwards secured in the possession of his throne by an express stipulation in the treaty between Cæsar and his British opponents. The alliance of Rome seems to have promoted the aggrandizement of the Trinobantes: Cunobelin, king of that tribe, was potentate of considerable name, and some coins of his yet extant attest the commencement of civilization and the arts in this county. [BRITANNIA.] Cataractacus (*Καταράκτακος*, Dion.), or, as he is commonly called (after Tacitus), Caractacus and Togodumnus (*Τογόδομνος*, Dion.), sons of Cunobelin, succeeded to their father's power, and had to bear up against the weight of Roman hostility when the invasion was renewed in the reign of Claudius (A.D. 43). After sustaining several severe defeats, the Britons retired into the marshes of Essex, and fighting with the vigour of despair, were enabled for a time to repel their assailants, though with the loss of Togodumnus, one of their leaders. But the arrival of the Emperor Claudius was the signal for the renewal of the attack. The Trinobantes were subdued, and their capital, Camulodunum (*Καμουλοδουνον*, Dion. *Καμουδολανον*, Ptol.), was taken, and subsequently made the seat of a Roman colony, which was however destroyed in the revolt of the Britons under Boadicea, and the Roman garrison slaughtered. The defeat of the ninth legion, which was coming to the relief of the colony, under the command of Cerealis, who escaped with his cavalry to his camp and there stood a siege, added to the exultation of the Britons, who captured Londinium and Verulamium and massacred the inhabitants: but the bloody overthrow of Boadicea by Suetonius (A.D. 61) put an end to their revolts, and decided, though it did not complete, the reduction of South Britain. Several of these events occurred in this county. In the Roman division of Britain, Essex was included in Flavia Cæsariensis.

Mr. Lethieullier (Morant's *Essex*) places the final defeat of Boadicea 'somewhere between Epping and Waltham,

near which a fine camp remains;' but others place it in the fields immediately north of London. [BRITANNIA.]

Several Roman stations were in Essex. Of these the most important is Camulodunum, upon the determination of the site of which depends that of the others. Three sites in this county have been proposed, Walden, Maldon, and Colchester. One antiquary (N. Salmon) places it at Castle Camps, in Cambridgeshire; other opinions, which place it in Yorkshire or in Scotland, may be dismissed at once. For Walden little seems to be urged but the pleasantness of the situation, an attribute which Tacitus ascribes to Camulodunum; for Maldon there appears to be little evidence, except the resemblance of the name and the opinion of Camden; while abundance of Roman antiquities, the pleasantness of its situation, the agreement of its distance from London with that given in the *Itinerary* of Antoninus, and the termination of its name—chester—a usual indication of a Roman station, agree in supporting the claim of Colchester. Perhaps the first part of its name also may be taken as evidence; for although the names of our waters are commonly of British origin, we may suppose that the Colne (whence Colchester) obtained its designation from the Roman *colonia*, which graced its banks.

The two Iters of the Antonine *Itinerary* which connect Camulodunum with Londinium are thus given:—

| Iter IX. à Camuloduno. | | Iter V. à Londinio. | |
|------------------------|------------|---------------------|--------------|
| Canonio | M.P. IX. | Cæsaromago | M.P. XXVIII. |
| Cæsaromago | M.P. XII. | Colonia | M.P. XXIV. |
| Durolito | M.P. XVI. | | |
| Londinio | M.P. XV. | | M.P. LII. |
| | | | |
| | M.P. J.II. | | |

It will be observed that although the distances between Cæsaromagus (the only intermediate station mentioned in both Iters) and Londinium and Camulodunum respectively do not agree, the total distance between the two extremes is the same in both, viz., Millia Passuum LII, about equal to 48 English miles, which is nearly the distance of Colchester from London in a straight line, and it is known that the Roman roads were commonly straight. The distances given in Iter IX, which we take to be the most correct, will agree tolerably well with the positions assigned to the other stations in the map of antient Britain, published by the Society for the Diffusion of Useful Knowledge, viz., Durolitum, near Romford; Cæsaromagus, near Widford, a village about a mile south-west of Chelmsford; and Canonium, near Kelvedon. If these positions are fixed with tolerable approximation to accuracy, the Roman road must nearly have coincided with the modern road from London to Colchester, which is probable.

It is supposed however to have crossed the Lea at Oldford, not Stratford; but this seems doubtful; possibly there were two branches of the road, one passing at each place. The positions assigned to these stations in Morant's *Essex* agree with those in the Society's map, except that Durolitum is placed below Brentwood, and Cæsaromagus at Chelmsford, or rather Writtle, which is a mile or two west of it, and not far from Widford. Another station of the Antonine *Itinerary*, Ad Ansam, was probably on the border of the county, perhaps at Stratford, just across the Stour, in Suffolk. It is given as distant from Camulodunum M.P. VI, which accords very well with Stratford.

A Roman road, the line of which is still visible in many places, crossed the county from Bishop Stortford, in Herts, by Dunmow, Raine Hall, Coggeshall, and other places, to Colchester. A record of the time of John describes this as 'calcea quæ tendit de Sterteford versus Colcestr.'

Roman antiquities have been dug up in many parts of the county, but especially at Colchester, where urns, pavements, and medals have been found in great abundance, and almost every antient building shows a greater or less proportion of Roman materials worked up in its walls. Round Colchester are the remains of intrenchments and other military works. Tesselated pavements and other antiquities have been discovered on Mersey Island, which Morant supposes to have been the residence of a Roman functionary, the 'Comes Littoris Saxonici,' or count of the Saxon shore. Roman remains have also been found at Wanstead; at Canewdon, not far from Rochford; at Coggeshall; at Toppesfield, not far from the Heddinghams; at Ridgwell, in the same part of the county, near which a

Roman road was formerly visible; at Watsoe bridge, between Birdbrook and Steeple Bumpstead parishes, near the Stour, where is a Roman camp; and at Great Chesterford (near Saffron Walden), which was undoubtedly the site of a Roman station. Antiquaries have sought to identify this station with the *Camboricum* or *Iciani* of Antoninus; but it is very difficult to reconcile its site with the distances of the *Iter v.* of Antoninus, in which it is mentioned.

Colchester appears to have been, in the latter period of the Roman dominion, the seat of a bishop's see. Adelfius, the bishop of Colchester, assisted at the councils of Arles, A.D. 314; Sardica, A.D. 347; and Ariminum, A.D. 359.

When the Saxons established themselves in Britain, Essex, with some parts of Hertfordshire and Middlesex, constituted a small kingdom, the possessors of which were, from their relative situation, called the East Saxons; from them the county has derived its present designation. Middlesex also, it may be observed, owes its name to its situation between the East and West Saxons; although it never had the rank of an independent kingdom.

Essex, according to Morant, was part of the territory extorted from Vortigern or Gwrtheyrn (A.D. 477) by Hengist, a chieftain whose fame, like that of other heroes in semi-fabulous periods, seems to have been augmented by the achievements and acquisitions of others of inferior reputation. Mr. Turner (*Hist. of Anglo-Saxons*), with better judgment refers the foundation of the kingdom of Essex to a later period (A.D. 530), and to a leader, whose name he does not give, but who is elsewhere called Erchenwin. Morant supposes this Erchenwin to have revolted from under the weak government of Octa, king of Kent, without, so far as appears, any reason except that he had originally included Essex in the conquests of Hengist, and therefore in the kingdom of Kent. This kingdom of Essex gradually extended across the Lea into Middlesex and Hertfordshire, and comprehended London, then a flourishing trading place, and which appears to have become the capital of the East Saxon kingdom. The successor of Erchenwin was Sleda, and the successor of Sleda Sæbyrht or Sabert. The latter was the nephew of Æthelbyrht or Ethelbert, king of Kent, the first of the Saxon princes that embraced Christianity, and was in subjection to his uncle, at that time the most powerful of the Anglo-Saxon kings. Sæbyrht embraced Christianity; the episcopal church of St. Paul in London was founded by Æthelbyrht, and Mellitus, who had been sent from Rome to assist the missionary St. Augustin in evangelizing England, was appointed bishop of Essex, into which kingdom he had been sent as missionary by Augustin. Sæbyrht himself founded the abbey and church of Thorney, afterwards called, from its situation with respect to St. Paul's, West Minster (A.D. 604-611). We notice these events because, though not immediately connected with the county of Essex, they are among the most important occurrences in the scanty annals of the East Saxon kingdom.

Upon the death of Sæbyrht (A.D. 616), Saxred, Siward, and Sigebriht ascended the throne, and reigned conjointly: they restored Paganism and persecuted Christianity, and appear to have been killed together about A.D. 623. Sigebriht the Little reigned after them from A.D. 623 to 653; and after him reigned Sigebriht or Sigeberht the Good, who, being converted by his friend Oswy, king of Northumberland, whom he used frequently to visit, and baptized by Finan, bishop of Lindisfarne, restored Christianity in Essex, and sent for some Northumbrian monks to come and instruct his subjects. Cedd, one of these, was consecrated bishop of the East Saxons (A.D. 653). Sigebriht was assassinated two years afterwards (A.D. 655). The subsequent kings of Essex were as follows:—Swithelm, Sibbi, and Sighere; the latter died A.D. 683, and Sibbi turned monk A.D. 694: Sigehard and Senfrid: Offa, who went to Rome, and turned monk, A.D. 707: Suebriht, called Selred by some, but erroneously: Swithred was reigning A.D. 758. There were a few others, whose very names are unknown. The dates are from Morant chiefly, but in so uncertain and confused a period they cannot be relied on as very exact.

In A.D. 823, Egbert of Wessex, who had just gained over Beornwulf of Mercia that victory which established the permanent supremacy of Wessex over the other kingdoms of the Octarchy, despatched his son Ethelwulf and the war-

like statesman Ealstan or Alstan, bishop of Sherbourne, into Kent and Essex; and these kingdoms, which had sunk into mere dependencies of Mercia, were subdued, and probably united under the designation of the kingdom of Kent, occupied by Ethelwulf as subordinate to his father, and of which mention is occasionally made in the history of Ethelwulf and his sons, until the reign of Alfred, by whom the Saxon kingdoms were finally incorporated; and England, with the exception of those parts which were occupied by the Danes or retained by the Britons, was consolidated under one sceptre.

When Alfred, after the recovery of his throne, assigned to the piratical Northmen, or Danes, a settlement in and about East Anglia (A.D. 878), Essex was included in the ceded territory. One or two of the naval conflicts between the ships of Alfred and those of the piratical Danes who continued to infest the coast, were fought off the Essex shore. Thirteen or sixteen sail of Danish vessels were destroyed in the mouth of the Stour, near Harwich (A.D. 884); but the victorious fleet was destroyed near the Thames mouth by some ships fitted out by the colonists of East Anglia in violation of their engagements with the king. On the death of Godrun (A.D. 890) Essex returned under the government of Alfred, who appointed Berthelolf earl of the county. When Hastings invaded England, A.D. 894, and the main part of his army had been defeated at Farnham, in Surrey (A.D. 894), part of the fugitives escaped over the Thames and marched across Middlesex and Essex pursued by Alfred, until they crossed the Colne and found refuge either in Mersey Island (Turner), or more probably in the peninsula of Brightlingsea (Breklesey, Speed, Morant), where some of their ships had come, and where the king had not any navy at the time to press the siege. Alfred in person, and afterwards when he was called away, his generals, maintained a close blockade on the land side, and at last the Danes sued for peace and agreed to retire from England; but instead of doing so, they hastened to join Hastings, who, with another part of his forces had, in the mean time, landed at South Bemfleet, or Benfleet, in Essex, on the estuary of the Thames, and built a fort there. In the absence of Hastings, the Londoners and the troops who had blockaded Mersey, stormed his fort, took his wife and two of his children prisoners, recovered a quantity of plunder, and broke up and burned many of his ships, or carried them away to London and Rochester. The wife and children of Hastings were loaded with presents by Alfred and sent back to the piratic chief; but his hostility was not thereby softened. He erected another fortress (of which large traces appear still to remain) at South Shoebury, in Essex, a few miles from his former one. With his main army he crossed the island to the Severn; but was compelled to return with baffled and weakened forces. Before the winter came on he assembled another army, and marched to Chester and into North Wales; but being every where watched by the vigilance of Alfred, he marched back through Northumberland and Mercia to Mersey Island, in Essex, the coast of which he always chose for his strongholds, and in which he seems to have wished to establish a kingdom. Ultimately the Danish chief was compelled to abandon England after three years of incessant hostility (A.D. 894—896), and Essex returned peaceably under the West Saxon sway.

After the death of Alfred (A.D. 901), and the choice of Edward the Elder as his successor, Æthelwald, or Ethelwold, son of Ethelbriht or Ethelbert, Alfred's elder brother, claimed the throne, and having taken to a piratical life, and obtained foreign aid, returned and subdued Essex. The subsequent death of the invader in battle (A.D. 905) put an end to the strife, and restored Essex to the sway of Edward, who subsequently rebuilt or fortified Witham (A.D. 913), in order to bridle the rebellious temper of the Danish colonists; and some years after (A.D. 920) fortified Maldon. In A.D. 921 he took by storm Colchester, which the Danes, with whom he was now at war, had held, and strengthened the place by repairing the fortifications; he also defeated an attack of the Danes upon Maldon.

In A.D. 991, in the reign of Ethelred II., Essex was again the object of Danish attack. A large force landed and attacked Ipswich, in Suffolk, and marching from thence to Maldon, defeated and slew the governor, or earl of the county, who had collected some forces to oppose them; they were bought off by the payment of a large sum. In

A.D. 994 the coast of this county was ravaged by them; they were again bought off. Essex was one of the counties ceded by Ethelred to Svein, king of Denmark, by treaty A.D. 1010 or 1011.

In A.D. 1016 Essex was the scene of a fierce battle between Canute and Edmund Ironside, who had succeeded to the thrones and the hostility of their respective fathers, Svein and Ethelred. Canute, by the treachery of Edric (brother-in-law and foster-father to Edmund), obtained the victory. The battle was fought at Assandun, which some suppose to be Ashdon, in the north-western part of the county, near Saffron Walden; others, with more probability, fix the scene of conflict at Assingdon, or Ashingdon, in the hundred of Rochford. At Canewdon (the name of which is probably derived from that of the victor), a parish which adjoins Assingdon on the east, are the remains of a camp, supposed to have been that of the Danes; its form is oblong, and it comprehends an area of about six acres: the vallum has been levelled, but the fosse is yet visible. (*Beauties of England and Wales.*)

The history of the county is not marked by any particular event until the civil war between king John and his barons. In A.D. 1215 the earl of Winchester, one of the confederated lords, with an army of foreigners whom he had brought into the country, besieged Colchester castle, but withdrew upon hearing that relief was coming from London. However, he or some of his party soon afterwards took it and plundered the town. The king however retook it after a few days' siege. During the minority of Henry III. Colchester fell into the hands of the Dauphin Louis (A.D. 1218), who had been invited over by the discontented nobles. At the siege of Calais by Edward III. Colchester furnished five ships and 170 mariners.

In the reign of Richard II. occurred the arrest of Thomas of Woodstock, duke of Gloucester, the king's uncle, who was at the time residing at his castle of Pleshy in Essex, about 6 miles north-west of Chelmsford. There the king visited him, and at the close of his visit invited him to return to town. At Stratford the king had placed in ambush the earl marshal and his followers, who arrested the duke on a charge of high treason. he was subsequently smothered at Calais, and his body being brought to England was buried in the church of Pleshy, which he had himself founded.

Of the troubled period to which the above incidents may be referred Essex contains several memorials in the encampments, castles, and other ruins which are found in it. Various camps may yet be traced referrible to the British, Roman or Saxon periods, as that which incloses the village of Danbury (Danes-byrig), on a high hill between Chelmsford and Maldon; those at Maldon (probably the work of Edward the Elder), at Witham, at Ambresbury banks, near Epping, at Ruckholt, near Barking, at South Weald, near Brentwood, at Canewdon, and at Blunt's walls near Billericay. Many of these have been already mentioned. Of the castles of the Norman period there are also several remains. Those at Colchester, Hedingham, Walden, Ongar, and Raleigh, have been noticed in this article or under their respective heads. Pleshy was the site of a Roman camp or station, and some Roman antiquities have been found at it. The castle was probably built by William de Magnaville, to whose father, Geoffrey de Magnaville, the place had been granted by the usurper Stephen. The keep with the moat which surrounded it were within the Roman intrenchment: the mound on which the donjon was built, and the bridge which led to it over the surrounding moat, are all that remain of the once proud structure. Of Hadleigh Castle, near Raleigh, dilapidated portions of two towers yet remain, forming picturesque masses of ruin. At Clavering in the north-west part of the county are the mound on which the keep stood and the moat of a castle, long since destroyed.

Of the halls and manor-houses which succeeded the Norman castles and gave indication of a quieter period, though showing by their massive strength that the nation had not quite settled into peaceful security, may be mentioned Heron Hall, near East Horndon, Nether Hall, near the confluence of the Lea and the Stort, Tolleshunt Beckingham or Tolleshunt Magna, between Maldon and Colchester, Laver Marney Hall, in the same neighbourhood, Belhus or Bellas House, near Purfleet, Covey or Covell Hall, near White Roding, Eastbury, near Barking, Dan-

bury Place, between Chelmsford and Maldon, New Hall, near Chelmsford, and Toppinghoe Hall, between Chelmsford and Witham. Of Heron Hall two picturesque round towers remain; and of Nether Hall, a vast gateway with two half hexagon towers, one on each side, so massive as to prevent their destruction when the rest of the mansion was pulled down, about A.D. 1773. Of Tolleshunt manor-house there remains an ancient brick gateway, with four embattled turrets. Of Laver Marney Hall, the gateway and part of the south side are yet standing, and are converted into a farm-house and offices: it was originally a large quadrangular building, inclosing a spacious court, to which the existing gateway was the principal entrance. Of Covey Hall there remains a gateway of brick, much ornamented. The other houses are, we believe, entire, except New Hall, of which however a large portion remains, formerly occupied by some English nuns from Liege, who took refuge in England from the French Republican armies. Other ancient houses have been already noticed in the course of this article, and we have only further to mention Gosfield Hall, near Halsted, which belongs to the duke of Buckingham, and is probably of the time of Henry VII. This mansion is of brick, and incloses a quadrangular court, into which all the lower tier of windows formerly opened. There were no outside windows on the ground-floor, and those of the upper story were strongly barricaded, so as to give to the place considerable strength. The house as originally built consisted of only one room in thickness, and there was no communication round the inside but by passing through every room; but various improvements and additions have been made in modern times. There are a few good pictures, the rest have been removed to Stow, another mansion of the duke. The park is extensive.

At the Reformation Essex possessed several religious houses, of which there are some remains. There were at the time of the Suppression seven of the greater monasteries, that is, of those which according to the valuation of their lands and endowments possessed a clear yearly revenue of above 200*l.*; they were as follows:—

| Place. | Description. | Yearly revenue. | | | |
|-----------------------|------------------------------|-----------------|----|---------|-----------------|
| Berking (Barking) | Abbey for Benedictine nuns | £1084 | 6 | 2 gross | £863 12 5 clear |
| Chich (or St. Osynth) | Abbey for Augustinian canons | 758 | 5 | 8 | 677 1 2 |
| Coggeshall | Abbey for Cistercian monks | 998 | 8 | 0 | 251 2 0 |
| Colchester | Benedictine Abbey | .. | .. | .. | 523 17 0 |
| Stratford Langthorne | Abbey for Cistercian monks | 573 | 15 | 6 | 511 16 3 |
| Walden | Abbey for Benedictine monks | 406 | 15 | 11 | 379 18 1 |
| Waltham | Abbey for Augustinian canons | 1079 | 12 | 1 | 900 4 3 |

For any further particulars of these see above, or in the articles BARKING and COLCHESTER.

Of the smaller religious houses, the following remains may be noticed in addition to such as have been already mentioned.

The remains of Bileigh or Beleigh Abbey, near Maldon, have been converted into a farm-house and offices; the chapel, the most perfect portion, having been used as a hogsty. It is small, 36 feet long by 18 broad, formed of a fine-grained limestone, and has groined arches, supported by three slender Purbeck columns. These ruins are chiefly in the Perpendicular style, with some portions of earlier date.

Of Tilney priory, between Dunmow and Thaxted, the east end of the church remains, and is now used as the parish church: there are also a few of the cloisters yet standing. The church is a remarkably fine specimen of decorated work, with bold buttresses at the eastern angles, and two rich niches for statues. The east window is very fine, ornamented with tracery, and in the interior of the church are some rich stalls.

Of Byoknacre Priory, between Chelmsford and Maldon, the central arches of the church and a small portion of the ancient wall remain. They are of very late Norman or Early English character. Of Latton Priory, near Harlow, there are some remains used as a barn; they show that the building contained some good Decorated work. Of Lees Priory, between Chelmsford and Braintree, there is a gatehouse, with an embattled octangular tower at each corner, of Perpendicular character. Of Thoby Priory, between Brentwood and Ingatestone, there are some slight remains. The churches of Blakemore or Blackmore Priory, between

Ingatstone and Ongar, and of Hatfield Peverel Priory, between Chelmsford and Witham, have been made parochial: the latter has been much altered; it retains a good Norman door, with zigzag mouldings.

Of the early churches, beside those which we have already had occasion to mention, the following deserve notice—Greenstead church, near Ongar, is a very curious edifice, and one of the most antient in the kingdom: it seems probable that it was built as a sort of shrine for lodging the body of St. Edmund, king of East Anglia, on its being taken back from London to Bury St. Edmund's, in the early part of the eleventh century; and that it was afterwards enlarged to serve as a parish church. The nave is entirely composed of wood, the sides being formed of the trunks of large chestnut-trees (or oaks) split or sawn asunder, and set upright close to one another. They are let into a wooden sill at bottom, and into a plate at top, and secured with wooden pins: two vacancies are filled up with plaster. There is a boarded tower at the west end, but this does not appear to be so antient as the nave: also a wooden porch on the south side of the nave. The chancel is partly of brick, and the nave is strengthened by brick buttresses. The entire length of the original or wooden part of the church is 29 feet long by 14 broad, and 5½ high to the spring of the roof, which is tiled, and not so antient as the sides. 'Little Maplestead church (near Halsted) is a building of great interest, being the latest of the few round churches in the kingdom; it is of pure Decorated character, and its details plain, but very good.' The chancel end of this church is also semicircular, and is probably the latest erection of that form in England. The diameter of the circular part is about 26 feet (or 30 feet according to others); it has a peristyle of six clustered columns, supporting pointed arches: the whole length of church and chancel is about 60 feet. South Ockendon church, near the Thurrocks, has a round tower, such as may be commonly seen in Norfolk, but not much elsewhere: it has an elaborately and variously enriched Norman door: Corringham and some other churches have Norman portions.

When the Catholic religion regained a temporary pre-dominance over the Reformation under Mary I., the persecution was very severe in Essex. Seventeen persons (five of them women) were burnt at Colchester, and one died in prison; and two persons (one a woman) were burnt at Stratford.

The year 1571 was remarkable for the settlement of the Flemish refugees at Colchester; they introduced the woollen manufacture into that and several other towns in Essex.

When the Spaniards were expected to attack England with their Invincible Armada (A.D. 1588), a camp was formed at Tilbury, where a body of more than 18,000 men, under the earl of Leicester, was posted. Tilbury Fort was then a block-house, which had been built by Henry VIII. to defend the passage of the river; it was at a subsequent period (upon the alarm caused by the Dutch sailing up the Medway, A.D. 1667, and burning the ships at Chatham), enlarged and made a regular fortification, as it is at present. The camp at Tilbury was visited by Elizabeth, whose presence increased the general enthusiasm. Colchester on this occasion furnished two ships and a pinnace to the English fleet. In 1595 the same town furnished three ships for the expedition to Cadiz.

In the war with Spain at the beginning of the reign of Charles I., a Spanish fleet caused alarm by appearing off Harwich; but they made no attempt to land (A.D. 1625). In the civil war at the close of the same reign, Essex was almost entirely in the interest of the parliament, and joined in an association for mutual aid and succour with the other eastern counties of Norfolk, Suffolk, Cambridge, and Herts; this was called the Eastern Association. The towns of Essex and Suffolk, upon a requisition from the committee of both houses, raised 2000 men for the service of the parliament, besides large supplies both of men and money which they sent to the parliament at other times. The county appears to have been exempt from the immediate sufferings of the civil war during the continuance of the main contest; but in the year 1648 it was the scene of one of those isolated and abortive attempts of the royalists, the narratives of which form so many episodes in the great history of the war. A part of the royalist forces, which had been raised in Kent under Goring, earl of Norwich, and

Sir William Waller, and were pressed by Fairfax and the parliamentary army, crossed the Thames into Middlesex, and retreating thence into Essex, were joined by the royalists of that county (who had previously seized the parliamentary committee at Chelmsford) and by some royalist gentlemen from Hertfordshire. Their leaders were the earl of Norwich, Lords Loughborough and Capel, Sir Charles Lucas, Sir George Lisle, Sir Bernard Gascoigne, Sir William Campian, Sir William Compton, Sir William Leyton, Sir Richard Hastings, and many other officers and gentlemen. They retired first to Chelmsford, from thence to Braintree, taking in their way Lees House, the seat of the earl of Warwick, and from thence to Colchester, which they entered by convention, after a slight skirmish with the townsmen. To this place Fairfax with his army advanced in pursuit of them, and made a desperate attempt to storm the town. The royalists repulsed him, but with the loss of one of their men of note, Sir William Campian, and nearly 200 men killed and wounded. The Parliamentarians' loss was probably nearly 1000 killed, wounded, and taken. Fairfax now laid close siege to the town, which was blocked up on every side; and two small frigates of ten and eleven guns, which lay in the river to assist the king's party, were taken by some parliamentary vessels from Harwich. After a siege of between two and three months and several severe actions, the royalists were forced to surrender at discretion. The parliamentary general, deeming it necessary to make an example of the leaders of this rising, and being sanctioned by the determination of a council of war, ordered Sir Charles Lucas, Sir George Lisle, Sir Bernard Gascoigne, and Colonel Farre to be executed the day the town was given up. Farre had escaped; Gascoigne, who was a Florentine, was reprieved; but the other two were shot under the walls of Colchester Castle.

In A.D. 1665 and 1666 Colchester suffered severely from the plague. In the abovenamed years 4731 persons died of it: nearly 200 of them in one week. In A.D. 1684 the charter of Colchester was surrendered to the crown, and a new charter granted the same year, which was remodelled by James II. A.D. 1688; but after the Revolution the original charter was restored.

The history of the county presents no later events of any interest.

(*Morant's History of Essex; Beauties of England and Wales; Ordnance Survey of Essex; Conybeare and Phillips's Outlines of the Geology of England and Wales; Young's Agriculture of Essex; Rickman's Gothic Architecture; Turner's Anglo-Saxons; Excursions in Essex; Parliamentary Papers, &c.*)

STATISTICS.

Population.—Essex is an agricultural county, and but few of its inhabitants are engaged in manufactures. Of 79,023 males twenty years of age and upwards, living in the county in 1831, 43,683 were engaged in agricultural pursuits, and only 871 in manufactures or in making manufacturing machinery. Of these latter 500 were employed in the manufacture of silk goods, principally at Braintree, Great and Little Coggeshall, and Bocking; at Halsted there were 59 silk-machine makers; about 30 men were engaged in the manufacture of gunpowder at the government establishment at Waltham Abbey. At West Ham, in the vicinity of the metropolis, operative chemistry gives employment to several of the inhabitants. Essex ranks the eighth on the list of agricultural counties, and in this respect retains the same position as in 1811.

The population of this county at each of the four periods in which the census was taken during the present century was—

| | Males. | Females. | Total. | Incr. per cent |
|------|---------|----------|---------|----------------|
| 1801 | 111,356 | 115,081 | 226,437 | |
| 1811 | 124,839 | 127,634 | 252,473 | 11.49 |
| 1821 | 144,909 | 144,515 | 289,424 | 14.63 |
| 1831 | 159,015 | 158,492 | 317,507 | 9.50 |

Showing an increase between the first and last periods of 91,070, or a little more than 40 per cent., which is 17 per cent. below the whole rate of increase throughout England.

The following table is a summary of the population, &c., of every hundred as taken in 1831:—

| HUNDREDS, &c. | HOUSES. | | | | OCCUPATIONS. | | | PERSONS. | | | |
|--------------------------------|------------|-----------|------------|--------------|---|---|--|----------|----------|---------|----------------------------|
| | Inhabited. | Families. | Buildings. | Uninhabited. | Families chiefly employed in agriculture. | Families chiefly employed in trade, manufactures, and handicraft. | All other families not comprised in the two preceding classes. | Males. | Females. | Total. | Males twenty years of age. |
| Barstable | 2,247 | 2,614 | 4 | 59 | 1,815 | 502 | 297 | 7,019 | 6,162 | 13,181 | 3,521 |
| Becontree | 6,118 | 7,197 | 51 | 358 | 2,312 | 2,239 | 2,646 | 16,609 | 18,315 | 34,924 | 8,020 |
| Chafford | 1,784 | 1,992 | 13 | 40 | 989 | 603 | 400 | 5,092 | 4,896 | 9,988 | 2,726 |
| Chelmsford | 4,916 | 5,648 | 32 | 138 | 2,892 | 1,838 | 918 | 13,900 | 13,279 | 27,179 | 7,156 |
| Clavering | 809 | 870 | 8 | 17 | 612 | 149 | 109 | 2,044 | 2,018 | 4,062 | 1,013 |
| Dengie | 1,609 | 1,949 | 6 | 36 | 1,345 | 404 | 200 | 5,184 | 4,731 | 9,915 | 2,608 |
| Dunmow | 2,367 | 2,663 | 7 | 36 | 1,781 | 521 | 361 | 6,538 | 6,253 | 12,791 | 3,307 |
| Freshwell | 1,332 | 1,488 | 19 | 21 | 1,079 | 266 | 143 | 3,445 | 3,362 | 6,807 | 1,761 |
| Harlow | 1,365 | 1,682 | 1 | 26 | 1,052 | 333 | 297 | 3,933 | 3,863 | 7,796 | 1,974 |

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of

| £. | £ s. d. |
|--|---------|
| 1801 were 137,140, being 12 1 for each inhabitant. | |
| 1811 " 312,230 " 1 4 8 " | |
| 1821 " 254,837 " 17 7 " | |
| 1831 " 272,593 " 17 2 " | |

The sum expended for the same purpose in the year ending March, 1836, was 185,394*l.* 1*s.*; and assuming that the population had increased at the same rate of per centage since 1831 as in the ten preceding years, the above sum gives an average of 11*s.* for each inhabitant. These averages are above those for the whole of England and Wales.

The sum raised in Essex for poor-rate, county-rate, and other local purposes, in the year ending the 25th of March, 1833, was 311,961*l.* 18*s.*, and was levied upon the various descriptions of property as follows:—

| | £. | s. |
|---|---------|----|
| On land | 251,571 | 18 |
| Dwelling-houses | 52,157 | 2 |
| Mills, factories, &c. | 6,859 | 2 |
| Manorial profits, navigation, &c. | 1,373 | 16 |

The amount expended was:—

| | £ | s. |
|--|---------|----|
| For the relief of the poor | 265,629 | 6 |
| In suits of law, removal of paupers, &c. | 8,190 | 5 |
| For other purposes | 39,928 | 3 |
| | 313,747 | 14 |

In the returns made up for subsequent years, the descriptions of property assessed are not specified. In the years 1834, 1835, and 1836 there were raised 291,010*l.* 2*s.*, 260,424*l.* 5*s.*, and 228,811*l.* 19*s.*, respectively, and the expenditure of each year was as follows:—

| | 1834. | 1835. | 1836. |
|---|-------------|-------------|-------------|
| For the relief of the poor | £320,946 7 | £310,045 16 | £185,394 17 |
| In suits of law, removals, &c. | 6,898 3 | 7,318 13 | 8,444 9 |
| Payment towards the county-rate | 39,484 9 | 18,283 14 | 17,470 10 |
| For all other purposes | | 23,716 5 | 30,700 7 |
| Total money expended | £367,328 19 | £359,384 8 | £239,010 3 |

The saving effected in the whole sum expended in 1836, was compared with that expended in 1834, was therefore P. C., No. 599.

about 20 per cent.; and the saving effected on the sum expended for the relief of the poor was not quite 23 per cent. in 1836, as compared with the expenditure in 1834.

The number of turnpike trusts in Essex, as ascertained in 1834, is 11; the number of miles of road under their charge is 249; the annual income in 1834, arising from the tolls and parish composition, was 34,504*l.* 15*s.* 1*d.*, and the annual expenditure 39,557*l.* 12*s.* 4*d.*

The county expenditure in 1834, exclusive of that for the relief of the poor, was 18,847*l.* 10*s.* 6*d.*, disbursed as follows:—

| | £. | s. | d. |
|--|--------|----|----|
| Bridges, buildings, and repairs, &c. | 728 | 2 | 0 |
| Gaols, houses of correction, &c., and maintaining prisoners, &c. | 10,311 | 17 | 2 |
| Shire halls and courts of justice—building, repairing, &c. | 245 | 9 | 8 |
| Prosecutions | 2,382 | 13 | 8 |
| Clerk of the peace | 1,385 | 7 | 4 |
| Conveyance of prisoners before trial | 758 | 5 | 1 |
| " of transports | 297 | 7 | 0 |
| Vagrants—apprehending and conveying | 315 | 18 | 0 |
| Constables—high and special | 562 | 6 | 2 |
| Coroner | 345 | 17 | 6 |
| Miscellaneous | 1,524 | 7 | 11 |

Total 18,847 10 6

The number of persons charged with criminal offences, in the three septennial periods ending with 1820, 1827, and 1834, were 1908, 2686, and 3837 respectively; making an average of 273 annually in the first period, of 384 in the second period, and of 578 in the third period. The number of persons tried at quarter-sessions, in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county-rates, were 386, 35*r.*, and 398 respectively. Among the persons charged with offences, there were committed for—

| | 1831. | 1832. | 1833. |
|------------------------|-------|-------|-------|
| Felonies | 293 | 319 | 321 |
| Misdemeanors | 93 | 32 | 77 |

The total number of committals in each of the same years was 407, 445, and 460 respectively.

| | 1831. | 1832. | 1833. |
|--------------------------------------|-------|-------|-------|
| The number convicted was | 323 | 315 | 337 |
| " acquitted | 52 | 59 | 72 |
| Discharged by proclamation | 32 | 71 | 81 |

In 1836 at the assizes and sessions 619 persons were charged with crimes in Essex. Of these 49 were charged with offences against the person, 31 of which were for common assaults; there were 74 offences against property, committed with violence; and 442 committed without violence; 1 for sending threatening letters; 8 for forging and uttering false money; 1 for killing cattle; 2 for deer stealing; and 42 for riot. Of the whole number of offenders, 446 were convicted, 123 were acquitted, and against 51 no bill was found, or no prosecution ensued. Of those convicted, 20 were condemned to death, none of whom were executed, 17 had their sentence commuted for transportation, and three for imprisonment; 133 were sentenced to transportation for various periods; 279 to imprisonment, 235 of whom for only six months or under; 2 were whipped; 5 were fined, and 6 discharged on sureties. Of the number of offenders, 547 were males and 72 females; 293 could neither read nor write; 283 could read and write imperfectly; 31 could read and write well, and only 1 had received superior instruction; the state of instruction of the remaining 11 could not be ascertained.

The number of persons qualified to vote for the county members of Essex is 11,119, being 1 in 29 of the whole population, and 1 in 7 of the male population, twenty years of age and upwards, as taken in 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 159*l.* 5*s.* 9*d.*, and were paid out of the general county-rate.

There are fifteen savings' banks in Essex. The number of depositors and amount of deposits on the 20th of November were:—

| | 1832. | 1833. | 1834. | 1835. | 1836 |
|----------------------|----------|---------|---------|---------|---------|
| Number of depositors | 8086 | 8535 | 9051 | 9390 | 9827 |
| Amount of deposits | £268,333 | 277,754 | 289,767 | 302,061 | 312,386 |

The various sums placed in the savings' banks in 1835 and 1836 were distributed as under:—

| | 1835. | | 1836. | |
|-------------------|-------------|-----------|-------------|-----------|
| | Depositors. | Deposits. | Depositors. | Deposits. |
| Not exceeding £20 | 5734 | £37,301 | 5388 | £38,307 |
| " 50 | 2375 | 73,299 | 2495 | 76,480 |
| " 100 | 1150 | 78,931 | 1204 | 83,189 |
| " 150 | 416 | 50,139 | 406 | 49,270 |
| " 200 | 221 | 37,734 | 243 | 41,534 |
| Above 200 | 94 | 24,657 | 91 | 23,606 |
| | 9390 | 302,061 | 9827 | 312,386 |

Education.—The following summary is taken from the parliamentary returns on education, made in the session of 1835:—

| | Schools. | Scholars. | Total. |
|---|----------|-----------|--------|
| Infant schools | 88 | | |
| Number of infants at such schools; ages from 2 to 7 years:— | | | |
| Males | | 684 | |
| Females | | 756 | |
| Sex not specified | | 932 | |
| | | | 2,372 |

| | | | |
|---|------|--------|--------|
| Daily schools | 1075 | | |
| Number of children at such schools; ages from 4 to 14 years:— | | | |
| Males | | 13,559 | |
| Females | | 12,993 | |
| Sex not specified | | 4,053 | |
| | | | 30,605 |

| | | | |
|--|------|--------|--------|
| Schools | 1163 | | |
| Total of children under daily instruction | | | 32,977 |
| Sunday schools | 438 | | |
| Number of children at such schools; ages from 4 to 15 and 16 years:— | | | |
| Males | | 12,594 | |
| Females | | 13,354 | |
| Sex not specified | | 3,712 | |
| | | | 29,660 |

If we assume that the population between the ages of 2 and 15 has increased in the same proportion as the whole population since 1821; and that the whole population has increased in the same ratio since 1831 as during the ten years preceding that period, we find that the number of children between the ages of 2 and 15 residing in Essex in 1834 was 109,011

Thirty-seven Sunday-schools are returned from places where no other schools exist, and the children (1513 in number) who are instructed therein cannot be supposed to attend any other school; at all other places Sunday-school children have opportunity of resorting to other schools also, but in what number or in what proportion duplicate entry of the same children is thus produced must remain uncertain. Seventy-seven schools, containing 5250 children which are both daily and Sunday-schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. At a few of the Sunday-schools some scholars are 16 and 17 years of age. Making allowance for these two causes therefore, it appears that perhaps not more than one-half of the children between the ages of 2 and 15 are receiving instruction in this county.

Maintenance of Schools.

| Description of Schools. | By endowment. | | By subscription. | | By payments from scholars. | | Subscrip. and payment from scholars | |
|-------------------------|---------------|-----------|------------------|-----------|----------------------------|-----------|-------------------------------------|-----------|
| | Schols. | Scholars. | Schols. | Scholars. | Schols. | Scholars. | Schols. | Scholars. |
| Infant Schools | .. | .. | 5 | 259 | 65 | 1,030 | 18 | 1090 |
| Daily Schools | 97 | 3476 | 112 | 5,690 | 767 | 15,673 | 99 | 5766 |
| Sunday Schools | 22 | 1369 | 333 | 25,293 | .. | .. | 39 | 7008 |
| Total..... | 119 | 4835 | 500 | 31,235 | 832 | 16,703 | 150 | 2864 |

The schools established by Dissenters included in the above statement are:—

| | Schools. | Scholars. |
|----------------|----------|-----------|
| Infant schools | .. | .. |
| Daily | 31 | 1235 |
| Sunday | 91 | 7600—8835 |

The schools established since 1818 are:—

| | Scholars. |
|--------------------------------|------------------------|
| Infant and other daily schools | 647, containing 18,533 |
| Sunday-schools | 230, containing 18,581 |

One hundred and one boarding-schools are included in the number of daily schools given above. No school in the county appears to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists, together with schools for children of Roman Catholic parents.

Lending libraries of books are attached to forty-five schools in this county.

ESSEX, EARLS OF. **WALTER DEVEREUX**, first earl of Essex, the son of Sir Richard Devereux and Dorothy, daughter of George, earl of Huntingdon, was born in Caermarthenshire, at the castle of his grandfather, Walter Viscount Hereford, about the year 1540. He succeeded to the titles of Viscount Hereford and Lord Ferrers of Chartley in his nineteenth year, and was early married to Lettice, daughter of Sir Francis Knolles. When the rebellion, headed by the earls of Northumberland and Westmorland, broke out in 1569, he raised a considerable body of troops, and, in conjunction with other forces, compelled the rebels to retreat into Scotland. The courage that he displayed during this warfare recommended him to Queen Elizabeth, who had ever esteemed his loyalty and superior intelligence: in gratitude for the service that he had rendered her, she conferred on him the order of the Garter, and created him earl of Essex (1572). He now became so great a favourite with the queen, that Leicester and others about the court, jealous of his increasing influence, encouraged Essex to enter upon a scheme for subduing and colonizing a district of the province of Ulster. He had for some time contemplated such an expedition, and having been persuaded to take the command, embarked from Liverpool in August, 1573, in company with Lord Darcy, Lord Rich, and other persons of distinction. He contracted to furnish one half of the expense of the undertaking, in consideration of which he was to have one half of the colony as soon as it was established. His arms at the outset met with various success; but after a time his English friends deserted him, and their loss, together with the enmity of many courtiers at home, soon multiplied difficulties round him. He was obliged to resume the government of Ulster, which he had previously resigned; and he was compelled to make peace with O'Neil when his pursuit of the rebels under that leader gave every prospect of success. He was required to give up his command when he had nearly dispossessed the Scots, who had invaded the western islands in his territory, and with no higher title than that of captain was made to serve at the

head of a small body of 300 men. Feeling himself harassed and oppressed, he returned to England; but having received, with the title of Earl Marshal of Ireland, promises that he should have greater liberty of action allowed him if he would go back to that country, he consented to return to his post. The improvement of his situation, however, was so small that his spirits were affected; the effects of grief were soon visible in his constitution; a dysentery attacked him, and, after a month's pain and misery, he died at Dublin, on the 22nd of September, 1576: his body was removed for interment to the parish church at Caermarthen. The sudden failure of his health gave rise to a suspicion of his having been poisoned; but no evidence whatever could be adduced to prove the fact. The speedy marriage of the Countess of Essex to Leicester, who was charged with the murder of her late husband, did not tend to throw discredit on the report. Essex left two sons and two daughters. Of the sons we subjoin a further account. Of the daughters, Penelope first married Robert Lord Rich, afterwards Charles Blount, earl of Devonshire; and Dorothy first Sir Thomas Perrot, and afterwards Henry Percy, earl of Northumberland. (*Biog. Britan.; Criminal Trials*, vol. i.)

ROBERT DEVEREUX, earl of Essex, the son of the preceding Walter Devereux and Lettice Knolles, was born at Netherwood, in Herefordshire, in November, 1567, and was educated, according to his father's wish, under the superintendence of Lord Burleigh, by whose direction he was sent to Trinity College, Cambridge, in 1577, and remained there four years. Upon leaving the university, he retired for some time to his estate in South Wales, and did not appear at court till 1584. His station, his agreeable manners, handsome person, and vigorous mind soon brought him into notice. He was reconciled to Leicester, now his father-in-law, who had been suspected of causing his father's death; and received the appointment of Master of the Horse from the hands of the queen, who also made him a Knight of the Garter. Elizabeth at the same time remitted the debt to the exchequer incurred by his father; and when Leicester went with an army into the Netherlands in 1587, she gave to Essex, who accompanied him, the responsible commission of a captain-general of the cavalry. On the death of Leicester in 1588, Essex became her chief favourite. In 1589 he suddenly joined the expedition of Drake and Norris, who had undertaken to restore Antonio to the throne of Portugal. The queen, exasperated at his departure from court without giving her notice, despatched the earl of Huntingdon to Plymouth with a peremptory order for his return. The messenger was too late; Essex had sailed. He joined the expedition on the coast of Portugal, marched to Lisbon as a volunteer, behaved himself throughout the enterprise with great gallantry and humanity, and on his return to England found that, in spite of his disobedience, he retained beyond all comparison the first place in the queen's favour. His chief rivals in her esteem were Sir Walter Raleigh, whose removal from court by the means of an appointment in Ireland has been attributed to the contrivance of Essex, and Sir Charles Blount, of whom he was so jealous, that upon the queen's bestowing a trifling mark of favour upon him at a tilting match, Essex used such insulting expressions to him that a duel ensued, in which the earl was wounded in the knee. In 1591 (a year after he had married a daughter of Sir Francis Walsingham, the widow of Sir Philip Sidney, whom the queen angrily declared to be in all respects unworthy of him), Essex was despatched to assist Henry the Fourth of France in his resistance of the king of Spain, who sought to obtain possession of the duchy of Brittany. He encamped under Rouen, and here, as at Lisbon, idly challenged the governor to a duel. The expedition was wholly unsuccessful, and the earl lost, by a musket-shot, his only brother Walter Devereux, to whom he was greatly attached.

In 1594, Essex, who had once before come into collision with the Cecils respecting the appointment of the queen's secretary, became a second time at variance with them. Having, as he conceived, discovered a plot in which Lopez and others had resolved to murder the queen, he apprised her majesty of his suspicions; but Lord Burleigh and Sir Robert Cecil, who, at the queen's desire, had examined into the case, declared the accusation to be unfounded, so that the queen severely rebuked Essex. Mortified both at this rebuke and at the conduct of his rivals, he renewed the inquiry, and eventually elicited evidence upon which Lopez

and his confederates were executed. The opposition of the Cecils to the counsels of the earl of Essex was renewed in 1596. Lord Howard, then lord admiral, advised the queen again to invade Spain, a proposal which Essex warmly seconded; Burleigh, on the contrary, denounced the scheme as impolitic and imprudent. The queen gave her consent to the expedition: Howard and Essex sailed; Cadiz was taken, plundered, and burned; fifty-seven Spanish ships of war and merchantmen were taken or destroyed; and the Spanish government suffered considerable loss. But though the enterprise was successful, and commanded with the greatest gallantry, the benefits resulting to the English government were hardly equivalent to the expense incurred. After some trifling attacks upon the coast of Spain, the fleet, which had been absent little more than two months, returned to England. The enemies of Essex had endeavoured, during his absence, to poison the mind of the queen to his prejudice, but his publication of the 'Censure of the Omissions in the Expedition to Cadiz' completely reinstated him in her favour. He continued to meet with disappointments in his endeavour to obtain official situations for his friends, but was himself created Master of the Ordnance. In July, 1597, Essex, as commander-in-chief, with Lord Thomas Howard as vice-admiral, and Sir Walter Raleigh as rear-admiral, sailed against the Spanish fleet, with a view also of making conquests among the Azores. The English ships, shattered and crippled by a storm, were immediately driven back to Plymouth. In August they again set sail, and though they could not burn the Spanish ships which they now found in harbour, they succeeded in making captures to the amount of 100,000*l.*, with which booty they returned to England in October. The queen received Essex with reproaches and discontent, and the expedition was generally deemed a failure. He now retired to Wanstead, angry on several accounts: the chief of these was the elevation of the lord admiral to the earldom of Nottingham, by which he thought himself doubly affronted; first, because Lord Howard's services at Cadiz were recited, and, in the second place, because, by his new title, Lord Howard gained precedence of him according to a regulation made in the reign of Henry VIII. He was pacified by being appointed hereditary Earl Marshal, which by the same regulation restored him to his rank. In 1598 a quarrel occurred between the queen and Essex, who, having differed from her respecting an Irish appointment, angrily and contemptuously turned his back upon her in the presence of several of the ministers. The queen, unable to bear the affront, gave him a box on the ear, and bade him 'go and be hanged.' Essex immediately seized his sword, and the lord admiral stepping in between, he swore 'that he neither could nor would put up with an affront of that nature, nor would he have taken it at the hands of Henry the Eighth himself.' He withdrew from the court, and some months passed before he would make any submission, or suffer a reconciliation to be effected. His friends dated his ruin from this unfortunate circumstance. It was hastened by the death of Burleigh, which was on the whole a great misfortune to Essex. Had Burleigh lived, Essex might not have undertaken the unfortunate Irish expedition on which he at this time entered (1599). The province of Ulster was in a state of rebellion; and with the hope that his rank and military popularity and power might prevail in that country, he accepted the commission of lord lieutenant of Ireland. His government in that country was inconsiderate and ill-advised; and his opposition to the queen's wishes in the nomination of Lord Southampton to the generalship of the horse, which he was peremptorily ordered to revoke, gave great offence. His delay in sending troops to Ulster, the loss of men and money consequent on the delay, and the ultimate failure of the expedition, were the causes of many and loud reproaches. Essex returned to England in September: at their first interview the queen received him in a friendly manner, but on the following day he was put into 'free custody,' and detained a prisoner in his house. In June, 1600, he was denied the privileges and authority of his offices; and it was not until the 26th of August that he was liberated. The queen still denied him access to court, and refused the renewal of a valuable patent for the monopoly of sweet wines, which his friends used all their endeavours to procure, declaring that 'in order to manage an ungovernable beast, he must be stinted in his provender.'

The weight of these grievances upon his haughty and impetuous mind told the more heavily from the knowledge

that his general popularity was undiminished. So deep was his impression of resentment against those whom he conceived to have biased the queen against him, that he listened to the rash and desperate advice of Cuffe, his secretary, to remove Cecil, Cobham, and Raleigh by force from the queen's councils. In order to strengthen his interest, the gates of Essex House were thrown open to all persons who were discontented with the queen or her advisers. With the same view, he courted both the Roman Catholics and Puritans, and a concourse met daily to hear sermons in his house. The multitude that attended the delivery of these discourses could not fail to attract the attention of the vigilant government. Essex was warned to be careful of his safety, and his attendance was required before the council. At this summons he took alarm, fearing a renewal of his imprisonment, and consequently the defeat of his scheme. He determined therefore to commence his proceedings on the following morning (Sunday, February 8, 1600-1); and during the night messengers were sent in all directions to acquaint Essex's friends that his life was threatened by Raleigh and Lord Cobham. In consequence of this intelligence, Lords Sandys and Montague, the earls of Rutland and Southampton, with nearly 300 other gentlemen, assembled at Essex House, where it was divulged that Essex had resolved at once to rid himself of his enemies by forcing his way to the queen, and informing her of his danger from those who had so long abused their influence with her majesty. Essex having shut up within his gates the lord keeper, the chief justice, and others whom the queen, aware of what was passing, had sent to inquire into the cause of the tumult, proceeded with his friends to the city, where, crying 'For the queen, for the queen, a plot is laid against my life,' he tried to enlist the citizens in his favour. But notwithstanding his popularity, not one man took arms. The cause of the tumult was either mistaken or unknown. At length the earl endeavoured to return home, but a party of soldiers met him at Ludgate, and a skirmish ensued, in which he was twice shot through the hat. At length he reached Essex House, but after a short defence he was compelled to surrender himself, and with Lord Southampton was committed to the Tower: the rest of the conspirators were lodged in various other prisons. He was tried for treason in Westminster-hall on the 19th of February, condemned, and executed 25th of the same month. (*Criminal Trials*, vol. i.)

A sketch of the character of Essex has lately appeared in an article in the *Edinburgh Review* (vol. lxx., p. 21), which also displays the ingratitude of Lord Bacon towards his zealous friend and patron. We extract the following remarks:—'Nothing in the political conduct of Essex entitles him to esteem; and the pity with which we regard his early and terrible end is diminished by the consideration that he put to hazard the lives and fortunes of his most attached friends, and endeavoured to throw the whole country into confusion for objects purely personal. Still it is impossible not to be deeply interested for a man so brave, high-spirited, and generous: for a man who, while he conducted himself towards his sovereign with a boldness such as was then found in no other subject, conducted himself towards his dependants with a delicacy such as has rarely been found in any other patron. Unlike the vulgar herd of benefactors, he desired to inspire not gratitude but affection. He tried to make those whom he befriended feel towards him as towards an equal.' His mind was ardent and susceptible, and naturally disposed to the admiration of all that is great and beautiful.

He left one son (of whom we give an account in the next article) and two daughters. Frances married first the earl of Hertford, and afterwards the duke of Somerset. Dorothy was the wife first of Sir Henry Shirley, and lastly of William Stafford, of Blatherwyck, in Northamptonshire.

ROBERT DEVEREUX, third earl of Essex, was born in Essex House, in the Strand, in 1592. He was sent to Eton by his grandmother, who, after his father's death, received him into her house; and in 1602 he was removed to Merton College, Oxford, where the warden, Mr. (afterwards Sir Henry) Savile, who had been an intimate friend of his father, took charge of his education. He was restored to his hereditary honours in 1603, and three years afterwards was unhappily married to lady Frances Howard, a child of no more than thirteen years old. The new-married couple being too young to live together, Essex was sent to improve himself abroad; while the bride, who was celebrated

for her beauty, continued with her mother. It was four years before he returned to claim his wife, and in the mean time she had contracted so great an affection for lord Rochester, afterwards earl of Somerset, that until she was compelled by her father, she could not be brought to cohabit with her husband. The union never was a happy one. Not many months after they had met, she instituted proceedings against him praying for a separation on a real or pretended charge of physical disability. A divorce was granted, and the lady was soon after married to lord Rochester. The slur thus cast upon Essex drove him to the retirement of his country-house and the pursuit of rural occupations. After some years however, a solitary life became irksome to him. Tired of inaction, he joined lord Oxford in 1620, raised a troop, and marched with the Elector Palatine in the war against Holland. In the winter he returned to England, where his opposition to the government rendered him unpopular at court; indeed the reception that he met with at home was so little agreeable that he willingly renewed his military avocations abroad during the two following summers, and in 1625 again raised a troop, with which he sailed to aid the United Provinces. His disposition and capability for military service now struck the king, and he was appointed vice-admiral of a fleet which was employed in a fruitless expedition against Spain. He engaged in another expedition in the Low Countries, and was afterwards bold enough to marry a second time. In this second choice of a wife (the daughter of Sir William Paulet) he was scarcely more fortunate than in his first. It is true indeed that the lady soon after her marriage bore a son, which Essex owned and christened after his name, but her familiarities with Mr. Uvedale gave him cause to suspect her fidelity, and after much mutual crimination, on the one side for inconstancy, on the other, a renewal of former charges, a separation took place. The child died at the age of five, and Essex never showed further inclination to matrimony. Between his journey to Ireland in 1632 and his appointment in the fleet that sailed to Holland in 1635, he spent his time either in his house at Chartley, or in London. His inclination to seek popularity among the presbyterians was evident and undisguised; nevertheless the king employed him as lieutenant-general of his troops that were sent against the Covenanters (1639). In 1640 he was one of twelve peers that signed a petition that a parliament should be called and an attempt made to settle the difficulties of the state without further bloodshed. He was also one of the commissioners sent to Ripon to treat with the Scots; and when, at the opening of the Long Parliament, the king saw that it was necessary that he should endeavour to conciliate the presbyterian party, he made Essex lord chamberlain. It was the wish of many of the royalists that Essex, whose popularity was great among the presbyterians, should also have been placed at the head of the army, but Charles, who disliked him on account of the roughness of his manner, and doubted the firmness of his attachment to him, refused to appoint him, and would yield to their requests no further than to make him lieutenant-general of his forces south of the Trent. When the Commons demanded of the king that a guard should be raised in the city of London, it was Essex whom they desired to have placed at its head. Charles, unwilling to listen to this request, left London suddenly, and called upon Essex to follow him; but Essex, indisposed to the king on account of the thankless incivility with which he had always been treated at court, refused to follow, pleading his duty to remain in attendance of parliament. Vehemently angry at this refusal, the king instantly deprived him of all his offices. Essex now became the chief favourite and leader of the parliamentary or presbyterian party. He became parliamentary general in 1642, and was in consequence proclaimed a traitor by the king. He opposed Charles in person at Edgehill (1642); he also took Reading (1643), but on account of a disease with which his troops were infected, he was obliged to abandon any further attack; at which the disappointment of the parliamentary leaders was so great, that they nearly dismissed him from his command. On the recovery and reinforcement of his soldiers he triumphantly entered Gloucester, from which he had driven the king away, surprised Cirencester, and after fighting courageously at the doubtful battle of Newbury, succeeded in covering London. As the supporters of the parliament were supposed to be numerous in Cornwall, in the hope of increasing his forces he marched to that county pursued

by the royalist troops; the number of adherents now ever had been exaggerated, his expectations were disappointed, and as he was completely hemmed in by his pursuers, the scarcity of provisions began to be severely felt. At this crisis the king proposed a treaty; but Essex had no authority to make any agreement without the sanction of his parliamentary masters; and as the royalists, finding that he did not comply with the king's offer, continued to press their advantage, after some of his troops had abandoned him, he was obliged to escape by sea from Fowey. Having sailed from Plymouth to London, he once more collected an army, and was placed at its head, but an illness compelled him to quit his command. When he returned to London he found a state of confusion and distrust that scarce could be exceeded. At a meeting held at his house it was proposed to impeach Cromwell, but this served no other purpose than to irritate that leader. The independents soon afterwards succeeded in carrying the 'self-denying ordinance,' which forbade members of either house of parliament to hold any command in the army: thus Essex ceased to be parliamentary general. It was voted that for his services he should be raised to the rank of a duke, and be granted a pension of 10,000*l.* a year. He did not however live to enjoy these honours, being carried off by a sudden and violent illness in the fifty-fifth year of his age. He was publicly interred in Westminster Abbey.

The chief defects in his character were indecision and vacillation; when he erred it was more from want of judgment than from bad intention. His bearing was always manly, and his courage has never been impeached. At his death the title became extinct. (Hume's *History of England*; *Biographia Britannica*; *Biographie Universelle*.)

ESSLINGEN, the seat of provincial government for the Würtemberg province of the Neckar, as well as for the bailiwick of Esslingen, lies in a fine and fertile country on the banks of the Neckar, surrounded by heights crowned with forests and vineyards, in 48° 44' N. lat., and 9° 19' E. long. It is an old town, and was a free city of the German empire, and the favourite residence of some of the emperors. The inner town has massive walls and towers round it; and the five suburbs, one of which stands on an island in the river, while another is attached to the old burg which lies upon a hill, are also protected by stout walls. It has five churches, that of St. Mary being distinguished by its fine Gothic spire, a handsome town-hall, an hospital richly endowed with the property of some suppressed religious houses, a high school, the head seminary of the kingdom for educating teachers, an orphan asylum, several elementary schools, and a population of about 6250, of whom about 100 are Roman Catholics and 100 Jews. Esslingen has manufactures of woollens, cotton and woollen yarns, wine, lackered iron and tin ware, paper, &c., and a good trade in agricultural produce. The parish of Esslingen comprises the well-known Esslingen-Gebiet, a succession of hamlets scattered along the heights between the town and Rothenberg, and carried up to the very summit of the range.

ESSLINGEN, or ESSLING, is likewise the name of a small village of about 280 inhabitants, in the circle of the Lower Mannhartsberg, in Lower Austria, about seven miles east of Vienna. It is connected by historical recollections with the adjacent village of Aspern which lies to the west of it. The ground between these two places was the scene of a severe conflict between the French under Napoleon, and the Austrians, which begun on the 21st and terminated on the 22nd of May, 1809, when the latter remained in possession of Aspern, and the former of Esslingen. By the Austrians the conflict was therefore called that of Aspern; but by the French that of Essling, from which village Marshal Massena covered the retreat of Napoleon's forces, and afterwards derived the ducal title bestowed upon him by the French emperor.

ESSOIGNS, Latin *Essonium*, French *Essoigne*, or *Exoine* (apparently from the Latin *Exonerare*, to exonerate, but see Du Cange, in voc. *Sunnis*), is the allegation of an excuse for non-appearance by a person summoned to answer an action at law, or to perform service at a court baron. There were various causes of excuse, such as illness, falling among thieves, floods, &c.

A party might essoign himself three times by sending a substitute to explain the reasons for his non-appearances, and it formerly served as an imparlance or a craving for a longer time by a defendant to make answer in real and mixed actions.

Essoign day of the Term. The first return day in every term was, properly speaking, the first day of the term (until essoigns were no longer allowed to be cast in personal actions), and on that day the courts sat to take essoigns or excuses from such as did not appear to the summons or the writ; wherefore it was called the essoign day.

The essoign or general return day is now regulated by 1 William IV., chap. 3, which enacts 'That all writs usually returnable before any of his majesty's courts of King's Bench, Common Pleas, or Exchequer, respectively, on general return days, may be made returnable on the third day exclusive, before the commencement of each term, or on any day, not being Sunday, between that day and the third day exclusive before the last day of the term; and the day for appearance shall, as heretofore, be the third day after such term.'

ESTATE, in law, signifies that title or interest which a man has in lands, tenements, hereditaments, or other effects. It is either real, comprising lands, tenements, and hereditaments held or enjoyed for an estate of freehold; or personal, comprising interests for terms of years in lands, tenements, and hereditaments, and property of every other description. Personal estate [CHATELS] goes to the executors, and is primarily liable for payment of debts.

Real estate may be considered under three heads:—(1) the quantity of estate, *i. e.*, the amount of interest in the owner; (2) the time when that interest is to commence; and (3) the quality of estate, or the mode in which it is to be enjoyed.

1. All real estates not being of copyhold tenure [COPYHOLD], or what are called customary freeholds, are either of freehold or less than freehold. The former may be divided into two kinds; freeholds of inheritance, and freeholds not of inheritance. Freeholds of inheritance admit of a further subdivision, into inheritances absolute, called fees simple, and inheritances limited, called qualified or base fees, and fees conditional. A freehold of inheritance absolute or fee simple is the largest estate which the law allows to a subject; the owner may freely dispose of it to whom he pleases in his lifetime by deed or by will, and if he dies without making any disposition, it descends to such of his kindred as the law marks out as his heir.

A qualified or base fee has some qualification or limit annexed, which may determine the estate, as in the instance of a grant to A and his heirs *tenants of the manor of Dale*. Whenever A or his heirs cease to be tenants of that manor, their estate is entirely determined, though during its continuance the proprietor has the same rights and privileges as if he were absolute tenant in fee simple.

A conditional fee at common law was a fee restrained to some particular heirs exclusive of others, as to a man and the heirs male of his body, by which limitation his lineal heirs female and collaterals were excluded; and this is the origin of estates tail. It was held that if the donee, in the case supposed, had no heirs male of his body, or if, after a male child was born, no alienation were made, the land should revert to the donor on the failure of heirs male of the donee's body: in fact, for all purposes of alienation it was a fee simple, on condition that the donee had male issue; for it is a rule of law, that when any condition is performed it is thenceforth entirely gone, and the thing to which it was annexed becomes absolutely and wholly unconditional. The nobility however, being anxious to preserve their estates in their own families, procured the Stat. Westm. the Second, 13 Ed. I., c. 1, commonly called the Statute de Donis Conditionalibus, to be made, which enacted that the will of the donor should be observed, and that the land should go to the heirs specified, if there were any, or if none, should revert to the donor. Thus the donor acquired an estate in reversion, which could only be allowed, consistently with the nature of estates in reversion, by considering the conditional fee to be changed into a limited, or, as it is called in technical language, a particular estate. This kind of estate was called an estate *tail*, from the word *talliare*, to cut, being as it were a portion of the whole fee. Means were soon however discovered by the ingenuity of the lawyers to enable the donee and his heirs of the specified description to cut off the entail, as it was called. [CONVEYANCE, FINE, RECOVERY.]

A freehold, not of inheritance, is an estate which the owner has for his own life only, or the life of some other person, or until the happening of some uncertain event. The following are instances:—A gift to A until B returns from Rome; but if the gift had been to A and his heirs

until B returns from Rome, the estate would have been a qualified or base fee; and if B had died without returning from Rome, would have become a fee simple absolute. Some freeholds not of inheritance, arise from operation of law, as tenant in tail after possibility of issue extinct, which is where an estate is limited to A and the heirs of his body to be begotten on the body of B his wife, which is called an estate tail special (as distinguished from an estate tail general, *i.e.* to A and the heirs of his body, without specifying the woman from whom they must spring). If B dies without children, A is no longer tenant in tail, but tenant in tail after possibility of issue extinct, and is regarded by the law, as to the duration of his estate, as simple tenant for life. As to tenant by courtesy and tenant in dower, see **COURTESY** and **DOWER**.

Of estates less than freehold there are three kinds—estates for years, at will, and by sufferance. An estate for years (which includes an estate from year to year) is personal property, and, like other chattels [**CHATELS**], upon the death of the owner, without having disposed of it in his lifetime, devolves upon his executors or administrators. An estate at will arises where a man lets lands to another expressly at the will of both parties or without limiting any certain estate; either party may put an end to the tenancy, though, for the sake of general convenience, the courts strive to construe them as tenancies from year to year, for the purpose of rendering a six months' notice necessary to their determination. An estate by sufferance arises where a tenant, who has entered by lawful title, continues in possession after his interest has determined: this estate may be put an end to at any time by the lawful owner, though, after acceptance of rent, the law would consider it as a tenancy from year to year, as in the case of a tenancy at will.

Neither of these two last estates confers any power of alienation. All these estates, real and personal, freehold or less than freehold, freeholds of inheritance or not of inheritance, may become subject to another qualification, and be called estates upon condition, being such whose existence depends upon the happening or not happening of some uncertain event whereby the estate may be either originally created or enlarged or finally defeated. [**CONDITION**; **MORTGAGE**.]

2. Estates are either in possession or in expectancy.

The former kind of estate requires no explanation here. The latter, involving some of the nicest and most abstruse learning in English law, are divided into estates in remainder and reversion, and by executory devise or bequest; and again, remainders are divided into estates in remainder vested or contingent. [**REMAINDER**; **REVERSION**.] An executory devise or bequest is such a limitation of a future estate or interest in lands or chattels as the law admits in the case of a will, though contrary to the rules of limitation in conveyances at common law. It is only an indulgence allowed to a man's last will and testament, where otherwise the words of the will would be void; for wherever a future interest is so limited by a will as to fall within the rules laid down for the limitation of contingent remainders, such an interest is not an executory devise, but a contingent remainder. [**WILL**.]

3. Estates may be enjoyed in four ways; in severalty, in joint tenancy, in coparcenary, and in common.

An estate in severalty is when one tenant holds it in his own right without any other person being joined with him.

An estate in joint tenancy is when an estate is granted to two or more persons at the same time, in which case the law construes them to be joint tenants unless the words of the grant expressly exclude such construction; they have unity of interest, of title, of time of vesting, and of possession, and upon the decease of one, his whole interest, unless disposed of by him in his lifetime, remains to the survivor or survivors.

An estate in coparcenary is when an estate of inheritance descends from the ancestor to two or more persons, who are called parceners, and amongst parceners there is no survivorship.

An estate in common is when two or more persons hold property, by distinct titles and for different interests, but by unity of possession.

All these three last-mentioned modes of joint and undivided possession may be put an end to by the parties interested, either by prescribed modes of conveyance or by partition. [**PARTITION**.]

Estates are also legal or equitable. It is a legal estate when the owner is in the actual seisin or possession, and also entitled to the beneficial interest himself or in trust for some other person. An equitable estate is when some other person, not the person who is the actual and legal owner, is entitled to the beneficial interest of the property of which that other is in possession. The power of the beneficial owner over his equitable estate is as complete as if he were possessed of the legal estate. [**TRUST**; **EQUITY**.]

ESTE, HOUSE OF, one of the oldest historical families of modern Europe, and the oldest among those which have retained sovereign power to the present time, the house of Savoy perhaps excepted. Some chronologists, such as Pigna, have endeavoured to trace back the genealogy of the house of Este to the fifth century of our æra, when we find the names of Atius, Aurelius, and Tiberius mentioned as princes of Este, Vicenza, and Feltre. But to pretend to ascertain the lineal succession of these princes down to the ninth century is a matter at least very dubious. The more sober and judicious Muratori, in his '*Antichità Estensi*,' has traced the ancestry of the Este to the dukes and marquises who governed Tuscany as a great imperial fief under the Carolingian emperors, and who were probably, like most other great Italian feudatories at that time, of Longobard origin. Some old chroniclers, such as Mario Equicola, in his '*History of Mantua*,' state positively that they were Longobards, and related to the Longobard dukes of Spoleto. The succession, however, of these marquises or dukes, among whom are registered two of the name of Adalbert, in the ninth century, is not clearly ascertained until we come to another Adalbert, who is styled marquis, but of whom little is known, and who died about A.D. 917. He left, however, two sons, Guido and Lamberto, who were stripped of their fiefs by Hugo and Lotharius, kings of Italy. A son or nephew of either Guido or Lamberto, named Oberto, took the part of Berengarius II., who was elected king of Italy about A.D. 950; and this Oberto was possessed, either by inheritance or through the favour of Berengarius, of several fiefs in Tuscany and Lunigiana. Being afterwards dissatisfied with the conduct of Berengarius, he was one of the Italian nobles who repaired to Otho of Saxony to offer him the crown of Italy. Otho, on his exaltation, appointed Oberto comes sacri palatii, which was one of the first dignities of the kingdom, and gave him in marriage his daughter Alda. Oberto died about the year 972, leaving two sons, Adalbert and Oberto II., the latter of whom was lord of Lunigiana and of the county of Obertengo in Tuscany. Oberto took the part of Hardouin, marquis of Ivrea, against Henry of Bavaria, for the crown of Italy. Oberto died about 1014, and was succeeded by his son, Alberto Azzo I., who in his turn was succeeded by his son Alberto Azzo or Albertazzo II. This Albertazzo, besides his paternal fiefs of Lunigiana and Tuscany, inherited also from his uncle Ugo the fiefs of Este, Rovigo, and Casalmaggiore, in Lombardy. In the year 1045 he was appointed by the emperor Henry III. count and governor of Milan; and soon after he married Kunitza, or Cunegonda, of the great German house of Welf, and sister to Welf III., on whom the Emperor Henry had bestowed the duchy of Carinthia and the march of Verona. Welf III., dying without issue, his inheritance fell to his sister's eldest son by Albertazzo, who took the name of Welf IV. This Welf IV. was made duke of Bavaria about 1070, and from him the line of Brunswick and Hanover, known also by the name of Este-Guelphs, is descended.

Albertazzo having lost his German wife, married Garisenda, countess of Maine in France, by whom he had two sons, Folco and Hugo. To Folco he left his Italian estates, and Hugo inherited the French property of his mother, namely, the county of Maine, which he afterwards sold. Hugo married a daughter of Robert Guiscard, the conqueror of Naples, and died without issue. Muratori transcribes a diploma of the emperor Henry IV., dated A.D. 1077, confirming the possessions of the Italian fiefs to Hugo and Folco, sons of the marquis Azzo of Este. Folco after his father's death was sued by his half-brother Welf for a share of his paternal inheritance; but after a long contention, an arrangement was made by which Folco retained the greater part of the Italian estates, including the fief of Este. Folco died in 1135, and his son Obizzo succeeded him. Like his father, he assumed the title of marquis of Este, from the town of that name, by which his house was designated ever after. The town of Este, built near

the ruins of the antient Ateste, lies in the Venetian state, north of the Adige, in the province of Padua. The emperor Frederic Barbarossa, at a court held at Verona, A. D. 1184, bestowed upon Obizzo the investiture of the marquisates of Milan and Genoa, which were then merely nominal, as the two cities had become free; yet the emperors would not discontinue the prerogative of appointing the titular marquises of those former imperial jurisdictions.

In Obizzo's time the foundation of the dominion of the House of Este over Ferrara was first laid. The family of Adelardi had long been the popular leaders at Ferrara, and enjoyed the chief authority in that community. Marchesella, the last offspring of this family, was betrothed by her uncle and guardian Guglielmo on his death bed to one of the Torelli, a rival family. But the girl was carried away and compelled to marry Azzo of Este, the son of Obizzo, and from that time the Este were considered as citizens of Ferrara. 'A veil has been thrown over the whole transaction, which seems to imply that fraud or violence had been committed.' (Litta, *Famiglie celebri Italiane*.)

This Azzo, styled the Fifth, died about the end of the twelfth century, and was succeeded by his son Azzo VI., who was elected in 1208 by the citizens of Ferrara as vicar or lord of that city, with power to appoint his successor. 'This,' says Litta, 'was the first example of a free Italian city giving itself over to a lord, and the beginning of those numerous principalities into which Italy became divided.'

Aldobrandino succeeded his father Azzo VI. in 1212, and was himself succeeded by Azzo VII., called also Azzo Novello, who took part with the Pope against Frederic II.; for the Este were naturally of the Guelph party. He was mainly instrumental in the fall of the tyrant Eccelino: he favoured learning, patronized the Provençal troubadours who resorted to his court at Ferrara, and established schools in that city. He was succeeded by Rinaldo, and the latter by Obizzo in 1252. Obizzo was elected lord of Modena in 1288, and of Reggio in the following year, according to the prevailing fashion of the Italian cities at that period. These lordships of Ferrara, Modena, and Reggio, however, were not held by the Este in undisturbed possession, for they were repeatedly invaded and recovered during the frequent wars of the Italian states in the fourteenth century. While the family of Este were acquiring a princely dominion, they lost the original fief from which they derived their name. About 1293 the Paduans took possession of the town and territory of Este by conquest, and annexed it to their community. It afterwards, in 1405, passed into the hands of the Venetians. (Alessi, *Ricerche Istoricocritiche delle Antichità di Este*.)

Nicholas, called 'the Lame,' one of the successors of Obizzo, was vicar of Ferrara from 1377 to 1389: he fought for the pope against Barnaba Visconti, duke of Milan. He was succeeded in 1389 by his brother Albert, and Albert by another Nicholas, who died in 1440, leaving two legitimate sons yet in their infancy, and several natural sons grown up, to one of whom, Lionel, he bequeathed his dominions. Lionel proved a good prince: he restored the university of Ferrara, and after nine years of a mild and liberal administration he died in 1450, leaving the government of the state to his brother Borso, who was illegitimate like himself. Borso was one of the most distinguished princes of his age. He was a patron of arts and letters, and was generous, enlightened, and just. He recalled his two legitimate brothers, Ercole and Sigismondo, from Naples, treated them with brotherly affection, and in order to secure the succession to them after his death, he abstained from marrying. In 1452 Borso received from the emperor Frederic III. the titles of duke of Modena and Reggio and count of Rovigo; and in 1471 pope Paul II. gave him the title of duke of Ferrara, upon which town the Roman see claimed a right of patronage. Borso died soon after, leaving a large and prosperous state to his brother Ercole. 'More fortunate than Lorenzo de' Medici, who lived in the same age, Borso had not to encounter the violence of parties and opinions; he ruled over a contented and submissive population, and while the conspiracies against Lorenzo were looked upon as acts of patriotism, those against Borso were considered as private plots, the result of personal envy and malice; so that when he had occasion in 1451, 1459, and 1469, to punish several conspirators with all the severity of the laws, he did not lose on that account the veneration of his subjects. He enjoyed a great reputation for uprightness, and his fame spread so far that he received presents from

some Indian princes, who believed that he was king of Italy.' (Litta, *Famiglie celebri Italiane*.)

His successor Ercole I. was likewise a man of considerable talents and a patron of literature. He was also remarkable for that wary and cautious policy which has been stigmatized as peculiarly Italian, but which was in reality indispensable to the Italian princes in order to protect themselves from the overbearing violence of foreign invaders, after Ludovico Sforza through ambition committed the suicidal act of calling the French into Italy. Ercole checked the fury of Louis XII., who, after he had driven the Sforzas from Milan, was bent on exterminating all the other Italian princes. Ercole was fond of travelling: he visited the various Italian courts, and encouraged tournaments, festivals, and hunting parties. He gave the first theatrical entertainments exhibited at Ferrara, where the *Menæchi* of Plautus was performed in 1486. His court was frequented by Bojardo, Collenuccio, Tibaldeo, Guarino of Verona, and other learned men of his time. He caused many Greek MSS. to be translated, and had a Hebrew press established at Ferrara in 1476.

Alfonso I., son of Ercole, succeeded him in 1505. He married the daughter of Pope Alexander VI. [BORGIA, LUCREZIA.] Alfonso had a long and troubled reign. He was attacked by Julius II. and the Venetians; he lost Modena and Reggio, and the Venetians also threatened Ferrara. The death of Julius afforded him some respite. Leo X. continued to withhold Reggio and Modena from him, and made also an attempt to surprise Ferrara. Alfonso displayed considerable abilities and great perseverance. He and his brother, Cardinal Ippolito, the patron of Ariosto, often took the field in person: their artillery was the best served in Europe; and they defeated the Venetians. After the death of Leo X., Alfonso, who had till then sided with the French, made his peace with Charles V., who by an imperial decree dated 21st April, 1531, confirmed the rights of the house of Este over Modena, Reggio, and Rubiera, upon the duke paying him 150,000 sequins; and thus Alfonso was restored to the possession of those states. Alfonso died in 1534 and was succeeded by Ercole II., and the latter by Alfonso II., who is unfavourably known by the misfortunes of Tasso, which however the poet brought upon himself. Litta is of opinion that Tasso was in love with Eleonora the duke's sister, and that her sister Lucrezia was in love with him. 'In 1575 Tasso was sent away from Ferrara, his papers were seized, and among them were found poems with such images and descriptions as ought never to have been written.' Tasso was subsequently confined to the mad-house of St. Anna, from which he was liberated after seven years, by the intercession of Vincenzo Gonzaga, prince of Mantua, who came to Ferrara for that purpose. [Tasso.] Alfonso II. dying in October 1597, without issue, Pope Clement VIII. immediately sent Cardinal Aldobrandino with troops to take possession of Ferrara as having devolved to the see of Rome, which had first invested Borso with the title of Duke. Cesare d'Este, Alfonso's cousin and heir, entrusted Lucrezia, Alfonso's sister, with full power to negotiate. Lucrezia, who had hated the Marquis of Montecchio, son of Alfonso I. and father to Cesare, on account of the share he had taken in the transactions of 1775 relative to Tasso, disliked Cesare also. Cardinal Aldobrandino having offered her the title and revenues of Duchess of Bertinoro in the Romagna, she signed a hasty convention, by which she gave up, in the name of the house of Este, Ferrara, Comacchio, and their dependencies, to the see of Rome. Cesare transferred his court to Modena, and Lucrezia died at Ferrara a few days after the entrance of the Papal troops, in February, 1598. The city of Ferrara, which, under the house of Este, had a population of 60,000 inhabitants gradually became reduced to 20,000.

Cesare, duke of Modena and Reggio, died in 1628. His son Alfonso III., who had remained as hostage at Ferrara, had shown in his youth marks of a violent disposition. In 1619 he caused Ercole Pepoli to be assassinated at Ferrara. Stung by remorse, he abdicated the dual crown soon after his father's death, and became a Franciscan monk. He distinguished himself as a zealous preacher, and founded several convents. 'But,' says Litta, 'he could not totally change his nature. He was still a lion under the coarse tunic and hood. He was treated by the other monks with all the deference due to his rank, but was closely watched to prevent his doing mischief. He died in 1644, in a convent in the mountains of Garfagnana, which he had founded.' His

son Francis I. was not much better than his father. He affected a great zeal for religion, had his food scrupulously weighed on fast days, and he sentenced a relative of Marshal Gassion to be shot for want of proper respect while at church. He first separated the Jews from the rest of the population at Modena in 1630, and confined them to the Ghetto. He began the magnificent ducal palace at Modena as well as the country residence and gardens at Sassuolo. His successor, Alfonso IV., received in 1660 of the emperor Leopold the investiture of the principality of Correggio, which he had previously purchased. Alfonso loved the fine arts, and he was the founder of the Este gallery of paintings. He left at his death a son two years old, who was afterwards duke by the name of Francis II. During his minority his mother, Laura Martinozzi, Cardinal Mazarin's niece, held the government. She collected together all the bad characters in her dominions, and delivered them over to the Venetians, who employed them in the war of Candia against the Turks. Francis II. founded the university of Modena as well as the splendid library called Estense, of which Zaccaria, Muratori, and Tiraboschi were successively librarians. Francis II. dying in 1694 without issue, was succeeded by his uncle, Cardinal Rinaldo, who, after resigning his hat, married a daughter of the Duke of Brunswick Lunenburg, and sister-in-law to the emperor Joseph I. By this marriage the two branches of Este and Brunswick, which had been separated since 1070, became again connected. During the war of the Spanish succession, the Duke Rinaldo, notwithstanding his professed neutrality, was obliged by the French to quit Modena and to take shelter at Rome. The victorious Austrians, commanded by Prince Eugene of Savoy, restored him to his dominions, where he resided quietly till 1733, when the war for the succession to the crown of Poland, in which Italy had no concern whatever, but for which Italy was as usual devastated by the belligerents, obliged Rinaldo again to leave his territories, which became the theatre of war between the French and Piedmontese on one side, and the Austrians on the other. In 1736 Rinaldo returned to Modena. His repeated misfortunes affected and perhaps improved his disposition: he became serious and economical after having been inclined to pomp and magnificence. He enlarged his dominions by the purchase of the duchy of Mirandola and the county of Bagnolo. Rinaldo was succeeded in 1537 by his son Francis III., who was serving in Hungary against the Turks at the time. During the war of the Austrian succession he took part for the house of Bourbon, and commanded the Spanish armies in Italy. The peace of Aix-la-Chapelle restored him to the quiet possession of his dominions. In 1754 Duke Francis was appointed by Maria Theresa governor of Lombardy during the minority of her son the Archduke Ferdinand, who was betrothed to the duke's grand-daughter Beatrice d'Este, a child then four years old. In 1771 Francis gave up his trust to the Archduke Ferdinand, but continued to reside in Lombardy, and died at Varese in 1780. His son Ercole Rinaldo, the father of Beatrice, succeeded him as duke of Modena. His administration was peaceful and economical. He was ever watchful against the temporal interference of the court of Rome in his dominions; and he was equally averse to the remains of feudality which still lingered in his states. When the French entered Italy in 1796, the duke made a convention with Bonaparte, paid a heavy contribution, gave up some valuable paintings, but not trusting to the faith of the conqueror, he withdrew to Venice with his treasures, leaving a council of regency at Modena. An insurrection excited at Reggio by some Corsican soldiers in the French service afforded a pretext to Bonaparte to violate the convention, and to occupy the states of Modena, which were afterwards annexed to the Cisalpine republic. (Botta, *Storia d'Italia*; Paradisi, *Lettere a Carlo Botta*.) When in the following year the French occupied Venice, the duke had escaped to Trieste, but a deposit of 200,000 sequins which he had left behind was seized. Ercole Rinaldo died in the Austrian States in 1803. His daughter Maria Beatrice, the last offspring of the house of Este, lost her husband, the Archduke Ferdinand of Austria, in the year 1800, and their eldest son, Francis IV., was restored by the peace of Paris in 1814 to the dominions of his maternal ancestors, namely, the duchy of Modena, Reggio, and their dependencies, including the district of Garfagnana, on the borders of Lucca. By the death of his mother he has also inherited the duchy of

Massa and Carrara, of which his grandmother, of the house of Cibo Malaspina, was the heiress. [CARRARA; MODENA] ESTELLA. [NAVARRA.]

ESTHER. The Book of, a canonical and historical book of the Old Testament, placed after that of Nehemiah, but coming chronologically between the 6th and 7th chapters of Ezra. It is thus denominated from the Persian name of the Jewish woman, Hadassah, whose history it relates. She was an orphan niece and adopted daughter of Mordecai, from a Benjamite family of the Babylonian captives of Nebuchadnezzar (ii. 5-7). The scene of the narration is in the city Shusan, or Susa, now Sus (not Shuster, as stated by Dr. Adam Clarke—see *Trans. Geog. Soc.*, vol. iii.), which, throughout the book, is in English mistranslated Shushan the palace, though, in the Septuagint version, it is rightly ἐν Σούσαις τῇ πόλει, that is, 'in Susa the city.' Augustin, Epiphanius, and Isidore supposed the author to have been Ezra. Eusebius assigns a later date. Some writers have attributed it to the high priest Joachim; others believe it to have been composed by the Jewish synagogue, to whom Esther and Mordecai wrote (ix. 20-29); but by the greater number Mordecai himself is thought to be the author, and Elias Levita, in his *Mass. Hamum*, asserts this to be a fact unquestionable. The original, according to Dr. Adam Clarke, was probably written in the language of antient Persia. St. Hieronymus and several other fathers regarded this book as wholly uncanonical, because the name of God or religion is not once mentioned or alluded to, and they have been followed by some modern writers, as Cajetan and De Lyra; but the Council of Trent pronounced it to be wholly canonical; and while the Protestant churches admit into the canon only what is found in the Hebrew copies, that is, as far as to the end of the third verse of chap. x., the Greek and Roman churches use as canonical the Greek version and Latin Vulgate, which contain each ten more verses of chap. x. and six additional chapters. By the Jews the book has been always considered as one of the most precious of their sacred scriptures, and as a perfectly authentic history of real events which took place about a.c. 519. They call it מגילה, Megilah, that is, *The Volume*, and hold it in the highest estimation; believing that whatever destruction may happen to the other scriptures, Esther and the Pentateuch will always be preserved by a particular Providence. Copies exist in the Hebrew, Syriac, Chaldaic, Greek, and Latin; each of which widely differs from the others, and all, especially the Greek and Chaldaic, are greatly different from the Hebrew. The Chaldaic text contains five times more than the Hebrew, and a notice of the various readings would fill a large volume. (See the London Polyglot Bible.) Commentators differ much in determining to which of the Persian and Median kings belongs the name of Ahasuerus, whose kingdom extended from India to Ethiopia over 127 provinces (i. 1). Some suppose him to be Darius Hystaspes. Scaliger and Jahn say Xerxes. By Capellus he is identified with Ochus, and by Archbishop Usher with Darius the son of Hystaspes. Dean Prideaux and Dr. Adam Clarke with greater probability take him to be Artaxerxes, who received the cognomen of Longimanus, or Longhanded. The following is a brief abstract of the book of Esther in the words of the text. This monarch (chap. i.), after having entertained all his nobles and princes with sumptuous festivity during more than six months, gave a great feast in his palace garden to all the men of Susa, great and small, while the women were separately feasted by the queen in the royal house. To the men royal wine was supplied in abundance, and the drinking was according to every man's pleasure; when, the king being, on the seventh day, merry with wine, sent his seven chamberlains with orders to bring the queen to exhibit herself (the Talmud says naked) before his guests; but Vashti (which in Persian means the beautifully fair) refusing to come, he was very wroth, and his anger burned within him. Ahasuerus however punished her by degradation and banishment, and by his royal mandate letters were despatched to the people of each province, decreeing that every man bear rule in his own house. To furnish the royal harem with the greatest means of choice there was made throughout the empire (ch. ii.) a general levy of the fairest virgins, and Esther, the beautiful young Jewess, being preferred by Hege, the keeper of the king's women, before all others of the numerous assemblage, she succeeded to the place of the banished queen Vashti. The twelve months' cosmetical purification of the maidens previous to their admission to the king (ver. 12) was required, says Dr. Clarke,

'to show if they were with child, that the monarch might not be imposed on by fathering a spurious offspring, and because many having been brought up in low life, and fed on coarse, strong, and indigestible food, they had a copious and strongly odorous perspiration, which was far from pleasant.' Esther's foster father, Mordecai the Jew (chap. iii.), having refused to do reverence to Haman, the chief minister and favourite of Ahasuerus, he, with all the other Jews from Babylon, then dispersed throughout the Persian empire, were by Haman devoted to destruction, and the royal mandate being accordingly issued 'to destroy, to kill, and to cause to perish all Jews, young and old, little children and women, in one day, and to take the spoil of them for a prey (ver. 13), the king and Haman sat down to drink;' but the fickle tyrant, influenced in the mean time by the pathetic entreaties of Esther, and by the recollection that Mordecai had discovered a conspiracy against his life, was induced to hang his favourite Haman on a gallows thirty yards high, which that minister had prepared for Mordecai. He then promoted Mordecai to the highest honours in the empire; and still yielding to the influence of the fair Jewess and of Mordecai, he hastily issued orders empowering all the Jews 'to destroy, to slay, and to cause to perish all the people that would assault them, both little ones and women, in one day, throughout all the provinces of King Ahasuerus, and to take the spoil of them for a prey' (viii. 11, 12), so that 'the Jews smote all their enemies with the sword, with slaughter and destruction, and did what they would unto those that hated them' (ch. ix. 5). By the special request of Esther, the ten sons of Haman were hanged on the gallows, and in the city of Susa the Jews massacred eight hundred of the king's Persian subjects, and in the provinces seventy-five thousand (ix. 12, 13, 15, 16). This signal revenge of Haman's intended destruction of the Jews in Persia has ever since been commemorated (ix. 21-28) on the 14th and 15th days of the month Adar, in the Jewish 'Feast of Purim,' that is, in Persian, *the lots*; with reference to those which, on this occasion, were cast before Haman (ch. iii. 7; ix. 26); and the lower class of Jews, like the similar class of Irish with respect to St. Patrick's day, consider that on these 'Days of Purim' to be drunk is a pious duty. It is here worthy of remark, that the word which in the authorized version is repeatedly translated *gallows*, should properly be *cross* or *tree*. Hence it was that, in the first ages of Christianity, the Jews, when celebrating this feast of Purim, were accused of deriding the Christian crucifixion, in abusing and setting fire to an effigy of Haman affixed to a lofty wooden *cross*; a custom which, on this account, was abolished in the Roman empire by the decrees of Justinian and Theodosius. It has been observed that apparently the only good moral sentiment derivable from the statements of this book, the inspired authority of which was doubted by several early fathers, is a detestation of the sensuality and cruelty of such royal despots as the king Ahasuerus. (Dr. Prideaux's *Connection of the Old and New Test.*; Horne's *Introduction to the Bible*; Commentaries by Dr. A. Clarke and others; *Lectures on the Book of Esther*, by Dr. Lawson, 1809; *Eclect. Review*, vol. iii.; Calmet's *Dict. of the Bible*; Dr. A. Clarke's *Succession of Sacred Literature*.)

ESTHONIA, or REVAL, a Russian government or province constituting one of the five provinces included in the grand subdivision of Russia in Europe, which is called the 'Baltic (East Sea) Provinces.' It is not known by this name among the native inhabitants, but by that of 'Wirova,' border-land, or 'Meie Maa,' our land. The boundaries of Esthonia are, on the north, the gulf of Finland; on the east, the government of St. Petersburg; on the south, lake Peipus and the government of Livonia; and on the west, the Baltic. It was subjugated by the Danes in 1220, and in 1346 sold by them to the Teutonic knights, whose grand master, the first duke of Livonia and Esthonia, acknowledged the king of Poland as lord paramount in 1561. After being an object of continued contest between the Russians, Poles, and Swedes, it became at length a province of Sweden in 1660. It was wrested from the Swedish crown by Peter the Great in 1710, and was ceded finally to Russia under the treaty of Nystädt in 1721. Including the islands of Dagoe, Worms, Wrangel, Nargen, the two Roogs, Odensholm, Nuckoe, Eckholm, Heft, Kranholm, and fifty-nine smaller islands, the total area of this government is 6804 square miles, of which one thirty-fifth part belongs to the seventy islands. The extent of coast is about 260

versts, or 173 miles; and the population, which was 196,285 in 1783, 227,001 in 1819, and 229,398 in 1828, is now estimated at about 240,000. The general character of the surface is level, occasionally varied by isolated hills and eminences, which the people of the country denominate mountains. The northern coast from Reval, or Revel, to Narva, is several fathoms higher than the Baltic, and strewn with masses of granite: the western coast is lower, but both are edged for some miles inland by a deep bed of sand. The soil of the interior districts of Esthonia, which are the most fertile, is a mixture of loam, sand, and clay; in all parts are large swamps, many of which are impassable, except when hardened by the frosts of winter. The proportion of the cultivated to the uncultivated and wooded soil is estimated by Bienenstamm at one part only in three.

Esthonia contains 228 small lakes, besides the northern end of lake Peipus, and the left bank of the Narova, which flows out of the Peipus into the Baltic and divides the government from that of St. Petersburg. This province has no streams, but rivulets and brooks, some of which flow under ground, and occasionally contain pearl muscles. There are sulphurous and saline springs.

Though the temperature is moderate when compared with that of the adjacent provinces, the winter is of long duration, and winds and fogs prevail throughout the year.

The soil, though deficient in fertility, yields more than sufficient for the maintenance of the population. Agriculture is the principal branch of industry, and about one-fifth of the whole surface is under the plough. The chief crops are rye, barley, and oats; some wheat, Indian corn, hemp, flax, hops, and tobacco are also raised. The whole produce of grain is estimated at 506,000 quarters, which being more than is consumed, the surplus, about 180,000, is applied to making brandy. The Weissenstein districts, in the south-east, produce much hemp and flax. As the harvest season is attended by heavy rains, the farmers have subterranean kilns in most parts, into which the moist grain is carried, for the purpose of being dried. Esthonia has large meadows, and produces abundance of hay; it has likewise good grazing grounds. Vegetables are of universal growth, but little attention is given to fruits. The woods and forests, composed of the fir, pine, elm, birch, larch, and beech, occasionally intermixed with the oak, alder, linden, crab-apple, &c., spread over an area of about 3300 square miles; they are densest in the eastern districts of Wesenberg and Weissenstein.

Next to agriculture the rearing of cattle is the most important branch of rural industry. The native horse is small in stature but strong and enduring, and the breeds called the Reval Klepper and Doppelklepper are in much esteem. The horned cattle are small, but afford much milk, and large droves of oxen from the Ukraine are fattened for the St. Petersburg market. Much has been done to improve the breed of sheep, which are of the German white or blackish species. Goats, swine, and poultry are reared in great numbers. The wild animals are the bear, wolf, fox, badger, marten, and squirrel; a few elks are to be met with in the Wesenberg forests. The fisheries along the coast and in lake Peipus are very productive. The mineral products are stone for building, potter's clay, and gypsum; there is abundance of peat.

The majority of the inhabitants are Esthonians: they are of Finnish descent, of diminutive stature, and have light-coloured hair, in general blue eyes, a small flat nose, and flattened countenance. They were sunk until late years in abject slavery. The landholders are universally of German or Danish extraction, and constitute the aristocracy of the country; and there are some Russians, and a few Swedes and Finlanders intermixed with them. In 1819, when the population amounted to 227,001, it comprised 210,240 Esthonians, and 8836 Germans. In 1830, when it amounted to 228,000, the number of births was 10,881, and deaths 7055. In 1828, when it was 229,398, the towns contained 24,063, and the rural districts 205,335; in that year also the number of males was 100,363, and females 104,972.

Esthonia contains 563 estates, which, with the exception of eight, the property of the crown, and 45 belonging to the clergy, are in the hands of the nobility. The peasants' families are estimated at 30,000. The Lutheran is the predominant religion of the province; even the Russo-Greeks

have not more than eight or ten churches in it. The superintendence of all ecclesiastical affairs in the Lutheran church is vested in the provincial consistory at Reval, and the number of parishes is 134. The department of education, which includes a gymnasium at Reval, and about fifty other schools, with about 1500 pupils only, is under the control of the university of Dorpat. In 1831 the proportion of pupils to the whole population was not more than one in every 148 individuals.

The manufactures of Esthonia are extremely limited; the peasantry are clothed not only with linen but with coarse woollen cloth woven in their own houses. The only establishments of any importance are in Reval, where hats, leather, powder and starch, vinegar, and some iron ware are made. In 1830 indeed, there were but three large manufactories in the whole province, and 297 workmen attached to them. Vessels are constructed in the capital and in the islands; and brandy is made on many estates as well as in the towns, and even by the farmers themselves; the distilleries of this spirit amount to nearly 400.

Reval is the emporium of trade, but for want of water communications it is not of any great extent. The exports consist of grain, brandy, salt fish, skins and hides, butter, tallow, smoked herrings and salmon, and salt.

Though public affairs are administered on the same footing as in the other Russian governments, the country retains some vestiges of its antient constitution, among which are a provincial college or council, an inferior tribunal of justice, a consistory, and the right of making brandy without a license from the government.

Esthonia is divided into four circles, viz., North-west, Reval, or Revel, formerly Harria, chief town Reval (13,000 inh.), with the islands of Nargen (250), Wrangel (600), Rokshaer, Malus, Ramosaar, the Roogs, and Odensholm; South-west, Hapsal, formerly Wiek, chief town Hapsal (1450), with the islands of Dagoe (10,000), Worms (1100), and Nuckoe (450); South-east, Weissenstein, formerly Yerven, chief town Weissenstein (600); North-east, Wesenberg, chief town Wesenberg (400), with the islands of Eckholm, Heft, and Kranholm: besides the districts of Kunda, chief town Kunda (400), and of Laal (324 inhabitants).

ESTIENNE. [STEPHENS.]

ESTOPPEL, an impediment or bar to a right of action, arising from a man's own act, or the act of some person through whom he claims. There are three kinds of estoppel. 1. *By matter of record*, as letters patent, pleading, &c. Thus in an action against a patentee by his assignee, the patentee is estopped from pleading that the patent is invalid.

2. *By matter of writing*, as by deed, &c. parties and privies are estopped from alleging any thing contrary to the deed. It is frequently laid down that an indenture is more effectual in working an estoppel than a deed poll [DEED]; but from the statement in the book from whence this position is derived (*Shep. Touch*, 53) it does not appear that the fact is so, inasmuch as it is there admitted that if both parties sign and seal a deed poll, they are equally estopped as if the deed had been indented.

3. *By matter in pais* (in the country), i. e., transactions between the parties not evidenced by record or writing, as livery, entry, acceptance of rent, &c. Thus after acceptance of rent a landlord cannot treat his lessee as a trespasser. The rules which govern the application of this doctrine are laid down 1 *Inst.*, 352 b.

ESTOVERS. Spelman, in his *Law Glossary*, says that this word is derived from the French *étouffe*, and that from *étouffer*, which is to supply with necessities, and is of the same signification as the Saxon word *bote*. In legal phraseology it is the liberty which the owner of an estate for life as well as a tenant for years (in the absence of any stipulation to the contrary) possesses of taking a reasonable and necessary supply of wood from the estate for the use or furniture of his house or farm, and this, according to the use to which it was applied, was either called house bote, plough bote, cart bote, or hedge bote. *House bote* is a sufficient allowance of wood to build or repair the house, or to burn in it, which latter is also sometimes called *fire bote*; *plough bote* or *cart bote* is the wood employed in the making or repairing all instruments of husbandry, as carts and ploughs, narrows, rakes, &c.; *hedge bote* or *hay bote* for repairing hedges, fences, pales, stiles, and gates, and to secure inclosures.

If a tenant takes more than is needful for these purposes he may be punished for waste, as if he cuts down wood to burn when he has sufficient dead wood upon the estate; and a tenant, although he may cut down and take sufficient wood to repair pales and fences as he found them, still he cannot do so to make new ones.

A rector may also cut down wood for the repair of his parsonage-house or the chancel, and even for any old pews which belong to the rectory; and, like other tenants for life, he is entitled to estovers for repairing the barns and out-houses belonging to the parsonage.

Bracton uses the word estovers in a different sense, viz., as the sustenance, which a man committed for a felony, is to have out of his lands and goods for himself and family during his imprisonment; it also occurs in the statute 6 Ed. I. c. 3, as an allowance of meat or cloth; but the more common and usual signification by which it is known to lawyers has been already stated. (Woodfall, *Landl. and Tenant*; Comyn.)

ESTRAY, any valuable tame animals found wandering at large within any manor or lordship, and whose owner is unknown. Having been impounded, and proclaimed in the church and the two nearest market-towns on a market-day, they become, if not claimed in a year and a day, the absolute property of the king, as lord paramount of the soil, though generally the lord of the manor or liberty is the special grantee of the crown. Animals upon which the law sets no value, as a dog or a cat, or such as are of a wild nature, as a fox or a wolf, cannot be taken as estrays. Swans may be taken as estrays, but no other fowl. The king or the lord does not acquire the absolute property in the estray, until the full expiration of the year and a day, which runs from the first proclamation, and not from the seizure; therefore if it escape before the time to another manor he cannot reclaim it.

The king or the lord is bound to take care of the estray, and find it in provision; he must not use it, but is liable to an action for so doing, though he may milk a cow or the like, for that tends to the preservation of the animal, and is necessary. The owner on the other hand, if he claims within the time allowed, must pay the charges of finding, keeping, and proclaiming the estray.

It may be observed, that if any person not being entitled to estrays, finds and takes care of another's property, the owner may recover it or its value without being obliged to pay for the expenses incurred in keeping it.

ESTREAT, from the Latin word *extractum*, is a true copy or note on the rolls of a court of some original writing or record, especially of fines and amerciaments which are to be levied by a bailiff or other officer. In all cases of felony or misdemeanor where persons bound by recognizance either to appear themselves, or for the attendance of any witness on trials of felonies or misdemeanors, neglect to do so, the recognizance becomes forfeited; an officer of the court, whose duty it is at the end of the assize or session, prepares a list of the defaulters, and when the same has been approved by the judge presiding, the fine or forfeiture mentioned in the recognizance is said to be estreated or certified into the Exchequer, and process is awarded for its recovery.

These fines, when levied, are paid into the Treasury, or the lords of the Treasury may, if they think fit previously to the issuing of the process, stay the execution and remit the fine.

The barons of the Exchequer were also empowered by a standing writ of privy seal to discharge, mitigate, or compound forfeitures estreated into the Exchequer from other courts; and by the 4th Geo. III., cap. 10, they are also authorized, upon affidavit and petition, to discharge estreated recognizances and forfeitures, except those incurred before justices of the peace. (*Term Reports*; Burn's *Justice*.)

The various acts of parliament which now regulate the mode in which fines are to be levied upon estreated recognizances, &c., are the 4th Geo. IV. cap. 37, with regard to those before justices of the peace; the 7th Geo. IV., cap. 64, before judges of assize, recorders, &c., and the 3rd and 4th Wm. IV., cap. 99, which relates to such only as are forfeited in the Houses of Lords and Commons.

ESTRELLA. [PORTUGAL.]

ESTREMADURA, a province of Spain, bounded on the north by the province of Salamanca, on the east by New Castile, on the south by Andalusia, and on the west by

Portugal. Its length from north to south is about 180 English miles, and its average breadth is about 90 miles from east to west. Its area is reckoned at about 14,800 English square miles. Two large rivers, the Tagus and the Guadiana, both coming from Castile, cross the province from east to west, and their respective basins form the two natural divisions of the province, that of the Tagus being Northern Estremadura, called also Alta or Upper Estremadura, and that of the Guadiana forming the southern part, which is called Baja, or Lower Estremadura. A range of mountains, which is a continuation of the montañas de Toledo, in New Castile, and which, under the various names of Sierra de Guadalupe (5000 feet), Sierra Marchal, and Sierra de San Pedro crosses Estremadura in a south-west and west direction, and then joins itself to the Sierra del Portalegre, on the frontiers of Portugal, forms the division between the waters which flow into the Guadiana and those which run into the Tagus. To the north the basin of the Tagus is bounded by another and still loftier ridge, the Sierra de Gredos, a continuation of the mountains of Avila, in Old Castile, which runs westward under the names of Sierra de Francia and Sierra da Gata, along the boundaries between Estremadura and Salamanca, and afterwards entering Portugal joins the Sierra d'Estrella in the neighbourhood of Alfaiates and Penamacor. From this northern ridge several considerable streams, such as the Alagon and the Tietar, flow southwards into the Tagus. The Alagon rises in the mountains of Las Batuecas, waters the fine plain of Plasencia, passes by Coria, and enters the Tagus above Alcantara. Its whole course is about 70 miles. Of the streams which enter the Tagus, on the opposite or southern bank, the principal one is the Salor, which rises in the Sierra de San Pedro, and enters the Tagus below Alcantara. The principal towns of the northern division of Estremadura are: Plasencia, a bishop's see, with 6700 inhabitants, and a fine aqueduct: it lies in the midst of one of the finest and best cultivated territories in all Estremadura: the convent of S. Justo, in which Charles V. ended his days, lies at the foot of the Sierra de Gredos, to the east of Plasencia: Cáceres, south of the Tagus, with 10,000 inhabitants, the residence of the audiencia, or upper judicial court of the province: Alcantara on the Tagus, with 3300; its handsome bridge built by Trajan was partly destroyed during the Peninsular war: Valencia de Alcantara, near the frontiers of Portugal and at the foot of the Sierra Fria, with 4700 inhabitants: Truxillo, near the borders of Castile, the birth-place of the Pizarros, with 4600 inhabitants: Coria, north of the Tagus and west of Plasencia, with 2500.

The basin of the Guadiana, or southern division of Estremadura, is bounded to the south by a continuation of the Sierra Morena, which, under the name of Sierra de Guadalcanal and Sierra de Monasterio, divides the waters of the Guadiana from those of the Guadalquivir, running westwards along the borders of the provinces of Estremadura and Seville, and then entering that part of Alentejo which is east of the Guadiana. This branch of the Sierra Morena is comparatively low, few if any summits reaching 2000 feet above the sea. The banks of the Guadiana, especially below Badajoz, are low, flat, and unhealthy. The finest districts of this part of Estremadura are those of Llerena, near the foot of the Sierra Morena, of Xeres, and la Serena. Badajoz is the capital of all Estremadura, and the residence of the captain-general. [BADAJOZ.] The other towns of the southern division are: Merida, the ancient Emerita Augusta, with about 5000 inhabitants, a handsome Roman bridge on the Guadiana, restored by Philip II., a triumphal arch, the remains of a theatre, of a naumachia, and circus, and numerous other traces of its former splendour; Xeres de los Caballeros, south of Badajoz, with 9300 inhabitants: Alburquerque, north of Badajoz, and near the frontiers of Portugal, with 6700 inhabitants; Olivenza, a fortified place formerly belonging to Portugal, with 2000 inhabitants; Llerena, near the foot of the Sierra Morena, with 6500; Zafra, an industrious place, with tanneries, and manufactures of hats, &c., 7500 inhabitants; Medellin, on the south bank of the Guadiana, the birth-place of Cortes, with 1700 inhabitants.

The whole population of Estremadura is vaguely reckoned at 550,000 inhabitants, divided among seven towns, 212 villas or boroughs, and 121 aldeas or villages, mostly thinly inhabited. The ecclesiastical division consists of three bishoprics, namely, Badajoz, Plasencia, and Coria, and 415

parishes. There were also 170 convents previous to the late suppression. Estremadura is one of the least populous provinces of Spain; its depopulation dates from the expulsion of the Moors, and the subsequent establishment of the Mesta, or administration of the flocks of migrating sheep which took possession of the vast tracts which had remained abandoned. About four millions of sheep come to graze, during winter, from the other provinces on the open spontaneous pastures of Estremadura. Other tracts are covered with underwood and wild odoriferous herbs. There are also forests of oak, beech, chestnut, and pine trees, where numerous herds of swine feed: the flesh of these animals forms a considerable article of commerce with other provinces of Spain. Game of every sort is plentiful. The cultivated parts produce some wheat, oats, Indian corn, flax, hemp, and the *vase*, *lave*, mulberry, and lemon trees. Excellent honey and wax are also gathered. Many ruined and deserted villages are met with over the country, with traces of former cultivation and of a population which has disappeared.

The Estremeños, or inhabitants of Estremadura, are reckoned the most grave and taciturn of all the people of Spain. Living in a remote inland province, with few means of communication with the rest of the world, they have, generally speaking, no notion of the luxuries or even comforts of other countries, and therefore do not exert themselves to acquire them. When they have an object in view, they are capable of great exertion and perseverance: they are frank, sincere, and honourable, and robust of body, and disposed to military service, especially in the cavalry. Some of the boldest adventurers who discovered and conquered America were natives of Estremadura. The great number of emigrants who left this province for the New World during the sixteenth century has been considered, but with little reason, as one of the causes of the depopulation of the country. The name of Estremadura is said to be derived from the Latin 'extrema ora,' it being the furthest and latest conquest of Alonso IX. over the Moors in 1228.

The high post-road from Madrid to Lisbon crosses Estremadura, and is kept in good repair. The other roads are bad, and impassable for carriages in the rainy season. The posadas or inns on the roads are among the worst in Spain; provisions are scarce, and the markets few and ill supplied. On the side of Portugal, the frontier north of the Tagus between Estremadura and Beira is marked by a ridge of hills, an offset of the Sierra de Gata, which extends from Penamacor, a town within the Portuguese frontier, southwards to the Tagus, a few miles west of the bridge of Alcantara. A road leads from Plasencia across these hills by Zarza and Zibreira to Castello Branco in Portugal. South of the Tagus, the western boundary of Estremadura is much further advanced towards the west; beginning near Montalvão, about 35 miles west of Alcantara, it continues southwards, passing a little to the east of Castello de Vide and Campo Mayor, which are in Alentejo, down to the Guadiana, a few miles below Badajoz. From thence, for about 30 miles southwards, the Guadiana serves as a boundary, after which an ill-defined tortuous line, of about 50 miles more, first south and then south-east, marks the limits between Estremadura and Alentejo, to the foot of the Sierra Morena, which forms the north boundary of Andalusia.

Estremadura has mines of copper, lead, and iron; and one of silver at Lagrosan, near Alcocer. The manufactures are few, consisting chiefly of leather and hats at Badajoz, Zafra, and Cáceres. The annual net income derived from the land belonging to lay proprietors is estimated by Miñano at 55 millions of reales vellon, or little more than half a million sterling, and that belonging to the clergy both regular and secular, before the late suppression, at 21 millions and a half, or about 210,000*l.* sterling. (Miñano, *Diccionario Geográfico*, article 'Estremadura;' and also 'Statistical Tables' annexed to the art. 'España;' Ancillon; Bowles.)

ESTREMADURA, a province of Portugal, is bounded on the north by Beira, on the east partly by Beira and partly by Alentejo, on the south by Alentejo, and on the west by the Atlantic Ocean. The length of the province from north to south, from the village of Lavaos, which lies on the sea-coast south of the mouth of the Mondego, to the borders of Alentejo near Melides, south of the lagoon of Setubal, is about 140 miles, and its greatest breadth from east to west is about 85 miles. The ridge of the Estrella, which crosses part of Beira from east

to west, sends off a branch to the south-west, which enters Estremadura east of Pombal, and runs obliquely through the length of the province under the various names of Serra de Louzaõ, Serra de Alberdos, Monte Junto, and Serra de Baragueda. The Sierra de Baragueda stretches to near Torres Vedras, and there meets at an oblique angle the ridge which spreads from east to west from the Tagus to the sea across the peninsula in which Lisbon is situated. This latter ridge, which is separated from the former by a narrow but deep ravine extending from Torres Vedras towards Sobral, furnished Lord Wellington in 1810 with a valuable position of defence against the French invading army under Marshal Massena. The line of hills extends from the mouth of the Zizandre, west of Torres Vedras, to the town of Alhandra on the Tagus, a distance of about thirty miles. The village of Sobral lies in front of the centre of the line.

The central ridge or continuation of the Estrella chain already mentioned divides the waters which flow into the Tagus from those streams which run direct into the ocean. Among the tributaries to the Tagus, the most considerable are—1. The Zezere, a rapid stream which has its source in the mountains of Guarda in Upper Beira, enters Estremadura near Pedrogão, and running southwards receives the Narvaõ from Thomar, and then enters the Tagus at Punhete below Abrantes. 2. The Azembuja, called also Rio Mayor, which rises north of the town of Rio Mayor, and flows in a tortuous course, passing near Cartaxo, and at the foot of the hill of Santarem, and enters the Tagus above Villa Franca. The streams which flow from the north-west slope of the ridge into the ocean are—1. The Lis, which rises near Alcanhede, flows by Batalha, receives the Lena near Leiria, and enters the sea south of Cape Paredes. 2. The Alcoa, which rises south of the Lis, is joined by the Baça (the two together giving the name to the town of Alcobaça), and after a short course enters the sea. 3. The Arnoya, a small stream which rises in the group of Monte Junto, passes by Obidos and Rolixa, where the first engagement between the English and the French in the Peninsula took place on the 17th of August, 1808, and then enters the lake or lagoon of Obidos which communicates with the sea. 4. Farther south towards Torres Vedras is the river Marceira, which passes by Vimieiro, and after a short course enters the sea south of Peniche Point. 5. The stream Zizandre rises below Sobral, flows through the ravine above mentioned between the Serra de Baragueda and the ridge of Torres Vedras, and enters the sea at the west extremity of the lines.

That part of Estremadura which lies north-west of the central ridge and between it and the sea is mostly flat and sandy towards the coast, and either barren or covered with forests of pines. Leiria lies in a fine valley on the Lis, at the foot of the hills which are covered with olive plantations. The country which lies to the south-east of the ridge sloping towards the Tagus is finer and better cultivated, especially the plains about Thomar and Santarem, which are very fertile, and abound with olive and other fruit-trees, and fine pasture grounds. The country about Cartaxo produces much wine. But the finest part of the whole province is that which lies to the south of the lines of Torres Vedras towards Lisbon. A second range of hills rises behind the first, extending from Mafra and Ericeira on the sea, to near Povoa on the Tagus, the high summit called Cabeça de Montachique standing in the centre; and south of these are the hills of Cintra, Queluz, Bellas, &c., which command the city of Lisbon and the banks of the Tagus down to Fort St. Julian. Between these various ranges are delightful valleys, covered with villages, convents, and quintas or country-seats, and with gardens, orchards, and vineyards, remarkably well cultivated. This pleasing exception to the generally slovenly state of agriculture over the greater part of Portugal was attributed, in the last century, and by authorities not liable to a suspicion of partiality, to the example of the English residents at Lisbon, who being partial to rural life, took pains to embellish their country-houses and gardens according to the fashion of their native country, and thus inspired the Portuguese with a taste for imitating them by availing themselves of the abundant resources which a fine soil, a favourable site, and a genial climate afford. (Du Chatelet and Bourgoing, *Voyage en Portugal*.) The vineyards of Bucellas, Carcavellas, and Collares, produce excellent wine. The neighbourhoods of Mafra, Cintra, Collares, Queluz, Cascaes, are justly celebrated for their romantic position. A pleasing sketch of these de-

lightful spots is given in Beckford's *Recollections of Portugal*, 1835.

The southernmost part of Estremadura, which lies on the left or southern bank of the Tagus, is not so fine as that on the right bank, being mostly low and flat, and unhealthy in several places. A range of hills which is a continuation of the Serra de Portalegre in Alentejo, which is itself joined to the mountains of Spanish Estremadura, runs from east to west at some distance south of the Tagus, enters Portuguese Estremadura north of Setubal, and terminates on the peninsula of Almada opposite to Lisbon. But the limits between Estremadura and Alentejo are not marked by this range, the line of demarcation being a tortuous and capricious one, beginning from the sea north of Cape Sines, then taking a semicircular sweep to the eastward, crossing the river Sadaõ and the range above mentioned east of Alcaer do Sal, and then turning northwards and following the course of the river Canha to the Tagus. The country inclosed within this line, the sea and the Tagus, forms the comarca or district of Setubal which is included in the province of Estremadura. But farther to the east Estremadura again encroaches upon Alentejo, extending along the left bank of the Tagus from Salvaterra up to Perales, which lies nearly opposite Abrantes and the hills called Cimes de Ourem: the limits between Estremadura and Alentejo are marked on this side by the course of the rivers Soro and Zatas, the latter of which falls into the Tagus. This part of Estremadura contains the territories of Chamusca, Almeirim, and Salvaterra, which are included in the administrative districts of Santarem and Alemquer beyond the Tagus. According to a new territorial division planned by the Cortes of 1822, the Tagus was to form the southern boundary of Estremadura, the whole left bank being considered as belonging to Alentejo. But the political convulsions that followed prevented the new plan from being put into execution.

Estremadura is divided into the following comarcas or districts:—1. Lisbon, which includes the capital and its suburbs; Belem, with its splendid monastery; Bemfica, near the fine aqueduct of Agoas Livres, which carries the water to Lisbon; Campo Grande, with an important manufactory of silks; Bellas, with 3400 inhabitants; Oeiras on the Tagus below Belem, once the residence of the marquis de Pombal. The population of the comarca of Lisbon is estimated at 360,000. 2. Torres Vedras, with the town of that name, 3400 inhabitants; and also Mafra, with 3000, and its splendid palace, church, and convent, called the Escorial of Portugal, and a vast royal park; Ericeira, near Mafra, a small fishing harbour; and the port of Cascaes, near the entrance of the Tagus. 3. Villa Franca, with the pretty town of that name on the Tagus above Lisbon, with 4000 inhabitants; and Alhandra, with 2000, a manufactory of lime, and brick kilns, which supply Lisbon with bricks. 4. Alemquer, with the town of that name, 2600 inhabitants, and a paper manufactory; and the town of Chamusca beyond the Tagus, with 3000. 5. Santarem: the town of that name stands on a steep hill rising above the Tagus, with several massive convents and other extensive buildings, and an old castle, and 7300 inhabitants. The other towns of this district are: Torres Novas, a lively place in a fine country, with about 4000 inhabitants; Golegão on the Tagus, where one of the principal fairs of Portugal is held; Salvaterra de Magos, on the left bank of the river, with a royal villa and hunting park, which contains wild boars. 6. Thomar, containing the town of Thomar, east of Santarem, with 4000 inhabitants, a large manufactory for spinning cotton, manufactories of hats and worsted stuffs, and a vast convent belonging to the military order of Christ. The other towns are: Abrantes, on the slope of a hill above the Tagus, with 5000 inhabitants, the fine church of St. Vincent, and a bridge of boats over the Tagus. The navigation of the river does not extend much above Abrantes, which is about 90 miles above Lisbon by the course of the river. Punhete, at the confluence of the Zezere with the Tagus, with 3000 inhabitants, and Pedrogão, at the foot of the Estrella, belong also to the district of Thomar. 7. Ourem, north-west of Thomar; the town of that name has 3000 inhabitants. 8. Leiria, containing the town of the same name, with 2000 inhabitants, with a bishop's see and a castle, on a steep rock. Near it is the village of Marinhagrande, with a glass manufactory, established by an English speculator. The other towns of this district are: Pombal, near the bor-

ders of Beira, with 4800 inhabitants. Batalha, near Leiria, with its splendid convent and church, one of the finest specimens of Norman Gothic architecture; it was built by King John I. after the victory which he gained over the Spaniards at Aljubarrota, in the neighbourhood. The church contains the tombs of the kings of Portugal. 9. Alcobaca, containing the town of Alcobaca, south-west of Leiria, with about 1300 inhabitants and a magnificent convent. The harbour of San Martinho is near Alcobaca, and farther south is the strong castle of Peniche, on a promontory facing the Berlengas Islands. 10. The district of Setubal. The town of that name, often by corruption called St. Ubes, is at the mouth of the river Sadao, has a good harbour and 15,000 inhabitants, and exports large quantities of salt, which is made from sea-water in the neighbourhood, and also wine and fruits, especially oranges. It is, next to Lisbon and Oporto, the most commercial place in the kingdom. The river Sadao rises in the Serra de Monchique, on the borders of Algarves, and is navigable for about 30 miles above Setubal. The other towns of this district are: Almada, opposite to Lisbon, with 4000 inhabitants. Aldea Galega, higher up the river, which is the common landing-place from Lisbon to the southern provinces; it has about 4000 inhabitants, chiefly boatmen and fishermen. Cezimbra, west of Setubal, near Cape Espichel, with a small harbour and 4000 inhabitants, chiefly fishermen. Alcacer do Sal and Azeitao are small towns in the interior.

The whole population of Estremadura is reckoned by Miñano at 800,000 inhabitants. Its area has been variously stated; according to Antillon and Miñano it is 750 square Spanish leagues of 20 to a linear degree of latitude. The climate is generally healthy, being free from the excessive heats of Alentejo and from the cold winters of Beira. The westerly winds, which find an opening along the wide valley of the Tagus, refresh the air. The rivers, as well as the sea-coast, abound with fish. The principal products of the country are wine, oil, maize, fruits of every sort, and cattle. Wheat and oats are rather scarce; but Lisbon imports corn and flour from other countries.

ESTREMOS, one of the strongest fortresses in Portugal, agreeably situated on the Tarra in Alentejo. It consists of the upper and the lower towns; the former with the citadel standing on an eminence, the latter in the valley below. Population 6500. Here Schomberg gained a victory over the Spaniards in 1663; 38° 46' N. lat., 7° 23' W. long.

ESTUARY. [ÆSTUARY.]

ESTERIO is a kind of fruit consisting of achenia, or small closed up seed-like seed-vessels, placed upon a succulent receptacle. The strawberry and the raspberry are of this nature, and are very incorrectly called *berries*, in the botanical sense of the word berry. [BACCA.]

ETAMPES, a town in France, in the department of Seine and Oise, on the road from Paris to Orléans, 28 miles in a direct line south by west of Paris, or 31 miles by the road. Etampes is on the bank of two little streams, that unite just below the town with the river Juine (or, as it is sometimes called, the river Etampes), which flows into the Essonne, a feeder of the Seine.

In the year 911 Etampes was burnt by the Northmen or Normans under Rollo. In the latter part of the same century, or the beginning of the next, Constance, wife of Robert, King of France, built here a castle, and Robert himself converted the Oratory of the castle into a collegiate church. The castle was held for the king in the eleventh and twelfth centuries by officers who had the titles of Pré-vôt, Bailli, or Vicomte. There was a Jews' synagogue at Etampes, which, on the expulsion of that people from France by Philippe Auguste, A.D. 1182, was converted into a church, that of Notre Dame, yet standing. In the fourteenth century Etampes, which had previously been a royal domain, was given by Philippe le Bel to his brother Louis, Count of Evreux. It afterwards came successively into the hands of the Dukes of Berri, Bourgogne, Bretagne, and again of Bourgogne. In the sixteenth century Etampes, with its territory or county was erected into a duchy in favour of Jean de Broesae, whose wife was mistress of Francois I. In the religious wars of France, A.D. 1562, the town was taken by the Germans brought into France by the Prince of Condé. In A.D. 1567 it was taken by assault by the Huguenots; in A.D. 1589 it was the rendezvous of the troops of the League, from whom it was taken by Henri III.

In A.D. 1590 it was taken from the party of the League, into whose hands it had again fallen, by Henri IV., who caused the fortifications of the castle to be razed. The town suffered much from the exactions of the contending parties in the civil war of the Fronde.

The town is in a tolerably fertile valley, and consists principally of one street. The tower of Guinette is the only remain of the ancient castle. There are at present four churches. That of Notre Dame has a lofty tower and spire; the semicircular arch may be observed in it. The church of St. Giles is also very ancient; it has the semicircular arch, with zig-zag mouldings. There are in the town several houses built about the time of the revival of the arts, especially that of the Duchess of Etampes, mistress of Francois I. The town-hall is an ancient turreted building. There is a large public granary erected recently. Etampes is surrounded by promenades planted with trees. Near the town is an ancient building, probably of Roman origin, but popularly called 'the tower of Brunehaut.' A modern castle has been erected upon these ruins.

The population of Etampes in 1832 was 8109. They manufacture soap, leather, woollen yarn, cotton counterpanes, and hosiery; and trade in wool, corn, flour, and honey. There are more than forty mills of different kinds on the two brooks which water Etampes: sandstone is quarried in the neighbourhood, and much garden-stuff raised for the supply of Paris. Etampes is the capital of an arrondissement (which had in 1832 a population of 41,208), and has a subordinate court of justice (tribunal de première instance), a high school, and an agricultural society. Guittard and Geoffroy de St. Hilaire were natives of this town.

ETAWEH, a district in the province of Agra, bounded on the north by Furruckabad and Alighur, on the east by the kingdom of Oude, on the south by Cawnpore, and on the west by the district of Agra. The district of Etawah forms part of the Doab, and was acquired by the English from the king of Oude in 1801. The principal towns are Etawah, the ancient capital, and Minpooree, the modern capital; Kanoje, Belah, and Shekoabad. The town of Etawah stands on the east bank of the Jumna, in 26° 47' N. lat. and 78° 53' E. long., about 70 miles south-east from Agra. Minpooree is a large town on the banks of the Issa, in 27° 14' N. lat. and 78° 54' E. long., about 62 miles east from Agra. It stands in a fertile country, and is a populous place. Kanoje stands on the west side of the Ganges, in 27° 4' N. lat. and 79° 47' E. long., about 65 miles west-north-west from Lucknow. This is a very ancient place: it was formerly of considerable extent, and at the period of the Mohammedan invasion was the capital of a powerful empire, but at present consists of only one street. It is two miles distant from the Ganges, but is connected with that river by means of a canal. Belah is about 21 miles south-south-west from Kanoje, in 26° 49' N. lat. and 79° 27' E. long. Shekoabad is situated in 27° 6' N. lat. and 78° 27' E. long., about 37 miles east-south-east from the city of Agra. The soil, productions, and climate of this district have already been described. [AGRA; DOAB.]

ETCHING. [ENGRAVING.]

ETFU. [EDFU.]

ETHAL, a substance separated from spermaceti by Chevreul. It is a solid, fusible at nearly the same point as spermaceti, and on cooling crystallizes in plates. It is insoluble in water; but in alcohol at 150° Fahr. is much more soluble than spermaceti. It is susceptible of union with various bases, with which it forms salts or soaps.

ETHELBALD, king of Wessex, was the eldest surviving son of Ethelwulf, who resigned to him the throne of that state in 855 or 856. [ETHELWULF.] On the death of Ethelwulf in 857 or 858, Ethelbald married his young step-mother, Judith of France; but the vehement remonstrances of Swithin, bishop of Winchester, prevailed upon him, after some time, to abandon the incestuous connexion. Judith afterwards became the wife of Baldwin, count of Flanders, and the ancestress of Matilda, the wife of William the Conqueror, and, through her, of all the succeeding kings of England. The chroniclers speak in very favourable terms of the subsequent conduct of Ethelbald; but although he had greatly distinguished himself in the wars with the Danes in his father's time, his own reign is not marked by any military events. He died in 860, and was succeeded by his next brother, Ethelbert.

ETHELBERT, or, as the name is written by Bede,

AEDILBERT, was the fourth king of Kent in lineal descent from Hengist, through Eric or Aesc, Ocha or Ohta, and Ermeric, whom he succeeded while yet a child in the year 560. As the representative of the first leader of the Anglo-Saxons and the founder of the oldest kingdom of the Heptarchy, Ethelbert, as soon as he attained manhood, engaged in a contest for the title of Bretwalda with Ceawlin, king of Wessex, who claimed that supreme dignity as the grandson of Cerdic. [ENGLAND.] He invaded Wessex in 568; but the war was speedily ended by his defeat in a great battle fought at Wibbandune, now Wimbledon, in Surrey. This was the first instance of one of the states of the Heptarchy drawing the sword against another. Ethelbert, however, according to Bede, came to be acknowledged as bretwalda about the year 589, after the decline of the fortunes of Ceawlin, who was deposed about this time by his subjects, and ended his days a few years after. Ethelbert retained the supremacy during all the remainder of his reign, though it would seem that his title never was acknowledged by the kings of Northumbria.

The most memorable event in the reign of Ethelbert was his conversion to Christianity and the establishment of that religion in his dominions by the ministration of St. Augustine. [AUGUSTINE, ST.] Ethelbert professed himself a Christian, and was baptized on the feast of Pentecost A.D. 597. The Christian worship, however, must have been familiar to him long before this time; for he had been married to a Christian wife, Bertha, the daughter of Charibert, king of Paris, in the year 570, and she and her attendants had ever since practised their own religion under the guidance of Liudhard, a bishop who had accompanied her from France. After his conversion, Ethelbert exerted himself with zeal in the diffusion of his new faith. He founded the bishopric of Rochester about the year 604 in his own dominions, in addition to the archbishopric of Canterbury, the establishment of which is dated from the arrival of Augustine. To him also must be principally attributed the foundation, about the same time with that of Rochester, of the bishopric of London, in the state of Essex, which was at this time governed in subordination to Kent by Sebert, Sebert, Sabert, Sæbryht, or Saba, a nephew of Ethelbert. Bede says that the cathedral of London, which was dedicated, like the others that have since been built on the same site, to St. Paul, was erected at the joint expense of Ethelbert and Sebert. The conversion of the king and people of Essex had previously been effected through the influence of the king of Kent. It was also through his daughter Edilberga, who married Edwin, king of Northumbria, that Christianity was introduced into that state. [EDWIN.]

Ethelbert deserves especial remembrance in English history on another account. He is the author of the earliest of our written laws, the collection of 'Dooms,' as Bede calls them, 'which he established with the consent of his witan in the days of St. Augustine.' They are written in Saxon, or English, as it is termed by Bede, although all the other Teutonic nations employed the Latin language in their codes; and they are the earliest laws that exist in any barbarous or modern tongue. There is no reason however to suppose that the regulations which they established were in general new. They relate, to quote the words of Sir F. Palgrave (*Eng. Com.* p. 44), 'only to the amount of the pecuniary fines payable for various transgressions, the offences against the church being first enumerated. These were of new introduction; but every other mulct was known before; and it is probable that the principal benefit of the law consisted in a fairer apportionment of the compensation to the crime than could be obtained according to the older customs.' The collection consists altogether of eighty-nine enactments or clauses; at least as it has come down to modern times. But the only copy of it which we possess is that contained in the volume called the 'Textus Roffensis,' which was compiled by Ernulfus, bishop of Rochester, in the early part of the twelfth century; and 'it is difficult to believe,' as Sir F. Palgrave has observed, 'that the text of an Anglo-Norman manuscript of the twelfth century exhibits an unaltered specimen of the Anglo-Saxon of the reign of Ethelbert. The language has evidently been modernized and corrupted by successive transcriptions. Some passages are quite unintelligible. . . . Neither is there any proof whatever of the integrity of the text. It cannot be asserted with any degree of confidence that we have the whole of the law. Destitute of any sta-

tutory clause or enactment, it is from the title or rubric alone that we learn the name of the legislator.' The next oldest Anglo-Saxon laws that have been preserved (those of Hlothære and Eadric, also kings of Kent) are more than a century and a half later than Ethelbert.

Ethelbert died in 616. He appears in his old age to have married a second wife, but her name has not been recorded. All that we know of her is, that after the death of Ethelbert, her youth and beauty were sufficient to tempt his son and successor, Eadbald, to take her to his bed, and of course to renounce at the same time the profession of Christianity. After a short time however Eadbald dismissed his stepmother, and returned to the faith he had abandoned, of which he ever after continued a firm supporter. The dignity of Bretwalda went, on the death of Ethelbert, to Redwald, king of the East Angles.

ETHELBERT, king of Wessex, was the second surviving son of Ethelwulf, by whom he was made king of the subordinate state composed of Kent, Essex, Sussex, and Surrey in 852, on the death of Athelstan. [ETHELWULF.] On the death of his elder brother Ethelbald, in 860, although excluded by his father's will from the succession to the supreme crown of Wessex, he was preferred by the Witan to his younger brother Ethelred, who claimed under the will. The chronicles celebrate the courage and military talents of Ethelbert: but no events of his short reign are distinctly recorded. It appears however that the Northmen continued to make occasional descents both on the coasts of Wessex, and on those of other parts of the island. All that we are told of Ethelbert is, that he died in 865 or 866. He appears to have left a son, Ethelwald, and other children; but he was succeeded on the throne of Wessex by his younger brother Ethelred.

ETHELRED I. (called also Edelerd and Ethered), king of Wessex and head of the Heptarchy, was the third surviving son of King Ethelwulf, who in his will (ratified by the Witan) appointed Ethelred to succeed to the throne immediately after his eldest brother Ethelbald; he did not however succeed till after the death of his elder brother Ethelbert in 866. [ETHELWULF and ETHELBERT of Wessex.] The reign of Ethelred was eminently disastrous both for Wessex and for the other states of England. In the last year of the preceding king, the great Danish chief, Ragnar Lodbrog, had been taken prisoner while making an attack on Northumbria, and put to death with cruel tortures. It appears to have been with the purpose of avenging this loss that the various Scandinavian nations immediately united their strength in that great expedition against England, which terminated in the conquest of half the country. The invaders, to the number of several thousands, under the command of Ingvar (or Ivar) and Ubbo (or Hubba) landed on the coast of East Anglia, immediately after the accession of Ethelred to the throne of Wessex. Having encamped and passed the winter on shore, they marched into Yorkshire in the spring of 867, took possession (1st March) of the city of York, and having there (12th April) repulsed with great slaughter an attack of the Northumbrians under Osbert and Ella, made themselves masters of all the kingdom of Northumbria to the south of the Tyne, and placed Ingvar over it as king. They then marched into the kingdom of Mercia, and passed the winter of 867-8 in the town of Nottingham. Beorhed, the Mercian king, now solicited the aid of Ethelred; and the king of Wessex, accompanied by his younger brother Alfred, whom he appears to have admitted to a share of the royal power, advanced with an army against the foreigners. The Danes however did not venture to engage the allied forces of Wessex and Mercia; and a treaty was made by which they agreed to evacuate Nottingham and to retire to York. In that city they remained quiet for the remainder of this year, and all the next, during which England was afflicted by a severe famine, followed by a terrible mortality both of human beings and cattle. But, in the spring of 870, disregarding the late pacification, they resumed hostilities, carrying their arms across the Humber into Lincolnshire, which was included in the dominions of Mercia. Notwithstanding some attempts to check their progress, which were made by Earl Algar, the governor of the district, they speedily overran all Lincoln, and pushed their way into the adjoining territory of East Anglia, sacking and destroying in their course the abbies of Croyland and Medehamstead (or Peterborough), the town of Huntingdon, and the nunnery of Ely, and massacring and laying waste wherever they appeared.

with unheard-of ferocity. At a village called Hoxton, in Norfolk, they seized Edmund, the East Anglian king, and put him to death: he sustained the torments they indicted upon him with such constancy that he was afterwards revered as a martyr, and the 20th November, the day on which he met his fate, was assigned to him in the calendar. His death made the Danes masters of East Anglia, over which they placed Godrun, one of their chiefs, as king. They now resolved to invade Wessex, the only state which they had not either conquered or rendered powerless. They entered Berkshire, under the command of Halfden and Bacseg, and took the town of Reading without encountering any resistance; but they were soon after attacked by Earl Ethelwulf at the neighbouring village of Inglesfield, and driven from their ground with the loss of Sidnor, one of their most renowned captains. Four days after they were fallen upon at Reading by King Ethelred and his brother Alfred; but on this occasion the Saxons were repulsed with great loss, the brave Earl Ethelwulf being among the slain. The battle of Reading, however, was followed in four days more by another more important encounter at a place which the old writers call Aescsedun, or the Ash-tree Hill, and which has been supposed by some to be Ashbury in the west, by others Ashton in the east, of Berkshire. The Danes were here attacked with great impetuosity and valour by Alfred, and, notwithstanding their advantageous position, were, after a struggle of some length, completely defeated and put to flight. It is said that the English chased them for the whole of the night and next day over the country till they reached the town of Reading, in which they again shut themselves up. But a fortnight after the battle of Ash-tree Hill they again met the two kings of Wessex at Basing, in the north of Hampshire, and this time the English were worsted. A similar result attended the next battle, fought, about two months after, at a place called Merton, which has been variously conjectured to be Merton in Surrey, Merton in Oxfordshire, Merden in Wilts, and Morton in Berkshire. In this engagement, which must have taken place early in 871, Ethelred received a wound, of which he died soon after Easter, leaving the now almost shadowy inheritance of the crown of Wessex, and what would at a later period have been called the suzerainty of England, to his younger brother Alfred.

ETHELRED II., surnamed the Unready, king of the Anglo-Saxons, was the youngest son of King Edgar, by his second wife, the infamous Elfrida. On the murder by Elfrida of his elder brother, Edward the Martyr, in 978, he was reluctantly acknowledged as king by the Witan, in the absence of any other individual having pretensions to the crown; even Dunstan, who had steadily opposed the party of Elfrida throughout the late reign, finding himself now obliged to acquiesce in the accession of her son. He was crowned by Dunstan, at Kingston on the Thames, on the 14th of April, being at this time only a boy of ten years old. The reign of Ethelred the Unready is on the whole the most calamitous and disgraceful in English history. The feeble and distracted government that arose out of his minority and the circumstances of his accession immediately drew once more upon England the attention of the northern piratical powers, who had now remitted their attacks for nearly a century. A small body of Danes landed at Southampton in 980; and scarcely a year passed afterwards in which one part or other of the coast was not in like manner visited and ravaged, usually with impunity. At length, in 991, a much larger force than had before appeared arrived under two leaders, named Justin and Gurthmund, and after taking the town of Ipswich, proceeded to Maldon, and there encountering the English army commanded by the alderman Brithnot, obtained a complete victory, Brithnot himself being slain. On this it was resolved by the English Witan, on the advice, it is said, of Siric, who had succeeded Dunstan as the king's chief counsellor, to buy off the invaders with a sum of money. They agreed to accept 10,000 pounds of silver, which was accordingly paid to them, being raised by an impost on all the landed property in the kingdom, which from this time became a regular tax, under the name of the Danegeld, and was perhaps the first direct tax imposed in England. It was felt however that this was a very precarious expedient to trust to; and, as soon as the Danes were gone, the government proceeded to fit out a formidable fleet, which might perhaps have been of service if it had been ready to meet them when they arrived. As it was, it was no sooner afloat than it was rendered useless

by treachery and mismanagement. A squadron of Danes having again appeared on the coast in 992, Alfric, the commander of the English fleet, when sent to surprise them, secretly gave them information of the intended attack, and then went over and joined them. The next year, when the Northmen made a descent upon the coast of Northumberland, and took by storm the castle of Bamborough, the leaders of the force sent against them in like manner deserted to the enemy. In 994 a much more powerful armament than had yet appeared sailed up the Thames under the command of Sweyn or Svein, king of Denmark, and Olave king of Norway; it consisted of ninety-four ships, and directed its first efforts against London, which however defended itself successfully against the assault. The invaders then overran and laid waste a great part of Essex, Kent, Sussex, and Hampshire. In the end they were again bought off by the payment of a sum of money, their demand this time rising to 16,000 pounds of silver. Olave now consented to embrace Christianity; and he faithfully kept his promise of never again molesting England. Not so the king of Denmark; his forces continued their attacks year after year; and at last, in 1001, Ethelred found himself once more compelled to rid himself of them for the moment by his old expedient. He was now obliged to pay them 24,000 pounds of silver.

For what length of time the relief which he thus purchased might have lasted it is impossible to say. Ethelred now resorted to another mode of dealing with the evil, which was of a very different character from that to which he had hitherto adhered, but combined the qualities of being at once still more unjustifiable and still less likely to prove efficacious. On the 13th November, the festival of St. Brice, in the year 1002, the English inhabitants, in obedience, it is said, to secret instructions received in every city from the government the evening before, suddenly rose in all parts of the kingdom upon the Danes who were resident among them, and put them to death, men, women, and children. There has been some dispute as to the precise extent to which the massacre was carried, and it cannot be supposed to have comprehended all the persons of Danish descent resident in the country, for in many districts it is certain that the majority of the inhabitants were of this description; but there can be no doubt that a very large number of persons perished. This atrocious and in every way unwise proceeding did not long remain without its fit punishment. The next year Sweyn, whose sister, married to an English earl, had been among the butchered, again appeared on the south coast; and from this time it may be said the kingdom had no rest. After the devastations of the invaders had been continued for four years, they were once more bought off in 1007 by a payment of 36,000 pounds of silver. The next year, by extraordinary efforts, a numerous fleet was built, and assembled at Sandwich; but a dispute arising among the captains, one of them deserted with twenty vessels, and turned pirate, and nearly all the rest were soon after destroyed by a tempest. Meanwhile, all the other forms of public calamity combined to afflict the nation. The king was an object of general hatred or contempt; the nobility were divided into hostile factions; and famines and contagious diseases vied with the swords of the invaders in destroying the miserable people. In 1009 a new Danish force arrived, under a leader named Thurchil, who for the three following years spread devastation throughout the only part of the country that had hitherto afforded an asylum from the foreigners, the fens of East Anglia. At last, after he had sacked and burned the city of Canterbury, Thurchil was bought off in 1012 by a payment of 48,000 pounds of silver, and he and his followers agreed, on being allowed to settle in the country, to become the subjects of the English king. But the next year Sweyn himself again made his appearance, now avowing his determination not to depart till he had effected the conquest of the country. Entering the Humber, he received the submission both of the Northumbrians and of the parts of Lincoln that were in like manner chiefly inhabited by a population of Danish descent. He then marched across the country to London, putting all the males to the sword as he advanced; but the capital, which was defended by Ethelred and Thurchil, resisting his assault, he turned to the west, and, compelling the nobles to make their submission to him wherever he passed, he proceeded to Bath, and there caused himself to be proclaimed king of England. Soon after this London submitted to his authority; and in

the middle of January, 1014, Ethelred fled to the court of Richard duke of Normandy, whose sister Emma he had married some years before. He had previously sent thither Emma and her two children.

On the 2nd of February however Sweyn died. His son Canute was immediately proclaimed king by the army; but the English determined to recall Ethelred. He was brought back accordingly, after entering into a solemn agreement with the Witan, that he would be a good lord to them, and amend all they wished to have amended, and that all things should be forgiven which had been done or said against him, they on their parts promising that they would all turn to him without fraud, and would never again permit the Danes to have dominion in England. Canute deemed it prudent to take flight before the national enthusiasm of the moment; and it is said that another general massacre of the Danes that were left behind in the country signalized the restoration of a national government. But Canute returned the following year with a powerful fleet: he was immediately joined by Thurchil, who, till now, had remained faithful to his English allegiance; other chiefs followed Thurchil's example, and a great part of the country appears to have again speedily submitted to the Danes. Ethelred was confined to his bed by illness when Canute arrived, and he died in London on the 23rd of April, 1016, at the moment when the enemy was preparing to attack that city. He was succeeded by Edmund, surnamed Ironside, his eldest son by a lady named Elfleda, who is said to have borne him six sons and four daughters, but to whom it is doubtful if he was ever married. Edward, one of his two sons by Emma of Normandy, whom he married in 1002, also afterwards ascended the throne. [EDMUND IRONSIDE, and EDWARD THE CONFESSOR.]

ETHELWULF was the son of Egbert the Great, whom he succeeded in the throne of Wessex and the supremacy over the other states of the Heptarchy, in 836. The provinces of Kent, Essex, and Sussex, which Egbert had conquered and annexed to his dominions, and also that of Surrey, which had hitherto been included in Wessex, were at the same time formed into a separate but subordinate kingdom, and put under the government of Athelstane, whom some of the chroniclers state to have been the eldest son, others a younger brother of Ethelwulf. There is no older authority than that of Malmesbury (whose account is indisputably incorrect in several particulars and improbable in others) for the story that Ethelwulf was a monk at the time of his father's death. His early education is recorded to have been conducted first by Helmstan, bishop of Winchester, and afterwards by Swithin, whom, on coming to the throne, he advanced to the same see; and he had also served with distinction in the field in the lifetime of his father. When he succeeded to the crown he retained as his chief counsellor the able Alstan, bishop of Sherborne, who had been in great favour with Egbert. What has been preserved of the history of the first fourteen or fifteen years of the reign of Ethelwulf consists almost exclusively of the detail of a series of contests with the Danes, who now continued with incessant perseverance those descents upon the English coasts which they had commenced in the preceding reign. In 837 three squadrons of them made attacks on different points nearly at the same time. The next year they landed again in great strength in Lincolnshire, and, after defeating the troops sent to oppose them, marched across and ravaged the country down to the Thames. In 839 three hard battles are recorded to have been fought at Rochester, Canterbury, and London, besides an action at sea, near Charmouth, in which the English fleet, commanded by Ethelwulf in person, sustained a defeat. For some years after this however the Northmen, abandoning Britain, directed all their efforts against the coasts of France. But in the latter part of the year 850 a body of them landed in the Isle of Thanet, when, so ill-prepared was Ethelwulf for the attack, that the foreigners were enabled for the first time to pass the winter in the country. In the spring of 851 they were joined by great numbers of their countrymen, and the whole multitude ascending the Thames in a fleet of 350 vessels, plundered Canterbury and London. They then penetrated into Surrey; but here they were met by Ethelwulf at Okeley, and after a long and obstinate battle, were defeated with immense loss. They were soon after worsted in another battle at Wenbury, in Devonshire, and also in a sea-fight near Sandwich by Athelstane, the king of Kent. The consequence was, that

the Danes did not again make any attempt on England during the reign of Ethelwulf.

In 852, on the death of Athelstane, the kingdom of Kent was assigned by Ethelwulf to his second son, Ethelbert, he himself retaining the chief sovereignty as before. The following year, at the request of Beohred, or Burhred, king of Mercia, he led an army against the Welsh, and marched through their country as far as the Isle of Anglesey, compelling them to acknowledge themselves the subjects of himself and Beohred. On the termination of this expedition he gave his daughter Ethelswitha in marriage to the king of Mercia. In 855 he undertook a journey to Rome, accompanied by his youngest son Alfred, who had been also carried to that city in the preceding year by bishop Swithin. Ethelwulf had by this time lost his first wife Osberga, a daughter of Oslac, designated the king's cup-bearer; and now, on his return through France, he fell in love with Judith, daughter of Charles the Bald, king of that country, and married her, although she had not yet reached her twelfth year. Meanwhile however his eldest son Ethelbald, taking advantage of his father's absence (whom perhaps he represented as being in his dotage), had entered into a scheme for seizing the throne. It is said that among his accomplices was the prime minister Alstan, and that he was also supported by the chief nobility, from which we may conjecture that the attempted revolution was not without some strong reasons in its favour. And although the return of Ethelwulf is said to have prevented the full success of the design, it was substantially carried into effect. It was agreed at a solemn meeting of the Witan that Ethelbald should become king of Wessex, and that Ethelwulf should reign as sovereign, with Ethelbert under him, in Kent and the other eastern provinces. It may be supposed that in his new position Ethelwulf enjoyed little more than a nominal authority. He spent the remainder of his days mostly in exercises of devotion, and died in 857 or 858. By his will, which was confirmed by the Witan, he left the kingdom of Kent to his second son Ethelbert, and that of Wessex in succession to his other sons, Ethelbald, Ethelred, and Alfred.

One of the legislative acts of the reign of Ethelwulf has given rise to much discussion, namely, the grant which he made in 854 or 855, with the consent of the Witan, in favour of the church, and which was wont to be considered as the original foundation of the right of the clergy to the tithes. The grant is recited by Ingulfus, Malmesbury, and Matthew of Westminster, but not in the same terms. Lingard observes that 'the copies are so different, and the language is so obscure, that it is difficult to ascertain its real object; whether it were to exempt from all secular services the tenth part of each manor, whoever might be the possessor, or to annex that portion of land to the possessions which had already been settled on the church.' It cannot, Turner thinks, have been the original grant of the tithes of all England. The 'words,' he observes, 'imply either that it was a liberation of the land which the clergy had before been in possession of from all the services and payments to which the Anglo-Saxon lands were generally liable, or that it was an additional gift of land, not of tithes, either of the king's private patrimony, or of some other which is not explained.' Palgrave contends that it was not a grant of tithes, but a grant of the tenth part of the land by metes and bounds, to be held free from all secular services; yet he admits that the interpretation which construes the grant into an enfranchisement of all the lands which the church then possessed, is 'not altogether void of probability.' (*Eng. Com.* p. 159.) There is a dispute also about the date of the grant. Palgrave conceives that Ethelwulf made it on his return from Rome; Turner and Lingard both place it before his journey thither. The latter adds: 'This charter was at first confined to the kingdom of Wessex; but in a council of the tributary states, held at Winchester in 855, it was extended to all the nations of the Saxons.'

ETHER. [ÆTHER.]

ETHEREGE, sometimes written ETHERIDGE, SIR GEORGE, born about 1636, was a distinguished wit and dramatic writer of the reign of Charles II. According to the usual routine of a gentleman's education at that time, he studied law at an inn of court and travelled. In 1664 he made his first public appearance as author of the comedy called 'Love in a Tub.' 'She Would if she Could' followed in 1668, and 'The Man of Mode, or Sir Fopling Flutter,' in 1676. All these were received with much favour by the

public, but 'Sir Fopling Flutter' has been the most esteemed. They placed him, with Buckingham, Rochester, Sedley, &c., in the first rank of the wits of the day. Ease and brilliance of dialogue are their characteristic excellence; but they have an ingrained taint of licentiousness running through the whole conception as well as the language, which has long excluded them from the stage. If the characters are supposed (which is the author's best excuse) to be but highly coloured copies of the fine gentlemen and ladies of the day, we shall marvel that the name and estimation of gentlemen should ever have been sullied by such a total want of truth and honour. Sir George Etherege's verses are not numerous, and consist of occasional pieces, lampoons, songs, and short amatory poems, some of which are of a very licentious character. Their style may be guessed from his appellations of *easy Etherege* and *gentle George*. Rochester, in his 'Session of the Poets,' gives high praise to our author, in saying that

Of all men that writ,
There's none had more fancy, taste, judgment, and wit.

Fancy and wit may be allowed him: the taste and judgment suited Rochester's own. Etherege's private life may be guessed from his writings: play injured his fortune, debauchery his constitution. He repaired the former by marrying a rich widow, whose price was a title; and to win her he purchased his knighthood. He was in James II.'s household, and was afterwards employed by that king as minister to Ratisbon, where, by some accounts, he died from a fall down stairs after a convivial entertainment; but this appears uncertain. The time of his death seems to have been about the Revolution.

There is an edition of his Plays and Poems in 8vo., London, 1704, and one in 12mo., London, 1715.

ETHEREUM, a theoretic carburetted hydrogen, consisting of 4 equivalents of carbon = 24, and 5 equivalents of hydrogen = 5: its equivalent is therefore 29. Among the various theories which have been proposed respecting the constitution of ethers, that which supposes it to contain etherium (as it is termed by Dr. Kane, and *ethule* by Berzelius), as a base combined with oxygen, is perhaps to be preferred to all others. It is indeed true that etherium has never been obtained in a separate state, but allowing its existence, ether may be regarded as an oxide of etherium, alcohol a hydrated oxide of etherium or a hydrate of ether, and sulphuric acid may be viewed either as a hydrated bisulphate of oxide of etherium, or a hydrated bisulphate of ether.

ETHEREA, Lamarck's name for a genus of Conchifers, placed by many authors among the *Chamidae*, but separated by Deshayes and others from that family for the reasons assigned under the article **CHAMACEA**.

Animal closely approximating to that of *Unio*. Lobes of the mantle disunited throughout their length, and, consequently, without either tubes or syphons. Below the foot, the branchiæ of the right side unite themselves to those of the left side in the medial line, and leave below them a rather large canal, in which the vent terminates. The branchial leaflets are unequal, strongly striated and festooned on their free border. The mouth is rather large, and furnished on each side with a pair of palps like those of the *Uniones*. Finally, (and, as Deshayes observes, it is a great singularity in an animal that lives attached to foreign substances,) it is provided with a very large foot, which may be compared in regard of its form and position with that of *Unio*.

Shell adherent, thick, nacreous, very irregular, inequivalve, inequilateral; *umbones* short, thick, indistinct; *hinge* toothless, irregular, undulated, callous; *ligament* longitudinal, tortuous, external, penetrating pointedly into the interior of the shell; *muscular impressions* oval, irregular, one superior and posterior, the other inferior and anterior; *pallial impression* narrow and small.

Obs.—M. Deshayes observes that on examining the shells of this genus, in which the ligament is not ruptured, it appears that the ligament is not entirely internal or sub-internal, like that of the oysters, but that it has completely the structure of external ligaments. It is when the shells are young that the structure of the ligament is most easily recognized. There are two muscular impressions, always very distinct in old individuals; but, in the young ones, it sometimes happens that one only can be distinguished, and it was upon an individual in this state of growth that M. de Férussac established his genus *Mulleria*, which, in the

P. C., No. 601.

opinion of M. Deshayes, cannot be retained. With regard to the crenulations on the hinge adverted to by M. de Férussac, M. Deshayes states that he had seen on the very individual which M. de Férussac had in his hands some small fractures resulting, as it appeared to M. Deshayes, from this cause, namely, that the shell having been taken with the animal, the valves had been separated by attacking the ligament with a sharp instrument.

Geographical Distribution, Habits, &c.—Lamarck considered the genus *Etheria* to be marine, and accounted for its having escaped the notice of zoologists because it was attached to rocks at great depths in the sea. Mr. G. B. Sowerby, after noticing the locality attributed to the genus by Lamarck, remarks that two circumstances observable in the *Etheria* (*E. semilunata*), figured in his plate, would have induced him to suspect that this was a fresh-water shell, or at least an inhabitant of estuaries at the mouths of rivers; 1st, its having an epidermis, which remains only in those parts least exposed to the action of the water, the greater part especially of the upper valve being eroded in a very irregular manner; and 2ndly, its being partly covered with the remains of those ovate vesicular bodies, supposed to be the eggs of some molluscous animals so frequently seen on fresh-water shells. M. Cailliaud was the first to make known the fact that the genus is an inhabitant of the fresh waters, and M. de Férussac (*Mémoires de la Société d'Histoire Naturelle*, vol. i.) published a paper on the subject from M. Cailliaud's materials, in which the former also made a revision of the species. M. Deshayes, in his treatise on the genus (*Encyclopédie Méthodique*), states that individuals of the same species adhere by the one or the other valve indifferently, which, he remarks, is not the case with the oysters or the *Chama*. That *Etheria* may be attached indifferently by either valve there is no reason to doubt after the assertion of M. Deshayes; but Mr. Broderip (*Zool. Trans.*, vol. i.) observes that the same species of *Chama* is sometimes attached by the right, sometimes by the left valve. [**CHAMACEA**, vol. vi., p. 470.] M. Rang, during a voyage to Senegal, made some interesting observations on *Etheria* which live 200 leagues from the mouth of the river in the Senegal, and, together with M. Cailliaud, who received the animal from the Nile, published a memoir (*Mémoires du Muséum d'Histoire Naturelle*) full of interest, in which the animal was described for the first time. The rivers of Africa and Madagascar appear to have afforded the specimens (which are still rather scarce in cabinets) hitherto collected. M. de Férussac, in his memoirs, gives the following information from M. Cailliaud. 'We first meet with *Etheria*,' says that zealous traveller, 'after passing the first cataract; and they do not appear to exist below; they become very abundant in the province of Rebata, beyond the peninsula of Merœ. The inhabitants collect them on the banks of the river, to ornament their tombs with them, and they say that they come from the more elevated parts of the Nile, from Saïda, where they are eaten.' M. Cailliaud found them as far as Fazoql, the most distant country into which he penetrated from the Blue River. In Sennaar, the inhabitants informed M. Cailliaud, that during the summer season, when the river was low, they took them with the animal; but notwithstanding all his endeavours, M. Cailliaud could not obtain any living specimens, the river being then always too high. They are said to be very common in the Jaboussi, a river which runs into the Blue River, and in all appearance the numerous confluent streams of this great arm of the Nile produce them also. The number found upon the tombs throughout Ethiopia is so great, that it is astonishing that Bruce and Burckhardt should not have mentioned them. (*Zool. Journ.*, vol. i.)

Lamarck recorded four species of *Etheria*, which he divided into two sections, each containing two species. The first of these consists of species which have an oblong callosity in the base of the shell; the second, of those which have no encrusted callosity at the base of the shell. These four species M. de Férussac (with justice in the opinion of M. Deshayes) reduces to two; so that the sections, as left by Lamarck, would each, in that case, consist but of one species, viz., the first of *Etheria elliptica*, and the second of *Etheria semilunata*. M. Deshayes remarks that Lamarck saw but a very small number of individuals, and not being aware of their extreme variation, established species from the form of the shell; and it is certain, he adds, that if we were to follow the same indication at the present day, we

VOL. X.—H

might establish a species for each individual. He notices M. Rang's judicious observation, that in the same species there are individuals armed with spines, and others devoid of those appendages, and that the shades of this character are so gradual that it is impossible to regard it as of the smallest importance. In following out this principle, M. Rang considers *Etheria tubifera* of Sowerby and *Etheria Cailliaudi* of Férussac as identical, and *E. Corteroni* of Michelin to be the same as *E. plumbea* of Férussac. It is to the last-named species that M. Deshayes thinks that the genus *Mulleria* should be referred.

Etheria semilunata.

Etheria, or, as some write it, *Ætheria*, has not yet been discovered in a fossil state. It should be remembered that Rafinesque uses the term for a genus of Macrourous Crustaceans belonging to the *Palæmonidae*.

ETHERINE, a peculiar carburetted hydrogen, which has also been regarded as the basis of æther. It is supposed to consist of 4 equivalents each of hydrogen and carbon.

ETHERO-SULPHURIC ACID—ETHIONIC ACID. This acid is prepared by passing the vapour of anhydrous sulphuric acid slowly into absolute alcohol kept cold; by their mutual action an oleaginous fluid is formed, without the evolution of any gaseous matter. This fluid is to be mixed with water and saturated with barytes, by which a portion of sulphate is separated, and ethero-sulphate of barytes is obtained by evaporation in vacuo.

The acid in this salt is stated to consist of—

| | |
|------------------------------------|----|
| Two equiv. of sulphuric acid . . . | 80 |
| One equiv. of etherine | 28 |
| One equiv. of water | 9 |

Equiv. of ethero-sulphuric or ethionic acid 117

It may be considered either as a hydrated bisulphate of etherine, or as an anhydrous bisulphate of æther, or of oxide of etherium.

ETHICS is the science which relates to our mental affections, not simply as phenomena, but as they are virtuous or vicious, right or wrong. (Dr. Thomas Brown's *Lectures*, p. 486, Edinb., 1830.) The term is derived from the Greek *êthikê*, which, in signification, is equivalent with the Latin *mos*, *mores*, whence the adjective *moralis*, and the English word *morale*. Aristotle, in the second book of his *Ethics*, addressed to his son Nicomachus, says that moral science received the name of ethics from the word *êthos* (*ἦθος*), 'habit, use, or custom,' (*ἡθικὴν, ἀπὸ τοῦ ἔθους*,

or *ἀπὸ τῶν ἡθῶν*), since it is from habitual experience, and the routine of customary conduct that moral dispositions and principles are gradually formed and changed. Cicero, in his work on moral ends (*De Finibus*, l. 1 and 5) briefly defines ethics, or morality, as the 'ars vivendi,' or 'doctrina bene vivendi,' that is, the art of living wisely. The scholastic treatises on ethics divide the practical part of the science into three departments *êthike* (*ἠθικὴ*), which shows, by appropriate precepts what is the duty of a good man; *oecônômike* (*οἰκονομική*), which shows what is the duty of a good father of a family; and *politike* (*πολιτικὴ*), which exhibits the duty of a good citizen, and of a good magistrate. [MORALS.]

ETHICUS, or ÆTHICUS, is conjectured to have lived about the fourth century of our æra, and is the reputed author of a *Cosmography* or short description of the world, being an enumeration of the seas, islands, provinces, mountains, rivers, and towns of the then known world, with a short account of the sources and course of the principal rivers. In speaking of the Tiber's course through Rome, he mentions the gate of St. Peter, that of St. Paul, and the Via Portuensis, or of 'the martyr St. Felix.' He also speaks of Rome as the mistress of the world, of the games held by the Romans, of the præfectus urbis, &c. These circumstances may serve to fix the time of the compilation of the work towards the end of the fourth century, when Rome had become completely Christian, but yet before Alaric's invasion. Æthicus and his *Cosmography* are mentioned by several writers of the following ages, and among others by Isidorus of Seville, who lived in the early part of the seventh century. Rabanus Maurus (*de Inventione Linguarum*), a writer of the ninth century, calls Æthicus 'a Scythian;' and Flodoardus, a writer of the following century, calls him 'Ister' from 'Istria.' (Vossius, *de Historicis Latinis*, b. iii.) At the beginning of his *Cosmography* Æthicus states that Julius Cæsar, during his consulship with M. Antony, by virtue of a senatus consultum, ordered a survey of the Roman world to be taken, and that the work was entrusted to three geometers, Zenodorus for the eastern part, Polycleitus for the south, and Theodotus for the north, who completed their work under Augustus. This survey was probably the source from which the Antonine Itinerary was derived, which Itinerary in its present shape has also been attributed by some to Æthicus. [ANTONINUS, ITINERARY OF.] The *Cosmography* in most publications is followed by another and somewhat fuller description of the various parts and provinces of the world, apparently of the same period, entitled 'Alia totius Orbis Descriptio,' and generally attributed to Æthicus also, though there are doubts concerning his authorship. This second work is also found almost literally in Orosius, forming the second chapter of his history. It has been suggested that Orosius may have copied it from Æthicus, and the text of Orosius has certainly the appearance of a copy, as he has shortened the beginning or introductory part, and also left out the concluding sentence, in which the author of the description, as we have it separately, promises to give a continuation of his work, or an ampler description of the towns, &c., beginning from Rome, which he styles 'Caput Mundi et Domina Senatus.' (Simler's edition of Æthicus, Basil, 1575.) This last sentence promising a fuller account, which the author did not fulfil or which has been lost, would not have fitted Orosius's historical narrative, and therefore he left it out. But it is also worthy of remark that in two MSS. of Orosius in the national library at Paris, Nos. 4875 and 4882, the second chapter ends with these words, which are not found in the other MSS. and printed editions of Orosius: 'Percensui breviter ut potui provincias et insulas Orbis Universi, quas Solinus ita descripsit.' This would seem to attribute the work to Solinus.

To the two *Cosmographies* attributed to Æthicus is added, in some editions, another extract, which is styled 'Julii Honorii Oratoris Excerpta quæ ad Cosmographiam pertinent.' It is in its plan similar to the first *Cosmography* of Æthicus, only perhaps still dryer and more incorrect. The three have been published, together with Pomponius Mela, by Gronovius, Leyden, 1635.

ETHIOPIA (*Ἀἰθιοπία*) was the name given by the ancient geographers to the countries south of Egypt. In a more general and vague sense they called Ethiopians all the inhabitants of the south part of Africa, from the Red Sea to the Atlantic. Herodotus (iv. 197) speaks of the Ethiopians as inhabiting the whole of South Libya (Libya is with

him synonymous with our Africa), as distinguished from the Libyans who inhabited the Mediterranean coast and the interior adjoining it. He also speaks of the Ethiopian Troglodytes (iv. 183) who lived to the south of the Garamantes, and tells strange stories of them; but these particular Ethiopians must be considered included under the general name. Strabo places the Hesperian Ethiopians near the Atlantic Sea, and south of the Pharusii and Negretes, who were themselves south of the Mauri. In this general sense, Ethiopians corresponded with the inhabitants of the countries south of the great desert, of which the ancients knew very little. Herodotus (vii. 70) also speaks of Asiatic Ethiopians, who formed part of the great army of Xerxes; but their locality is not easily determined. The historian however observes that the Asiatic Ethiopians were black, like those of Libya, but differed from them in language, and had straight hair; whereas those of Libya had very curly hair, by which term some modern writers have perhaps too hastily concluded that the woolly hair of the negro is intended. But Eastern Ethiopia, properly called Ethiopia above Egypt (Herod., vii. 69), and also Ethiopia Orientalis, was a distinct and better-defined country. It included those regions which we now call by the name of Nubia and Sennaar, and perhaps part of Abyssinia, but to the south its limits were not known. Herodotus, however, it should be observed, clearly distinguishes the Ethiopians immediately south of Egypt from those whom he calls long-lived Ethiopians (iii. 17), whom he places on the shores of the southern sea. But what country we must consider as inhabited by these long-lived Ethiopians, it seems impossible to say.

Meroë, which lay above the confluence of the Astaboras (Tacazze) and the Nile, was the ancient capital of Ethiopia, in the limited and more definite sense of Ethiopia above Egypt, in which sense we shall now consider the term. The Troglodytes bordered upon Ethiopia to the east, extending along the coast of the Red Sea. To the west of Ethiopia were the Blemmyes, a barbarian tribe, of whom wonderful stories were told as having no heads, but eyes and a mouth fixed in the breast. Ethiopia was a country early reduced to a fixed social state, and was held traditionally to have been the parent of Egyptian civilization and religion. Its government was monarchical, but the monarch was subordinate to an all-powerful hierarchy, more absolute than that of Egypt. Diodorus (iii. 6) says, 'in Ethiopia, when the priests think proper, they send a message to the king with orders for him to die, the gods having so communicated their pleasure, which no mortal should dispute.'

It has been long a subject of discussion among the investigators of antiquity whether the arts of civilized life descended from Ethiopia to Egypt, or ascended from Egypt into Ethiopia. Here, as in many other contested historical points, much discrimination is required. It would appear, from tradition, that at a very remote period religious colonies came down from Meroë into Egypt. Herodotus (ii. 29) says, 'at Meroë, the great city of the Ethiopians, the people worship only Zeus and Dionysus (Ammon and Osiris), and them they honour greatly. They have an oracle of Zeus, and they make their expeditions whenever and wherever the Deity, by his oracular answers, orders them.' This shows that the priests of Meroë sent colonies into other countries, and Egypt was naturally one of the first lands to which they would resort. The worship of Ammon (the Zeus or Jupiter of the Greeks and Romans), which was carried by them down the Nile, was a simpler and purer form of worship than the absurd assemblage of deities which afterwards gained ground in Egypt. The procession of the Holy Ship, with the shrine of the ram-headed Ammon, which took place annually at Thebes, and which was carried across the Nile to the Libyan side and brought back after a few days, was in commemoration of the first advent of the god from Ethiopia by the river. This ceremony is sculptured on several Egyptian and Nubian temples, and especially on the great temple of Carnak. Homer probably alludes to it when he speaks of Jupiter's visit to the Ethiopians and his twelve days' absence. It appears also that the worship of Isis descended the Nile from the farthest regions of Ethiopia. Diodorus (iii. 3) says that 'the people above Meroë worship Isis and Pan, and besides them Hercules and Zeus, considering these deities as the chief benefactors of the human race.' Isis' heads have been found by Cailliaud at Naga, near Shendy, (about 17° N. lat.) in Upper Nubia, the sculptures bear-

ing all the marks of an original style, though of a coarser art than that displayed in the same figures in the Egyptian temples. The head of Isis is placed above that of Typhon, as in some of the temples of Egypt. These temples of Naga however may be supposed, from their style and sculptures, to be of a later date than those at El Mecaourah, which are also in the district of Shendy, in a valley in the desert, at some distance from the Nile, and about twelve miles nearly north of Naga; they consist of eight temples, of small dimensions, the largest being only thirty-four feet long, connected by galleries and terraces, with a great number of small chambers, the whole being surrounded by a double enclosure. There are no tombs nor remains of private habitations in the neighbourhood. Traces of a large tank are seen, protected from the sand by mounds of earth all round it, the water of which served probably for religious and other purposes. The materials of the buildings are on a small scale, as well as the buildings themselves, the stones seldom exceeding one foot in length and half that in height. No sculptures or hieroglyphics adorn the walls; only on the six pillars which form the portico of the larger temple are there hieroglyphics and figures in the Egyptian style. This temple seems to be of a much later date than the rest. (Cailliaud, *Voyage à Meroë*, and *plates*, and an article on the same in the *Foreign Quarterly Review*, No. 4, June, 1828.) It is supposed that this secluded enclosure may have been the sacred city of Meroë, the college of its priests, and the original seat of the oracle of Jupiter Ammon, whence issued those religious colonies which carried religion and civilization from Ethiopia as far as the Delta and the Oasis of the Libyan desert. According to the tradition of the country, the name of El Mecaourah was that of the ancient fakirs or recluses who inhabited these edifices.

The ruins of Meroë itself are now believed to be those discovered by Cailliaud at Assour, above the confluence of the Atbara or Tacazze and the Nile, and its situation between the two rivers probably gave rise to the appellation of the Island of Meroë. The extent of the ruins is said to be more considerable than that of Napata, near Barkal, or of any other place yet examined in Nubia; they are also in general more dilapidated, and vast mounds of rubbish appear heaped up everywhere, as if formed by the ruins of private as well as public buildings. The latter consist, as at Napata, of temples and pyramids. Of the temples there is not one the remains of which can be traced with any certainty; the front wall of the largest appears to have been twenty-five feet thick. The pyramids stand in groups on the borders of the desert. The largest is about sixty feet at the base, but most of them are much smaller, and generally in a ruinous state. Most of the pyramids have little exterior sanctuaries attached to them, and in one of them Cailliaud found the roof arched with a key-stone, as in those of Mount Barkal.

The connection between Egypt and Ethiopia was renewed at various periods remote from each other, and under various circumstances. Herodotus says that he saw in the records of the priests of Memphis (ii. 100), 18 Ethiopian kings registered among the 330 successors of Menes, who preceded Sesostris. Whatever we may think of this scroll of kings, still it shows that a tradition existed of a very remote influence of Ethiopia over Egypt. This perhaps was the epoch when the worship of Ammon and Osiris was introduced into the latter country. Osiris, according to tradition, led a colony from Ethiopia into Egypt, which received also from the parent state the practice of deifying kings, together with hieroglyphical writing, the usage of embalming, the whole sacred ritual, and the forms of their sculptures. (Diodorus, iii. 3.) Afterwards Sesostris is said to have conquered Ethiopia; but this was probably a partial incursion, for Herodotus (ii.) says that Ethiopia was never conquered by any foreign power. We hear nothing of the intercourse between Ethiopia and Egypt for many centuries afterwards, during which the latter country made great progress in civilization and the arts, and built its stupendous monuments. In the eighth century B.C. the Ethiopian invasion of Egypt took place, and Sabakos, an Ethiopian king, reigned over both countries. Herodotus, who lived between two and three centuries later, says that Sabakos evacuated Egypt in obedience to an oracle, a fact which shows that the power of the Ethiopian hierarchy still continued in full vigour. Still we find other Ethiopian kings ruling successively over at least part of Egypt; among others, Tir-

hakan, mentioned in the Scriptures as having fought against Sennacherib. The commentators on the book of *Kings* (ii. 19) have considered Tirhakah to be an Arab chieftain; an error disproved, as it is considered, by the existence of his name on one of the buildings of Thebes. This period of renewed intercourse between Egypt and Ethiopia, under circumstances highly favourable to the latter, was probably the time when the improved arts of Egypt were introduced into Ethiopia, and it was probably then that the splendid structures of Mount Barkal were executed; a supposition which would be confirmed, if it be true that the name of Tirhakah is found in the hieroglyphical cartouches in the Typhonium of Barkal, according to Champollion's system. Again, under the Ptolemies there is evidence to show that Græco-Egyptian colonies found their way into the regions of the Upper Nile, and along the shores of the Red Sea, and even as far as Axum and Adule in Abyssinia [ADULE; AXUM]: these colonies or adventurers probably spread the Egyptian arts as improved by the Greeks into Ethiopia. All these vicissitudes may account for the various styles of building and sculpture found along the banks of the Upper Nile. The monuments of Assour and el Meçaurah are probably older than those of Naga, and these much older than those of Barkal, which are probably anterior to the temple of Soleb. We know from a passage of Diodorus that after the Ptolemies came to reign in Egypt a great change took place in Ethiopian politics. In the time of the second Ptolemy the Ethiopians had a king Ergamenes who had a knowledge of Greek manners and philosophy. Being weary of the yoke of the hierarchy, he went with a band of soldiers to the inaccessible place (Barkal?) which contained the golden temple of the Ethiopians, and massacred all the priests. (Heeren's work on Egypt, and the *Egyptian Antiquities in the British Museum in the Library of Entertaining Knowledge*.)

Of the manners of the Ethiopians we know little, except what we may infer from their monuments and the scanty records we have of their religion and institutions, as above stated. Their sacred language appears to have been the same as that of the Egyptian priests. From some sculptures at Barkal, it would seem that human sacrifices were occasionally in practice. [BARKAL.] A peculiarity in the Ethiopian institutions is, that their women sometimes went to battle, and were not excluded from the throne. Strabo (Casaub., p. 820) speaks of the Ethiopian warrior queen named Candace. (See also *Acts of the Apostles*, viii. 27.) On the propyla of one of the temples of Naga, besides the hero or king, is a female figure likewise of regal dignity, with a large knife in each hand, going to cut off the heads of a number of captives; the vulture is hovering over her head. The figures of both king and queen are remarkable for the magnificence of their dress, and though they have many characteristics of Egyptian style, they are much thicker than the Egyptian form, especially the female, which is remarkably large from the vest downwards. (See Caillaud's Plates, 14. 16.)

After the Romans became possessed of Egypt, we read of several expeditions into Ethiopia, but of no permanent impression made by them upon that region. Caius Petronius, prefect of Egypt under Augustus, is said to have advanced as far as Napata, called Tenape by Dion, the first town of Ethiopia after Meroe. He defeated Queen Candace, who was obliged to sue for peace. But the Romans ultimately kept none of their conquests in that quarter. In subsequent times it appears that they conquered again, and retained a strip of territory along the banks of the Nile of seven days' march above the first cataract, but this was given up by Diocletian to the Nubæ or Nabatæ, on condition that they should prevent the Ethiopians and the Blemmyes from attacking Egypt. Of the vicissitudes and ultimate dismemberment of the antient kingdom of Meroe we have no information.

The early Christian historians seem to restrict the name of Ethiopians to a people occupying part of the country now called Abyssinia. Procopius and Cedrenus call the Axumites Ethiopians. [See the articles ADULE and AXUM.] From those times the name of Ethiopia has been given more particularly to Abyssinia, and the Geez or sacred language of that country has been called Ethiopian. [ABYSSINIA.]

The origin of the name 'Ethiopia' is uncertain. Salt says that Itiopjawan is the favourite term by which the Abyssinians designate themselves; but this name was pro-

bably introduced among the Abyssinians by the half Greeks of the kingdom of Axum. The word in Greek has the appearance of being significant, and is sometimes interpreted 'dark-coloured;' but like many other Greek names of nations, it is probably a native Asiatic or African term corrupted into the semblance of a genuine Greek word.

ETHIOPIAN LANGUAGES. Under the general designation of the Ethiopian languages, three different dialects are usually comprised, viz., the antient Ethiopian, or Geez, the Tigré, and the Amharic. The antient language properly called the Ethiopian is now extinct, or at least survives only as the language of books and of learned men (whence it is also called *lesana mas'haf*, or book-language); and its place is now supplied by the two other dialects, of which the Tigré approaches nearest to the Ethiopic, whilst the Amharic has more widely departed from it. [AMHARIC LANGUAGE.]

The Ethiopian belongs to the family of languages usually called the Semitic, and among them it shows the closest affinity to the Arabic. It is written from the left to the right, in a peculiar alphabet, which however appears to be of Semitic origin. (Compare the Ethiopian letters *kaf, nahar, atn, and geml*, with the corresponding Phœnician and Punic characters in Pl. v. and vi. of Gesenius' *Palæographische Studien*, Leipzig, 1835, 4to., and Pl. i. of the same author's *Scriptura Lingueque Phœnicie Monumenta*, Leipzig, 1837, 4to.) The alphabet consists of twenty-six consonants and seven vowel sounds; but the latter are not expressed by distinct characters, nor by points or accents, but by slight changes in the shape of the consonants, so that each character represents an entire syllable. It is well known that the antient Devanagari alphabet of the Hindus, and the system of orthography of many of the modern languages of India, are modelled on a similar principle. Several of the Ethiopian letters are now no longer distinguished in pronunciation; there are, for instance, three *h's*, two *s's*, two *f's*, and *aleph*, and *ain*, which are sounded alike, though still kept distinct in writing.

Gesenius calculates that about one-third of the roots and primitive words of the Ethiopian language exists also in Arabic; and a considerable portion of the remainder is found in Hebrew, or in the Chaldee and Syriac dialects. In the inflection of the Ethiopian verb ten conjugations are distinguished, consisting, like those of the Hebrew, Syriac, or Arabic verb, of certain modifications of the original import of the simple root, expressed according to strict analogy by modifications of the form of that root. We subjoin a paradigm showing the third person of the preterite in each of the ten conjugations with the corresponding inflections of an Arabic root. The Ethiopic verb *gabera* is used in those conjugations only to which we have added a Latin interpretation.

| | Ethiopic. | Arabic. |
|----------|--------------------------------------|------------------------|
| Conj. i. | <i>gabera</i> , fecit | i. <i>Kabala</i> |
| ii. | <i>gabbāra</i> , fieri curavit | ii. <i>Kabbāla</i> |
| iii. | <i>gābara</i> | iii. <i>Kābala</i> |
| iv. | <i>agbara</i> , coegit | iv. <i>akbala</i> |
| v. | <i>agabura</i> | |
| vi. | <i>tagabera</i> , factus est | v. <i>takabbala</i> |
| vii. | <i>tagabbāra</i> , opus fecit | vi. <i>takābala</i> |
| viii. | <i>tagābara</i> | vii. <i>inkabala</i> |
| ix. | <i>angabara</i> | viii. <i>istakbala</i> |
| x. | <i>aslagbara</i> , exegit (pecuniam) | |

From any of these conjugations a passive voice may be derived by prefixing *ta-*. Each conjugation has, as in the other Semitic dialects, a preterite and a future tense, with a distinct subjunctive or optative form, similar to the apocope future (*aoriste conditionnel* of De Sacy) in Arabic: an imperative and infinitive, but no participle. There is no separate inflection for the dual number either in the verb or noun. In the declension of nouns, cases are sometimes characterized by terminations analogous to those of the Arabic language. From masculine adjectives feminines are derived, nearly as in Arabic, by subjoining *-t*. The gender of substantives is twofold, masculine and feminine; yet the distinction of the two is but little attended to in Ethiopian writings. The plural is expressed as in Arabic, either by terminations (*-ān* in masculines, *-āt* in feminines), or by certain modifications of the vowels within the limits of the word.

The literature extant in the Ethiopian language is almost

exclusively biblical and ecclesiastical. The Ethiopians possess a complete translation of the Old and New Testament, made by an unknown author from the Alexandrian text of the Greek version, probably not anterior to the fourth century; besides an apocryphal writing, peculiar to themselves, called the book of Henoch, which is supposed by De Sacy to have been written during the reign of Herod the Great, and to be the book quoted in the Epistle of St. Jude (v. 14). (See *The Book of Enoch the Prophet*, &c., translated by Richard Lawrence, Oxford, 2nd edit. 1833.) There exists moreover a translation of the Didascalia, together with 56 *canones* and 81 *constitutiones* or rules of the early Christian church, considered by the Ethiopians as apostolical; besides a collection of the decrees of the councils, extracts from the writings of the early fathers, liturgies, martyrologies, and histories of saints. Hymns are not unfrequent: they are not written in any regular metre, but sometimes show a rude sort of rhythm, and often every three or five lines end in the same consonant, which constitutes a kind of rhyme. The profane literature of the Ethiopians comprises several chronicles, which appear to be of considerable interest, but have not yet been made generally accessible. Among these the *Chronicle of Axum* deserves to be particularly noticed, a copy of which was brought to Europe by Bruce, and is now preserved at Chelsea College, in the possession of the family of that traveller, along with numerous other oriental manuscripts left by him.

The Ethiopians have no grammars nor a dictionary, properly so called, of their antient language, and only possess vocabularies, in which words are classed according to the subjects to which they refer. In Europe the Ethiopian language was almost unknown till Job Ludolf (or Leutholf), assisted by a native of the country, made himself master of it. His first attempt at an Ethiopic dictionary and grammar was published at London, in 1661, in 4to; a much improved and enlarged edition of both works appeared at Frankfort in 1702. Since the publication of these works, little progress has been made in our knowledge of the Ethiopian language; to them therefore we refer such of our readers as may wish for further information on the subject.

ETHIOPS, a term now obsolete, but formerly used by the old chemists to denote various dark-coloured metallic preparations; as *Ethiops Martialis*, which is black oxide of iron; *Ethiops Mineralis*, which is a black mixture of mercury and sulphur, &c.

ETHULE. [ETHEREUM.]

ETHUSA, a genus of brachyurous crustaceans (Tribe *Dorippians*), established by M. Roux at the expense of the genus *Dorippe* of Fabricius and other naturalists.

M. Milne Edwards observes that this genus is easily distinguished from *Dorippe* by the conformation of the apertures leading to the respiratory cavity, which here present the normal disposition.

Carapace, nearly quadrilateral, but rather longer than it is wide, and very much flattened; *front* large, *orbits* directed forwards, very incomplete; *eyes* carried on a rather long and very projecting peduncle; they pass beyond the external angle of the carapace, and are not retractile. The *internal antennæ* are bent back (se reploient) forwards, in fosses placed under the front; the *external antennæ* are rather long; their first joint is cylindrical, and separates the antennary fossette from the orbit; the third is longer than the second. The buccal frame (*cadre buccal*) is triangular, and reaches to the border of the antennary fossettes; the *jaw-feet* are much shorter, and leave naked the anterior portion of the jaw-feet of the first pair, which complete forwards the canal of the respiratory cavity; the third joint of the external jaw feet is shorter than the second, nearly oval, sharply truncated forwards, and articulated with the following joint by the middle of its anterior border. The *Pterygostomian regions* are nearly quadrilateral, and are not prolonged between the base of the external jaw-foot and of the first thoracic foot, as in the *Dorippes*. The *Sternal Plastron* is oval. The anterior feet are short and slender in both sexes; in bending they form a double elbow, as in *Homola*. The succeeding feet are long, especially those of the third pair; those of the fourth pair are, on the contrary, extremely short, and inserted below the preceding; finally, the posterior feet, longer than the fourth pair, are inserted above and in front of them, and, like them, are terminated by a very short, hooked, and subcheliform tarsus. The *abdomen* in the male has seven distinct joints; in the female

it has only five: the two first rings are directed backwards and on the same plane with the carapace.

Example, *Ethusa Mascarone* (Roux), *Cancer Mascarone*, Herbst.

Ethusa Mascarone

ETIENNE. [STEPHENS.]

ETIENNE, ST., a town in France, in the department of Loire. It is on the left or south-west bank of the Furand, a tributary of the Loire, 255 miles south-south-east of Paris in a straight line, or 317 miles by the road through Fontainebleau, Nemours, Montargis, Briare, Nevers, Moulins, Roanne, and Montbrison; or 318 miles by the road through Melun, Sens, Joigny, Auxerre, Avallon, Autun, Châlons sur Saône, Macon, and Lyon; from which last town it is distant 33 miles. It is in 45° 26' N. lat., and 4° 23' E. long.

St. Etienne is of comparatively modern origin. In the troubled reign of Charles VII. the townspeople obtained permission to inclose their town with walls: this was granted A.D. 1444, but the space inclosed is said to be only a tenth of that which St. Etienne now covers. The town was then called Furania: it takes its modern name from St. Etienne, a bishop of Lyon, at the beginning of the sixteenth century. The particulars which follow are chiefly from the 'Itinéraire Descriptif' of Vaysse de Villiers, Paris, A.D. 1816, corrected by some later though less ample authorities.

The site of the town may be distinguished at a distance by a dense cloud of coal-smoke. It is situated in the midst of a coal-field, and coal is the only fuel employed in the various manufactories and workshops. The town is, especially the outskirts, very dirty; in summer the streets are dusty, in winter muddy, and when it rains the black dust, washed by the rain from the roofs, converts the streams that fall from the gutters into little better than ink. The houses, both in the centre and outskirts of the town, are built of a coarse-grained grey sandstone (un grès gris à gros grains), sometimes squared, at other times unhewn, the colour of which adds to the sombre character of the place, and deprives the town of that handsome appearance which its wide and tolerably straight streets and well-built houses would otherwise give to it. The centre of the town is occupied by a large and handsome though irregularly-shaped open space or 'place,' in the middle of which is a fountain adorned with a small obelisk. From this 'place' opens a new street running above half a mile in a straight line in the direction of Roanne, and terminating in the only promenade which the town possesses: the road continues in the same line for two or three miles to the village of St. Priest, where the ruins of a Gothic castle on a hill terminate the view. There are baths, a theatre, and a town-hall; the last building is handsome.

The population of St. Etienne, in 1832, was 33,064; including the neighbourhood it may be calculated at more than 50,000. Its increase of late years has been very great. The town owes its prosperity to its situation in the coal district, which not only furnishes the inhabitants of the neighbourhood with a considerable article of export (for much coal is sent to Paris), but enables the townspeople to carry on their various manufactures. The coal is abundant and of good quality; the colliers belong rather to the neighbourhood than to the town itself. The inhabitants of the town are employed either in the manufacture of fire-arms (which are made here to a far greater extent than in any town of France), knives, locks, and other hardware, or in the weaving of ribands, in which it is also pre-eminent. Whole families devote themselves to each kind of manufacture: the women work in the same factory with the men, and sometimes share with them the most laborious parts of their task. There were, a very few years since, a roya.

manufactory of fire-arms, forty manufactories of arms of all kinds, ten of cutlery, forty-five of hardwares, and one hundred and fifty of ribands and velvet. The waters of the Furand, which is but a small brook, are well calculated for tempering iron and steel, and also for dyeing. A railroad, more than 34 miles long, connects St. Etienne with Lyon: this work has been carried on in spite of great difficulties; hard rocks have been cut through and hollows filled up: there is a tunnel through a mountain near St. Etienne. As many as 1800 carriages are said to pass daily between the towns: stone is quarried near St. Etienne.

St. Etienne has a high school, a school for miners, a deaf and dumb school, a course of instruction in geometry and mechanics, applied to the arts, a society of agriculture and trade, and a public library.

It is the capital of an *arrondissement*, containing in 1832 a population of 149,189: the *arrondissement* is small, but there are in it several towns which are engaged in various branches of trade, similar to those carried on at St. Etienne; Chambon and Firmini, where nails and ribands are made; St. Chamond, where ribands are manufactured; and Rive de Gier, where coal is dug and iron cast. A late return assigned to the *arrondissement* 47,750 workmen of all kinds; of whom 3000 were colliers, 2400 engaged in iron and steel works, 3800 in manufacturing cutlery and hardwares, 2800 in making fire-arms or weapons for war or the sports of the field, 3000 in making nails, 1800 in glass works, 2900 in preparing silk, and 27,500 in the manufacture of ribands. The value of the raw materials on which these workmen were employed was estimated at 36,885,000 francs, or about 1,500,000*l.*; and it was considered that this value was doubled by the various processes of manufacture.

Before the Revolution, St. Etienne had several religious houses.

ETI'SUS, a genus of brachyurous crustaceans (Cancerians of M. Milne Edwards).

Carapace less oval and wide than in most of the Arched Cancerians (Cancériens arqués). The front is large, lamellar, and divided on the mesial line by a fissure, as in the *Xanthi*; but the two large and truncated lobes which form the principal part are separated by a deep notch of the anterior and superior angle of the orbit, which is rounded and projecting; the latero-anterior borders of the carapace are strongly toothed. The *Internal Antennæ* are bent back nearly longitudinally, and the basillary joint of the *External Antennæ*, which is very large, unites with the front, and presents on the external side a prolongation which fills the hiatus of the internal orbital angle; finally, the moveable stem of these antennæ, which is very short, is inserted completely out of this hiatus, below the front and nearer to the antennary fossette than to the orbit. The external *jaw-feet* present nothing remarkable; the *feet* of the first pair are rather large, and the *chelæ*, which are much enlarged and rounded at the end, are deeply hollowed into a spoon-shape.

M. Milne Edwards, who gives the above description, divides this small group, which he considers as forming the passage between the *Xanthi* and *Platycarcini*, into the two following sections.

a.

Carapace scarcely knobbed above.

Example, *Etisus dentatus*. Length three or four inches; colour reddish. Locality, the Indian Archipelago.

Etisus dentatus.

β.

Carapace covered with knobs, separated by deep furrows
Example, *Etisus anaglyptus*; length about an inch and a half; colour whitish? Locality, Australasia.

ETNA. [ÆTNA.]

ETON. [BUCKINGHAMSHIRE.]

ETRURIA was the name given by the antient Romans to a region of Italy extending in their time from the river Macra to the Tiber, and from the Apennines to the Tyrrhenian Sea, the inhabitants of which they called Tusci, and at a later time Etrusci. The natives of Etruria however called themselves Rasena. The Greeks called them Tyrrheni, confounding them, according to the opinion of some critics, with the Tyrrhenian Pelasgi, who had occupied the western coast of Italy at a more remote date, and who being driven away by the Umbri, the Etruscans, and other Italian nations, wandered back to the Grecian islands and coasts, where they became known as pirates. But the traditions of these early migrations into and from the Italian peninsula are so extremely obscure, the statements of antient writers concerning them are so conflicting and perplexing, that the investigation is become a real labyrinth, and we can only refer inquisitive readers to Niebuhr's *History of Rome*, i., p. 1—145, and to the different systems maintained by several Italian writers, and especially by Micali in the last and much improved edition of his work, *Storia degli Antichi Popoli Italiani*, 3 vols., with an Atlas, 1832, in which he examines and combats several of Niebuhr's positions. Leaving aside the question of the origin of the Tusci or Etrusci, we find this people several centuries before the time assigned for the building of Rome settled in Italy, both north and south of the Apennines, in the plains of the Po, and on the banks of the Arno. They had conquered a great part of this vast tract of country from the Umbri, one of the oldest Italian people of which history has preserved the name. The Etruscans are said by Pliny the Elder (iii. 14) to have conquered 300 towns or villages belonging to the Umbri, who, after their subjugation, appear to have become in a great measure incorporated with the conquerors, who thus extended their dominions across the centre of the Peninsula from the Adriatic to the Mediterranean. Cupra maritima, now Grottamare, in the territory of Fermo, on the Adriatic coast, and Cupra montana, which stood near the banks of *Æsis*, not far from the present village of Masaccio, in the province of Ancona, were Etruscan colonies. Of the great plain of the Po, the Etrusci occupied the central part, from the left bank of the Ticinus and the right bank of the Trebbia, which separated them from the Ligurians on that side to the Athesis or Adige, which divided them from the Veneti, who remained in possession of the coast of the Adriatic as far as the mouths of the Po. (Livy, v. 33.) South of the Po the Ligurians retained possession of the highlands of the Apennines as far eastward as the sources of the Arno, which river formed at first the boundary between them and the Etruscans, who afterwards extended to the Macra, where they built Luna. The Etruscan towns in the plain of the Po are said to have been twelve, like those of Middle Etruria, south of the Apennines; but Mantua and Felsina (Bologna) were the only two remaining in the time of Pliny. The others had been destroyed by the Gauls long before. The Etruscan origin of Adria has been disputed. For the names of the other Etruscan towns north of the Apennines see Mazzocchi *Catalogo alfabetico de' Luoghi compresi nell'Etruria circumpadana*.

Towards the south, Etruria is known to have extended as far as the Tiber previous to the existence of Rome. But the Etruscans at one period went also far beyond that river. There was a tradition of their having conquered the Volsci, who afterwards recovered their independence. (Servius in *Æneid*. xi. 567.) Their regular settlement in Campania, where they are said to have also built twelve towns, was how ever of a later date, probably in the second or third century of Rome, when the Etruscan power, south of the Apennines, was at its height, and after they had lost by the Gallic irruption all that they possessed in the plains of the Po. The Etruscan colony founded at Capua would fall, according to Cato's statement, about the year 283 of Rome. The war of the Etruscans against Cumæ, in which they were defeated by the Syracusans in a naval fight, had happened some time before. According to this calculation the Tuscan dominion in Campania did not continue long, as the country was conquered by the Samnites about the year 330 of Rome. The extent of the Etruscan possessions in

Campania, and the number of towns which they built or colonized there, is a matter of much doubt. (Niebuhr, vol. i., *On the Opicans and Ausonians*, and, for a conflicting opinion, Micali, vol. i., ch. 7.)

The permanent power of the Etruscans lay in Etruria Proper, or Etruria Media as it has also been called, which corresponds in great measure to the present Tuscany, with the addition of that part of the papal state which lies on the right bank of the Tiber. For a geographical description of the country we refer to TUSCANY. They had twelve principal cities or states, all situated between the Arno and the Tiber, for the country between the Arno and the Macra was annexed at a later period by conquest over the Ligurians. Each state formed an independent community, the twelve being bound together by a sort of loose confederacy: at times indeed very loose, for we find repeatedly one state going to war without the assistance or interference of the rest. Of these twelve towns, eight are mentioned by Livy (xxviii. 45) on the occasion of his enumerating the allies who volunteered to assist in equipping Scipio's armament against Carthage: they are Cære, Tarquinii, Populonium, Volaterræ, Arretium, Perugia, Clusium, and Rusellæ. These must be added Veii and Vulturni, which had been previously conquered by the Romans. The two remaining may be selected from among Cortona, Cosa, Capena, and Fesulæ. It must be observed that long before that time some of the old cities of Etruria had dwindled away, such as Vetulonia, which had disappeared before the historical age of Rome, and of which even the site is not positively ascertained. Populonium, which was originally a colony from Volaterræ, probably took the place of Vetulonia among the twelve.

Antiquities.—We may here point out those towns in which Etruscan antiquities are still found, and thus convey some general idea of what we know of the state of the arts among that people:—

1. Arretium [AREZZO] was destroyed by Sulla, and no traces of Etruscan construction now exist. The remains of the amphitheatre are of the Roman period, when the town was restored by Mæcenæ. But there are numerous Etruscan inscriptions, vases, coins, and other remains in the Museum Bacci at Arezzo, and a quantity of the red embossed pottery, 'Aretina vasa,' for which Arezzo was renowned of old, and of which enormous heaps of fragments have been found in the neighbourhood. Some of the figures are most delicately formed, and may be seen in the plates to Inghirami's work: *Monumenti Etruschi o di Etrusco Nome*. Some of the moulds have also been found. 2. Perugia [PERUGIA] is said by Cato, quoted by Servius, x. 201, to have been built by the Sarsinates, an Umbrian people, before the Etruscan time. It has no remains of Etruscan structures, except the sepulchral building called la Torre di San Manno, about a mile outside of the walls, with an arched vault of large polished stones, bearing an Etruscan inscription in three lines, which is styled by Maffei 'the queen of inscriptions,' and the gate, vulgarly called Arco di Augusto, which however is believed to be of Etruscan construction. (Orsini, *Dissertazione sull' Arco Etrusco di Perugia*, 1807.) A rich collection of Etruscan antiquities however is found in the Gabinetto Archeologico, with about 80 inscriptions, one of which consists of 45 lines, the fragments of an Etruscan quadriga, described by Inghirami (vol. vi., p. 360), and some handsome painted vases, bronzes, &c. (Vermiglioli, *Saggio dei Bronzi Etruschi trovati nell' Agro Perugino*, 4to., 1813.) 3. Cortona, the ancient Corym, retains unchanged the original circuit of its Etruscan walls, though repaired in several places. (*Pianta Topografica di Cortona* in Micali's *Atlas* annexed to his *Storia dei Popoli Italiani*.) The walls are built of enormous polygonal stones, well fitted together, without cement. There are other remains of Etruscan construction, among others the substructure of the palace Laperelli. An Etruscan tomb, called by the natives Grotta di Pitagora, is seen in one of the suburbs of the town. [CORTONA.] Other hypogæa have been discovered in the country around, from which the bronzes and vases have been transferred to the town museum, but they belong mostly to the Roman period. (Repetti, *Dizionario Geografico Storico della Toscana*, 1835.) The Accademia Etrusca, established in 1726, whose president is called Lucumo, has published 10 vols. 4to. of *Memoirs*. 4. Fesulæ, now Fiesole, one of the oldest Etruscan cities, though perhaps not one of the twelve metropolitan ones. Its massive walls are its only Etruscan structure now existing; the theatre and other remains are of the Roman time, probably of the date of Sulla's colony.

(See plan and views of Fiesole, plates 5, 11, and 12 of Micali's work, and also Bandini, *Lettere Fiesolane* and *Itinerario di una Giornata d' Istruzione a Fiesole*, 1814.) 5. Clusium, Camars in ancient Etruscan, now called Chiusi, the country of Porsenna, built on a hill above the valley of the Chiana, was one of the most distinguished Etruscan cities. Of its old walls there remains nothing but a fragment built of large polygonal stones behind the choir of the cathedral. The present town is entirely modern. There are very rich collections of antiquities, urns, vases of old Etruscan manufacture, single coloured, and later ones, or Campano Etruscan as they have been styled, with figures of one or two colours different from the ground, gold ornaments, engraved stones, &c., in the houses Paolozzi, Sozzi, and Casuccini. The last mentioned is the richest, and a description of it by Valeriani, with above 200 plates, has been published under the title of *Museo Etrusco Chiusino*, 2 vols. 4to., 1833. 6. Volaterræ, Volterra, on a hill about twenty miles north-west of Siena, was about four miles in circumference: many parts of its walls as well as one of the gates, called Porta dell' Arco, are of old Etruscan construction, being built of large rectangular stones generally six feet in length, though some are much larger, set in horizontal layers without cement. In some places two of them alone, set side by side, form the thickness of the wall. Maffei considered the walls of Volterra as the best calculated to give a true impression of former Etruscan greatness. In the thermæ which were discovered by Guarnacci was found a mosaic, which is now in the city museum, together with numerous sepulchral monuments, statues, bassi rilievi, both in alabaster and sandstone, vases, pateræ, &c. On these monuments of the ancient Etruscans we may, in some measure, read the history of their civilization and social economy, as we read those of Egypt on the monuments of that country, in default of written records. Guarnacci published a *Museum Antiquorum Monumentorum Etruscorum e Volaterranis Hypogeis Erutorum, cum Observationibus*, A. F. Gori, fol., 1744; see also Giorgi, *Dissertazione Accademica sopra un Monumento Etrusco ritrovato negli Antichi Suburbani di Volterra*, l'anno 1746, 4to., Firenze, 1752. But one of the most extensive and satisfactory works on Etruscan antiquities is the recent one of Inghirami already mentioned, *Monumenti Etruschi o di Etrusco Nome*, 5 vols. 4to. of text, with 6 vols. of plates, and 1 vol. index. Inghirami's collections represent chiefly objects found in the territory of Volterra, in the numerous hypogæi discovered there; and they are intended to illustrate the state of the three fine arts among the Etruscans, for which purpose they are arranged in six classes. I. Funeral urns and cinerary vases in alabaster or sandstone, with sculptures. II. Pateræ, which Inghirami calls 'specchi mistici,' or mystical mirrors, with specimens of Etruscan linear drawing. III. Bronzes of cast or chiselled workmanship. IV. Specimens of Etruscan architecture, taken from their hypogæi or sepulchral monuments, some of which are from Tarquinii, and other parts of ancient Etruria. V. Vases, some such as those of Arezzo, all of one colour, either red or bluish black, with embossed figures, others with figures of different colour from the ground. VI. A collection of monuments, most of them not Etruscan, but which serve to compare with, and form a contrast to, those of Etruscan art. Inghirami has not included in his collection the inscriptions, cameos, gems, coins, lamps, &c., which may be found in other works, and especially in Lanzi, *Saggio di Lingua Etrusca*, 3 vols., 8vo., Rome, 1789, a work much more valuable for the quantity and variety of monuments which it illustrates, than for its hypothetical and now generally rejected system of Etruscan grammar and etymology.

Among the other Etruscan towns which are now destroyed, and of which nothing but ruins remain, may be mentioned—1. Cosa or Cossa, called Ansedonia in the middle ages, on a hill east of the lake of Orbetello, the walls of which are in tolerably good preservation, with several towers, and two gates. See *Pianta Topografica di Cosa e suoi Contorni* in Micali's *Plates*. 2. Populonium, near Porto Baratto, on the coast north of Piombino. The only remains are part of the walls, which are standing. Micali has given a plan of Populonia. 3. Rusellæ, the ruins of which are on a hill above the plain of Grosseto, about three miles from Batignano, and near the left bank of the Ombrone; the circuit of its walls, which consist of large rectangular blocks, is about two miles. Micali has given a plan of this also. 4. Saturnia, called also Aurinia, on the left bank of the river Albegna, near the foot

of the mountain of Santa Fiora, and on the borders of the Papal States, shows some fragments of its walls built of polygonal stones. 5. Tarquinii, the site of which is on the left bank of the Marta, near Corneto, exhibits no remains above ground, but the great number of hypogei, forming a vast necropolis in the neighbourhood, give an idea of its former importance. They are excavated in the rock, which is of volcanic formation; some of the chambers are square, fifty feet on each side, and about six feet high; the ceiling is carved into square compartments, and is supported by square pillars of the rock itself; the sides are adorned with stuccoes and paintings, some of them allegorical of the state of the soul after death, others representing funeral processions, games, banquets, &c. A number of urns, vases, mosaics, arms, and some skeletons, have been found within these sepulchres, which may be said almost to rival, for the interest they excite, those discovered in Egypt by Belzoni. The first Tarquinian hypogei were discovered about 1780, by Cardinal Garampi, and representations of them are given in D'Agincourt's work, vol. iv., plates 10 and 11. But the greatest discoveries have been made of late years, engravings of which are given in Inghirami's and Micali's works.

Farther inland, about ten miles north of Tarquinii, near the village of Canino, Lucien Bonaparte has discovered a vast quantity of similar remains of Etruscan art, of which he has formed a valuable museum at Canino, and of which he has published a description. (*Museum Etrusque de Lucien Bonaparte, Prince de Canino*, in parts, 1829.) These discoveries have revived the question between the partizans of an original Etruscan civilization, and those who derive it from the Greeks. Probably the question might be solved by admitting various epochs of Etruscan art, one anterior and the other posterior to the intercourse which existed between the Etruscans and the Greeks about the second or third century of Rome. Even in the monuments of Tarquinii and Canino two styles are discernible. Other proprietors in the same district have made further discoveries. On the right bank of the river Fiora, in the district of Montalto, extensive remains seem to mark the site of the Etruscan Vulcia, which was conquered by the Romans at the same time as Vulsinii, about the year 473 of Rome. Here also a vast necropolis has been found, with a quantity of vases, paintings, and other antiquities. At a place called la Cucumella, a group of buildings of large rectangular stones, consisting of cells and two towers, one square and the other circular, above thirty feet high, have been found buried in an artificial mound or barrow. At the top of the towers were winged sphinxes in stone, and below some lions and griffins. Micali, plate 62, gives the plan and views of these monuments, which are one of the most curious Etruscan discoveries hitherto made. In 1832 only one-third part of the mound had been dug up, so that further structures may still be found.

The site of Cære or Agylla lay near the village of Cerveteri or Cervetri, between Rome and Civitavecchia. Its port, Pyrgos, was near where the coast-tower of Santa Severa is now. No remains of either have been discovered. The ancient Vulsinii has been likewise completely destroyed [BOLSENA]. The site of Veii has been long a subject of dispute, but it seems now ascertained to be on a steep hill, at the foot of which two streams unite, and form the Cremera which falls into the Tiber. This hill is about a mile and a half east of the hamlet of La Storta, the last stage on the northern road to Rome. The farm called Isola Farnese occupies part of the site of ancient Veii. The remains which have been discovered on the spot since 1810 belong to the Roman colony sent there by Livia. The walls of Falerii, which still exist in a desert spot near Civita Castellana, are not always numbered among the Etruscan remains, as that town is said to have been built before the Etruscan conquest. The amphitheatre cut in the rock at Sutri is attributed to the Etruscans.

History and Social State.—Varro mentions the Etruscan annals existing in his time as having been written in the eighth age of Etruria, which is supposed to correspond to the fourth century of Rome. Two Latin writers, Valerius Flaccus and Cæcina, the latter a native of Volaterræ, wrote histories of Etruria, and the emperor Claudius wrote in Greek his *Tyrrhenicon* or *History of Etruria*, in twenty books; but all these are lost, as well as the books of Dionysius, in which he treated more particularly of the Etruscans. The little we know therefore of the national history of

Etruria previous to their wars with Rome, is gathered from fragments and incidental notices in Greek and Roman writers. The Etruscan power appears to have been at its height in the third century of Rome, about the beginning of the fifth century before Christ. Their dominion extended over the country of the Umbrians to the Adriatic on one side, and to the Gulf of Luni on the other. After Persenna had dictated a humiliating peace to Rome, the Tuscans overran Latium, and conquered Campania. By sea they rivalled the Carthaginians, with whom they at first allied themselves against the Phœceans, who had settled at Aleria in Corsica, but afterwards the allies quarrelled together for the possession of the same island. They fought against the Cumans and Syracusans united about the year 279 of Rome, and were defeated. Half a century later they lost Campania to the Samnites, after which the Romans began to encroach on that part of Etruria which lay between Mount Ciminus and the Tiber. Veii was the first Etruscan city that fell by the Roman arms; Falerii and Fescennia next; Sutrium submitted: Cære and Tarquinii became the allies of Rome; and the Ciminus ridge with its haunted forests formed the boundary between Rome and Etruria. The Roman arms halted nearly a century longer before they passed that boundary. The total defeat of the confederated Etruscan forces at the lake Vadimonis, in the year 444 of Rome, opened to the Romans the access into the Etruria Transcimina. Vulsinii and Vulcia fell before the slow but sure progress of their arms; the other cities, such as Arretium, Perusia, Volaterræ, Populonium, disguised their submission under the name of allies, but Etruscan independence was gone. This appears to have been a period of general corruption of manners, when all national spirit and independence became extinct, but wealth, luxury, and internal peace remained, and sensual pleasures were the chief occupation of the people; and this was also the time when the earlier Roman writers who speak of the Etruscans, such as Plautus, Cato, and Varro, became acquainted with that people. The wars and proscriptions of Sulla gave a final blow to the existence of the Etruscans as a nation; their towns were destroyed, and their lands were given to military colonists. The proscriptions of Octavianus after the battle of Perusia, completed the desolation of Etruria. The language itself gradually became obliterated among the people, and was only known to the priests, with whom it became finally extinct, probably by the spreading of Christianity in the fourth century of our æra. It is now acknowledged by Micali, Orioli, Inghirami, as well as by Niebuhr, that the Etruscan language is lost, and that its pretended affinity to Greek, as maintained by Lanzi and others, has no foundation.

With regard to the political and social institutions of the Etruscans, we cannot do better than refer to Micali's work (vol. ii., chapters 21 to 24), in which he gives a fair and tolerably well authenticated sketch of their government, their religion and morality, and their domestic manners. We ought to bear in mind that all the accounts we have of the Etruscans were written after their subjugation to Rome, and that a nation which had a political existence of eight or ten centuries must have undergone considerable changes in its manners and institutions. Each of the twelve principal cities of Etruria ruled over the population of its respective district, which was perhaps originally a conquered race. In the city itself were two orders, the hereditary families of patricians or senators, and the commonalty. Political and religious power were in the hands of the former, who elected from their own body the annual magistrate called Lucumo. We know that the lucumo at times contrived, especially in times of war, to protract his term of office, and sometimes to retain it for life; but all attempts to make it hereditary appear to have failed. The patrician and hierarchal order appears to have maintained to the last its sway among the Etruscans, the arts of divination, of which it was in exclusive possession, being a powerful instrument in its hands, among a people so much fashioned to religious observances and rites, for repressing all attempts of the commonalty. Accordingly we hear of no struggles of the kind in Etruria, as at Rome; but we hear of revolts of slaves against their masters, as in the case of Vulsinii, for the Etruscans had numerous slaves. Their sway over the people whom they conquered, such as the Umbri, appears to have been mild: they did not destroy their towns, but surrounded them with walls, or built new ones; they taught them agriculture and other arts, they instructed them in religion

and they are acknowledged to have been the civilizers of a great part of Italy. Rome derived its earlier civilization from Etruria. The art of fortifying towns with walls and towers is attributed to them. They wrought the iron which they drew from the island of Elba, they cast bronze, and they made silver vases and gold ornaments: they engraved on stone, and sculptures of primitive art are found on their oldest monuments. They are supposed by many to have been the inventors of the arch at a very remote period; Tuscan masons employed it in constructing the Cloaca Maxima of Rome. They understood hydraulics, especially the art of filling up marshes by diverting into them the course of muddy streams, which is still practised with great success in Tuscany under the name of 'colmatae.' The invention of the termini, or stones fixing the limits of property, is attributed to them. The rights of property, those of paternal authority, of testamentary will, of connubia or marriages, were all fixed by law and consecrated by religious rites. Their laws concerning debtors appear to have been more humane than those of Rome, if we are to trust to a passage of Heracles in which he speaks of the Tyrrhenians.

The Etruscans were fond of good living and of sumptuous banquets, and they are called gluttons, fat, and corpulent, by the Roman satirists. Virgil (xi. 735) accuses them of being given to all kinds of sensual pleasures. Their women seem to have had no great reputation for chastity (Plautus, *Cistell.* 2. 3. 20, and Horace, iii. *Ode* x. 11); yet we find the female sex in higher honour among them than among most nations of antiquity. The women reclined at table on the same triclinia with the men, as appears by their monuments. Their funerals were pompous, and accompanied by athletic games, but the combats of gladiators appear to have been of a late introduction, and it is believed that they originated in Campania, and from thence spread over the rest of Italy about the fifth century of Rome. From some sculptures found on their monuments it would appear as if human sacrifices were at one time in practice among them unless these representations be symbolical, as some suppose. The mythology of the Etruscans was partly of native, partly of oriental invention. They believed in two principles, a good and an evil one, each having its respective agents or genii, and their paintings and sculptures are often representative of the perpetual struggle between the two. Twelve gods, six male and six female, at the head of which was Jupiter, formed the upper hierarchy; other inferior divinities presided over the various elements and phenomena of this earth, as well as over the occupations and domestic comforts of man. Cicero speaks very favourably of Etruscan theosophy, saying that they referred every thing to God, and that all their religious institutions were studiously calculated for the prosperity and security of the state. For further particulars on these subjects, see Micali, ch. 22 and 23, Bossi, *Storia d'Italia*, lib. i., chap. 6, and Müller, *die Etrusker*; Dempster, *De Etruria Regali*, with the continuation by Passeri, is also a work of much information, apart from the system and favourite hypothesis of the writers. These, with the other works already mentioned, form the best Etruscan library that can be collected.

ETRUSCAN ARCHITECTURE. We have no remains of Etruscan temples or other buildings, but we can form some idea of their style from their hypogæi or sepulchral monuments, and also from some of their cinerary urns which represent a temple. (Micali, plate 72.) But the monuments which serve perhaps to throw most light on this subject are those discovered at Castel d'Asso, the Axia of Cicero (*Pro Cæcina*, 7), five miles south-west of Viterbo, where the rock forming one side of the valley facing the old castle is sculptured all along for more than a mile in the shape of so many fronts or façades of sepulchral monuments, the vaults themselves being excavated underneath. Similar sculptures on the rock are found at Norchia, about 15 miles south-west of Viterbo. (See Inghirami's *plates*.) These monuments, which represent a primitive style of Etruscan building, strike by their resemblance to the Egyptian style in its ruder and simpler form. Plate 62 of Micali represents a monument between Monte Romano and Corneto, with projecting architrave and lateral pillars. Vitruvius, although he lived in an age when Etruscan art had undergone considerable alteration, characterizes their buildings as 'baricephalæ, humiles, latæ,' low, wide, with heavy top ornaments. And this seems to be in keeping

P. C., No. 602

with the character of the people, grave, and more fond of internal comfort than of external show. What is now called the Tuscan or Tuscanic order appears to have been a sort of rude Doric, which they probably adopted from the Greeks. [CIVIL ARCHITECTURE.] Vitruvius (iv. 7) gives a description of these temples with three cellæ, but they appear to have been neither large nor splendid: the ornaments, bronzes, and plastic figures appear to have been more elaborate than the structures themselves. In the time of Vitruvius the houses of the wealthy Etruscans had external porticoes or vestibula, in which the crowd of servants and clients remained in waiting. The Atrium is also supposed by some to be of Etruscan invention. [ATRIUM.] If not the inventors of the arch, the Etruscans were certainly acquainted with it at a very early period: it is found in their sepulchral monuments, in their gates, and they used it in constructing the Roman cloacæ. Another cloaca of similar construction has been discovered near Tarquinii. Their skill in fortifying towns with walls and towers and ditches, and leaving an open space around called *Pomærium*, is attested by the Roman writers, and by the inspection of the remains of their walls. The use of large polygonal stones in the construction of walls was common to other Italian people as well as the Etruscans and primitive Greeks; and the name of Pelasgic, which has been given to these walls, appears to be incorrect, as it does not distinguish any particular class of these walls or the walls of any particular locality from other walls of the same kind. If by this term Pelasgic it is meant to assert that all such walls are really of Pelasgic origin, this is more than can be proved or presumed. In most instances, however, the Etruscans appear to have used rectangular stones, ranged in horizontal layers, and uniformly without any cement. For more complete information of what is known of Etruscan architecture, we must refer to Micali, ch. xxv., Inghirami's *text and plates*, Series IV., and Orioli, *Dei Sepolcrali Edifizi dell' Etruria Media*, also quoted by Inghirami.

ETRUSCANS. [ETRURIA.]

ETSCH. [ADIGE.]

ETYMOLOGY. [LANGUAGE.]

ETYMOLOGICUM MAGNUM (τὸ μέγα ἐτυμολογικόν) an important vocabulary of the Greek language, of which the author is unknown. Some suppose it was written by a grammarian of the name of Magnus. The idea that it was compiled by Marcus Musurus, the first editor or the Calliergi, is disproved by the fact that this dictionary is referred to by Eustathius. Sylburg considers it as old as the tenth century: much older it certainly was not; for Theognotus, a writer of the ninth century, is quoted in it. The derivations in this work, like most of those attempted by the Greeks themselves, are based upon no principle, and though in some instances accidentally right, they are generally full of the wildest absurdities, as one might expect from the author being confined to mere guess-work. It is valuable however for containing a great many traditions with regard to the meanings of old or uncommon words, and it often enables the scholar to correct the errors of the corrupt but inestimable lexicon of Hesychius. The edition of Sylburg (1594) is very useful, and has an admirable index: the edition of the *Etymologicum Magnum*, by Schäfer, Lips., 1816, is a reprint of Sylburg's edition. The edition by Sturz, Lips., 1818, 4to., intitled *Etymologicum Græcæ Linguae Gudianum*, &c., is founded on the Codex Gudianus, which is more complete than that on which the edition of Musurus and the others already enumerated are based.

EU, a town in France, in the department of Seine Inférieure, on the south-west bank of the little river Bresle, near its mouth. Eu is 91 miles in a direct line N.N.W. of Paris.

In the middle ages Eu became a strong and flourishing place: but on the threat of a descent by the English it was burnt, in 1475, by order of Louis XI., and has never recovered the blow Dieppe and other neighbouring places profited by its downfall. Only the churches and a few houses that were overlooked escaped the general destruction. The massive ruins of the walls and towers yet remain.

Eu has several churches: the finest, that of Notre Dame, is large and of beautiful Gothic architecture. A crypt contains the monuments of the counts of Eu: these monuments were much damaged in the Revolution. A small church adjoining the High School, formerly the Jesuits' College, contains the monument of the duke of Guise, murdered at

Vol. X.—1

Blois in 1588. There are two châteaux. Of one of these, built by a daughter of the duke of Penthièvre, afterwards duchess of Orléans, only half remains, the rest having been destroyed in the Revolution. The situation of the château is charming. The park has an avenue of fine beech trees. There is an hospital attended by the *Sœurs de la Charité*. The market-place is good. La Chaussée d'Eu is a suburb of Eu, on the opposite bank of the Bresle. Tréport, at the mouth of the river, is the port of Eu: it has a church singularly situated on the extreme verge of a lofty and almost perpendicular cliff, and a projecting doorway of beautiful Gothic architecture.

The population of Eu in 1832 was 3356, that of Tréport 2061, together 5417: the population of the respective communes was 3543 and 2267, together 5810. The population of La Chaussée d'Eu is not given in our authorities. The manufactures of Eu are linseed oil, soap, locks and other ironmongery, leather, cotton yarn, glass, sail-cloth, linen and lace. Eu serves as a mart for the corn of the department of Somme, which is imported into that of Seine Inférieure. There is a school of mutual instruction, which was established by the King of the French when duke of Orléans. There is a tribunal de commerce or court for the decision of mercantile disputes.

EUBŒA (Εὐβοία), now called Negropont, is an island of the Mediterranean, lying along the coasts of Attica and Bœotia, from which it is separated by the Euripus, a very narrow channel, over which a bridge has been thrown, connecting the island with the main-land. It is 90 miles in length in a north-west direction, and 30 miles in extreme breadth; but in one part, between Aliveri Bay and Port Petries, it is scarcely 4 miles across from shore to shore. The only towns are Egripos and Karystos; the former situated where the island approaches nearest to the main, and the latter at the southern extremity of the island, at the bottom of a bay bearing the same name.

The island generally is elevated, and contains among its mountains some of the highest in this part of Europe. Mount Delphi rises on the eastern shore to the height of 7266 feet above the sea, and its summit is scarcely ever free from snow; Elias of Karystos, at the southern extremity, is 4748 feet high; Mount Khandhili, 4200 feet, and Telethrius, 3100 feet, are both on the western shore north of Egripos. The general formation of these mountains is grey limestone, with much clay slate.

It appears from the map constructed from Captain Cope-land's recent survey, that the small peninsula to the north-west, which terminates in Cape Lithada, is mountainous, and contains one elevation, Mount Lithada, which rises to the height of 2837 feet above the sea. A little south of the point where this peninsula joins the mass of the island, and on the west coast opposite to Bœotia, is Mount Telethrius, with some hot springs near its base. From Telethrius the mountains spread out north-east to Cape Amoni, the most north-eastern point of the island, and eastward to the coast, filling the northern part of the island, and containing several elevations above 2000 feet. Along the northern coast of the island, opposite to Thessaly, and stretching at the base of this mountain group, is the fertile and extensive plain of Oreos, the antient Hestiotis. South of Telethrius there is high land, with some interruptions, along the west coast as far as Cape Politika: within these limits is Mount Khandhili, near the coast, and another mountain 2694 feet high. Between Cape Politika and Egripos, and extending several miles inland, is the fertile plain of Egripos, bounded on the north and north-east by the high mountains which extend to the eastern coast. The centre of this mountain mass is Delphi, already mentioned, and it contains several other elevations which are between 4000 and 5000 feet. Between the mountains which we have described as occupying the north part of the island and the mass of which Delphi is the centre is the small plain of Mandhoudi on the east coast of the island. South of the narrow channel on which Egripos is situated there is a tract of low land along the Bay of Vathia, backed by the range of Mount Vathia (3821 feet), which appears to be separated by a depression from the group of Delphi, and forms part of the south-east boundary of the plain of Egripos. Farther south and near the west coast there is also the plain of Aliveri. The rest of the island south of Aliveri, along the west coast, and the whole of the eastern coast from the plain of Mandhoudi, appears to be mountainous. The southern extremity of the island is filled by the mass of

Mount Elias (4748 feet), which presents to the Archipelago an iron-bound and dangerous coast.

To the southward the plains are generally cultivated with corn and olives, but those to the northward, called the Plains of Oreos, are more particularly devoted to the vine, from which a light red wine is made, which is the common beverage of the Greeks, and forms a staple article of trade. The wine is kept in pig-skins, well coated with resin, which communicates its unpleasant flavour to the contents, which otherwise would not be unpalatable. A deleterious ardent spirit is distilled from the husks of the grapes. Cotton is also planted more to the northward.

On the shores of the Bay of Oreos are some ruins on an eminence, apparently only a military post; a few huts now surround its base, but about two miles in the interior is a large village called Xero Chori, or dry village.

The island is not populous: it is conjectured to contain between 60,000 and 70,000 inhabitants, nearly all Greeks. The villages are few, and, as is the case every where in the Archipelago, built at some distance from the beach, generally on an elevation difficult of access. This precaution has been taken on account of the numerous depredations of the pirates, who were accustomed to land, sack a village, and embark before morning, so that unless the place were tolerably large and populous, there was no safety for life or property.

The passage between Thessaly and Eubœa, called the Trikirri Channel, from the town of that name at the eastern entrance to the Gulf of Volo, is about 4 miles in average width; the narrowest part, which is towards the western extreme, is not quite $1\frac{1}{4}$ mile; the depth of water is regular, steep from both shores, and decreasing gradually from about 50 fathoms at the entrance to 30 towards the western end of the Negropont, off which lie some small rocky islands called Lithada Islands. Passing these islands, and turning to the southward, is the Gulf of Talanda, so called from the town of that name on the Bœotian shore. A remarkable feature in this part of the channel is the amazing depth of water under Mount Telethrius, where, for about 12 or 15 miles, there is no bottom with 220 fathoms within half a mile of the shore; but from this point the water shoals gradually towards Egripos. Towards the north-west extremity of this shore there is a very safe and excellent harbour, now called Port Ghialtra (formerly Port Kalos). There are two villages on its shores, Ghialtra to the westward, and Elypsos to the eastward: near the latter are some antient remains and beautifully sculptured fragments of white marble.

At Cape Therma, the eastern point of the bay, there are hot springs (already mentioned) of the same kind as, but more abundant than, those of Thermopylæ. The water rushes down in a copious stream into the sea, the vapour from which is visible for a considerable distance. Between this point and Egripos there are only three villages, Orovia, Glim, and Politika, all small; but at each of them there are Venetian remains.

In the southern part of the channel there are many islands along the Eubœan shore, which offer good anchorage, more especially among the Petalion Islands, which abound in rabbits, but possess only one spring of fresh water. From Egripos to Karystos there are only two villages, Aliveri and Stura, in the bays called respectively from their names. The bed of this part of the channel is level, but compared with the northern part it is shallow; the general depth is from 35 to 40 fathoms.

The eastern side of Eubœa is a continuation of rocky coast, the high land descending precipitously to the shore with few interruptions of level ground, and this only, as already mentioned, towards the northern part of the island. In the bight between Capes Doro and Oetonia, it is an unbroken line of precipitous shore, in which it is scarcely possible to find a ravine sufficiently wide to haul a boat up. Fragments of wreck are found at the height of eighty feet perpendicular, washed up by the heavy sea which a north-east wind throws into this bay. These winds, which always blow very strong, are called by the Greeks 'meltem,' probably a corruption of 'mal tiempo.' In addition to this, the Dardanelles current, preserving the course communicated to it by the direction of that strait, sets strong to the south-west into this bay, and renders it a most dangerous coast: no vessel once embayed here can escape destruction. The current being deflected to the southward sweeps round Cape Doro, frequently at the rate of three miles an hour

Port Petries is the only refuge which this coast offers, and so little has hitherto been known of this shore that even this snelter has only recently been discovered. The village of Koumi, in the bay of that name, is populous, and being celebrated for its wine, has considerable trade in that article by the small caiques, which however are always obliged to be hauled up on the beach for safety. Along the whole extent of this coast, which is upwards of 100 miles, there are only five or six villages near the shore.

The small number of Turks resident in Eubœa left the island on its being surrendered for the purpose of forming an integral part of the Greek kingdom, of which it will not be the least valuable portion. The mountains are said to contain copper, and the marble quarries near Karystos have long been famous. (Strabo, p. 446.) The soil, favoured by the diversities of climate which such a variety of elevation affords, is capable of yielding the productions of tropical as well as of more northern regions, and of supporting an infinitely larger population than now occupies the land. The island abounds in sheep of an excellent breed; but bullocks are scarce, and bred principally for agricultural purposes. In the mountains are abundance of wild boar and deer, and the plains are overrun with hares and rabbits. Among the trees are the olive, oak, fir, chestnut, walnut, mulberry, and oriental plane. In the whole island there is not a stream deserving the name of a river into which the smallest boat could enter, and the inhabitants generally supply themselves with water from wells.

On the summit of Mount Elias (the Oche of Strabo) are the remains of an antient temple, consisting of rude unornamented blocks of limestone, and columns of the same material.

The town of Egripos, the antient Chalcis, the chief town in the island, is in 38° 36' N. lat., and 23° 37' E. long., at that part of the island where it is separated from the coast of Boeotia by a narrow channel of only forty yards. It is a walled town, and further defended, where the walls are not washed by the Euripus, by a deep and wide dry ditch. The walls are turreted, slight, and built without regularity, and the numerous winged lions of St. Mark leave no doubt of their Venetian origin. The area enclosed is about 800 yards in length by about 500 in width, which was formerly inhabited exclusively by the Turks; the streets are very narrow, but the houses capacious. The town has several gates constructed with great intricacy; that leading over the Euripus is particularly tortuous, and well defended; the drawbridges have been replaced by frail fixed bridges of logs, to the great peril of passengers.

Another defence is the fort Karababa, on the main, which stands on an eminence about 130 feet high, commencing its rise immediately from the bridge; this may be deemed the citadel of the place, as it overlooks and commands the town. It is a very misshapen structure, of an oblong form, about 400 yards long, and 150 broad. The walls are in some places so low, that an active man might vault on them; they are similar to and coeval with the walls of the town.

Outside the town to the north is a suburb appropriated to trade, and inhabited (when the writer of this article visited the place) by the Greeks and Jews. It consists of one main street about 300 yards in length, from which minor streets branch off. The houses are very small, and the shops are chiefly coffee-houses, or contain general stores and articles of dress: the whole is enclosed in a stockade. There is no commerce except in supplies of fruit and vegetables, principally from Volo, distant about ninety miles to the north, which is all carried on in small boats. The surrounding country is flat and rich, but poorly cultivated. A subsoil of stiff clay offers materials for brick-making and potteries, which are already commenced on a small scale. The market is well supplied, especially with fish; beef is difficult to be procured, but mutton very plentiful; water is scarce, and procured chiefly from wells.

There are facilities for building vessels of large size, as the shore goes off suddenly into deep water; but the inhabitants have advanced no farther yet than the repairs, clumsily executed, of their small boats, which are built generally at some of the Greek islands. The forests on Mount Delphi of fir and oak (the latter of an inferior quality) would supply wood, which might with facility be brought to the town.

Immediately opposite Egripos the land rises suddenly to

hills of considerable height, beyond which lie the plains of Thebes, which town is distant about 4 hours, or 12 miles.

The breadth of the Euripus is diminished by a rock in mid-channel, on which a fort is built, dividing it into two channels: that towards the main, though rather the broader is only practicable for small boats, as there is not more than three feet water at any time. Between the rock and the walls of Egripos is a distance of 33 feet, and the least depth at the highest water is 7 feet. It is here that the extraordinary tides take place for which the Euripus was formerly so noted: at times the water runs as much as eight miles an hour, with a fall under the bridge of about 1½ feet; but what is most singular, is the fact that vessels lying 150 yards from the bridge are not in the least affected by this rapid. It remains but a short time in a quiescent state, changing its direction in a few minutes, and almost immediately resuming its velocity, which is generally from four to five miles an hour either way, its greatest rapidity being however always to the southward. The results of three months' observation, in which the above phenomena were noted, afforded no sufficient data for reducing them to any regularity.

The port to the northward of the bridge, though not capacious, is secure: four or five frigates might moor in it, and it would contain many sail of merchantmen. It is about three-fourths of a mile in depth, decreasing in width from half a mile to the bridge, towards which the water shoals gradually from eleven and twelve fathoms, with a muddy bottom: outside is a good roadstead, with excellent holding-ground. The entrance is clear and free from danger, and although open to the Gulf of Talanda, there is never any sea of consequence; but the gusts which come down off Mount Khandhill are very heavy.

To the southward of the bridge there are two ports; the inner is supposed to be the Port Aulis, where the Grecian fleet assembled previous to the Trojan war. It is about a mile across each way, with six fathoms generally all over it, but a bank of 14 feet in the strait which communicates with the outer port confines its access to vessels of that draught of water. The outer port, which is two and a half miles long and one broad, is joined to Port Aulis by a channel nearly half a mile in length and 400 yards broad, but its outlet to the southward is narrow and intricate. Opposite Egripos Island water may be procured for shipping, though it is not always good or plentiful: the quantity of vegetable substance in the pools which are formed previous to its flowing into the sea renders it frequently unwholesome. A round tower on the eastern point, called the Bourg, is a good mark for the entrance of this port from the southward.

In and about Egripos fragments of antiquity may be seen forming parts of the walls of houses, in common with the grosser materials, like diamonds set in lead. They are generally of white marble, beautifully chiselled; but in no place can any building be traced, or vestiges of walls. The pieces of columns are generally of the Corinthian order, fluted. On Egripos Island there is the appearance of a rude wall traversing the island; and on the mainland, at the southern shore of the channel, between the two ports, where the land rises to about 400 feet, are the remains of Cyclopean walls of very high antiquity. The blocks of stone, which are very massive, rude, and irregular, but fitting closely, are of limestone, and in construction the walls resemble those of Mycenæ. This is most probably the antient Aulis; though there may have been houses at a less elevation and nearer the shore more convenient for commerce, the ascent to these ruins being steep and difficult. The site of Eretria in Eubœa has not been exactly discovered, but it must have been near the west coast and south of Chalcis

Coin of Eretria.

British Museum. Actual size. Silver. Weight 86½ grains.

The country around Egripos is flat for many miles, and very prettily studded with kiosks and small villages. An aqueduct which, commencing at the foot of Mount Delphi,

winds its way to within half a mile of the town, forms a very picturesque object. Though it no longer conveys water, it is by no means in a ruinous condition. It appears to be of Venetian construction, and there are several ruins of that age in the neighbourhood; one especially, called Kastro, situated on the apex of an insulated rise, and presenting towards the sea a steep cliff, resembles the baronial castles on the banks of the Rhine.

Egripos is capable of vast improvements, and of becoming of great commercial importance. Little expense would render the passage of the bridge practicable for vessels of 300 and 400 tons, should it be required, thereby avoiding the passage along the outer coast of the Negropont, which is the worst in the Archipelago, as the Dardanelles current sets on its iron-bound coast, which offers no port whatever, and is a lee-shore in the strong and prevailing north-east winds.

From Egripos there is a carriage road to Karystos, at the southern extremity of the island.

History of Eubœa.—The first inhabitants of this island were probably a Pelagic race, which is said to have occupied, before the historical times, most of the islands of the Ægean Sea. The Dryopes from Mount Ceta were said to have founded Carystus and Styra (Herodotus, viii. 46; Thucyd. vii. 57); and the Athenians founded Chalcis and Eretria, before the siege of Troy. Homer (*Iliad*, ii. 536) calls the inhabitants of Eubœa by the name Abantes, and mentions them as having taken a distinguished part in the expedition against Troy. The Hestiatots were said to be a colony of the Perrhæbi, a Pelagic tribe: but the Athenians appear to have been from a very remote epoch the principal colonizers of Eubœa. At the dawn of the historical times we find Chalcis and Eretria, two independent but allied towns, which had advanced to a high state of prosperity, holding dominion over the islands of Andros, Tenos, and Ceos, and sending colonies to the coasts of Macedonia and Thrace, as well as to the shores of Italy and Sicily. Naxos, the first Greek settlement in Sicily, and Cuma, one of the oldest in Italy, were colonies of Chalcis. Eretria and Chalcis however quarrelled, and Thucydides (i. 15) mentions the war between the two states as one of the oldest wars on record among the Greeks. This war however was not one of extermination; and we find in the sixth century B.C. the two communities still flourishing, under the government of their Hippobotæ, or wealthier citizens. Unfortunately for them, they co-operated with Cleomenes in his invasion of Attica, which followed the expulsion of the Pisistratidæ, in consequence of which, after the Athenians had repulsed Cleomenes, they invaded Eubœa, about 506 B.C., defeated the Bœotians, who had come to the assistance of Chalcis; and having taken the latter city, they punished it severely, put many of the citizens in fetters, until they ransomed themselves, confiscated all the property of the Hippobotæ, and gave their lands to Athenian colonists, whom they sent over to the island to the number of 4000 (Herodotus, v. 77). Eubœa now became in great measure a dependency of Athens. Afterwards, the Eubœans, together with the Athenians, sent assistance to the Ionians of Asia in their war against Darius Hystaspes; and their troops were among those which burnt Sardes (499 B.C.). The first invasion of Greece was the consequence of that expedition. The Satraps, Datis and Artaphernes, landed in Eubœa with an immense force, completely destroyed Eretria, and sent its inhabitants as slaves into Asia. The Persians then crossed over into Attica, where they were defeated at the battle of Marathon. In the subsequent expedition of Xerxes, Chalcis and other towns of Eubœa manned ships, which, uniting with the rest of the Greek fleet, fought with the Persians at Artemisium. The Hestiatots alone favoured the Persians. After the end of the Persian war we find the Athenians under Cimon, the son of Miltiades, making war in Eubœa against the Carystians, who had revolted, and reducing them to subjection. A general revolt of Eubœa against Athens broke out in 445 B.C., but Pericles, with 5000 regular troops, marched into the island, and recovered possession of it: the towns of Eubœa were reduced to the condition of tributaries to Athens, and an Athenian colony was settled at Oreus in the territory of the Hestiatots, which was the fertile plain on the north coast of the island. This island was of great importance to the Athenians: it furnished them with corn, supplied them with horses, and was considered of more value to them than all their other colonies put together. During the Peloponnesian war, after

the defeat of the Athenians in Sicily, another general revolt of Eubœa took place, and the island placed itself under the protection of Lacedæmon, but afterwards returned to the Athenian allegiance, when Athens had recovered its independence; and from that time its four principal towns, Chalcis, Eretria (which had been rebuilt near the site of the old town destroyed by the Persians), Carystus, and Oreus, possessed a kind of municipal independence under the supremacy of Athens, which supremacy was at times disputed by the Thebans, who were at last obliged to leave the island. The Eubœans however joined the Theban league against the Spartans, and fought under Epaminondas. In the general prostration into which the principal states of Greece fell after the death of Epaminondas, Eubœa seems to have been left in great measure to itself. Its principal towns came under the rule of chiefs, or tyrants, as they were called, without any interference on the part of the Athenians. About 350 B.C. Callias and Taurosthenes, sons of the late tyrant Mnesarchus, who were ruling in Chalcis, made overtures to Philip of Macedon, in order to have his assistance in subduing the rest of the island, an opportunity which was eagerly seized by Philip. Plutarch, who was at the same time tyrant of Eretria, applied to the Athenians to check Philip's interference. The Athenians sent an expedition under Phocian, who defeated the Chalcidians after hard fighting; but this led to no favourable result, as Callias remained in possession of Chalcis, and the Macedonian influence was established over the island. While Alexander was absent in his Persian wars, the Chalcidians increased and improved their fortifications, which extended to the main-land over the bridge they had built across the Euripus. When the Romans began to extend their influence to Greece, Chalcis and the other towns of Eubœa contracted alliance with Rome, and they remained steadfast to that alliance during the Ætolian war. (Livy, xxxv. 37. 39.) Chalcis afterwards submitted to Antiochus. (Livy, xxxv. 50, 51.) In the Achæan war, after the defeat at Corinth, Chalcis was taken and destroyed by the Romans, and the whole island fell under the dominion of Rome. It then gradually declined in population and importance; and Pausanias and Dion speak of its fallen state under the emperors.

In the dismemberment of the eastern empire by the Latins or Franks the Venetians obtained possession of Eubœa, which they called Negropont, a barbarous name, probably derived from the town of Egripos, a corruption of Euripus, built on the ruins of Chalcis, and from the word 'ponte,' meaning the bridge which united it to the main land. The Venetians lost the island in 1470, when the Turks took the capital, Negropont, and massacred all the inhabitants. The Venetian doge and general Morosini blockaded it in 1688, but after a murderous siege he was obliged to re-embark with great loss. The people of Eubœa took part in the last revolt of the Greeks against the Turks, and the island now forms part of the new kingdom of Greece.

Coin of Eubœa.

British Museum. Actual size. Silver. Weight 61½ grains.

EUCALYPTUS, a genus of New Holland plants, consisting of lofty trees, with a volatile aromatic oily secretion in their leaves and a large quantity of astringent resinous matter in their bark. They belong to the alternate-leaved division of Myrtaceæ, and are generically known among those plants by their corolla being absent, and the limb of their calyx consolidated into a hemispherical or conical cap, which is thrown off when the stamens expand.

This genus occurs in the Malayan Archipelago, but is chiefly Australian, and, together with the leafless Acacias, gives a most remarkable character to the scenery. The species exist in great profusion, and form the largest trees in the forests of that part of the world. A modern writer upon the plants of Van Diemen's Land says, that Eucalyptus seems as if it had taken undisturbed possession of those Australian regions, clothing as it does with a stupendous mantle the surface both of Van Diemen's

Land and New Holland, while the intermixture of other plants which this lordly tribe permits is, compared with its own great extent, but small and partial. Wherever you go, one species or other is constantly before you.

No trees in the world so constantly or rapidly arrive at gigantic dimensions: they often become hollow, and are then used by the traveller as roomy places of shelter at night. Frazer found a hollow Eucalyptus at Moreton Bay, used by the natives as a cemetery. Even at Swan River, where, according to the report of Frazer, the species are stunted, they also attain a huge size, as is proved by what that traveller says of the Angophoras, which he terms 'magnificent' and 'gigantic,' and which, in fact, are Eucalyptus calophylla. A height of 150 ft., and a girth of from 25 to 50 are not uncommon dimensions of these trees. Their timber is represented as highly useful for domestic and other purposes; being so soft at first as to render the felling, splitting, and sawing up of the tree when green a very easy process, and when thoroughly dry becoming as hard as oak. Their bark is often extremely hard, whence some species, especially *E. resinifera*, are called iron-bark trees by the colonists. The blue gum-tree and some others have the singular property of throwing it off in white or grey longitudinal strips or ribands, which, hanging down from the branches, have a singular effect in the woods.

In many species the leaves are so variable in their form and other characters at different ages of the tree, or in different situations, that it is a matter of difficulty to know how they are to be botanically distinguished from each other; and in fact the subject of the distinction of species has hardly yet been taken up, no botanist feeling competent to undertake the task without some personal acquaintance with the plants in a native state. The leaves, instead of presenting one of their surfaces to the sky and the other to the earth, as is the case with the trees of Europe, are often arranged with their faces vertical, so that each side is equally exposed to light.

Gum-tree is the universal name among the colonists for a Eucalyptus, and has arisen from the large quantity of an astringent gum-like juice, resembling gum Kino in its qualities, which all the species yield. In cutting down *E. robusta*, Mr. Backhouse says that 'we often find large cavities between the annual concentric circles of the trunk, filled with a most beautiful red or rich vermilion-coloured liquid gum, which flows out as soon as the saw has afforded it an opening. The gum yielded by *E. resinifera* is considered by druggists as not in the least inferior to the Kino which the *Pterocarpus* or Red Saunders wood of India produces.' (*Companion to the Botan. Magazine*, vol. i. p. 69.) At Moreton Bay and in Van Diemen's Land a kind of manna is yielded by certain species. It appears in the form of an exudation, which coagulates and drops from the leaves to the ground in small white particles, often as large as an almond, and with a sweet agreeable taste.

Upon the whole this genus must be considered the most important that New Holland produces. As it occurs so far to the south as Van Diemen's Land, it is almost certain that it might be naturalized in Devonshire, Cornwall, and on the west of Ireland. Even in the neighbourhood of London certain kinds bear moderate winters without shelter, especially *E. pulverulenta*.

It is very much to be regretted that some settled nomenclature is not introduced, for the colonists apply the same names to different species in different parts of the country; this renders it difficult to tell of what they are speaking. As far as we can collect the evidence, it appears that the following are, or should be, the botanical species to which the colonial names belong:—

| | |
|----------------------------------|--------------------------------|
| Blue Gum of Port Jackson | <i>E. piperita</i> |
| Ditto of Hobart Town | <i>E. globulus</i> |
| Stringy Bark | <i>E. robusta</i> |
| Iron Bark | <i>E. resinifera</i> |
| Kino Gum | Ditto |
| Peppermint Tree | <i>E. piperita</i> |
| Weeping Gum of Van Diemen's Land | Uncertain |
| Mountain Blue Gum of ditto | Ditto |
| Black Gum of ditto | Ditto |
| Black-budded Gum of ditto | Ditto |
| Cider Tree of ditto | Ditto |
| Manna Gum of ditto | Ditto |
| Ditto of Moreton Bay | <i>E. Manna</i> , <i>Cunn.</i> |
| Blood-wood of Port Jackson | <i>E. corymbosa</i> |
| White Gum of Van Diemen's Land | <i>E. resinifera</i> |

Ditto of Moreton Bay *E. subulata*, *Cunn.*
 Ditto of the S.W. Interior *E. Leucadendron*, *Cunn.*
 EUCHARIS. [BERG, vol. iv., p. 318; CILIOGRADA, vol. vii., p. 165.]

EUCARIST (*εὐχαριστία*, thanksgiving) is a Greek name of the Christian sacramental act otherwise called the Communion, or the Lord's Supper; and, in contradistinction from these appellations, it particularly expresses the idea of thankfully commemorating the mediatorial sacrifice of Christ; or, according to others, the name was assigned in reference to the fact that, when Jesus enjoined the observance of the rite, he gave thanks.

An elaborate account of the history and doctrines of the Eucharist is given in the learned dissertations on the subject by bishop Patrick, Dr. Waterland, and numerous other writers, of whom a list is furnished in Watt's *Bibliotheca Britannica*. (Cave's *Primitive Christianity*, part ii., c. 11; Bingham's *Origines Ecclesiasticæ*; Claude, *On the Eucharist*, fol., 1684; *Traité de la Cène du Seigneur*, fol., 1635; *Traité de l'Euchariste*, par Cardinal du Perron, fol., 1633.) [COMMUNION.]

EUCHYSIDERITE (*Achmite*), a mineral which occurs crystallized. Primary form, an oblique rhombic prism, of same cleavage and measurements as pyroxene. Colour brownish-black. Lustre vitreous. Nearly opaque. Sp. gr. 3.34. Hardness 6.0-6.5. Streak, yellowish-grey. Fracture, imperfect conchoidal.

It occurs in Norway. Before the blow-pipe alone, readily fuses into a brilliant black globule; with borax forms a coloured glass.

According to Berzelius it consists of—

| | |
|--------------------|-------|
| Silica | 55.25 |
| Oxide of iron | 31.25 |
| Soda | 10.40 |
| Lime | 0.72 |
| Oxide of manganese | 1.08 |

—99.70

EUCLASE, a crystallized mineral, the primary form of which is an oblique rhombic prism. It is either colourless and nearly transparent, blue, or pale bluish-green; it refracts doubly; the lustre is vitreous. Hardness 7.5; sp. gr. 3.998. Cleavage very distinct, parallel to the oblique diagonal, but indistinct parallel to the terminal plane and horizontal diagonal. The fracture is uneven, and the streak white.

It was first found in Peru, but has since been met with in detached crystals in alluvial ground in Brazil.

According to Berzelius it consists of—

| | |
|---------------|-------|
| Glucina | 21.78 |
| Silica | 43.32 |
| Alumina | 30.56 |
| Oxide of Iron | 2.22 |
| Oxide of Tin | 0.70 |

—99.58

EUCLID, the Geometrician. [GEOMETRY OF THE GREEKS.]

EUCLID (*Εὐκλείδης*) of Megara is said to be a different person from the geometrician of the same name. He was a scholar of Socrates, and the founder of the school called the Megaric, which may be considered as the predecessor of the Sceptical school of a later date. This school was distinguished by its dialectic subtlety, by which contradictory propositions could be proved, the consequence of which was universal doubt. The Supreme Good, according to Euclid, was always the same and unchangeable. He wrote six dialogues, which are lost. (*See De Megaricorum Doctrina ejusque apud Platonem et Aristotelem vestigiis*, Ferd. Deycks, Bonn, 1827, 8vo.)

EUCÆLIUM. (Zoology.) [SYNOICUM.]

EUCRA'TEA. [CELLARICA, vol. vi., p. 405.]

EU'DEA. [SPONGIDÆ.]

EUDIOMETER, an instrument invented by Dr. Priestley, and originally employed by him in ascertaining the goodness of atmospheric air obtained from various places and under different circumstances. By the use of this instrument and the modifications which it has received, it has been ascertained that the air is liable to no essential variation of composition except such as arises from local and temporary causes.

The use of the eudiometer, termed eudiometry, has, since its original contrivance, been extended to all gaseous mixtures, but especially to determining the quantity of oxygen which they contain when resulting from the operations of analysis; and it is an essential instrument in the chemical

in investigation of bodies, not merely such as are naturally gaseous, but which become so by the changes to which they are subjected during chemical research.

The principle upon which the use of the eudiometer depends, so far as atmospheric air and oxygen gas are concerned, is that of exposing them to the action of some substance, whether solid, fluid, or gaseous, which, on account of its affinity for oxygen, combines with it and leaves the gases with which it is mixed unacted upon.

The eudiometer invented by Dr. Priestley arose from and was connected with his great discovery of oxygen gas and the fact which he ascertained of its absorption by another gas, which he called nitrous air, since called by various other names, as nitrous gas, deutoxide of azote, binoxide of nitrogen, and nitric oxide gas.

This gas may be considered as nitric acid deprived of a large portion of its oxygen, which is effected by dissolving a metal in it, as, for example, copper, silver, or mercury, &c.; and of these the last mentioned is said to yield the gas in the greatest purity. The nitric oxide thus obtained being disposed to regain the oxygen which the metal has taken from it, absorbs it with great facility from all such gaseous mixtures as contain it; the evidences of its action are the formation of a red vapour, condensation of volume, and the reproduction of nitric acid; and the quantity of oxygen absorbed is determined by the degree of condensation which is produced by its action.

Dr. Priestley's method was extremely simple: he took a phial capable of holding about an ounce of water, filled it with water, and displaced it with atmospheric air, or with the gaseous mixture to be examined; the volume of this being noted, it was transferred, over water, into an air-jar about an inch and a half in diameter. An equal volume of nitric oxide was added to it, and they remained together for about two minutes: if the diminution was very considerable, another volume of nitric oxide was added. When this part of the process was over, the gas was transferred to a glass tube about two feet long, one-third of an inch in diameter, and graduated into 10ths and 100ths. After noting the volume of the gas, the result was expressed in measures and decimal parts; thus, when equal volumes of common air and nitric oxide were mixed, and they afterwards occupied the space of one volume and two-tenths, Dr. Priestley, in speaking of the air so tried, said the measures of the test were 1.2, or the standard of the air was 1.2.

Although Dr. Priestley determined the volumes of oxygen and nitric oxide required for mutual saturation, he appears mostly, if not entirely, to have confined his eudiometrical operations to comparing the results of them with those on atmospheric air; consequently, although what he calls the *standard* was learnt by his process, the exact quantity of oxygen which the mixture contained was not determined by it.

Numerous attempts have been made by chemical philosophers of the greatest eminence to render the eudiometrical application exact and certain, and if this could be effected, it would be rendered an extremely valuable method on account of the rapidity of its action. Omitting however all notice of the modifications which have been proposed by Cavendish, Fontana, Ingenhouz, Sardinani, &c., we may observe, that while both Dalton and Gay-Lussac imagined that they had removed the uncertainty of the process, the late Dr. Henry admits that he placed but little reliance upon it, and Dr. Thomson states that he has abandoned it altogether, excepting as far as it serves to indicate the presence or absence of oxygen gas in a gaseous residue under examination.

A very different and certainly an improved method, though rather an operose one, of employing nitric oxide was adopted by Davy. Dr. Priestley discovered that a solution of sulphate of iron is capable of dissolving nitric oxide gas, and that in this state it retains its power of combining with and condensing oxygen gas. It is prepared by passing the nitric oxide through the solution of sulphate; as the gas is absorbed the solution becomes of a deep olive brown, and when the impregnation is completed it appears opaque and almost black.

The instruments necessary for ascertaining the composition of the atmosphere by means of this solution consist simply of a small graduated tube divided into 100 parts, and greatest at the open end, and of a vessel for containing the fluid.

The tube, after being filled with the gaseous mixture to be examined, is introduced into the solution, and that the action may be more rapid, gently moved from a perpen-

dicular towards a horizontal position. Under these circumstances the gas is rapidly diminished; and in consequence of the dark colour of the fluid, it is very easy to observe the degree of absorption; in a few seconds the experiment is completed, and the whole of the oxygen is condensed.

The period of the greatest diminution is to be accurately noted; for shortly after this it begins gradually to increase. Davy states that the impregnated muriate of iron (chloride) acts more rapidly than the sulphate.

It is to be observed that this process is not applicable merely to the analysis of the air. It was employed by Allen and Pepys in their laborious and accurate experiments on respiration; and they added a simple solution of sulphate of iron to the residual gas, evidently for the purpose of separating any nitric oxide gas which might have escaped from the solution after arriving at the point of greatest condensation.

The eudiometer next to be mentioned is that invented by Scheele, which was probably the first proposed after Dr. Priestley's. This was a graduated glass tube containing a certain volume of air, which was exposed to a mixture of sulphur and iron-filings made into a paste with water. Although the oxygen was absorbed and the azote left by this operation, yet the process was not to be relied upon, for, by the formation of sulphuric acid, which occurred by the oxidizement of the sulphur, the iron was acted upon, and water being decomposed, its hydrogen was evolved, and interfered with the results of the operation.

This plan, however imperfect, had the merit of simplicity, for the quantity of oxygen absorbed was determined at once by deducting the volume of the residual gas from that of the whole quantity submitted to experiment.

De Marté, instead of using sulphur and iron, employed a solution of sulphuret of potassium prepared by dissolving sulphur in a solution of potash. It is stated that this solution when newly prepared absorbs a small portion of azotic gas; but the fallacy arising from this source is readily obviated by agitating the solution for a short time with a little atmospheric air previously to using it, by which it is saturated with azote. A tube divided into 100 parts and immersed in the solution is sufficient for the use of it.

Guyton employed sulphuret of potassium also in his eudiometer, but he used it in a solid state, and applied heat to expedite its action. In this case, as when the solution is used, both the sulphur and potassium are oxidized, and the result is sulphate of potash. It has been objected, and probably with reason, to this eudiometer, that sulphuretted hydrogen was elicited by the action of the heat upon the sulphuret. A description of this eudiometer, which has been but little used, is given in *Nicholson's Journal*, 4to. vol. i.

The eudiometer of Seguin is a glass tube, about an inch in diameter, eight inches long, and open at one end. It is to be filled with and inverted in mercury; a small piece of phosphorus is then put under the open end of the tube, and by its lightness it immediately rises to the top of it, where it is to be melted by the approach of a red-hot iron. A measured portion of the gas to be examined is then to be passed into the tube; the phosphorus inflames on each addition of the gas, and the mercury rises, owing to the condensation of the oxygen. When all the gas under examination has been thrown up into the tube, the hot iron is again used to ensure the completion of the process: the quantity of the residual gas is determined by transferring it into a graduated tube, and the difference between the quantity submitted to experiment and that left after it indicates that of the oxygen absorbed.

In this operation, owing to the affinity existing between the phosphorus and the oxygen, they combine and form phosphoric acid: it is however stated that the azote dissolves a small quantity of phosphorus, and that, owing to the expansion which this occasions, about $\frac{1}{4}$ of the volume of the azotic gas is to be deducted.

Berthollet also employed phosphorus in his eudiometer; but instead of heating it, as in the above-described method he allowed combination to take place between it and the oxygen, by what is termed slow combustion. He exposed a stick of phosphorus fastened to a glass rod in a narrow graduated glass vessel, filled with air, and standing over water: the phosphorus immediately begins to act on the oxygen of the air, as shown by the formation of the white vapour of phosphoric or phosphorous acid; but this occurs without visible combustion: in six or eight hours the whole of the oxygen disappears, and its quantity is, of course

immediately apparent, making the deduction above stated from the azotic gas.

Dr. Hope's eudiometer is represented in the annexed figure. It is used with a solution either of sulphate of iron impregnated with nitric oxide or with solution of sulphuret of potassium. This eudiometer consists of a small bottle, capable of holding about three ounces, for containing the eudiometric fluid, and it is perforated and furnished with a stopper at *b*. Into the neck of the bottle a hollow graduated tube, *a*, closed at the upper end, is accurately fitted by grinding; it holds precisely a cubic inch, and is divided into 100 equal parts. To use the apparatus, the bottle is first to be filled with the solution to be employed, and covering the mouth with a flat piece of glass, it is to be immersed in water; the glass being then removed, the open end of the tube containing the gas to be examined is to be inserted.

The instrument being removed from the water, is to be inverted. The gas ascending into the bottle, it is to be brought into thorough contact with the liquid by brisk agitation, by which absorption of gas occurs; to supply its place the stopper at *b* is removed under water, a quantity of which rushes into the bottle; the stopper is then replaced, and these operations are alternately renewed, till no further diminution takes place; the tube *a* is then withdrawn, the neck of the bottle being in water, and it is held inverted for a short time, and the diminution is then measured by the graduated scale.

Dr. Henry has pointed out some difficulties attendant upon the use of this eudiometer, to obviate which he has substituted a caoutchouc bottle for the glass one, as shown in the annexed figure at *b*. The tube *a* is accurately ground into a short piece of very strong tube of wider bore, as shown at *c*, the outer surface of which is made rough by grinding, and shaped as represented, that it may more effectually retain the neck of the elastic bottle when fixed by waxed thread. This instrument is used, in every respect, in the same manner as Dr. Hope's. The only difficulty is in returning the whole of the residuary gas into the tube, but the art of doing this is readily acquired by practice.

Pepys has contrived a eudiometer, in which a caoutchouc bottle is employed as in Dr. Henry's. This instrument, from the inventor's statement, appears to be susceptible of great accuracy; for he states that he is able to measure an absorption of only $\frac{1}{100}$ of the gas employed. For an account of this eudiometer, and of some experiments performed with it, see *Phil. Trans.*, 1807. The parts are too numerous for us to insert figures of, and without them a description would be scarcely intelligible.

Having now described the use of nitric oxide, sulphuret of potassium, and phosphorus, as eudiometrical substances, and noticed the more important instruments in which they are employed, we shall notice the eudiometer of Volta, and the eudiometric body which he made use of.

Volta's method of determining the composition of atmospheric air, or of the quantity of oxygen contained in gaseous mixtures, is by means of combustion with a known volume of hydrogen gas; for it having been ascertained that when a mixture of oxygen and hydrogen gases is fired, one-third of the diminution is owing to the condensation of oxygen, we have only to observe the measure of the contraction of volume to ascertain that of the oxygen which was present. Of Volta's eudiometer various modifications have been proposed, all agreeing however in the principle above mentioned. According to Berzelius, that invented by Mitscherlich is to be preferred, on account of the simplicity of its construction and the accuracy of its results. We shall therefore describe it instead of the original one, and it will at once occur to the chemical reader that it is a slight modification of Priestley's and Cavendish's detonating tubes.

This instrument, as represented by the annexed figure, consists of a very thick glass tube from 18 to 24 inches long, and about four lines internal

diameter; it is graduated, open at one end, and closed at the other. Near the top *A* the tube is perforated with platinum wires, placed at such a distance as readily to allow of the passage of the electric spark between them, and externally hooked; near the orifice, *B*, the tube is laterally perforated and furnished with a glass cock, which is shut after filling the tube with the gas to be examined: this is, of course, to prevent the loss of gas by the expansion accompanying the detonation by the spark. When this is over, the cock is turned under either water or mercury, and the fluid rising in the tube, the condensation is exactly noted by bringing the fluid within and without the tube to the same level.

Another variety of Volta's eudiometer is represented by the opposite figure. It is more simple in its construction than the foregoing, but less certain in its results, on account of the escape of gas which occurs if it be not immersed sufficiently deep in water or mercury: it is a modification of an instrument invented by Dr. Priestley. The only additional explanation required is, that *A* is a moveable metallic wire with a knob at the end, which is raised near enough to the knob at the top of the instrument to allow of the passage of the electrical spark.

Dr. Ure has also contrived a modification of Volta's eudiometer, which renders the experiment easy of performance by a single person. This instrument is shown by the figure. It consists of a glass siphon, having an interior diameter of from 2-10ths to 4-10ths of an inch; its legs are nearly of equal length, each being from six to nine inches long. The open extremity is slightly funnel-shaped; the other is hermetically sealed, and has two platinum wires inserted; the legs are about one-fourth to one-half an inch asunder. The instrument having been graduated, it is to be filled with water or mercury, and the gas transferred into it in the ordinary manner; then being upright, part of the fluid in the open leg is displaced by inserting a glass rod, or in some other manner. The open leg ought to contain at least two inches of air between the thumb and the mercury: this atmospheric column serves as a recoil-spring, enabling the operator to explode considerable quantities without inconvenience or danger. The open leg being grasped by the hand, the thumb is to be placed lightly over the aperture, so as to close it, and at the same time to touch one of the wires; a spark taken from the conductor to the other wire passes through the gas, inflaming it, and is conducted off by the thumb and hand. The gas in expanding depresses the fluid beneath it, whilst, as already noticed, the air in the part inclosed by the thumb acts as a spring to restrain the violence of the explosion. If a charge from a jar is to be passed, then the thumb must not be allowed to touch the wire whilst closing the aperture. When the jar is charged, the wire connected with the outer coating is first to be hooked upon the eudiometer wire nearest the thumb, and securely retained there, so as not to slip during the experiment; and then the knob of the jar is to be brought to the other wire and the gas inflamed.

After explosion, when the condensation of volume ensues, the thumb will feel pressed down to the orifice by the superincumbent atmosphere. On gradually sliding the finger to one side and admitting the air, the mercurial column in the sealed leg will rise more or less above that in the other; mercury is then to be poured in till the equilibrium is restored, and the resulting volume of gas is then read off.

Dr. Ure states that with the above instrument he has exploded half a cubic inch of hydrogen mixed with a quarter of a cubic inch of oxygen, as also a bulk nearly equal of an elephant gas explosive mixture, without any unpleasant concussion or noise.

Dobereiner has suggested a eudiometrical process, founded on his curious discovery of the property which spongy platinum possesses of causing the combination of oxygen and hydrogen gases. In this eudiometer the com-

hination occurs without explosion, and yields results of great accuracy. Dobereiner found that when the spongy platinum was mixed with certain substances, so as to prevent its immediate and explosive action, it caused the oxygen and hydrogen to combine with moderate rapidity. The late Dr. Henry, who performed a most important and accurate series of experiments on this eudiometrical process, recommended a mixture of three parts of spongy platinum and two of fine china clay made into a paste with water and moulded into spherules about the size of a pea; these were fastened to a platinum wire, that they might be removed after the action was over. They should be heated and suffered to cool a short time before use: they suffer no loss of power, and possess the great advantage over the electric spark, that they act upon gaseous mixtures which contain so little oxygen and hydrogen that they cannot be fired. The late Dr. Turner ascertained that it was possible to determine the presence of $\frac{1}{16}$ of hydrogen or oxygen in a gaseous mixture; whereas, when these gases formed $\frac{1}{16}$ of a mixture, they could not be detected by electricity. The effect takes place more rapidly in large than in small tubes.

There are various gases which impede the action of the platinum balls. It appears from the experiments of Dr. Henry, that when the compound combustible gases, mixed with each other, with hydrogen, and with oxygen, are exposed to the balls of platinum, the several gases are not acted upon with equal facility; that next to hydrogen carbonic oxide is most disposed to unite with oxygen, then olefant gas, and lastly, carburetted hydrogen.

Dr. Henry observed, that the property inherent in certain gases of retarding the action of platinum, when they are added to explosive mixtures of oxygen and hydrogen, is most remarkable in those which possess the strongest attraction for oxygen. Heat occasions the platinum balls to act in many cases in which no combination would occur without it.

In concluding this historical sketch of eudiometers and eudiometry, we repeat an observation already made, viz., that whatever volume of the mixed gases may disappear after detonation or by the action of the spongy platinum, one-third of such portion is to be considered as oxygen and two-thirds as hydrogen, the result of their combination being water, formed of these proportions of its constituent gases.

EUDOCIA, daughter of Loontius, an Athenian sophist, was called Athenais before her baptism. She was carefully instructed by her father in literature and the sciences. After her father's death, being deprived by her brothers of all share in the inheritance, she repaired to Constantinople, and appealed to Pulcheria, sister of Theodosius II., who was so pleased with her that she induced her brother to marry her, A.D. 421. Eudocia surrounded herself with learned men; but the emperor, through jealousy, dismissed all her court, and had her exiled to Palestine, where she continued to reside after the death of her husband. She there embraced the opinions of Eutyches, and supported by her liberality and influence the monk Theodosius, who forced himself into the see of Jerusalem, after driving away Juvenal, the orthodox bishop, and kept it until he was himself driven away by order of the Emperor Marcianus. Euthymius, called the Saint, by his reasonings brought back Eudocia to the orthodox faith, after which she spent the remainder of her days at Jerusalem, where she died in 460, protesting her innocence of the guilt with which her husband had charged her. Eudocia wrote several works, of which Photius quotes a translation in verse of the first eight books of the Old Testament. There is also a work attributed to her, which was translated into Latin by Echard, and was published under the title of 'Homerici Centones Græce et Latine, interprete Echardo,' Paris, 1578. It is a life of Jesus Christ, composed of lines taken from Homer. Most critics however believe that it is not the work of Eudocia, though Ducange is of the contrary opinion.

EUDOCIA the Younger, daughter of the preceding and of Theodosius II., married Valentinianus III. After the assassination of her husband by Petronius Maximus, she was obliged to marry the usurper. Eudocia, out of indignation and revenge, called in Genserius, king of the Vandals, who came to Italy, plundered Rome, and carried Eudocia to Africa with him. Some years afterwards she was sent back to Constantinople, A.D. 462, where she died.

EUDOCIA, the widow of Constantinus Ducas, married Romanus Diogenes, an officer of distinction, A.D. 1068, and

associated him with her on the throne. Three years after, Michael, her son, by means of a revolt, was proclaimed emperor, and caused his mother to be shut up in a convent, where she lived the rest of her life. She left a treatise on the genealogies of the gods and heroes, which displays an extensive acquaintance with the subject. It is printed in Villoison's *Anecdota Græca*, 2 vols., 4to. 1781.

EUDORA. [*MEDUSA*.]

EUDOXUS, a native of Cnidus, a city of Caria, in Asia Minor, and the son of Æschines, flourished about 370 B.C. He studied geometry under Archytas, and afterwards travelled into Egypt to study the sciences under the priests of that country. Diogenes Laërtius informs us that he and Plato studied in these schools for about thirteen years; after which Eudoxus came to Athens, and opened a school of his own, which he supported with such reputation that it excited the envy even of Plato himself. Proclus informs us that Euclid very liberally borrowed from the elements of geometry composed by Eudoxus. Cicero calls Eudoxus the greatest astronomer that had ever lived; and we learn from Petronius that he retired to the top of a very high mountain that he might observe the celestial phenomena with more convenience than he could on a plain or in a crowded city. Strabo (p. 119) says that the observatory of Eudoxus was at Cnidus, from which the astronomer saw the star Canopus. Vitruvius (ix. 9) describes a sun-dial constructed by him; and Strabo (p. 390) quotes him as a distinguished mathematician. Nothing of his works remains. He died in the fifty-third year of his age. [*ASTRONOMY*, p. 531.]

EUDOXUS, of Cyzicus, was sent by Ptolemy VII., of Egypt, on a voyage to India about B.C. 125. (Strabo, p. 98, Casaub.) The passage of Strabo referred to contains an account of his adventures. From this Eudoxus, or another of the name, Strabo derived some materials for his great work (379. 550. &c.).

EUDYALITE, a mineral which occurs both crystallized and massive. The crystals are generally small. The primary form is a rhomboid; the colour is red or brownish-red, and the crystals are faintly translucent or opaque. Lustre vitreous, sometimes dull. Sp. gr. 2.9. Hardness 5.0, 5.5. Streak white. Fracture uneven. The massive varieties are imbedded and amorphous.

It occurs at Kandarluarsuk, in West Greenland.

Before the blow-pipe it fuses into a leek-green scoria.

According to Stromeyer it consists of—

| | |
|--------------------------|-------|
| Silica . . . | 52.47 |
| Zirconia . . . | 10.89 |
| Lime . . . | 10.14 |
| Soda . . . | 13.92 |

EUDY'NAMYS. [*CUCULIDÆ*, *CUCULINÆ*, vol. viii., pp. 206 and 211.]

EU'DYTES. [*DIVERS*, vol. ix., p. 37.]

EUGENE, FRANÇOIS DE SAVOIE, commonly called Prince Eugene, was paternally descended, in the third degree, from the ducal house of Savoy, but was a French subject by birth, being a younger son of the Comte de Soissons, and born at Paris, October 18, 1663. He was designed for the church, but having formed a decided preference for a military life, and being also moved by certain wrongs which he conceived to have been done to his family by Louis XIV., and which he deeply resented, he entered the service of the Emperor Leopold. From this time he renounced his allegiance to France, and long after, when his reputation was at its height, rejected the most brilliant offers made by the French government to purchase his return to the service of his native country. His first campaign was against the Turks, at the celebrated siege of Vienna in 1683. Eminent bravery and talent, joined to high birth, ensured him rapid promotion. In 1688-9, on the breaking out of war between France and the Empire, he was employed on a diplomatic mission to the duke of Savoy, and in 1691 was raised to the command of the imperial army in Piedmont. During two campaigns he maintained a decided advantage over the French: in 1693 he was less successful. The duke having returned to the French alliance, we next find Prince Eugene commanding the army in Hungary, where he won a great victory over the Turks at Zenta, on the river Theiss, Sep-

tember 11, 1697. The peace of Carlowitz (1699) closed this scene of action; but a more brilliant one was opened in 1701 by the war of the Spanish succession. During two years Eugene maintained the imperial cause in Italy with honour against superior forces commanded successively by Catinat, Villeroy, and Vendôme, against the last of whom he fought the indecisive battle of Luzara, August 1, 1702, in which the flower of his troops was destroyed. At the end of this campaign he returned to Vienna, and was appointed president of the council of war.

In 1704 he commanded the imperial troops at the battle of Blenheim, August 13, 1704. The successes of the French in Piedmont made it expedient for him to return thither in 1705. He soon restored the duke of Savoy's declining fortunes, and won the decisive battle of Turin, September 7, 1706, after which the French evacuated the country. He was thus set again at liberty to co-operate with Marlborough in 1708, and had a share in the victory of Oudenarde, and in the capture of Lille, the siege of which was entrusted to him, while Marlborough protected his operations. In 1709 he was wounded at the bloody battle of Malplaquet, of which he was the chief adviser, and in which he led the attack upon the left wing. On the death of the Emperor Joseph in 1711, he took an important part in securing the succession to his brother Charles VI., and he visited England at the end of that year, in hope of preventing the secession of England from the alliance. He was received as his services deserved, but made no progress towards his object; for the dismissal of the Whig ministry was soon followed by the congress and peace of Utrecht. The emperor being no party to that treaty, Eugene invaded France in 1712 with little advantage, and it became evident that the interests of the empire would be best consulted by peace: the preliminaries were accordingly signed at Rastadt, March 6, 1714.

In 1716 Prince Eugene again marched against the Turks, and won the battle of Peterwaradin, August 6, against an enormous disproportion of numbers. In the following year he besieged Belgrade with 40,000 men. With troops wasted by disease, pressed by an army of 150,000 men from without and opposed by a powerful garrison from within, he was in the utmost danger, when, with the happy boldness which distinguished him, he seized the right moment, and inflicted a signal defeat on the army which threatened him. Upon this the town surrendered. Peace was concluded in the following year.

He took up his residence at Vienna, honoured and trusted by the emperor, in whose political service he was much employed. In 1733 a fresh quarrel with France called him again to command the imperial army on the banks of the Rhine. This war is said to have been undertaken against his advice: at all events age had diminished his energy: he contented himself with standing on the defensive, and used his influence to effect a reconciliation. Preliminaries of peace were signed at Vienna, October 5, 1735. He died suddenly in that capital, April 21, 1736, aged 73.

As a general, Prince Eugene ranks among the first of his kind, but that kind was not of the highest order of excellence. His name is memorable for no improvements in the art of war, neither was he famous for skill in manœuvring or combining the operations of distinct masses upon one object. His characteristics were penetration, quickness of perception, decision, and what usually goes along with them, readiness in amending a fault when made; so that his skill lay rather in making the best of given circumstances than in bending circumstances to his will beforehand. It is said that he always took great pains to learn the character of the general opposed to him. Careless of his own person (he was thirteen times wounded in battle), he was also somewhat prodigal of his soldiers' lives. However, he threw a glory round the Austrian arms such as has never dignified them either before or since.

The best account of his exploits is 'L'Histoire du Prince Eugène,' 5 vols. 12mo., by M. de Maubillon, but published without his name. In English, there is Campbell's Military History of Prince Eugene and the Duke of Marlborough, 2 vols. fol.; and several smaller works. Prince Eugene wrote memoirs of himself, which have been published both in French and English.

EUGENIA, a genus of dictyledonous polypetalous plants of the natural order of Myrtaceæ; so named in honour of Prince Eugene of Savoy, who was a patron of botany and horticulture. The genus, as at present constituted, contains nearly 200 species, though numbers have been removed to the genera Nelitris, Jossinia, Myrcia, Sisygium, Caryophyllus, and Jambosa, in which are now contained the Clove tree, the Rose apple, and Jamoon of India, formerly included in Eugenia. This genus is confined to the hot and tropical parts of the world, as Brazil, the West India Islands, and Sierra Leone, and extends from the Moluccas and Ceylon to Silhet and the foot of the Himalayas in Asia.

Eugenia is characterized by having the tube of the calyx of a roundish form and the limb divided into four parts; the petals equal in number, and inserted on the calyx. The stamens are numerous. The ovary 2-3 celled, with several ovules in each. Seeds one or two, roundish and large, with the cotyledons and radicle united into one mass. In habit and inflorescence the species resemble many myrtles. Like the family to which they belong, some of the species of Eugenia secrete a warm volatile oil in their herbaceous parts; abound in tannin; yield good wood; and a few have fruit which is edible, though not very agreeable, from being impregnated with the aroma of the oil.

The most remarkable species of the genus, and one of the few which it is necessary to notice, is the Allspice, Pimento, or Bay-berry tree. This is the *Eugenia Pimenta* of De Candolle; the *Myrtus Pimenta* of Linnæus and of the London Pharmacopœia. It is a native of South America and the West India Islands, especially Jamaica, and from being cultivated there is often called Jamaica Pepper. The tree is very handsome, often 30 feet high, and much resembles the Clove tree in the form and appearance of its leaves as well as in habit. The trunk is smooth, and much branched towards the top. The older branches are round, the younger compressed, and the twigs as well as the flower-stalks pubescent; the leaves are petiolate, oblong or oval, smooth, and marked with pellucid dots, forming a dense evergreen foliage; the flower-stalks are both axillary and terminal, and are divided into three-forked panicles; the flowers are small, without show, and conformable in structure to the character of the genus. The berry is spherical and crowned with the persistent calyx; when ripe, smooth, shining, and of a dark purple colour; usually one, occasionally two-celled, containing large roundish seeds.

The Pimenta is cultivated with great care in Jamaica, and abounds especially on the hills on the north side of the island. The trees are formed into regular walks, and begin to bear when three years old, but are not in perfection until they have been planted seven years. They thrive best in rocky lands, or a rich soil having a gravelly bottom. Mr. Bryan Edwards says that a single tree has been known to yield 150 lbs. of the raw fruit, or 100 lbs. of the dried spice; but the crop is uncertain, and plenteous perhaps only once in five years. The tree has been introduced into and flourishes in the southern parts of India.

The berries, being the valuable part of the tree, require care in gathering as well as drying; the processes for which are described by Browne in his 'History of Jamaica,' p. 248. They must be picked when they have arrived at full growth, but before they begin to ripen: they are dried in the sun, on raised boarded floors, and frequently turned during the first and second day; they are then put into sheets, often winnowed, and exposed to the sun until sufficiently dried, which is known by the colour and the rattling of the seeds in the berries. Browne says, 'Such of the berries as come to full maturity do, like many other seeds, lose that aromatic warmth for which they are esteemed, and acquire a taste perfectly like that of Juniper berries, which renders them a very agreeable food for the birds, the most industrious planters of these trees.'

The leaves and bark participate in the warm aromatic properties for which the berries are celebrated, and which have received their name of Allspice from their fragrant odour being thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Their taste being warm and aromatic makes them useful as a spice in cookery, and a stimulant in medicine.

Eugenia Micheli is a Brazilian species, cultivated in Martinique, whence it is called *Cerister de Cayenne*, as it yields a small edible fruit.

EUGENIACRINITES. [ENCENINITES, vol. ix., p. 393.] N.B. The Rev. Lansdown Guilding, in his notice of a perfect recent *Encrinurus*, found in the Caribbean seas, and which, according to him, comes nearest to the *Stag's Horn Encrinure* of Parkinson, says that its capture has enabled him:

to settle the point (which way he does not in terms state) as to whether the animal is locomotive or fixed. He gives no detailed description of the species *Encrinus ? Milleri*, but speaks of the *Sessile* genera of *Crinoidea*, and says that *E. Milleri* inhabits the Caribbean sea at great depths (in profundis), adhering to *Gorgonias*. He describes the *abdomen* of his species as being membranaceous, and situated between the bases of the arms. (*Zool. Journ.*, vol. iv. p. 173.)

EUGENIN, a substance which deposits spontaneously from the distilled water of cloves; it crystallizes in small laminae, which are colourless, transparent, and pearly, and in time they become yellow: the taste of eugenin is but slight, and the smell much less strong than that of the clove. It is soluble in alcohol and ether in all proportions: by the action of nitric acid, like the oil of cloves, it becomes immediately, even when cold, of a blood-red colour. It is composed of oxygen, hydrogen, and carbon, in the same proportions as constitute the oil of cloves, with one equivalent less of oxygen and hydrogen.

EUGENIUS I., a native of Rome, was elected by the Romans, A.D. 654, as successor to Martin I., who had been sent into banishment to the Thracian Chersonesus by order of the Emperor Constans II., who favoured the schism of the Monothelites. Martin dying in the following year, Eugenius continued in dispute with the court of Constantinople till he died in 657, and was succeeded by Vitalianus.

EUGENIUS II., a native of Rome, succeeded Paschas I., A.D. 824, in the midst of great disorder which occurred at Rome owing to the corrupt state of society and mal-administration of that city. To reform these, the emperor, Louis the Good, sent his son Lotharius to Rome, who corrected many abuses which, by the account of Eginhardt and other chroniclers, had grown to an enormous extent. He confirmed the right of electing the pope to the clergy and people of Rome, but under the condition that the pontiff elect should swear fidelity to the emperor before the imperial missus or representative. Eugenius held a council at Rome, in which, among other things, it was decreed that in every episcopal residence, as well as in every country parsonage, there should be a master for teaching the people and explaining the Scriptures. Eugenius died in 827, and was succeeded by Valentinus, who, dying also after a few weeks, was succeeded by Gregory IV.

EUGENIUS III., a native of Pisa, of the Cistercian order, and a disciple of St. Bernard, succeeded, A.D. 1145, Lucius II., who had died of a blow from a stone inflicted in a riot of the Roman people. Arnaldo da Bresoia was then preaching his reform at Rome, the senate had declared itself independent of the pope, and Eugenius was obliged to take up his residence at Viterbo. After some fighting and many negotiations between the pope, assisted by the people of Tivoli, and the Romans, Eugenius repaired to France in 1147, and the following year held a council at Rheims. He afterwards returned to Italy, and with the assistance of Roger king of Sicily defeated the Romans, and entered the city, A.D. 1149. New disturbances however arose, which obliged him to take refuge in Campania, where he received of St. Bernard the book *De Consideratione*, the subject of which was advice on his pontifical station and its duties. After having resided some time at Segni he made peace with the Romans, and returned to Rome in 1152. He died the following year, and was succeeded by Anastasius IV. It was under his pontificate that Gratianus, a Benedictine monk at Bologna, compiled his code of canon law called 'Decretum Gratiani,' which greatly favoured the extension of the papal power. [CANON LAW.]

EUGENIUS IV., Gabriele Condulmaro, a native of Venice, succeeded Martin V. in March, 1431. His was a most stormy pontificate. He drove away the powerful family of Colonna, including the nephews of the late pope, from Rome, charging them with having enriched themselves at the expense of the papal treasury. Two hundred of their adherents were put to death, and the palaces of the Colonna were plundered; but their party collected troops in the country and besieged Rome. Eugenius, through the assistance of Queen Joanna II. of Naples, defeated the Colonna, and obliged them to sue for peace and surrender several towns and castles they held in the Roman state. He afterwards made war against the various lords of Romagna, who were supported by the Visconti of Milan; and he appointed as his general the patriarch Vitelleschi, a militant prelate, who showed considerable abilities and little

scrupulousness in that protracted warfare, by which the pope ultimately recovered a considerable portion of territory. But as Vitelleschi intended to keep Romagna for himself, the pope had him put to death. The famous condottiere Sforza figured in all these broils. But the greatest annoyance to Eugenius proceeded from the council of Basel, which had been convoked by his predecessor, and which protracted its sittings year after year, broaching doctrines very unfavourable to papal supremacy. After solemnly asserting the superiority of the council over the pope, it forbade the creation of new cardinals, all appeals from the council to the pope, suppressed the annates, or payments of one year's income upon benefices, which were a great source of revenue to the papal treasury, and made other important reforms. Eugenius, who had been obliged to escape from Rome in disguise on account of a popular revolt, and had taken up his residence at Bologna, A.D. 1437, now issued a bull dissolving the council, recalling his nuncio who presided at it, and convoking another council at Ferrara. Most of the fathers assembled at Basel refused to submit, and summoned the pope himself to appear before them, to answer the charges of simony, schism, and others; and after a time proceeded against him as contumacious, and deposed him. Eugenius meanwhile had opened in person his new council at Ferrara, in February, 1438, in which, after annulling all the obnoxious decrees of the council of Basel, he launched a bull of excommunication against the bishops who remained in that assembly, which he characterized as a 'satanic conclave, which was spreading the abomination of desolation into the bosom of the church.' The Catholic world was divided between the two councils; that of Basel proceeded to elect a new pope in the person of Amadeus VIII. of Savoy, who assumed the name of Felix V., and was solemnly crowned at Basel. The council of Ferrara in the meantime afforded a novel sight. The Emperor John Paleologus II. came with Joseph, patriarch of Constantinople, and more than twenty Greek bishops, attended by a numerous retinue, and took his seat in the assembly. The object was the reconciliation of the eastern and western churches, which Eugenius had greatly at heart, and to which Paleologus was also favourably inclined, as he wanted the assistance of the powers of western Europe against the Turks. The plague having broken out at Ferrara, the council was removed to Florence. After many theological disputations on the subject of the Holy Ghost, of the primacy of the pope, of purgatory, and other controverted points, the decree of reunion of the two churches was passed, and signed by both parties in July, 1439. The emperor and patriarch returned to Constantinople highly pleased with Eugenius; but the Greeks took offence at the terms of the union, the schism broke out afresh, and the separation of the two churches has continued ever since.

A grave charge against Eugenius is, that he encouraged the Hungarians and Poles to break the peace they had solemnly sworn with the Turks, under pretence that their oaths were not valid without the sanction of the pope; he even sent Cardinal Julian as his nuncio to attend the Christian army. The result was the battle of Varna, 1444, in which the Christians were completely defeated, and King Vladislaus of Poland and Cardinal Julian lost their lives.

Eugenius died at Rome A.D. 1447, after a reign of sixteen years, and in the sixty-fourth year of his age. He left the church in a state of schism between him and his competitor Felix, his own states a prey to war, and all Christendom alarmed at the progress of the Turkish arms. In his last days he is said to have expressed himself weary of agitation, and to have regretted the loss of his former monastic tranquillity before his exaltation. He recommended peace and conciliation to the cardinals assembled around him. He was succeeded by Nicholas V., in favour of whom Felix V. soon after abdicated. The pontificate of Eugenius forms a most stirring and interesting period in the history of Italy and of the church. L'Enfant and Aeneas Silvius, afterwards pope, have written the history of the council of Basel. See also the general collections of the councils and Baluze's 'Miscellanies.'

EUKAIRITE, a seleniuret of silver and copper, discovered by Berzelius. It occurs in thin films of a shining lead colour; opaque; its texture is granular; it yields readily to the knife, and acquires a silvery lustre. It occurs in a copper mine in Sweden. Before the blow-pipe it exhales a

strong smell of selenium, and with charcoal fuses into a brittle metallic globule. It consists of—

EULABES. (Zoology.) [ROLLERS.]

EULA'LIA (Zoology), a genus established by Savigny, and placed by Cuvier among his Dorsibranchiate Annelids. [DORSIBRANCHIATA.]

EULEN-SPIEGEL. [ENGLISH DRAMA, vol. ix., p. 423.]

EULER, LEONARD, a celebrated mathematician of the last century, was born on the 15th of April, 1707, at Basle, in Switzerland; his father, Paul Euler, was the Calvinistic pastor of the neighbouring village of Riechen. He was a man remarkable for unostentatious piety, and imbued with a considerable knowledge of mathematics, which he had acquired under the tuition of James Bernoulli.

After being instructed by his father in analytical science, young Euler was sent to the university of Basle, in which John Bernoulli was at that time professor, and by his rapid progress and decided mathematical genius he so far gained the esteem of his teacher and of the sons, Nicholas and Daniel Bernoulli, that his father was easily dissuaded from his original intention of forming his son into a divine, and wisely allowed him to pursue unshackled the high distinctions then conferred by a profound scientific reputation.

A prize having been proposed by the French Academy of Sciences on the management of vessels at sea, the ambition of Euler, then only nineteen years of age, induced him to attempt an essay, which was received with considerable applause, though the prize was conferred on Bouguer, an old and experienced professor of hydrography.

The Academy of Sciences at St. Petersburg was then rising to a distinguished rank amongst similar institutions in Europe under the fostering patronage of Catherine I., who had invited several philosophers to her capital, among whom were the Bernouillis above mentioned. On the retirement of Daniel Bernoulli, Euler was appointed professor of mathematics under Peter I. in 1733; soon after which he married a Swiss lady named Gsell, by whom he had a numerous family.

His works previous to the date at which we have arrived were, with few exceptions, confined to those mathematical questions arising from the progressive march of the Integral Calculus, which, at that time, caused much emulation in different countries. In general, Euler was far more in his element in the abstruser parts of pure mathematics than in the applied; in many of the latter he was frequently conducted to paradoxical results.

In the memoirs of the Petropolitan Academy, 1729 and 1732, are found several of his memoirs on trajectories, tautochronous curves, the shortest line along a surface between two given points, and on differential equations; besides which he had published at Basle a physical dissertation on sound.

Euler found it convenient at this time to apply himself intensely to study, not more from his natural ardour for the sciences and the incentive of an increasing reputation than from the desire to avoid the political intrigues which, under a suspicious and tyrannical minister, then agitated Russia.

During this interval he published an excellent treatise on mechanics (Petersburg, 1736, 2 vols., 4to.), a treatise on the theory of music, and one on arithmetic, together with numerous papers in the Petersburg Memoirs, chiefly on astronomical and purely mathematical subjects, among which are contained his views on the solution of Isoperimetrical Problems, which embodied the profoundest researches on a matter of great analytical difficulty previous to the discovery of the Calculus of Variations by Lagrange. Upon the fall of Biren he gladly accepted an invitation from the king of Prussia to visit Berlin. When he was introduced to the queen-dowager in 1741, she was so much struck with the paucity of his conversation that on requiring an explanation, he replied that he had just returned from a country where those who spoke were hanged.

The princess of Anhalt-Dessau, being desirous to profit by the presence of Euler in Berlin, requested to be favoured with instructions on the known facts in the physical sciences. To this wish he fully acceded on his return to

Petersburg in 1766, by publishing his celebrated work, 'Letters to a German Princess' (3 vols., 8vo., 1768); in which he discusses with clearness the most important truths in mechanics, optics, sound, and physical astronomy, having published previous to this date several isolated treatises and some hundred memoirs touching on every known branch of theoretical and practical mathematics. During his residence in Prussia he was much employed by the enlightened monarch who then governed that kingdom in questions connected with the mint, with navigable canals, &c. In the midst of such varied employments he was not forgetful of the ties which bound him to his native home—having learned his father's death, he went in 1750 to Frankfurt to receive his widowed mother, and brought her to Berlin, where she lived until 1761, enjoying with a mother's feeling the glorious distinction to which her son by his talents and indefatigable industry had arrived.

An incident which occurred in 1760 showed how highly Euler was in general esteemed. The Russians having entered Brandenburg, advanced to Charlottenburg, and plundered a farm which belonged to Euler. When General Tottleben was informed who the proprietor was, he ordered immediate reparation to be made to an amount far above the injury, and the Empress Elizabeth presented him with 4000 florins.

In consequence of his unceasing application to study, Euler had the misfortune to lose the sight of one eye in 1735, and in 1766 that of the other; he however continued his valuable researches, some of his family acting as amanuensis, and his powers of memory are said to have been wonderfully increased even in his old age. He accepted the invitation of the empress Catherine II. of Russia to return to Petersburg in 1766, where he would have fallen a victim to an accidental fire which destroyed his house and property in 1771, but for the courageous efforts of a fellow-countryman (M. Grimon), who bore the old man away in his arms. His manuscripts were saved by the exertions of Count Orloff.

On the 7th of September, 1783, after some calculations on the motions of balloons, then newly invented, Euler dined with Lexell, and conversed on the lately-discovered planet Herschel. While playing with his grand-child, who was taking tea, he expired suddenly and without pain.

Euler was twice married in the same family, and had many children and grand-children; his habit of life was strictly religious, the labours of each day being closed with a chapter from the Bible and family prayer. A catalogue of his published and unpublished writings is given at the end of the 2nd volume of his 'Institutiones Calculi Differentialis,' 1787; and to the first is prefixed an eloquent Eloge by Condorcet.

Every useful subject of mathematical research engaged at some time the attention of Euler; and for relaxation he amused himself with questions of pure curiosity, such as the knight's move in chess so as to cover all the squares. His various researches have gone far towards creating the geometry of situation, a subject still imperfectly known. The following is one of the questions which Euler has generalized:—'At Königsburg, in Prussia, the river divides into two branches with an island in the middle, connected by seven bridges with the adjoining shores; it was proposed to determine how a man should travel so as to pass over each bridge once and once only.'

The memoirs of Euler are principally contained in the following works:—'Comment. Acad. Petrop.,' 1729-61; 'Novi Comment. Acad. Petrop.,' 1750-76; 'Nova Acta Acad. Petrop.,' 1777-81; 'Mem. de l'Acad. des Sciences,' 1765, 1778; 'Recueil de l'Acad.,' 1727, &c.; 'Miscell. Beroll.,' tom. vii.; 'Mem. de l'Acad. de Berlin,' 1745-67.

EULIMA, a genus of marine Testaceous Gastropods, established by M. Risso.

Generic Character.—Shell turreted, acuminate, polished, with many whorls; aperture ovate, acuminate posteriorly; external lip thickened, generally forming numerous obsolete varices. *Operculum* horny, thin, its nucleus anterior.

Mr. G. B. Sowerby, who gives this generic character, says (*Zool. Proc.* 1834) that this genus of marine shells appears to be most nearly related to *Pyramidella* and *Rissoa*. A species, he adds, which has been long known has had the appellation of *Turbo politus* among British Linnean writers; and a fossil species has been placed by Lamarck among the *Bulini*, under the specific name of *B. terbellatus*. Mr. Sowerby separates the genus into the two

divisions below stated, which are characterized by the two species above mentioned; one has a solid *columella*, and the other is deeply umbilicated. All the species, he observes, are remarkable for a brilliant polish externally, and the shells are frequently slightly and somewhat irregularly twisted, apparently in consequence of the very obsolete varices following each other in an irregular line, principally on one side, from the apex towards the aperture. He describes sixteen species, chiefly from Mr. Cuming's collection.

Geographical Distribution.—Wide; principally found, as yet, in warm seas (South and Central America, and Pacific Ocean, Australia) but there are several British species.

Habits.—The species found by Mr. Cuming were dredged or otherwise collected in sandy mud, coarse sand, and coral sand, on mother-of-pearl shells, or on the reefs; at depths (not including the reefs) ranging from six to thirteen fathoms.

a.

Perforate Eulimæ.

Example, *Eulima splendida*. Shell acuminate-pyramidal, brownish, articulated with white and chestnut near the sutures; umbilicus large; aperture angulated anteriorly. Length 1.45, breadth 0.6 inches. Locality, Saint Elena, South America. Mr. Cuming dredged a single specimen in sandy mud at from six to eight fathoms depth.

Eulima splendida.

β.

Imperforate Eulimæ.

Example, *Eulima major*. Shell acuminate-pyramidal, opaque, milk-white; external lip subarcuated. Length 1.6 inches, breadth 0.4. Locality, the Island of Tahiti. The largest specimen was found in coral sand on the reefs.

Eulima major.

FOSSIL EULIMÆ.

Mr. G. B. Sowerby says that the fossil species are found in the *calcaire grossier* near Paris.

EULIMENE. [BRANCHIOPODA, vol. v., p. 343.]

EULYMENE. [MEDUSA.]²

EUMEDONUS, a genus of brachyurous crustaceans, the first of the *Parthenopians* of M. Milne Edwards, and which, in his opinion, establish in some sort the passage between the *Stenorhynchi*, *Achaus*, on the one side, and *Eurynome*, *Lambrus*, and *Parthenope*, on the other. The form of the carapace is nearly pentagonal as in the latter, but it is, at the same time, thrown forwards, as it were, and scarcely overpasses the line of the feet of the hind pair of limbs, a disposition which recalls the construction of the former. The body is depressed; the rostrum, which is very large and projecting, is only divided towards its extremity; the eyes are very short, and their peduncle entirely fills the orbits, which are circular; a character which again approximates these crustaceans to the *Stenorhynchi*—the internal antennæ are folded back very obliquely outwards, and the external antennæ are but little developed. The epistome is shorter than in the majority of the *Oxyrhynchi*. The external jaw-feet present nothing remarkable. In the male the thoracic feet of the first pair are large and much

longer than the rest: all these are a little compressed, and their third joint is surmounted by a crest, which is not distinctly perceptible on the other joints; the feet of the second pair are rather shorter than those of the third and fifth pair, which are nearly as long as the fourth. The abdomen of the male is composed of seven articulations.

Example, *Eumedonius niger*. This small species, the only one known, is of a bronzed black colour, and inhabits the coasts of China. [PARTHENOPÆ.]

EUMENES, of Cardia, a town in the Thracian Chersonese, was an important actor in the troubled times which followed the death of Alexander the Great. [ALEXANDER III.; ANTIPATER; ARRHIDÆUS; PERDICCAS.] Being early taken into the service of Philip of Macedon, he served him for seven, and Alexander for thirteen years, in the confidential office of secretary. He also displayed great talent for military affairs through the Persian campaigns, and was one of Alexander's favourite and most esteemed officers. After Alexander's death, in the general division of his conquests, Cappadocia, Paphlagonia, and the coast of the Euxine as far east as Trapezus, fell to Eumenes' share. This was an expectancy rather than a provision, for the Macedonian army had passed south of these countries in the march to Persia, and as yet they were unsubdued. Perdicas, however, took arms to establish Eumenes in his new government, and did so, at the expense of a single battle. To Perdicas as regent, and after his death to the royal family of Macedon, Eumenes was a faithful ally through good and evil; indeed he is the only one of Alexander's officers in whose conduct any appearance of gratitude or disinterestedness can be traced. When war broke out between Ptolemy and Perdicas, B.C. 321, he was appointed by the latter to the chief command in Asia Minor between Mount Taurus and the Hellespont (Cor. Nep., c. 3), to resist the expected invasion of Antipater and Craterus. The latter he defeated; but the death of Perdicas in Egypt threw the balance of power into Antipater's hands, who made a new allotment of the provinces, in which Eumenes was omitted and Cappadocia given to another. The task of reducing him was assigned to Antigonus, B.C. about 320. The rest of his life was spent in open hostility or doubtful alliance with ANTIGONUS, by whom he was put to death, B.C. 315, as is related in that article, vol. ii., p. 101. Eumenes was an admirable partisan soldier, brave, full of resources, of unbroken spirits. Those parts of Diod. Sic., book xviii., which relate to him, and Plutarch's *Life*, will be read with pleasure by those who are fond of military adventure. Plutarch (*Life of Eumenes*, c. ii.) speaks of some of his letters. The reader may consult also Droysen, *Geschichte der Nachfolger Alexanders*, Hamburg, 1836.

Coin of Eumenes.

British Museum. Actual size. Silver. Weight, 263 grains.

EUMENIDES (the kind goddesses), a name given to the Erinyes or Furies, a set of goddesses whose business it was to avenge murder upon earth. They were also called Semnæ, or 'venerable goddesses.' The name Erinyes was derived from the old Arcadian word *erimuein* (*ἐριμύειν*), 'to be angry.' (Pausan. viii., 25, 6.) These goddesses appear in the play of Æschylus which bears their name, not only as the instruments of wrath and the pleaders for justice against the matricide Orestes, but also as the promisers of victory, prosperity, and all sorts of blessings to the Athenian people this mixture of characters is to be explained by the fact that their worship was connected with that of a Demeter Erinyas at Thelpusa, in Arcadia, and we have seen elsewhere how the goddess of the earth and its productions was also the goddess of the nether world. [BACCHUS; DEMETER.] The site of their temple at Athens, where their worship possessed a peculiar importance, was the north-east angle of the Areopagus, at its base. 'There is a wide long chasm there formed by split rocks, through which we enter a gloomy recess. Here is a fountain of very dark water'

(Wordsworth's *Athens and Attica*, p. 79.) The Athenians sacrificed to the Eumenides, among other victims, black sheep: no wine was mixed up with the libations offered to them, but only oil, honey, and water, in three separate libations, out of different vases. (Soph. *Ed. Col.*, 469, &c) Of the number of these goddesses we have contradictory accounts: in the play of *Æschylus* it is pretty certain that there were fifteen in the chorus. (Müller's *Eumenides*, § 10.) Every question connected with these divinities is accurately and satisfactorily discussed by Müller in the second essay at the end of his edition of the *Eumenides*, § 77—93.

EUMOLPUS, EUMOLPIDÆ. [EΛΕΥΣΙΣ.]

EUMORPHUS, a genus of coleopterous insects belonging to the section *Trimeri* of Latreille, and being the typical genus of the family *Fungicola*. These insects are characterized by having the antennæ longer than the head and thorax, the body oval, and the thorax irregularly square; the maxillary palpi filiform, or slightly thickened at the end, but not terminated by a large process as in some genera: the last joint of the tarsus is always deeply divided into two lobes.

Latreille (*Règne Animal*) divides the genus *Eumorphus* into several sub-genera. Some of the species have the third joint of the antennæ much longer than any of the other joints: these form the genus *Eumorphus* (proper), in which the antennæ are club-shaped. All the species are natives of America or the East Indies. Ex.: *Eumorphus immarginatus*. (Latr. *Gener. Crust. et Insect.*, tab. xi., fig. 12.)

2nd Sub-genus, *Dapsus* (Ziégl.). Some of the species have the antennæ club-shaped, as in *Eumorphus* proper, but straighter and more elongated, and with the joints bent laterally: among these, *Eumorphus Kirbyanus* (Latr.) is now placed. In other species of *Dapsus* the third joint of the antennæ is not longer than any of the others. Many of the species of *Dapsus* are indigenous in Europe, living in different fungi, whence the name of the family (*Fungicolæ*). Some of these insects are also found under the bark of the birch and other trees. 3rd Sub-genus, *Endomychus* (Fab.) has the three last joints of the antennæ bent laterally, larger than the others, and forming a triangular club-shaped mass. 4th Sub-genus, *Lycoperdina* (Latr.) has the maxillary palpi filiform, and the last joints of the labia are enlarged. [TRIMERI.]

EUNAPIUS, one of those writers known by the name of Byzantine historians, was born at Sardes, in Lydia, A.D. 347. He began his studies under the care of Chrysanthius the Sophist, by whose advice he is said to have composed the lives of some philosophers and physicians. In his sixteenth year he left Asia for Athens to attend the lectures of Proæresius, by whom he appears to have been subsequently treated with the utmost kindness. On his voyage he was seized with fever of a very violent kind, which yielded only to treatment of a peculiar nature. After attending Proæresius for five years he meditated a journey to Egypt, in imitation, as Hadrian Junius says, of Plato and Eudoxus; this intention however he was prevented from fulfilling. He practised medicine with considerable repute, and distinguished himself by a vehement antipathy to Christianity, produced, as is probable, by its growing corruptions.

Besides his biographical works, he wrote a continuation of Dexippus' history, from the reign of Claudius Gothicus, where he quitted it, to the year 404 A.D. It is violently in favour of the old creed, and, in the opinion of Hadrian Junius, shared those peculiarities of style which distinguish the Sophists. All that remain of his historical works are contained in the recent edition of the Byzantine Historians. There is a complete edition of his works by Boissonade, in 2 vols. 8vo., Amsterdam, 1822, with Wyttenbach's notes, and a life by Hadrian Junius. (See Photius, codd. 77, 219; Suidas, under the word *Ἐυνάπριος*; and Eunapius in his life of Proæresius.)

EUNOMIA. [MILLEPORIDÆ.]

EUNOMIUS, one of the chiefs of the Arian sect during the greater part of the fourth century, was a native of the town of Dacora, in Cappadocia, and at first was a lawyer. It is said that he also followed for some time the military profession. He then became a disciple of Aetius, under whom he very successfully studied the doctrinal theory of Christianity as understood by the Anti-Trinitarians. At Antioch he was ordained a deacon, and about A.D. 360 he was elected bishop of Cyzicum. The divinity of Christ

was at this period the all-absorbing subject of ecclesiastical controversy. The Trinitarians contended for the Athanasian or Homoousian doctrine (from *ὁμοούσιος*, of the same essence), against the Semi-Arians, who held the Homoiousian doctrine (from *ὁμοιούσιος*, of the like essence), and against the doctrine of the Anomoiens (from *ἀνομοίσιος*, of a different essence). In defence of the last theory, or that of unmodified Arianism, Eunomius exerted a high degree of natural abilities, asserting the impossibility of two principles in a simple substance, one of which is generated from the other, and exhibits the relation of a son to his father. The divine essence, he said, is necessarily characterized by oneness and indivisibility; the persons of the Godhead, like the divine attributes of wisdom, justice, mercy, &c., are merely the names of ideal distinctions of the one Supreme Essence, as considered in its different relations with exterior objects, and it is contradiction and manifest absurdity to suppose this simple essence to consist of a plurality of principles or parts. In reply to these psychological subtleties, the advocates of the Trinitarian doctrine alleged the total incomprehensibility of the nature of God. (St. Basil, *Epist.* 166, St. Chrysostom, *De Incomprehensibilitate Dei Naturæ*.) Eunomius still acknowledged a father, son, and holy spirit, but the father as supreme, eternal, and distinct; the son as generated from the father; and the holy spirit as generated from the son.

In the ceremony of baptism he dipped only the head and shoulders, regarding the lower parts of the body as disreputable, and unworthy of immersion in the holy water; and it is said he taught that those who faithfully adhered to his own theory of Christian doctrine might commit any degree of sin without incurring the danger of perdition; but this is probably a misrepresentation by his opponents, who also accuse him of being an Antinomian, that is, one of those who reject the Mosaic law. (Theodoret, *Hæret.*, l. 4, c. 3; St. Augustin, *de Hæres.*; Epiphanius, *Hæres.*, 76; Baronius, *ad an.* 356.) Eunomius experienced a great severity of persecution without swerving in any degree from the Arian tenets with which he commenced his career. He was thrice banished from his episcopal see; first, by Constantius to Phrygia; then by Valens to Mauritania; and lastly, by Theodosius to the Island of Naxos: however, he died in peace, at a very advanced age, in the year 394. Most of his works are lost, including a copious commentary on the Epistle to the Romans, in 7 volumes, and numerous letters. Two of his principal treatises are printed in the *Bibliotheca Græca* of Fabricius, in Greek and Latin (tom. 8, pp. 235—305): 'A Confession of Faith,' presented in 383 to the Emperor Theodosius; and an 'Apologetic Discourse' in 28 chapters. (Cave's *Prim. Christiani*, part 2, c. 11; Pluquet's *Dict. de Hérétiques*; Broughton's *Historical Dict.*; Dr. A. Clarke's *Succession of Sac. Lit.*, vol. i., p. 318; Basnage, in *Canisius*, i. 172.)

EUNUCH (*εὐνοῦχος*, *eunûchus*, literally, 'one who has the care of a bed'). The Greek word may be considered as descriptive of the functions of those who were made eunuchs, it being usual among the Persians to entrust the care of their wives and daughters to such persons. It does not appear that eunuchs were made by the Greeks, except as we shall presently mention. This peculiar species of barbarity was a Persian practice (Herod. vi. 32). It appears however that the Greeks sometimes carried on the trade of making eunuchs, whom they sold at Ephesus and Sardes to the Persians for high prices; the Persians considering that eunuchs generally were more trustworthy than other men. (Herod. viii. 105.) Tavernier tells us that in the kingdom of Bootan twenty thousand eunuchs were annually made in his time, to sell to other nations; and the seraglios of the East are principally served and guarded by them to the present day.

The Christian emperors of Rome forbade the practice of making eunuchs, particularly Constantine; and Justinian imposed a law of retaliation upon such as exercised this inhumanity. In Italy however the process of castration is still practised upon children intended to supply the operas and theatres of Europe as singers. The Council of Nice condemned those who from excess of zeal made eunuchs of themselves. Persons so mutilated were not admitted into holy orders. The reader who would know more on this subject may consult the 'Traité des Eunukes,' 12mo., 1707, by M. d'Ancillon.

Certain heretics of the third century bore the name of Eunuchs who had the folly or madness, after the example

of Origen, not only to castrate those of their own persuasion, but all whom they could lay hands on. They were also called Valesians, from Valesius, an Arab, who was their chief. (See Epiphanius and Baronius' *Annals*, under the years 249 and 260.)

EUPOMPHALUS. [TROCHIDÆ.]

EUPATORIA. [CRIMÆA.]

EUPATORIA/CEÆ, one of the tribes of composite plants admitted by De Candolle, who defines it thus:— 'Style of the hermaphrodite flowers cylindrical; the arms long, somewhat clavate, covered externally with downy papillæ at the upper end. The stigmatic series but little prominent, and usually disappearing before they reach the middle of the arms of the style.' Under this character are arranged 38 genera, the most extensive of which is the genus *Eupatorium*, including no fewer than 294 species.

EUPEN, a circle in the Prussian administrative circle of Aachen, or Aix-la-Chapelle, and in the western part of the province of the Lower Rhine, is, though wooded and mountainous, full of fine pastures. It contains about 76 square miles. It produces timber, grain, vegetables, flax, &c., and large quantities of cheese are made. There are considerable manufactures. Iron, calamine, and potters' clay, are among its mineral products. The population in 1816 was 17,419; in 1831, 19,058; and is now about 19,800.

EUPEN, the chief town (the Néau of the former department of the Ourthe), is situated in a fertile valley on the banks of the Weeze, in 50° 39' N. lat. and 6° 1' E. long. It is well built, and with its gardens and meadows covers a considerable surface. It has four churches and chapels, an orphan asylum, and a good school, and contains nearly 1200 houses. The number of inhabitants was 8805 in 1818; 10,534 in 1831; and is at present about 11,300. There are large manufactures of kerseymere and fine woollens. The other productions are woollen yarn, soap, chicory, powder, deals, blotting paper, &c. It is a place of extensive trade, and has several manufacturing villages in the neighbourhood.

EUPHEUS. [ISOPODA.]

EUPHORBIA, a genus of exogenous plants, giving its name to an extensive and important natural order. It has very small monandrous naked male flowers, crowded round an equally naked female one, in the inside of an involucre looking like a calyx, and formerly mistaken for that organ. The species have either a common leafy appearance, with the involucre proceeding from among large foliaceous bracts, or they are nearly leafless, with their stem excessively succulent, so as to resemble Cacti. Those with the former character are natives of most parts of the world, and are the only kinds found in Europe; the succulent species chiefly appear in the hottest and driest countries. Barren uncultivated places in the plains of Hindostan and the arid regions of Asia and the north of Africa are their favourite stations; in the Canaries, on volcanic soil, *E. Canariensis* and *laphylla* form great bushes with arms like candelabras. From Cacti, which some of these plants much resemble, they are readily known by their spines, when they have any, not growing in clusters, and by their emit-

ting, when punctured, an abundant discharge of milky juice. This, in a concrete state, forms what is called the gum-resin, or rather resin, called *Euphorbium*, an acrid, corrosive, most dangerous drug, principally furnished by *E. officinarum*, *antiquorum*, and *E. Canariensis*. The same properties exist in the herbaceous leafy species, diffused in some, concentrated in others.

E. Lathyris, a common weed in cottage-gardens, where it is called 'caper,' yields from its seeds an oil of the most violent purgative nature. If it were less dangerous it might be substituted for Tiglium oil. Fée states that with as much of this oil as could be sold for a franc ninety adults might be purged.

A few species, having the involucre of some showy colour, are cultivated as objects of ornament; otherwise they are looked upon as mere weeds.

EUPHORBIA/CEÆ, a natural order of exogenous plants, with unisexual flowers and trilocular fruit. Their real affinity is a matter of great uncertainty. Jussieu placed them among his *Diclinous Dicotyledons*, and probably he was right in so doing; nevertheless there are many strong marks of resemblance between them and *Malvaceæ*, *Celastraceæ*, and even *Elmagnaceæ* plants. The number of *Euphorbiaceæ* is unknown, but certainly very considerable. They vary from trees of the largest size to minute herbs, of only a few weeks' duration, and from having both calyx and corolla highly developed to the total absence of those organs. In fact they are constant in scarcely anything except the short character we at first assigned them, and in their sensible properties. Acridity, a virulent corrosive property, which sometimes is so concentrated as to render them most dangerous poisons, and sometimes so diffused as to be of little importance, with all imaginable intermediate qualities, exists throughout the order. Hence some are fatal, others drastic or purgative, and some simply laxative. They also occasionally secrete a farinaceous substance which, being separated from the poison is valuable for the food of man, as in the *Casava*.

Among the more dangerous species of this order are the *Manchineel*, whose very shade is asserted to be dangerous, the *Excæcaria*, which derives its ominous name from its juice producing blindness; and the *Euphorbias*, that yield *Euphorbium*, *Castor oil*, and oil of Tiglium, well known valuable purgative medicines. Among other products may be named *Cascarilla*, the bark of a *Croton*, *Turnsole*, afforded by a *Crozophora*, *Caoutchouc*, the produce of *Siphonia elastica*, *Hura crepitans*, and others, and a kind of bird-lime yielded by *Sapium aucuparium*.

Euphorbia officinarum.

Andrachne telephifolia.

1, a male flower; 2, a female flower; 3, an ovary nearly ripe; 4, a section of a ripe fruit.

EUPHORBBIUM, improperly called a gum, or gum-resin, since it is entirely destitute of any gum in its composition, is the concrete juice of several species of *euphorbia*, either exuding naturally or from incisions made in the bark. Much of the article found in British commerce is obtained from the *Euphorbia Canariensis*, while that which occurs on the continent is obtained from *Euphorbia officinarum* (Linn.) and *E. antiquorum* (Linn.), and other African species, particularly from an undescribed species, called by the Arabs *dergmuss*. The branches of this plant are used in tanning, and to it, according to Mr. Jackson (*Edinburgh*

Medical and Surgical Journal, vi. p. 457), the morocco-leather owes its peculiarities. By the most recent chemical analyses, euphorbium seems to consist of resin, wax, and saline matter (mostly malates). The resin is the active principle, and differs in some respects from most other resins.

Euphorbium is a powerful acrid substance, causing irritation and inflammation of the parts with which it comes in contact, and by sympathy affecting the nervous system. The dust received into the nostrils or eyes occasions violent sneezing and lachrymation, or even more serious affections of the eyes, so that it is necessary for those who grind this drug to protect the face by masks. Delirium and stupor approaching to apoplexy have followed the inhalation of the dust. When swallowed, it causes, in small doses, vomiting and purging; in larger doses it produces inflammation of the stomach, and sometimes proves fatal. It is now little used, even as an external application to produce vesication or ulceration, except by veterinary surgeons. It is sometimes used as an errhine, largely diluted with starch, and enters into the composition of some cephalic and eye-snuffs; but it is apt to be violent in its effects. In case of poisoning by it, demulcent or oily fluids should be given, and venesection employed if much inflammation ensue.

EUPHRATES. [*Tigris*.] As new information may be expected on the subject of the Euphrates, we have determined to treat of this double river system under the head of *TIGRIS*.

EUP'ION, a liquid obtained by Reschenbach from animal tar, especially that of bones or horns. The process for procuring it is operose and complicated. Its properties are—that it is very limpid, colourless, inodorous, and tasteless; it boils at about 340° Fahr., and distils unchanged; it remains fluid at 4°. It is insoluble in water, but dissolves in alcohol, oil of almonds and of olives, oil of turpentine, naphtha, &c.; it dissolves chlorine and bromine, which are cooled when it is heated, and it also takes up camphor, stearin, and naphthalin, at common temperatures, but when heated, in larger quantity; with iodine it forms a blue solution: it dissolves phosphorus, sulphur, and selenium, when heated, but the greater portion is deposited on cooling; caoutchouc swells in it, and when heated dissolves. It is not altered either by exposure to air, or by acids or alkalis. It has not been analyzed.

EUP'OLIS, a writer of the old comedy, was born at Athens about the year 446 B.C. (Clinton's *Fusti Hellenici*, ii. p. 63), and was therefore a contemporary of Aristophanes, who was in all probability born a year or two after. The time and manner of his death are involved in great obscurity. It was generally said that he was thrown overboard by the orders of Alcibiades, when that general was on his way to Sicily in 415 B.C., because Eupolis had ridiculed him in one of his comedies; but this story, which is sufficiently improbable in itself, was refuted by Eratosthenes, who brought forward some comedies which he had written subsequently to that period (Cicero *ad Attic.* vi. 1); besides, his tomb was, according to Pausanias (ii. 7, 3), on the banks of the Asopus, in the territory of the Sicyonians. Another account states that he fell in a sea-fight in the Hellespont, and that he was buried in Ægina. We have the names of twenty-four of his plays, but no adequate specimens of them. To judge from the titles, the object of Eupolis must have been, in almost every case, mere personal satire. The *Maricas*, which appeared in 421 B.C., was an attack upon Hyperbolus, the demagogue; the *Autolyous* (420 B.C.) was intended to ridicule a handsome parricidist of that name, who is the hero of Xenophon's *Symposium*; and the *Lacedæmonians* was directed against the political opinions of Cimon, who was too much attached to that people, and had even called his son Lacedæmonius (Thucyd. i. 45). From the concurrent testimony of Lucian (*Adv. Indoctum*, § 217), of Platonius, and of the scholiast on Juvenal (ii. 92), it appears that the object of Eupolis in writing the *Baptæ* was to ridicule Alcibiades for taking part in the obscene rites of Cotytto, and that it was for this attack that Eupolis was thrown into the sea. (See Buttmann's *Essay on the Cotytia and the Baptæ*, *Mythologus* ii. p. 159, &c.) Aristophanes and Eupolis were not upon good terms. Aristophanes speaks very harshly of his brother poet in *The Clouds* (551, &c.), and charges him with having pillaged from *The Knights* the materials for his *Maricas*; and Eupolis in his turn made jokes on the baldness of the great comedian (Schol. on *The Clouds*, 532).

Eupolis published his first play when he was only seventeen years old (Suidas).

EURE, a river in France, which rises in the marshes and pools which occupy the eastern extremity of the department of Orne, near the town of Longny. Seven or eight miles from its source it enters the department of Eure et Loir, through which it flows in a south-east direction for about 25 miles without receiving any considerable accession. It then turns northward, and flows in that direction for about 85 miles, through the departments of Eure et Loir and Eure, and past the towns of Chartres, Maintenon, Anet, Ivry, Pacy, and Louviers, into the Seine, which it joins just above Pont de l'Arche; receiving in succession the rivers Voise on the right bank; the Blaise, which waters Dreux, and the Arve or Aure from Nonancourt, on the left; the Vesgre, from Houdan, on the right; and the Iton, which passes Damville and Evreux, on the left. Its whole course is nearly 120 miles. It is navigable from Pacy, about 27 miles above its junction with the Seine, or, according to another authority, from St. George's at the junction of the Aure, about 20 miles higher up; but the navigation is liable to frequent obstructions. It is chiefly used for the conveyance of salt, and of wood for building and fuel for the supply of Rouen. The Eure never freezes in winter.

EURE, a department in the north of France, comprehending a portion of the antient Normandie. It is bounded on the north by the department of Seine Inférieure, from which it is partly separated by the Seine; on the east by the departments of Oise and Seine et Oise, from both of which it is in part separated by the river Epte, a feeder of the Seine; on the south by the department of Eure et Loir, from which it is partly separated by the rivers Eure and Arve, or Aure, the latter a feeder of the Eure; on the south-west by the department of Orne, and on the west by that of Calvados. The form of the department is very irregular; its greatest length is from north-east on the Epte, near Mainville, to south-west, near Monnay, on the road from Rouen to Alençon, 68 miles, and its greatest breadth at right angles to the length, from Figuefleur, on the Seine, to St. George's, at the junction of the Arve with the Eure, 65 miles. The area of the department is 298 square leagues, or 2297 square miles, rather more than the joint area of the English counties of Cumberland and Westmoreland, and rather less than the average of the French departments. Its population in 1832 was 424,248, or nearly 165 to a square mile, being considerably greater than both the relative and absolute population of the average of the French departments; and very far exceeding that of the two English counties just mentioned. The department lies between 46° 39' and 49° 29' N. lat., and 0° 15' and 1° 48' E. long. The capital is Evreux, in 49° 1' N. lat., and 1° 8' E. long.

The department has, properly speaking, no mountains, though that name is given to the crags which rise at the mouth of the Seine, near Quilleboeuf, and do not much exceed 300 feet in height. Mount Rôti is the highest hill in the department; its barren summit rises above the fertile plain round Pont Audemer. The rivers all belong to the basin of the Seine, except the Calone, which falls into the Touques at Pont l'Évêque, in the department of Calvados. The Seine crosses the eastern side of the department in a north-western direction past Vernon, Petit Andely, and Pont de l'Arche, and flows for a short distance along the boundary. In its sinuous course below Rouen it again touches the northern boundary of the department three times, separating it from that of Seine Inférieure: its course within the department is about 40 miles, and along the border 27 miles; for all which it is navigable. The Eure crosses the department in a northward direction; 10 miles of its course are upon and 36 miles within the border, for 26 of which, or according to some, for the whole of which it is navigable. [*Eure river.*] The Arve, or Aure, has nearly 30 miles of its short course within or upon the border of the department; it flows east by north and joins the Eure on the border of the department at St. George's; it passes Chênebrun, Verneuil, and Nonancourt. The Iton rises in the department of Orne, and crosses this department in a winding channel in a north-eastern direction; its length is 60 to 65 miles; nearly the whole of its course is in this department; it passes Bourth, Breteuil, Damville, and Evreux. The Rille rises in the department of Orne, and crosses that of Eure in a northward direction till it falls into the Seine between Quilleboeuf and Honfleur. It passes the towns of L'Aigle, in the department of Orne; and of Rugles, Neuve-

lire. Beaumont, Briône, Pont-Authou, Annebaut, and Pont-Audemer in that of Eure; it receives between Beaumont and Briône the Charentonne, which rises in the department of Orne, and flows north-north-east past Chabrières and Bernay; the Charentonne receives the Gruil. The length of the Rille is nearly 80 miles, that of the Charentonne about 35 miles, and that of the Gruil 16 to 18 miles. The Epte and the Andelle, both feeders of the Seine, rise in the department of Seine Inférieure, and water the eastern side of the department of Eure; they have a length of about 50 and 25 miles respectively. Part of the course of the Epte is on the border of the department; most of that of the Andelle is within it.

The Iton and the Rille are, in one part of their course, absorbed by the strata over which they flow: the Iton loses itself near Damville, and flows underground for two miles.

The department is almost entirely occupied by the chalk which encircles the Paris basin and the strata more immediately connected with it, and covered with a vegetable soil, for the most part clayey, and very thin on the crests of the hills. Along the bank of the Seine there are some tracts covered with barren sand, and other parts are covered with the debris of quartz and silex, quite incapable of cultivation. Below Quillebeuf, a marsh on the bank of the Seine, once covered by the tide, has been reclaimed and brought into cultivation.

The climate is in general mild, moist, and changeable, bearing a considerable resemblance to that of England. The west and north-west winds bring rain and fog; these winds, with the north and the south-west, are the most common. The country is better wooded than France generally is, though it does not admit of comparison in this respect with England. In descending towards Pacy on the Eure, on the road from Paris to Caen, the magnificence of the prospect is very striking. The valley of the Eure, broad and perfectly level, abounds with fine trees, which enclose the rich meadows. But though the country is rich and fertile, the habitations of the peasantry are very wretched, being clumsily built of wood and earth, like the habitations of five or six centuries ago in the rest of France, and covered with thatch. Bricks and tiles might be made in the department, and houses built less liable to destruction by fire.

The agriculture of the department is considered to be in advance of that of the greater part of France. The produce in grain is considerable; in wheat it is twice as great as the average produce of the departments; and in rye and mixed corn or maslin three times as great: a considerable quantity of potatoes is grown, a small quantity of oats, and very little barley or buckwheat. The quantity of woodland is nearly a sixth of the whole area of the department; the quantity of land occupied in vineyards is small, and the amount of wine made is trifling. The plum, the pear, and the apple, are the fruits most cultivated: the principal timber trees are the oak, the beech, the elm, the hornbeam, the aspen, the service tree, the chestnut, the birch, and, in the valleys, the alder, the ash, the poplar, and the maronnier, or large chestnut tree. In the arrondissements of Bernay and Pont Audemer, fine flax is grown from seed imported from Riga and Holland; and in various places, leguminous plants, hemp, weld or dyers' weed (for dyeing yellow), and teasles are cultivated. The farming is not very neat; and the hedgerows and ditches are not well kept. Plantations might be increased on the higher grounds. There are many natural meadows and pasture lands, and the cultivation of the artificial grasses is on the increase: the quantity of cattle is not much more than half the average of France, but the number of horses is above half as much again as the average. Horses are much employed in the labours of the field: the fine Norman breed, which the long wars had nearly destroyed, has been renewed with great care. The number of sheep is rather above the average of France: the wool is ordinary; but the flesh of those fed near the sea is delicate and in good repute. The number of swine and the quantity of poultry are considerable. Small game is tolerably plentiful; but the larger sorts the roebuck, the stag, and the wild boar, which were formerly abundant, have been almost entirely destroyed since the Revolution. The rivers abound with fish, especially tench; and great quantities of the salmon and the shad ascend them from the sea and are taken.

The mineral productions are iron, freestone, sandstone, millstones, lime and gypsum, potters' clay, brick earth, and fullers' earth. There are several cold mineral springs; those of Vieux Conches are in the highest repute.

The manufactures of the department are various and important: Dupin (*Forces Productives et Commerciales de la France*, Paris, 1827), states the number of establishments of various kinds at 1511, of workmen at 30,157, and the value of the articles produced at 26,772,297 francs, or above 1,100,000*l*. The workmen are thus classified by Malte Brun: in the woollen manufacture 8500; in the iron and copper works 8000; in the tape manufacture 6000; in the cotton manufacture 4500; in the leather manufacture 1000; in the manufacture of glass, paper, and hosiery 2000. The population is not however collected into large towns, there being no town with 10,000 inhabitants, and only five which have 5000; and taking the whole department, the rural population is to that of the towns as nearly 5 to 1. There are many iron-works, and at Romilly on the Andelle are some of the most extensive and important copper-works in France; nails and pins are made at Rugles on the Rille, cards for carding wool and cotton, and machinery at Louviers, and machinery in the arrondissement of Louviers. The manufacture of linens is widely extended; the linens of Bernay are much esteemed. The woollen cloths of Louviers are among the best in France: other cloths of inferior quality, druggets and flannels, are made in different places in the department. Leather of excellent quality is made at Pont Audemer, and there are tan-yards at Evreux and other places. Tapes are made at the town and in the arrondissement of Bernay, bed-ticks at Evreux, and printed calicos and other cotton goods in various places: cotton and woollen and linen yarn are also spun. To the above articles may be added hosiery (at Pont Audemer), thread (at Bernay), glass, paper, musical instruments, ivory and boxwood combs. Dyeing and bleaching have been carried to great perfection.

The exportations to foreign countries consist of woollen cloths of all kinds, bed-ticks, linens, cotton goods, leather, copper goods, and pins: similar articles, together with iron goods, wood for the shipwright and the builder, and for fuel, corn and cattle, are sent into other parts of France. The imports consist chiefly of the raw material for the various manufactures.

The navigation of the Seine enables the department to communicate readily with Rouen and Paris: a cut in one part shortens the navigation a little: the Eure is navigable for a considerable part, if not the whole of its course in this department: the Iton is used for floating during part of its course; but the Rille is no longer used for that purpose. It is navigable however up to Pont Audemer. The length of the navigable rivers and canals is half as much again as in the average of France. The department is also better provided with roads than the greater part of France: the road from Paris to Caen and Cherbourg crosses it from east to west through Pacy and Evreux; that from Paris to Rouen by Pontoise (department of Oise) and Ecouis; and that from Paris to Rouen by Vernon, Gaillon, and Pont de l'Arche, along the valley of the Seine, cross it from south-east to north-west. Roads from Rouen to Honfleur (department of Calvados) by Pont Audemer; to Alençon (department of Orne) through Bourgheroude, Briône, Bernay, and Chambray; and to Evreux through Pont de l'Arche and Louviers; and from Evreux by Vernon to Gisors, also cross it in different directions. The road from Paris to Dieppe just passes through Gisors in the eastern extremity of the department; and that from Paris to Alençon, Laval, Rennes, St. Brieuc, and Brest, crosses the department just within the southern boundary following the valley of the Aure or Arve through Nonancourt, Tillières and Verneuil. A road from Rouen to Beauvais just touches the north-east extremity of the department. The other roads are bye-roads.

The department is divided into five arrondissements: that of Les Andelys, in the east and north-east; that of Pont Audemer, in the north-west; that of Bernay, in the south-west; that of Evreux, in the south; and that of Louviers. central. The population is thus distributed among them—Les Andelys, 64,337; Pont Audemer, 89,744; Bernay, 82,828; Evreux, 118,397; and Louviers 68,942. The number of cantons or districts under the jurisdiction of a justice of the peace is 36; that of the communes 844.

The principal towns are Evreux, the capital, on the Iton, population 7988 for the town, 9963 for the whole commune; Louviers, on the Eure, population 8627 for the town, 9885 for the whole commune; Pont Audemer, on the Rille, population 5305; Bernay, on the Charentonne, population

4486 for the town, 6605 for the whole commune; and Les Andelys, on the Seine, population 3432 for the town, 5168 for the whole commune. [ANDELYS, LES; BERNAY; EVREUX; LOUVIERS.] The population is from the returns of January 1, 1832.

In the arrondissement of Les Andelys there are Gisors, Estrépagne, Ecouis, Maineville, Lions-la-Forêt, Charleval, and Ecosse.

Gisors is on the Epte, which divides it into two parts, and on the road from Paris to Dieppe, 39 miles from Paris. The castle was built about A.D. 1100. In the wars of the English in France under Henry V., Gisors was taken by them; but it was afterwards delivered up to the French by the treachery of the governor. In the war of the 'League of the Public Good' against Louis XI. this town was taken by the revolted lords. There are considerable remains of the castle at the extremity of the town towards Rouen, on the river Epte. From its position and general outline, it much resembles the remains of Launceston Castle in Cornwall. The inclosure of the castle is now used as a market-hall; the fosse is planted with trees, and forms a promenade. Some portions of the ancient town-wall yet remain. The church of Gisors is a large well-proportioned cross church, adorned with much elaborate sculpture; but its architecture is for the most part a jumble of Gothic and Roman. (Dawson Turner's *Tour in Normandy*.) It has some fine painted glass windows. The town itself is poor, but its situation is delightful, and the walks very pleasant. The population in 1832 was 3248 for the town, or 3533 for the whole commune. The inhabitants are engaged in bleaching calicoes and other fabrics, and manufacture cotton-yarn, printed calicoes, blonde and other lace, leather, glass and beer; they trade in corn and calves for the supply of Paris. There are a high school, a school of mutual instruction, a school for outline-drawing, and an hospital. Near Gisors is the ancient castle of Vaux, now in ruins.

Estrépagne, otherwise Estrépagne or Trépagne, a small town a short distance west by north of Gisors, has a substantially-built church. Its population, as given in Dulaure's 'Histoire des Environs de Paris' (Paris, 1828), our latest authority, was 1250. The inhabitants manufacture lace, cotton-yarn, and knit goods, and trade in grain, pulse, cattle, and hemp. There are two fairs in the year.

Ecouis is on one of the roads from Paris to Rouen. It has a market-place covered in with wood, a château of modern construction, and an ancient parish church, formerly collegiate. The last mentioned is a substantial but rather plain building in the form of a Greek cross; it contains the statues of several saints and the tomb of Jean de Marigny, archbishop of Rouen. The inhabitants are given by Dulaure at 634: they manufacture lace. There are two fairs in the year.

Maineville is near, but not on the Epte, a few miles north of Gisors.

Lions-la-Forêt is on the little river Lieur, which flows into the Andelle. It was inhabited in the Roman times, as appears from some ancient tombs, columns, painted walls, medals, and other antiquities discovered here at the beginning of the last century. There was in the middle ages a castle at Lions, where Henry I. of England died A.D. 1135. The population of the commune is given by Dulaure at 1900. The inhabitants manufacture printed calicoes and leather, and trade in corn.

Charleval is a small town at the junction of the Lieur with the Andelle. It takes its present name from a residence built here by Charles IX., of which there are some remains. Calicoes are printed and paper made. The neighbourhood is fertile.

Ecosse or Ecos, a very small place, is near the Epte, and between Gisors and Vernon.

Pont St. Pierre, a village on the Andelle, has fulling-mills, a cloth factory, and a cotton-mill, in which above 300 workmen are employed; and at Romilly, just across the river, is an extensive foundry, employing above 300 workmen. Copper, brass, and zinc in sheets, and brass wire for pins are produced. At these works zinc is used instead of lapis calaminaris in the manufacture of brass. The coal is brought from Anzin and St. Etienne, in France [ANZIN; ETIENNE, St.], and from Belgium.

In the arrondissement of Pont Audemer are Pont Audemer, Beuzeville, Conteville, Cormeilles, Lieurey, St. George du Vièvre, Pont Authou, Annebault or Apperville, P C., No. 604.

Bourghéroutte, Bourgachard, Routot, Bourneville, and Quillebœuf.

Pont Audemer is on the left bank of the Rille, and on the road from Rouen to Honfleur, 29 miles from Rouen. In the Norman period it was a military station, and was the first scene of conflict between Henry I. of England and his rebellious Norman barons: the victory was gained by the king, to whom the fortress immediately surrendered. In the fourteenth century it was defended successfully by its lord, the count of Evreux, against the generals of the king of France: this was the first siege in which cannon were employed in that kingdom. It was afterwards taken by Duguesclin, its castle razed, and the walls and towers of the town destroyed. It is a small neat place, at the foot of an eminence, with handsome streets and good brick houses. It is defended by walls and a ditch, which may be filled with water at will by means of sluices. It has four gates, and several places or squares. There are several churches, but some of them are now desecrated and converted to other uses. The population in 1832 was 5305: the inhabitants manufacture cotton yarn, printed calicoes, muslins, bed-ticks, tapes, hosiery, and especially leather. The leather is thought to be the best in France. There are an agricultural society and a theatre. The river is navigable up to this town: several of the arms into which its channel is divided have mills on their banks.

Beuzeville has a population of above 2000: the inhabitants are engaged in tanning leather and sawing marble. they have some linseed-oil mills.

Conteville is near the mouth of the Rille. The 'Dictionnaire Universel de la France,' our latest authority (Paris, 1804), gives its population at 900.

Cormeilles is on the road between Pont Audemer and Lisieux. It had formerly a Benedictine abbey, founded by William Fitzosborne, a relation of William the Conqueror. The church and other monastic buildings, which had gone much to decay, were repaired in the early part of the last century. The population, according to the 'Dictionnaire Universel de la France,' was 1210. There are an oil-mill, a paper-mill, and tan-yards; linen and calico are manufactured, and some trade carried on in corn.

Lieurey and St. George du Vièvre (population 900), where linen and paper are made, are between the Calonne and the Rille.

Pont Authou (population 628), where woollen yarn is spun and cloth made, and cattle sold, and Annebault (population 1150), where are the ruins of an ancient castle, are on the Rille. The population of these places is given from Dulaure: it is not the last return.

Bourghéroutte, near the boundary of the department, not far from Elbœuf, derives its name (in Latin *Burgus Thurolis*) from Thurol, one of the preceptors, and afterwards grand constable, of William the Conqueror. Its church was formerly collegiate. The inhabitants are given by Dulaure at 738.

Bourgachard is not far from Bourghéroutte. There was an abbey at Bourgachard, but it is now levelled with the ground; there is an hospital or almshouse. The population is given by Dulaure at 1114. The market is considerable.

Routot (population 1100, Dulaure), which trades in cattle and wool, and Bourneville (population 781, Dulaure), are on a bye-road from Bourgachard to Quillebœuf, which is on the left bank of the Seine, on a point formed by a bend of the river. Its port is much frequented by the boats which navigate the Seine, and those vessels which are too large to ascend the river as far as Rouen discharge their cargoes here. It was formerly a place of considerable strength. The inhabitants (1500, Dulaure) carry on a considerable fishery, or pilot vessels up the Seine; the women manufacture lace.

Montfort, on the Rille, between Pont Authou and Annebault, is given as a village in some of our authorities, as a town in others. It has the ruins of an ancient castle, besieged for thirty days in A.D. 1122 by Henry I. of England, and gives title to an English peer. The inhabitants (520, Dulaure) manufacture leather, paper, and woollen cloth, and trade in cattle and linen.

In the arrondissement of Bernay are Le Bec, Briène or Brionne, Beaumont le Roger, La Barre, Beaumenil, Chambray, Thiberville, and Harcourt.

Le Bec, sometimes distinguished as Le Bec Hellouin, is near the bank of the Rille. Here, before the Revolution, was a Benedictine abbey of the congregation of St. Maur, one of

the wealthiest in Normandie, founded by Hellouin, a noble of the country, about A.D. 1034. The abbot's patronage was very extensive. Soon after its foundation this abbey became the seat of a famous school, founded here by Lanfranc, one of the monks of the convent, afterwards archbishop of Canterbury. Anselm, Theobald, and Hubert, also inmates of this abbey, were subsequently raised to the same archiepiscopal see, and Roger, the seventh abbot, had the offer of that dignity, but refused it. The sees of Rochester, Beauvais, and Evreux, were filled by monks from this abbey, which furnished abbots to the convents of Chester, Ely, and St. Edmund's Bury. The Empress Maud, daughter of Henry I. of England, is said to have been buried here. The abbey was fortified when Henry V. invaded France, and stood a siege of a month before it was surrendered to the English. The greater part of the conventual buildings still exist. The tower, 150 feet high, a few ruined arches, and one of the side chapels, are the only parts of the church which remain. A part of the grounds are appropriated to a stud for keeping up the breed of Norman horses. The town of Le Bec is unimportant: its population is about 700.

Brionne was, under the dukes of Normandie, a place of some importance; it had three churches, an abbey, and a lazaret house, beside an antient castle, of which some slight remains exist, and it was the capital of an earldom, created in favour of a son or brother of one of the dukes of Normandie. The town is pleasantly and advantageously situated on the banks of the Rille. It has only one church now. The inhabitants may be estimated at about 2000. A mill for spinning cotton yarn employs 120 hands, and a cloth factory 500: rape and linseed oils are expressed.

Beaumont le Roger, on the Rille, had also a strong castle and a Benedictine priory. The inhabitants are given in the *Dictionnaire Universel de la France* at 1325: a cloth factory employs 400 hands, a glass-house 100; bottles, chiefly intended for Bretagne, are blown in great quantity at the latter establishment.

La Barre and Beaumenil are between the Rille and the Charentonne: their population was, according to the *Dictionnaire Universel*, 948 and 484 respectively.

Chambois is on the Charentonne, above Bernay; and Thiberville, near the source of the Calone; the inhabitants of the latter (population 1200 according to the *Dictionnaire Universel*) are occupied in weaving tape. This branch of industry employs at the neighbouring village of Drucourt and the surrounding communes, 4600 workmen.

Harcourt, not far from Brionne, gives title to an English nobleman: there are some remains of an antient castle, built by Robert de Harcourt, one of the companions of William the Conqueror in his invasion of England: the *Dictionnaire Universel* gives the population at 1297.

In the arrondissement of Evreux are Neuvelire, Rugles, Conches, Damville, Breteuil, Bourth, Chênebrun, Verneuil, Tillières, Nonancourt, Ivry, Pacy, St. André, Villiers-en-Desœuvre, and Vernon.

Neuvelire (otherwise Neuvelire) and Rugles are on the Rille; the latter is higher up the stream. Neuvelire has 600 inhabitants, who trade in corn and cattle; at Vielleire, near it, there are iron works. Rugles is of more importance; it is the centre of a pin manufacture which employs 2500 workmen, and of a nail manufacture which employs 3600 more. Zinc and copper are rolled out into sheets: the manufacture of iron cables, once carried on in this town, has been transferred to Nevers, in the centre of France.

Conches (pop. in 1826 1725) is on the river Conches, a small stream which joins the Iton between Damville and Evreux. Nails, agricultural implements, and other iron goods, are manufactured here: there are tan-yards, paper, oil and tan mills, and trade is carried on in iron, earthenware, hay, and cattle. The iron work of the bridges des Arts and d'Austerlitz at Paris were cast here.

Damville, Breteuil, and Bourth, are all on the Iton. Their population is given by Dulaure at 762, 2000, and 1670, respectively: there are iron works at all of them. Pins are made at Bourth; and at Breteuil, cannon of every calibre, projectiles of all kinds, screw taps, cauldrons, iron pots and other iron wares, tiles, and bricks. There are at Breteuil mineral waters and the remains of a castle, built by William the Conqueror.

Chênebrun, or Chennebrun, is on the Acre: it is very small; its population is about 360.

Verneuil is on the Acre: it is well laid out with broad

straight streets, but wretched and ill-built houses of earth and wood, with a few only of brick: it had in 1832 a population of 3722 for the town, or 4178 for the whole commune. The manufactures of this town and its vicinity consist of leather for bookbinders (but this branch of industry has much declined) and of cotton hose, but this is also languishing. There is a Gothic church in the town, the steeple of which is said to have been built by the English, and an old tower, the remains of a castle which formerly defended the town. This tower is popularly but erroneously ascribed to the Romans. The site of the ramparts has been laid out in promenades. The English obtained a victory over the French at Verneuil in the reign of Henry VI., A.D. 1424. There is a small library.

Tillières and Nonancourt are also on the Acre: they have a population (according to Dulaure) of 950 and 1359 respectively. At Tillières pins and nails are made; and at Nonancourt woolcombers' cards, machinery, woollen and cotton yarn, woollen cloth, calicoes, hosiery, linen, and paper; trade is also carried on in corn and cattle.

Ivry, on the Eure, at the junction of the Vesgre, is celebrated for the battle fought in the adjacent plain, in which Henri IV. routed the army of the League under the duke of Mayenne, A.D. 1590. A pyramid, overthrown at the Revolution, but restored by Napoleon, commemorates the battle. It is a town of 800 inhabitants (Dulaure), who manufacture musical wind instruments, ivory and boxwood combs, cotton yarn, and leather, and carry on trade in corn, cattle, and horses.

Pacy is on the Eure, at the point where, according to some of our authorities, the navigation begins, in a fertile valley. It was antiently a place of some importance, and was defended by a castle and strong ramparts. Before the Revolution it had three churches (one parish church and two others) and a Benedictine abbey. The inhabitants, 1364 in number (Dulaure), trade in cattle and horses (for which they have a large fair), corn, woollen and linen cloth, and iron.

St. André, between the Eure and Iton, had a population of 977 (Dulaure): some trade in cattle is carried on.

Villiers en Desœuvre, a short distance from the bank of the Eure, had a population of no more than 450 (Dulaure); it has some trade in cattle and horses.

Vernon is on the left bank of the Seine, and on the road from Paris to Rouen. Here was in antient times a castle, which William the Conqueror bestowed on his relation, Guy, son of the count of Bourgogne, and which was strengthened by Henry I., the Conqueror's son. The town is situated in a singularly beautiful valley, and is connected by a bridge of twenty-two arches with the suburb of Vernonnet, on the other bank of the Seine. Of the antient defences of the town there remains only a tower, in which the archives of the place are preserved. The church, part of which exhibits some very early Norman architecture, was formerly collegiate; it contained before the Revolution several monuments. The population in 1832 was 2703 for the town, or 4888 for the commune, including the suburb, Vernonnet. Cotton velvet, plain and printed calicoes, leather, and cotton yarn, are manufactured: there is an establishment for making the equipage of the artillery, and another for sawing stone; also lime, gypsum, and tile kilns: trade is carried on in corn, flour, wine, wool, feathers, and cattle.

The arrondissement of Louviers contains Pont de l'Arche, Gaillon, and Neufbourg.

Pont de l'Arche is on the left bank of the Seine, just below the junction of the Eure, and at the point where the tide ceases to be perceptible. It owes its origin to Charles le Chauve, who erected here a palace, in which he convened councils, held assemblies of his nobles, and drew up edicts; and built a fine bridge, defended at one extremity by a citadel, from which the name of the place (in Latin Pons Arcis) is derived, and which was demolished about the beginning of the Revolution. Pont de l'Arche was burned by the English under Edward III. The walls of the town yet remain flanked by circular towers. The bridge is the lowest stone bridge down the Seine, and the only one of any kind between Vernon and Rouen: it is a picturesque object, with mills in some part of its length, and a lock under one of the arches to facilitate the navigation of the river and render it secure. On the bank of the river near the town are the remains of a Cistercian abbey, founded, A.D. 1190, by Richard Cœur de Lion, in pursuance, it is said, of a vow which he had made when nearly lost in the rapid current of the Seine. The church of Pont

de l'Arche, though much dilapidated, is a fine building in the decorated style of Gothic architecture: it has some rich carving, and handsome painted windows. The population is given by Dulaure at 1480: the inhabitants manufacture woollen cloth, and trade in cattle, horses, and fruit-trees.

Gaillon is near the left bank of the Seine, between Pont de l'Arche and Vernon. This town was bestowed by St. Louis on the archbishop of Rouen, whose successors had a palace here up to the period of the Revolution, and enjoyed the sole right of trying civil and criminal causes. This palace, destroyed in the wars of the English, A.D. 1423, was rebuilt a century afterwards by the archbishop, George d'Amboise, and embellished by his successors: after being nearly destroyed during the Revolution it has been repaired and fitted up as a prison, and contains now 1200 to 1400 prisoners who are employed in making carpets and cotton goods, and plaiting straw. There was a Carthusian convent here before the Revolution, founded by one of the archbishops of Rouen. A fountain in the town has the property of incrusting with its deposits any object thrown into it. Gaillon is a poor place; its population is given by Dulaure at 1030. The inhabitants carry on trade in cattle and woven goods. Near Gaillon are vineyards, the most northern in Normandie: the grape grown is the small black cluster; the wine produced is of very inferior quality.

Neufbourg or Neubourg, between Louviers and Beaumont le Roger, has the remains of an ancient castle where the eldest son of Henry II. of England espoused Marguerite daughter of Louis VII. (*Le Jeune*) of France. The inhabitants, whom Dulaure gives at 1675, manufacture linens and calicoes, dimities, fustian, &c., and carry on trade in corn, wood, cattle, and iron goods.

The department constitutes the diocese of Evreux, the bishop of which is a suffragan of the archbishop of Rouen: it is in the jurisdiction of the Cour Royale of Rouen, and in the circuit of the 'Academie,' or council of education of that city. It is in the 14th military division, of which Rouen is the head-quarters. It sends seven members to the Chamber of Deputies. Education is more attended to than in the average of the French departments: it furnishes one male scholar for every twenty-four inhabitants. This department consists of parts of the former districts of Le Vexin Normand, Le Roumois, La Campagne, Ouche, Lieuvin, all in Haute or Upper Normandie.

EURE ET LOIR, a department in France, occupying a portion of the country between the Seine and the Loire. It is bounded on the north by the department of Eure, on the east by that of Seine et Oise, on the south-east by that of Loiret: on the south by that of Loir et Cher; on the south-west, for a short distance, by that of Sarthe; and on the west by that of Orne. Its only natural boundary is on the north, where it is separated from the department of Eure by the rivers Arve (or Aure) and Eure, and for a very little way on the north-east. Its greatest length is from north by east, near Villiers in Descœuvre (department of Eure) to south by west near Cloyes on the Loir, 68 miles, and its greatest breadth, at right angles to the length, is from near Nogent le Rotrou to the neighbourhood of Thoury, 55 miles. It is between 47° 57' and 48° 56' N. lat., and between 0° 45' and 1° 59' E. long. The area of the department is 304 square geographical leagues (French measure) of 25 to a degree, equal to 2325 English square miles, which is not much below the average area of the French departments, and a very little more than that of the two English counties, Kent and Surrey, taken together. The population in 1832 was 278,820, or 120 to a square mile, about three-fourths of the average population, absolute and relative, of the French departments, and not so much as three-tenths of that of the two English counties. Chartres is the capital.

There are no very lofty hills in the department, but the general level of the country is high; the western part is varied with hills and valleys, the hills being a prolongation of those which overspread Bretagne and Upper Normandie, and which enter this department from the north-west: in the south-eastern side of the department these hills expand into an elevated plain, or table-land, level and without water, though just between two of the largest rivers of France, the Loire and the Seine. This table-land extends on the south-west into the adjacent department of Loiret. The hills divide the department into the basins of the two rivers from which it takes its name; that of the Eure

occupying the northern part, and that of the Loir the southern.

The Eure enters the department not far from its source, and flows through it, or along the border, about 70 miles, first in a south-eastern direction past Belhomert, Pontgouin, and Courville, and then in a northward direction past Chartres, Maintenon, and Nogent le Roi. [Eure River] Its chief tributaries are the Voise (17 miles long), which rises near Auneau and flows into it from the south-east on its right bank below Maintenon, passing the towns of Guédelongroy and Gallardon; the Blaise (about 26 miles long), which rises near Senonches and flows into it from the south-west near Dreux, passing Maillebois and Dreux, and flowing in a channel continually dividing and re-uniting; the Aure, which has been noticed elsewhere [Eure Department]; and the Vesgre (22 miles long), which rises in the adjoining department of Seine and Oise, between Montfort L'Amaury and Rambouillet, and flows in a north-west direction through this department into the Eure at Ivry. The Mauvette, or Meuvette (14 miles long), rises near La Ferté Vidame and flows north-east past Brezolles into the Aure at Nonancourt; and the Oplon, which is a feeder of the Vesgre, and belongs to the department of Seine and Oise, flows for a very short distance along the eastern boundary of the department.

The Loir rises on the south-west slope of the hills which divide the two basins, a short distance south of Courville, and flows 10 miles south, past Illaire, or Illiers, just below which it receives the Thironne, and afterwards the Fouchard; it then flows south-east, and then south (12 miles) past Bonneval, near which it receives the Ozanne; all these join it on the right, or west bank. It then turns to the south-west, and flows 20 miles before it quits the department, receiving by the way the Connie, on the left bank, and the Yere on the right. The whole course of the Loir is about 160 or 170 miles, for nearly 30 of which (viz., from Château du Loir) it is navigable; it falls into the Sarthe just before the junction of that river with the Mayenne: the whole belongs to the system of the Loire (La Loire, feminine), from which the Loir (Le Loir, masculine) is to be carefully distinguished, both as to itself and its orthography.

The Thironne (12 miles long), the Fouchard (15 miles long), and the Ozanne (25 miles long), all rise a short distance east or south-east of Nogent le Rotrou, and all flow east by south into the Loir. The Connie, or Conie (above 20 miles long), rises in the adjoining department of Loiret, near Patay, and flows west-north-west into the Loir, receiving the Connie Palue (12 miles long), which has all its course in the department, on its right bank. The Yere rises in the south-west corner of the department, and flows east-south-east 22 miles into the Loir.

The Huine, a feeder of the Sarthe, just passes Nogent le Rotrou on the western side of the department; and the Braye, which separates the departments of Sarthe and Loir at Cher, and joins the Loir much lower down, has its rise just within this department.

The canal from Pontgouin to the aqueduct of Maintenon connects the upper part of the Eure at Pontgouin with the lower part of the same river at Maintenon. The canal is about 27 miles long. The aqueduct was originally designed to convey the waters of the Eure to Versailles, but the design was given up; and the aqueduct, a vast pile, is fast going to decay.

The étang, or pool, of Bois Ballu is supplied with water chiefly from a deep pit, from which, at certain periods, fishes of considerable size are ejected, which disappear a few days after.

The greater portion of this department is occupied by the chalk which encircles the Paris basin, or the *strata mœti* immediately connected with it: on the south-east a considerable tract is occupied by the various formations which overlie the chalk. The soil and produce are thus somewhat vaguely described in the *Dictionnaire Géographique Universelle*, Paris, 1827:—'The lands in this department are clayey, mixed with a small quantity of sand; there are also some calcareous soils mingled with clay and sand; others are clayey mingled with large flints (fragments grossiers de silex); others consist of a deep arid sand. The slopes of the south-west have little vegetable soil; they sometimes are composed of marl and flint (de marne et de silex), sometimes of a reddish sand and flint. The marl, which is found almost every where, is used for the improvement of the land. In the arrondissement of Nogent le Rotrou (the

western side of the department) there are many tracts of waste land scarcely capable of producing anything; the ashes of the heath and furze are used for manure. Two-thirds of the department consist of the former territory of Beauce, or Beausse [BEAUSSE], which is a great agricultural district: corn, especially wheat, which yields a great proportion of flour, constitutes its principal riches of this part of the department: the harvests are very abundant, and their produce is chiefly destined for the supply of Paris. In the rest of the department rye, barley, and oats are produced; pulse (légumes) is grown every where; the turnips of Gausaie, the melons of Nogent le Roi, and the onions of Chaudons are in high repute; few potatoes are grown; but in some parts rape, flax, hemp, dyers' weed (*reseda luteola*), and teasles are raised for the use of the manufacturers; hops grow spontaneously; the vine is cultivated in many places; the wine is of middling quality, and liable to turn sour in hot weather. There are few fruit-trees in the former district of Beauce, but many in the arrondissement of Nogent le Rotrou, especially apple-trees, which furnish cider for home consumption.

According to M. Dupin (*Forces Productives, &c. de la France*) the value of land and the aggregate rental of the department are above the average of France; the quantity of wheat grown is to the average produce of the other departments as more than five to two; that of oats nearly as four to two; and that of potatoes, contrary to what is stated in the above extract, is more than eight to two. 'The forests (we quote again from the *Dictionnaire Géographique Universelle*) occupy an extent of 45,000 hectares (above 111,000 acres), and consist, in a great measure, of oaks and birches: all the woodland is on the western side of the department, except some round Dreux, in the northern part. The pasture and meadow-land is not in proportion to the quantity of arable, but it is of good quality. A considerable number of horned cattle of a small race are reared; but not a sufficient number of horses for the wants of the agricultural districts: those which are bred in the arrondissement of Nogent le Rotrou are in request for the light cavalry. There are many sheep, some of which yield a fine wool; pigs, fowls (which are sent in great quantity to Paris), and bees. Game is abundant; the rabbits are in repute, as well as the red partridges, plovers, lapwings, and especially a species of the plover called guigard, from which the Chartres pies derive their reputation; pigeons are again increasing. The rivers abound with fish; the golden carp of the Loir, the crayfish of its affluent, the Connie, the trout of the Blaise, the Eure, and the Huine, are accounted excellent.' The number of horses, however insufficient, is given by M. Dupin at 35,967, nearly 8000 above the average of the departments: the number of horned cattle is given by him at 56,464, more than 23,000 below the average: the quantity of wool grown is to the average produce of the departments in the proportion nearly of five to two; and this is more available for exportation, as the woollen manufacture of the department is not great. The department is essentially agricultural; corn is sent not only to Paris, but into the neighbouring departments. There are about 600 flour-mills; a great number of them are on the Eure, the Blaise, the Loire, and other streams. The cottages of the peasantry are, in some parts at least, of a most miserable character; they call to mind the tents of the ancient Carnutes who occupied the country.

The only metal dug is some iron: but the mines supply only a part of the ore for the different iron-works, and are becoming exhausted: good freestone is quarried, and sandstone for pavement; there is much marl; peat for fuel is obtained in several places, also potters' clay, and clay for the finer kinds of earthenware produced in the manufactory at Sévres.

The manufactures are of small importance; they are chiefly in the arrondissement of Dreux, and in that of Chartres. The manufacture of linen is generally diffused, out it is only in one place that it is carried on on a considerable scale; some cotton yarn is spun and some cotton goods are woven; woollen cloths, serges, and other light woollen stuffs, blankets, flannel, knit and woven hosiery, foot carpets, and common hats are made; there are a considerable number of tan-yards; a small quantity of earthenware is made, and a little beet-root sugar.

The department is very ill provided with the means of water carriage; a small part of the course of the Eure, along the boundary of the department, is, according to some

of our authorities, navigable. With roads it is better provided. The great road from Paris through Tours to the south-west of France crosses the department, passing through Eprenon, Maintenon, Chartres, Bonneval, Châteaudun, and Cloyes; the great western road from Paris to Rennes and Brest just crosses the northern part through Dreux: these are the only roads of the first class. Of the second class are the Orléans road, passing just within the south-eastern boundary of the department, through Thoury; and the road which, branching off from the great south-western road at Chartres, runs through Courville Champ-rond and Nogent le Rotrou in the direction of Le Mans, Angers, and Nantes. Of roads of the third class are a road from Paris to Chartres through Guédelongroy, roads from Chartres to Dreux and to Orléans, and from Châteaudun to Nogent le Rotrou (and from thence to Alençon, in the department of Orne), and to Orléans. The other roads are bye-roads.

The department is divided into four arrondissemens that of Dreux, in the north, population in 1832 70,532; that of Chartres, in the east and centre, population 103,783; that of Châteaudun, in the south, population 59,758; and that of Nogent le Rotrou, in the west, population 44,747. These arrondissemens are subdivided into 24 cantons, or districts of justices of the peace, and 460 or 463 communes. The chief towns are Chartres, the capital, on the Eure, population 13,576 for the town, or 14,439 for the whole commune [CHARTRES]; Châteaudun, on the Loire, population 6461 [CHATEAUDUN]; Dreux, on the Blaise, population 5166 for the town, 6249 for the whole commune [DREUX]; and Nogent le Rotrou, on the Huine, population 5812 for the town, or 6825 for the whole commune. Of this last and the smaller towns an account is subjoined.

In the arrondissement of Dreux we have Bu, Anet, Nogent le Roi, Le Tremblay, Châteauneuf, Digny, Senonches, Maillebois, Brezolles, and La Ferté Vidame.

Bu (population 1549, Dulaure, *Environs de Paris*, Paris, 1828) was once a place of considerable strength; it has still the ruins of an antient castle, of which one tower is in pretty good preservation. It was the capital of a county. Its markets are well attended.

Anet (population 1500, Dulaure) is in the northern extremity of the department, in a pleasant valley between the Vesgres and the Eure; it has the remains of a magnificent residence, built by Henri II. for Diane de Poitiers, duchess of Valentinois, his mistress. There are tan and corn-mills, and in the neighbourhood paper-mills and iron-works; the inhabitants carry on trade in corn, wood, and hay.

Nogent le Roi (population 1242, Dulaure) is in a pleasant valley on the left bank of the Eure. The inhabitants carry on a trade in cattle. Nogent belonged to Philippe VI. de Valois, who died here A.D. 1350. It is probable that it derived from this prince its distinctive epithet of Le Roi; it was, with its territory, erected into a county in favour of Bautru, one of the courtiers of the cardinal de Richelieu. The castle of Nogent, built on a hill which commands the town on the western side, was an object of frequent contest in the times of feudal warfare and in the wars of the English in France under their kings Henry V. and VI. It was garrisoned by Henri IV. in his war with the League, taken by the inhabitants of the neighbouring towns, who had embraced the party of the League, and whom the garrison was an annoyance, and retaken by the royal forces.

Le Tremblay is very small; its population is under 500 (Dulaure); it lies a little out of the road from Dreux to Chartres.

Châteauneuf (population 1250, Dulaure) is in a fertile plain between Dreux and Nogent le Rotrou. Here was an antient castle, *Castrum Theodemerense*, a name which was corrupted into Thimer, and gave to the surrounding territory the name of Thimerais; whence Châteauneuf is sometimes distinguished as Châteauneuf en Thimerais. In A.D. 1589 it was taken by the troops of the duke of Mayenne and retaken by those of Henri IV. The inhabitants now carry on a trade in cattle.

Digny is not far from Châteauneuf, with a population, according to Dulaure, of 1197. Some of our authorities make this to be only a village.

Senonches and Maillebois are on the Blaise; the former near its source, the latter lower down. At Senonches (population 1911, Dulaure) steam-engines and hydraulic machines are made, and there are iron-works. Trade is carried on in cattle and horses. At Maillebois (760 inha-

bitants, Dulaure) woollen cloth and light woollen stuffs are made. Peat is dug in the neighbourhood.

Brezolles is on the Meuvette. Dulaure gives the population at 844. Trade in cattle is carried on.

At La Ferté Vidame (population 808, Dulaure), in the north-western part of the department, trade is carried on in horses and cattle. Some of our authorities make this to be only a village.

In the arrondissement of Chartres are Epernon, Maintenon, Gallardon, Guédelongroy, Auneau, Ouarville, Voves, Janville, Thoury, Illaire or Illiers, Courville, and Pont-gouin.

Epernon is on the high road from Paris to Chartres, in a delightful situation on the slope and at the foot of a hill, near the little river Guesle, a feeder of the Eure. It is tolerably well built: it was formerly walled in on three sides; on the fourth side (the north) it was defended by a castle on the summit of the hill, of which some picturesque ruins still remain. The country round consists of fertile meadows, watered by several brooks. The inhabitants (1462, Dulaure) manufacture leather: there are kilns for gypsum; and trade is carried on in flour, excellent pulse, horses, and cattle.

Maintenon is on the right bank of the Eure, at the junction of the Voise. It was erected into a marquise in 1683, in favour of the widow Scarron, wife of Louis XIV., better known in history by the name, which she took from this town, of Madame (or rather La Marquise) de Maintenon. The Château de Maintenon was built by Jean Cottureau, intendant of the finances, and sold by his descendants to Madame de Maintenon: some portions of Cottureau's edifice may be observed in the present structure. The chapel of the château is scrupulously preserved: the tradition that Louis XIV. and Madame de Maintenon were married there appears from the testimony of history to be unfounded. The apartment of Madame de Maintenon retains a portrait of her. The grounds are large and well kept up; they are intersected in every direction by numerous canals, over which are no less than 50 bridges. The town itself, though well laid out and well built, presents nothing remarkable: the inhabitants (1542, Dulaure) carry on trade in cattle. Collin d'Harleville, a dramatic author of note, was born here. The aqueduct of Maintenon has been already noticed. Near the town is a plain covered with Druidical remains, called the stones of Gargantua.

Gallardon is on the right bank of the Voise, at the junction of the little brook the Ocre; it had antiently a castle: the town was several times taken and retaken in the wars of the English in France in the fifteenth century. Dunois, who took it from the English A.D. 1443, destroyed the castle except one tower, which still remains. Gallardon was taken by the Huguenots under the Prince of Condé, in the religious wars of the sixteenth century. The inhabitants (1398, Dulaure) carry on trade in corn, pulse, horses, oxen, calves, and sheep.

Guédelongroy is on the Voise. Vaysse de Villiers, who terms it a village, assigns to it a population of 500.

Auneau is on a small stream running into the Voise. It has the remains of a castle, probably built at the latter end of the fourteenth century. In this castle, in the religious wars of the sixteenth century, a body of German cavalry, in the service of the Protestants, were surprised by the royal troops, and in great part killed. What remains of the castle is used as a dwelling-house; at the entrance is a tower of very substantial construction, which commands the surrounding country. The inhabitants of Auneau (1400, Dulaure) manufacture hosiery.

At Ouarville (population 733, Dulaure) hosiery, and at Voves (population 1136, Dulaure) hosiery and light woollen stuffs are manufactured; and at Ouarville trade is carried on in horses and cattle. At Janville (population 986) hosiery and light woollen stuffs are manufactured; and at Thoury or Toury, near Janville (population 1232, Dulaure), hosiery and beet-root sugar; a trade in horses, asses, mules, and cattle is also carried on.

Illaire is on the left bank of the Loir, near its source: its population, in 1832, was 2059 for the town, or 2937 for the whole commune: the inhabitants carry on trade in cattle, sheep, and wool; and manufacture woollen cloths, white serge, and other light woollen stuffs, and osiery: there are some tan-yards.

Courville and Pont-gouin are both on the left bank of the Eure, the first on the road from Chartres to Le Mans and

Angers, the second on a road branching from this at Courville to Belême, Mamers, and Alençon. At Courville (population 1341, Dulaure) some trade in horses and cattle is carried on. The château which the descendants of Sully possessed in this town has been entirely destroyed; but that at Villebon, distant two or three miles from Courville, where that great statesman died, is yet in good preservation, and is one of the finest remains of the sixteenth century. At Pont-gouin (population 1400, Dulaure) white serge is made.

In the arrondissement of Châteaudun are Sancheville, La Ferté Villeneuve, Bonneval, Cloyes, and Brou.

To Sancheville, which is, according to some of our authorities, a village, Dulaure assigns a population of no more than 886. La Ferté Villeneuve is still smaller.

Bonneval is on the road from Chartres to Tours, in a pleasant fertile valley on the left bank of the Loir, which here flows in several channels. It was formerly a place of some strength. The parish church has a lofty spire. The inhabitants (1750, Dulaure) manufacture carpets, counterpanes, flannels, woollen stuffs, calicoes, and printed cottons; and spin cotton and woollen yarn. Trade is carried on in corn, flour, wool, and cattle; and there are some considerable tan-yards. There are some Druidical monuments in the neighbourhood of the town.

Cloyes is also on the road from Chartres to Tours, and on the Loir: it is a place of very little trade, with a population of about 1500. (Vaysse de Villiers.) Brou is on the Ozanne, which flows into the Loir: it had, in 1832, a population of 1870 for the town, or 2263 for the whole commune. The inhabitants make serges, and other light stuffs, and some of the fittings of weavers' looms. There are some marl-pits of considerable depth in the neighbourhood.

In the arrondissement of Nogent le Rotrou are Nogent le Rotrou, Authon, Beaumont le Chetif, Champrond, La Loupe or La Louppe, and Belhomer or Belhomert.

Nogent le Rotrou is on the road from Paris by Chartres to Le Mans, Angers, Nantes, and other places in the west of France, 33 miles from Chartres. It is a small town in a pleasant valley, watered by the Huine, on the left bank of which the town stands. It is a long place in proportion to its size. There is a castle, a picturesque ruin, which commands the town, and possesses some interest as having been the residence of Sully. There are three hospitals, one of them founded by Sully, who, as well as his wife, was buried here; but the tombs were violated during the Revolution and the remains dispersed. The town had in 1832 a population of 5812, the commune of 6825: the manufactures are druggets, serges, and other light woollens, and cotton-yarn there are several tan-yards, some tan-mills, and a dye-house. There are a public library, a high school, and an agricultural society.

Authon is near the source of the Ozanne: its inhabitants (1211, Dulaure) make serges, druggets, and other light woollens. Beaumont le Chetif (a village, according to some of our authorities) is between Brou and Nogent le Rotrou: its inhabitants (591, Dulaure) manufacture earthenware. Champrond is a village, according to some authorities, with 904 inhabitants (Dulaure), who trade in charcoal and wood. There are in the neighbourhood iron-mines, iron-works, and peat-pits. La Loupe and Belhomer are on the road from Dreux to Nogent: they are both small; Dulaure assigns to them a population of 1096 and 451 respectively. At La Loupe some business is done in horses, oxen, and sheep.

The department constitutes the diocese of Chartres, the bishop of which is a suffragan of the archbishop of Paris. It is comprehended in the jurisdiction of the Cour Royale of Paris, and in the circuit of the Conseil Academique of that city. It is in the first military division, of which the head-quarters are at Paris. It returns four members to the Chamber of Deputies. The state of education in the department is favourable as compared with the greater part of France. The number of male children at school is in the proportion of one for every seventeen inhabitants.

This department consists of the former district of Chartrain, and a portion of Dunois, both of which were comprehended in the county of Beauce or Beausse, and in the province of Orléanois; of a portion of Orléanois proper; of a considerable portion of the county of Perche, comprehended in the province of Maine; and of a small portion of the district Mantois, in the Ile de France.

EURIPIA. [THEOPOIMATA.]

EURIPIDES of Athens is said to have been born at

Salamis in the year B.C. 480, on the day of the great victory obtained over the fleet of Xerxes. His father Mnesarchus and his mother Clito were among the refugees driven to Salamis by the progress of the invading army. They seem to have been Athenian citizens of the poorer class, as we find that the mean occupation of this poet's mother was made by Aristophanes one standing subject of the ridicule which he so perseveringly heaped upon him. Philochorus, on the contrary, says that he was of noble birth; but still his parents might be poor. (Suidas, *Εὐριπίδης*.) Euripides however found means to devote himself early and closely to the study of philosophy in the school of Anaxagoras, as well as to that of eloquence under Prodicus. While he was yet very young, the persecution and banishment of Anaxagoras appear to have deterred him from, or at least disgusted him with, the cultivation of philosophy as a profession, and combined with the strong natural bent of his genius to direct his exertions chiefly to dramatic composition. He is said to have commenced writing at the age of eighteen; and in the course of a long life he composed not fewer than seventy-five tragedies, or, according to other authorities, ninety-two, which rivalled in the public approbation the contemporary productions of Sophocles; and notwithstanding the constant and bitterly satirical attacks which, in the author's own time, they sustained from such as were exclusively and intolerantly attached to the elder tragic school, they secured him for all succeeding ages a place beside its two great masters. When upwards of seventy years old, weary, it should seem, of the feverish excitement in which he must have been kept alike by the petulant criticism and the turbulent applause that attended him at Athens, he accepted the invitation of Archelaus, king of Macedon, and went to live in honoured and tranquil retirement at his court. Here, however, a singular as well as tragical end awaited him. According to one account (for, in this as in many other matters of ancient biography, there are discrepancies), he had spent three years in this retreat, when, walking one day in a solitary spot, he was met by some of the king's hounds, which, rushing furiously upon him, tore him so violently that he shortly after died in consequence of the laceration. Aulus Gellius tells us that the Athenians sent to Macedon to ask for the body of Euripides, but that the Macedonians constantly refused it, in order that their own country might retain the honour of the magnificent tomb which they erected for him at Pella, and which, according to Ammianus Marcellinus, was sanctified by the thunder-stroke, as Plutarch informs us had been the case with that of Lycurgus. Thus Athens was obliged to content herself with engraving the name of Euripides upon an empty monument, which in the time of Pausanias was yet standing beside the road from the Piræus to Athens (Pausan. *Attic*. 1, 2), near the tomb of Menander.

Of the numerous tragedies of Euripides, nineteen survive—a much larger proportion than has descended to us of the works of either of the two elder tragic masters. We have already [DRAMATIC ART, &c., vol. ix. p. 131] pointed out his 'Electra' to the reader's attention, not as a favourable specimen of the general powers of Euripides—for, indeed, as a work of art it is decidedly one of the least meritorious of his extant pieces,—but as affording the clearest point of comparison between his most prominently distinctive features as a dramatist and those of his two great predecessors; this being the only instance in which we have a piece from each and all of the three composed upon one and the same historical or mythological subject. 'Orestes,' the subject of which, inasmuch as it relates to the persecution of that hero by the furies of his mother and his proscriptio as a matricide, is the same as that of the 'Eumenides,' of Æschylus, though in scene, incident, and character, excepting that of Orestes himself, they are wholly different, is more rigorous and more affecting than the 'Electra.' 'Iphigenia in Tauris' and 'Andromache' follow out still farther the fortunes of Orestes; both rank among those pieces of the second order in which the highest praise can be given only to certain portions. The same may be said of the six following pieces: the 'Troades,' the mournfully grand conclusion of which exhibits the captive Trojan women leaving Troy in flames behind them; 'Hecuba,' relating to the subsequent history of the captive queen; the 'Hercules Furens,' or 'Raging Hercules,' the 'Phœnisæ,' having the same historical groundwork as the 'Seven against Thebes' of Æschylus; the 'Heraclidæ,' which cele-

brates the Athenian protection of the children of Hercules, ancestors of the Lacedæmonian kings, from the persecution of Eurystheus; and the 'Suppliees,' which in like manner commemorates the interment of the Seven before Thebes and their army, gained, on behalf of Adrastus, king of Argos, by a victory of the Athenians over the Thebans. 'Helen' is a very entertaining and singular drama, full of marvellous adventures and appearances, being founded on the assertion of the Egyptian priests that Helen had in fact remained concealed in Egypt, while Paris had merely carried off an airy semblance of her. The genuineness of 'Rhesus,' taken from the eleventh book of the 'Iliad,' has been much disputed, chiefly on the ground of its great relative inferiority—an argument which is outweighed by certain internal characteristics of the piece itself, combined with the external testimony of the ancient writers ascribing it to Euripides. For beautiful morality and unaffected yet overpowering pathos, his 'Ion,' his 'Iphigenia in Aulis,' and above all, his 'Alcestis,' are peculiarly distinguished. He found subjects especially suited to the development of his finer powers in the purity and sanctity of the youth from whom the first of these three tragedies is named, in the unsuspecting innocence of the heroine of the second, and in the tender yet resolute devotedness of connubial affection portrayed in the third, to which Milton so beautifully alludes in his well-known sonnet, beginning

'Methought I saw my late espoused saint
Brought to me like Alceas from the grave,
Whom Jove's great son to her glad husband gave,' &c.

The 'Hippolytus' and the 'Medea,' exhibiting all the romantic violence of irregular and vehement feminine passions, are deservedly celebrated among the greatest and most thoroughly successful achievements of this dramatist. In the former the heroism of Hippolytus is sublime as well as beautiful; and as regards the conduct of Phædra, as Schlegel has well remarked, it merits the highest commendation for the strict observance of moral propriety in a subject of so critical a nature. After the 'Hippolytus,' the same eminent critic is disposed to assign the next place among all the remaining works of Euripides to the 'Bacchæ,' on account of its harmonious unity, its well-sustained vigour, and of the appropriateness to the very peculiar subject here treated, of that luxuriance of ornament which Euripides constantly displays. This piece also merits especial attention as being the only one remaining of the *serious* dramas that were composed expressly and immediately in honour of Bacchus himself, the patron deity of the theatre. In this instance the glory and the power of Bacchus are not merely the occasion—they form the subject of the tragedy; and the wildly picturesque chorus of Bacchantes, as Schlegel observes, 'represent the infectious and tumultuous inspiration of the worship of Bacchus with great sensual power and vividness of conception.'

An interest yet more peculiar attaches to the 'Cyclops,' as being the sole remaining specimen of the *satyric* tragedy, so called from the chorus of satyrs, which formed an essential part of its composition. This, therefore, seems to be the fittest place in which to give a brief account of that particular and somewhat remarkable dramatic species. From this piece itself and from all collateral evidence, it is to be inferred that the satyric drama was never acted but as a kind of shorter and lighter after-piece, to relieve the minds of the audience, especially the ruder portion of them, after the grave impression of the serious performances: for which purpose, however, it seems to have been very constantly employed, each tragic trilogy being almost invariably accompanied by one of these shorter and lighter productions. Thus we find mention made of five satyric pieces of Æschylus, seven or eight of Sophocles, five of Euripides, besides a number of others by various minor authors. Notwithstanding its burlesque ingredients, the tragic character was so far preserved in the satyric play, that the subject appears to have been always historical, and the action partly serious, though with a fortunate catastrophe. No less than tragedy and comedy, the satyric drama had its peculiar and appropriate stage decorations, representing woods, caves, mountains, and other diversities of the sylvan landscape. Satyrs old and young, with Silenus in his various ages, were distinguished from one another by the variety of their grotesque masks, crowned with long shaggy goats' hair; while the satyrs were negligently clad in skins of beasts, and the Sileni decorated with garlands of flowers skilfully

woven. The satyr parts too appear to have been sometimes acted by pantomimic performers moving on a kind of stilts, to give more completely the appearance of goats' legs. The choral dance, it is hardly necessary to remark, was thoroughly rustic, peculiarly lively, and quite opposite in character to the solemn and impressive movements which accompanied the serious tragedy. The piece of Euripides, as for its subject the adventure of Ulysses with Polyphemus, as related in the 'Odyssey,' with the addition of Silenus and his satyr band; the characters are accurately discriminated and consistently maintained; and the nature of the plot produces such natural contrasts and even blendings of the ludicrous with the horrible, as, above all things else, render this drama unique among the Grecian remains.

The editions of Euripides are numerous. The first edition, that of J. Laskaris, Florence, near the close of the fifteenth century, contains only the Medea, Hippolytus, Alcestis, and Andromache. That of Aldus, Venice, 1503, contains seventeen plays, among which is the Cyclops. Among subsequent editions are those by Canter, Antwerp, 1571; Barnes, Cambridge, 1694; Musgrave, Oxford, 1778; Beck, Leipzig, 1778-1788. The last complete editions are by Aug. Matthiæ, Leipzig, 1813, and by F. H. Bothe, Leipzig, 1825. The editions of separate plays are also numerous; among which that of the Hecuba, Orestes, Phœnisæ, and Medea, by Porson, is the best known. Euripides has been translated into German by F. H. Bothe, and into English by Potter. There are also translations in German of several of the separate plays.

EUROPE is one of the great divisions of the globe, forming the north-western part of the old continent, of which it occupies a little more than two-seventeenths; Asia contains nearly nine-seventeenths, and Africa somewhat more than six. The surface of Europe is calculated to contain about 3,900,000 square miles, if Mount Caucasus and the river Ural are considered as forming the boundary-line between it and Asia.

The name 'Europe' first occurs in a poem attributed to Homer. Herodotus says he does not know how the name came to be given to our continent, except it be from Europa, the daughter of the king of Tyre; but he seems hardly satisfied with this explanation, and we have no other to offer. If the history of the discovery of America were lost we should have a similar difficulty in conjecturing how the New World obtained its name.

Europe is separated from America by the wide expanse of the Northern Atlantic, which washes its western and northern shores, and from Africa by the Mediterranean Sea. The boundary-line which divides Europe from Asia is only in part indicated by nature. This line runs through the Archipelago, the straits of the Dardanelles, the sea of Marmara, and the straits of Constantinople to the Black Sea, which is traversed by it. So far all geographers agree, but they do not agree as to the remaining part of the boundary-line. In the last century this line was drawn through the straits of Yenikale and the sea of Azof, and then along the river Don as far as the point where it approaches nearest to the river Volga, and afterwards along this river to its confluence with the Kama. It then followed the Kama to its sources in the Uralian Mountains, and was continued along the crest of this range to the source of the Kara, and thence along that river to the gulf of Kara.

This boundary-line is now abandoned as being too vague, and another is substituted for it. This new line traverses the Black Sea to the western extremity of Mount Caucasus, south of Anapa; it then runs along the watershed of this range, east-south-east to its eastern extremity, where it reaches the Caspian Sea at Soomgait, north of the peninsula of Absheran. Thence it runs through the Caspian Sea, which it leaves at the mouth of the river Ural, whose course it follows up to its sources in the Uralian Mountains. The Uralian Mountains and the river Kara constitute the remainder of this boundary-line.

The most northern point of the European continent is Cape Nord Kyn, in 71° 6' N. lat.; North Cape, in 71° 10', is on an island called Mageröe. The most southern points are Punta de Tarifa in Spain (36° N. lat.) and Cape Matapan (36° 17') in Greece. The most western points are Cape St. Vincent (9° W. long.), Cape Roca (9° 28'), and Cape Finisterre (9° 27'). The most eastern point is in the Uralian Mountains, west of Ekstarkurg (68° 20' E. long.).

But some of the islands extend farther south and west than the continent. The most southern point of the island of Candia is 34° 55' N. lat. The Basket Islands on the west of Ireland lie in 10° 5' W. long. Cape Fugleberg in Iceland is near 25° W. long., and the most western of the Azores, Corvo and Flores, 31° W. long. The most northern extremity of Nowaya Szemlia is about 77° N. lat. A straight line drawn from Cape S. Vincent to the mouth of the river Kara on the Frozen Ocean, the north-eastern extremity of Europe, does not much exceed 3000 miles, and another drawn from Cape Matapan to Cape Nord Kyn, is 2400 miles long.

I. Progress of Discovery. The earliest notices of the history of Europe are in the writings of the Greeks, who inhabited the south-eastern corner of our continent. From this country the geographical knowledge of Europe extended by degrees to the west and north. Homer, who probably lived about 1000 years before the Christian era, was acquainted with the countries round the Ægean Sea or Archipelago. He had also a pretty accurate general notion respecting those which lie on the south coast of the Black Sea; but what he says about the countries west of Greece, on the shores of the Mediterranean Sea, is a mixture of fable and truth, in which the fabulous part prevails. It would seem that in his age these seas were not yet visited by his countrymen, and that he obtained his knowledge from the Phœnicians, who had probably for some time sailed to these countries, but who, according to the common policy of trading nations, spread abroad false accounts of these unknown regions, in order to deter other nations from following their track and participating in the advantages of this distant commerce. It is probable also that the Phœnicians long excluded the Greeks from the navigation of the Mediterranean; for when the Greeks began to form settlements beyond their native country, they first occupied the shores of the Ægean, and afterwards those of the Black Sea. As the European shores of the Black Sea are not well adapted for agriculture, except a comparatively small tract of the peninsula of Crimea, their early settlements were mostly made on the Asiatic shores, and consequently little addition was made by these colonies to the geographical knowledge of Europe. But the navigation of the Phœnicians was checked in the middle of the sixth century before Christ, apparently by their country being subjugated by the Persians. About this time also the Greeks began to form settlements in the southern parts of Italy and on the Island of Sicily, and to navigate the Mediterranean Sea in its full extent. Accordingly we find that in the time of Herodotus (450 before Christ), not only the countries on each side of the Mediterranean Sea and the northern shores of the Black Sea were pretty well known to the Greeks, but that, following the track of the Phœnicians, they ventured to pass the Columns of Hercules, and to sail as far as the Cassiterides, or Tin Islands, by which name the south-western part of England must be understood. It is even reported that some of their navigators sailed through the English Channel and entered the North Sea, and perhaps even the Baltic. It must be observed however that Herodotus professes himself totally unacquainted with the islands called Cassiterides (iii. 115); and Strabo (104, &c.) expresses a very unfavourable opinion of the alleged northern voyages of Pytheas.

Thus a considerable part of the coasts of Europe was discovered, whilst the interior remained almost unknown. When the Romans began their conquests, this deficiency was partly filled up. The conquest of Italy was followed by that of Spain and the southern parts of France, and not long afterwards Sicily, Greece, and Macedonia were added. Cæsar conquered Gallia and the countries west of the river Rhine, together with the districts lying between the different arms by which that river enters the sea. His two expeditions into Britain made known also in some measure the nature of our island and its inhabitants. Thus in the course of little more than 200 years the interior of all those countries was discovered whose shores alone had been previously known. In the mean time nothing was added to the knowledge of the coasts, the Greeks having lost their spirit of discovery by sea with their liberty, and the Romans not being inclined to naval enterprise.

After the establishment of imperial power at Rome, the conquests of the Romans went on at a much slower rate, and the boundaries of the empire soon became stationary. This circumstance must be chiefly attributed to the nature

of the countries which were contiguous to the boundaries. The regions north of the Danube are mostly plains, and at that time were only inhabited by wandering nations, who could not be subjected to a regular government. Such at least are the countries extending between the Carpathian Mountains and the Black Sea; and therefore the conquest of Dacia by Trajan was of short continuance and speedily abandoned. The countries between the Alps and the Danube were soon added to the empire; but as the nations who inhabited the tracts north of that river had not yet given up a wandering life, they were enabled to elude the Roman yoke. The most important addition to the empire and to geographical knowledge was the conquest of England during the first century after Christ, to which, in the following century, the south of Scotland was added.

Nothing seems to have been added afterwards. The Geography of Ptolemy contains a considerable number of names of nations, places, and rivers in those countries, which were not subjected to the Romans. Probably they were obtained from natives, and from Roman traders who had ventured to penetrate beyond the boundaries of the empire. But these brief notices are very vague, and in most cases it is very difficult to determine what places and positions are indicated.

The overthrow of the Roman empire by the northern barbarians destroyed a large part of the geographical knowledge previously obtained, except perhaps as to that portion of Germany which was subject to the Franks, which by degrees became better known than it was before. But two sets of men soon made their appearance, who contributed largely to extend the geographical knowledge of Europe—missionaries and pirates. The Christian religion had been introduced into all the countries subject to the Roman power. The barbarians who subverted the empire soon became converts to the Christian faith, and some of them ventured among other barbarous nations for the purpose of converting them also. They visited the natives who inhabited the eastern parts of Germany, but here their progress was at first slow; they did not cross the river Oder, or at least they did not venture far beyond it, and the geographical knowledge of this part of Europe was consequently not much increased. The progress of those missionaries was more important who penetrated from Constantinople into the interior of Russia, where they succeeded in converting to the Greek church the different tribes into which the Russians were then divided. This was effected in the ninth century. In the tenth the western missionaries got into Poland, and its inhabitants by degrees became converts. In the beginning of the thirteenth century the Prussians and Lithuanians had not been converted to Christianity, and the attempts of the missionaries were for a long time abortive. Christianity was however introduced among the Prussians during the thirteenth century by force of arms, the knights of St. John having conquered the country. The Lithuanians were the last to embrace Christianity, which was effected by a stroke of policy: their sovereign acquired the crown of Poland by embracing the new faith.

To the pirates we are indebted for our acquaintance with the northern parts of Europe, especially the Scandinavian peninsula; but this was not owing to pirates who went to but to pirates who came from these countries. The Northmen or Normans, who inhabited Denmark, Norway, and Sweden, first laid waste and then settled in part of France, and afterwards conquered England. In their new settlements they maintained a communication with their native countries, which thus gradually became known wherever the Normans had settled.

It is worthy of remark, that no part of Europe has been discovered or explored by travellers who went for that sole purpose. We must however make an honourable exception in favour of Alfred the Great, who sent two noblemen to explore the countries around the Baltic Sea; and in the account of one of them, Otho, or Otter, we find the first accurate notions respecting these regions, especially Prussia, more than 300 years before the Prussians were converted to Christianity.

II. Surveys of Europe. In the beginning of the last century trigonometrical surveys were first made with the view of constructing accurate maps. The first of these surveys was made in France under Cassini. Since that time other European governments have caused some parts at least of their respective territories to be surveyed, es-

pecially Prussia and Austria. England followed in the same steps towards the beginning of the present century, and to this great national undertaking we owe the publication of the Ordnance Maps. The southern parts of Sweden and Norway have likewise been surveyed. Thus we are now in possession of very exact maps of nearly one-half of Europe. The maps of the other countries of Europe rest on the partial surveys of particular districts, and on a greater or less number of astronomical observations; by means of which those parts which have not been surveyed can still be laid down within certain limits of accuracy. Though maps of this latter kind cannot altogether be relied on, the attention paid by all governments to their gradual improvement has been sufficient to correct very gross errors, and thus these maps have by successive and partial improvements attained a certain degree of correctness.

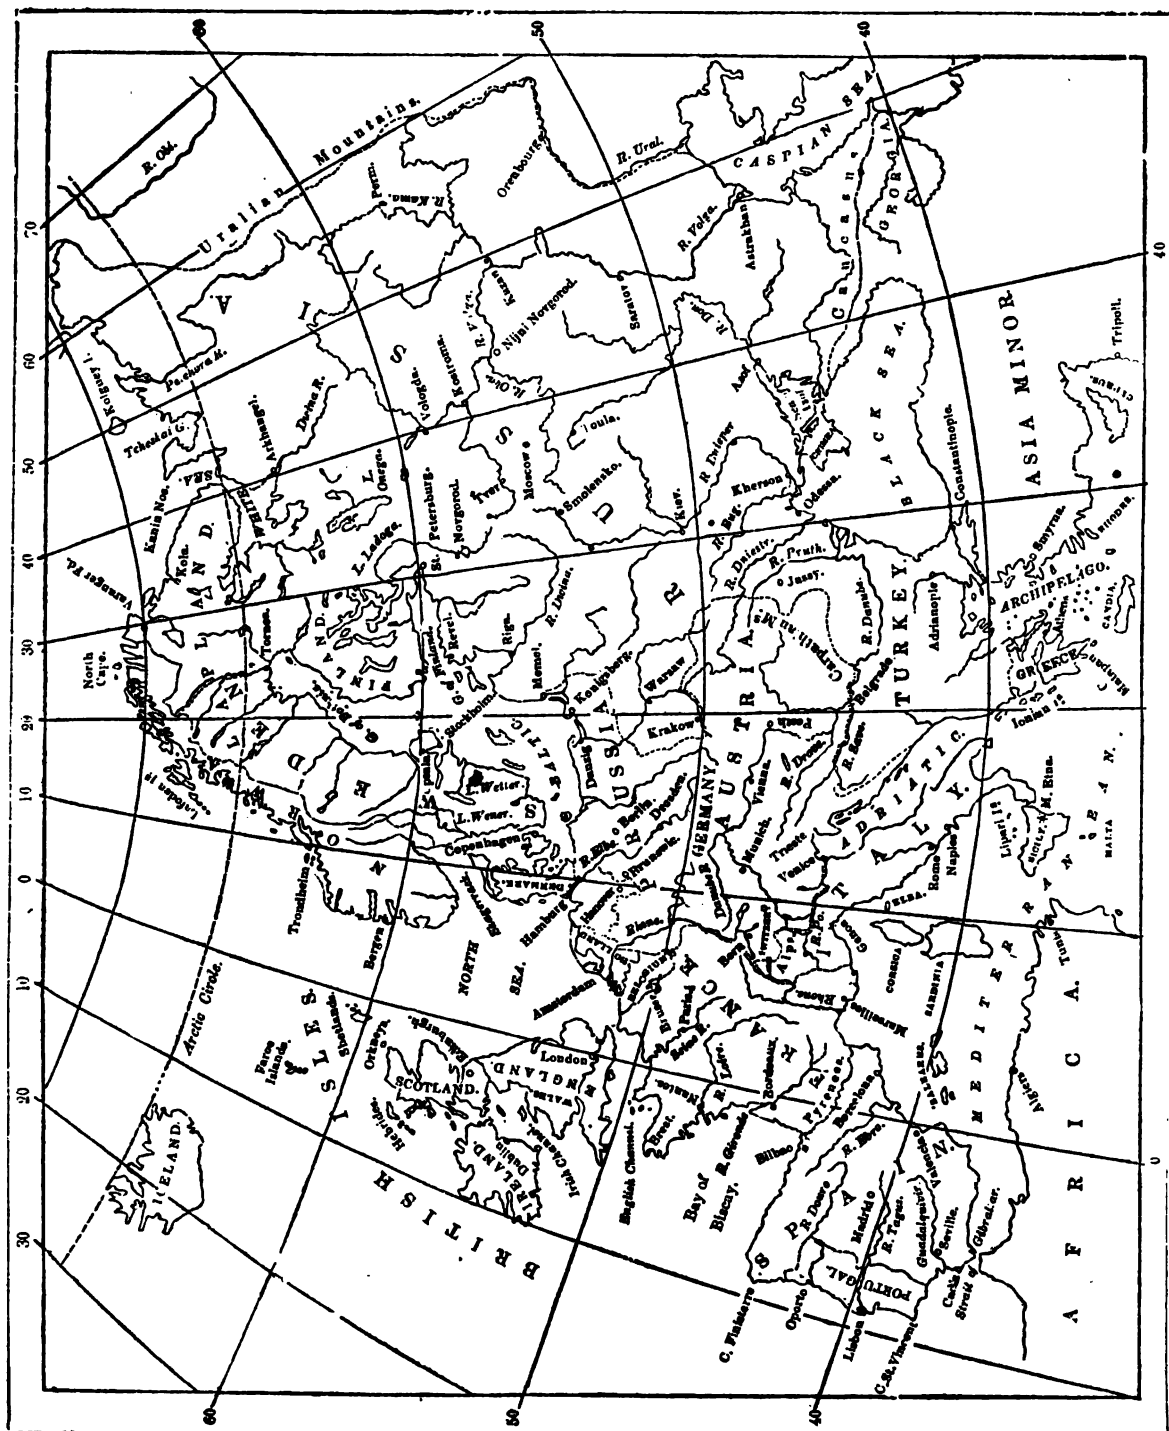

The great increase in commerce and navigation in modern times has convinced the respective governments of Europe of the necessity of a minute and accurate survey of their coasts. But all the coasts of Europe have not been surveyed, though more than half of them have been accurately laid down. The greatest part of the coast of Iceland has been surveyed by the Danish government, and this survey is still going on. The whole western coast of Norway, and east of Cape Lindesnaes, as far as the harbour of Christiansand, was surveyed by the Danes fifty or sixty years ago, but this survey is not considered accurate. The Baltic, including the Kattegat, has been surveyed by the governments to which the coasts belong, but not minutely, nor is the survey considered accurate. The coast between the mouth of the river Elbe and the Dollart was surveyed by the French, and continued to the Schelde by the Dutch. The coast between the Schelde and Gravelines was surveyed by the French, while the English ascertained the outer dangers.

Our government has shown great activity in surveying the British coasts. A minute and accurate survey has been made of the whole eastern coast of Great Britain south of the Murray Frith, and of the whole southern coast, except the tract between Sidmouth and Plymouth. The western coast, including the Bristol Channel, has been surveyed as far as Bardsey Island, and again between Holyhead and Liverpool. Farther north only the Solway Frith is partly surveyed. The coast of Ireland has been surveyed between Dublin Bay and Donegal Bay, inclusive, along the northern shores of the island. The Shetland and Scilly Islands, as well as Guernsey, Jersey, Alderney, &c., have been surveyed completely, but the survey of the Orkneys is not yet terminated.

The coast of France has been surveyed by the French government from the Strait of Dover to Bayonne, except a part of the coast of the Bay of Biscay from about Belle Isle to the Isle of Ré. Most of the harbours on the coast of Spain have been minutely surveyed by the Spanish government.

Most of the islands in the Mediterranean have been surveyed; Corsica and Elba by the French, Sicily and Sardinia by the English. The survey of the Adriatic has been completed by the Austrians and English co-operating. From the Adriatic to the Archipelago the coast has been surveyed by the English, and they have also carried on a survey through the islands and coasts of the Archipelago, which is nearly completed.

III. Physical Geography. Nearly two-thirds of the surface of Europe consist of an immense plain; the remainder is partly mountainous, and partly hilly. The plain occupies the east part of the continent; and the hilly and mountainous countries extend along its western and southern shores. On the eastern boundary the plain extends across the whole continent from south to north, from the mountain-range of the Caucasus and the shores of the Black Sea to those of the Arctic Ocean. In width it extends in this part of the continent from the Ural Mountains to 26° E. long. To the west of this meridian it terminates on the north on the shores of the Baltic, and in the mountain-region of Scandinavia; on the south it continues along the southern shores of the Baltic, and extends even farther west to the shores of Holland opposite the British Islands. If small eminences are not taken into account, it may even be said to continue in a south-west direction through Belgium and the northern parts of France to the banks of the Seine, where it terminates between Paris and the mouth of the river. The portion of the plain, west of the meridian of 26°, is narrowed on the south by the Carpathian Mountains, and other ranges which

are connected with them. Towards the eastern part it extends over ten degrees of latitude, but in its progress towards the west it becomes gradually narrower, partly owing to the mountains advancing farther north, and partly also owing to the seas which form its northern border running farther to the south. Here its mean breadth does not exceed three degrees of latitude, except where the peninsula of Jutland joins it. Along the coast of the North Sea it is still narrower.

By this narrow portion of the Great European Plain and the Baltic (which may be considered as its lowest part, being covered with water), the mountain-regions which constitute the western portion of the Continent are divided into two separate systems. To the north lies the system of the Scandinavian Mountains, and to the south what we shall here call the South European Mountain System.

The Great Plain occupies about 2,500,000 square miles, P.C., No. 605.

the South European Mountain Region 1,100,000, and the Scandinavian Mountain System about 300,000 square miles.

Scandinavian Mountain System.—This comprehends the whole of the Scandinavian peninsula, or Sweden and Norway. A line drawn from the mouth of the river Torneo, at the most northern angle of the Gulf of Bothnia, to the Waranger Fiord, a bay of the Arctic Ocean, would separate it from the north-western part of the Great Plain. A huge mountain-mass occupies the west part of this peninsula. It rises on the very shores of the sea to a height of some hundred feet, and attains, at a short distance from it, an elevation of 3000 or 4000 feet, and frequently more. South of 63° N. lat. it has not the form of a mountain-range, but of a mountain-plain, its surface frequently presenting a perfect level, and in some places swelling into hills. This elevated plain is from 100 to 150 miles across, and as it attains in many parts the line of perpetual congelation, which in this latitude is about 4200 feet above the sea, a great portion of

it is always covered with snow; while other districts, where the snow melts during several weeks in every year, afford pasture-ground. On the plain there rise a small number of summits, among which the Skagstölstind attains 8400 and the Sneehätten 8200 feet. The western side of the plain is indented by deep inlets of the sea, which penetrate from 30 to 60 miles, and even more, inland: the eastern side is furrowed by narrow and deep valleys, of nearly the same length.

North of 63° N. lat. the masses of rocks take the form of a high ridge, the summits of which however rarely extend more than a few miles, and frequently present a sharp-edged crest. Their ascent on the side towards the Atlantic Ocean is rapid and frequently precipitous, a character which increases as we advance farther north, because the highest part of the range gradually approaches the ocean till it constitutes its very shores. The highest summit is the Sulitelma, which rises to more than 6000 feet; but many other parts exceed the snow-line, which varies between 2000 and 3000 feet, and towards the north sinks much lower.

The country to the east of this range, and at the base of it, is more than 1000 feet above the sea, and descends towards the Gulf of Bothnia in long slopes, interrupted by small level plains, and intersected here and there by ridges of hills, running in the direction of the slopes, and approaching in some parts to the shores of the gulf.

Mount Styttfjellen is on the northernmost extremity of the mountain-plain, where it begins to contract to the dimensions of a range. It stands near 63° N. lat., and attains the height of 6486 feet above the sea. From it, as from a common centre, branch off several ridges to the east, south-east, south and south-west, and though they soon sink down to hills, they continue through the south-eastern part of the peninsula, the mean elevation of which is from 300 to 400 feet above the sea, and above which the hills rise a few hundred feet. The Scandinavian ridges enclose the great lakes of Mälarn, Wenern, and Weteren. To the south of the last lake these ridges unite, and form the table-land of Småland, whose surface is on an average about 500 feet above the sea, and which constitutes the most southern extremity of the Scandinavian system. It descends with a gentle slope, towards the east, but very rapidly to the south and west. The peninsula of Scania, which joins it on the south, is low and flat.

The Färoe Islands, which are between Norway, Cape Wrath in Scotland, and Iceland, and nearly equidistant from these three countries, resemble in their conformation the rocky plain of South Scandinavia, rising abruptly from the sea to more than 1000 feet, and presenting on their summits, at an elevation of more than 3000 feet above the sea, generally a level surface. This seems also to be the case with the south-eastern part of Iceland, which is called the Klofa Yökul, where a surface of more than 8000 square miles has never been explored, probably owing to the thick layer of snow which has accumulated on a mountain-plain which rises above the snow-line (3000 feet). The western and northern districts of Iceland, which in general rise only to a moderate elevation, though some isolated ridges and summits attain the snow-line, seem to be the produce of that active volcanic agency which has frequently laid waste this portion of Iceland.

Though the Scandinavian Mountains are not visibly connected with the South European Mountain system, we may perhaps be excused in considering the island of Great Britain as forming such a link. The most northern part of Scotland lies in the same parallel with the southern part of the Scandinavian mountain-plain, and bears a considerable resemblance to it in configuration, consisting of one enormous mass of high rocks, which rise abruptly from the sea, and exhibit on their surface extensive plains, sometimes flat and sometimes diversified with eminences. These plains however are not covered with snow, as they do not rise above 2000 feet, and sometimes attain only 1000 feet, or a little more, an elevation which falls considerably short of the snow-line. This description is applicable to the whole of Scotland north of the Central Grampians (57° N. lat.), with the exception of the greater part of the counties of Caithness and Aberdeen. Even to the south of 57° N. lat. we meet with an elevated plain, about 1000 feet above the sea, which, under the name of the Moor of Rannoch, extends more than thirty miles in every direction between Ben Cruachan and the southern chain of the Grampians. But farther south the Scandinavian character of the country is

lost, and the surface presents the broken character of ridges, valleys, and plains, by which the most northern portion of the South European mountain system is distinguished. This character of the country softens gradually as we proceed farther south. Between 57° and 54° N. lat. the plains are generally of small extent, and a great number of summits rise to 1000, 2000, and sometimes even to 3000 feet and upwards above the sea. South of 54° N. lat. however these lofty elevations, and the comparatively narrow valleys which accompany them, occur only along the western coast of Great Britain, in Wales, and the counties of Devon and Cornwall. East of the Severn the hills do not generally rise so high as 1000 feet, nor are their slopes abrupt; the whole surface consists of gentle swellings and slopes, with wide levels between them. Towards the North Sea it sinks down entirely, and forms (with few interruptions not worth mention in this general survey) a great plain, which occupies the counties of Lincoln, Cambridge, Huntingdon, Norfolk, Suffolk, and Essex. As these flats lie opposite to the western extremity of the Great European Plain, one might imagine that they are a continuation of that plain, and that in the island of Great Britain the three great systems which occupy Europe have their representatives. South of the Thames the country resumes its undulating surface, and approaches in its form to those districts of France which extend along the southern shores of the Channel.

South European Mountain System.—This system, which extends over the whole of South Europe, from Cape La Roca in Portugal to the Straits of Constantinople, presents a surface more diversified in its form than any other portion of the globe of equal extent, China perhaps excepted.

To give greater perspicuity to our description, we shall follow the natural division made by a valley which traverses the whole of this mountain-system from north to south, between 4° and 8° E. long. In the northern part of the valley flows the Rhine from Basel northwards, in the southern the Rhone from Lyon southwards. The middle portion of the valley is occupied by the vale through which the Saone, a tributary of the Rhone, and the Doubs, a branch of the Saone, have their course. The most northern bend of the Doubs lies nearly under the same parallel as Basel, and less than thirty miles from it. In this part there occurs a great depression in the mountains, which divide the Rhine from the Doubs, and the French government have taken advantage of it, by carrying through this depression a canal, which is called the Rhone and Rhine canal, and which unites the Doubs to the Ill, a tributary of the Rhine. The highest part of this canal is nearly 1760 feet above the sea.

In the region which lies west of this long transverse valley, nature has effected another natural division, by forming across the continent a wide plain, skirting the northern side of the Pyrenees, and extending from the Bay of Biscay to the Mediterranean. The western part of this plain is low and flat, and drained by the river Garonne; the eastern is traversed by low hills, but does not rise much higher than the western part. The canal of Languedoc, which is made through this portion of the plain, and unites the Garonne with the Mediterranean Sea, attains at its greatest elevation about 600 feet above the sea.

South of this plain the mountain-chain of the Pyrenees rises with a rapid ascent, and runs across the whole continent from the Bay of Biscay to the Mediterranean. In its central parts it attains a mean elevation of about 6000 or 7000 feet, but a much less height towards its two extremities. The highest summits are upwards of 11,000 feet high, as the Mont-perdu (11,282), the Maladeta (11,500), and there are many more which exceed 10,000 feet. The southern declivity runs out in long mountainous slopes, intersected by deep valleys, and terminates on the banks of the river Ebro. Not far from the western extremity of the Pyrenees another chain branches off, which may be considered as its continuation, since it runs directly to the west. As far as 6° W. lat. it is a single chain, with short offsets, but west of that meridian it divides into several ranges, which traverse the north-western part of Spain in different directions, and terminate respectively at the capes of Ortegal, Finisterre, and Silleiro. This chain, which may be called the Cantabrian range, rises in its eastern parts to about 4000 or 5000 feet, but west of 5° W. lat. it attains a height of 5000 or 6000 feet, and even more.

South of these ranges extends the table-land of Spain, the highest parts of which occur between 1° and 4° W. long., where they are from 2000 to 2500 feet above the level of

the sea. The country east of this line descends rapidly, but in high chains of hills, which contain some mountain summits, to the Mediterranean. On the highest part of the table-land also, a few high mountains occur, as the Sierra Urbion, which rises to 7272, and the Sierra Molina, to 4500 feet, but they do not form continuous chains. The country west of them is a plain, which presents a large extent of level ground, in some places a hilly surface, and in others ridges about 1000 feet above their base. Such are the ridges which divide the basin of the river Tajo from that of the Guadiana. But between the Tajo and the Duero the dividing ridge rises to 5000 or 6000 feet, and attains in the Sierra de Gredos even the elevation of 10,548 feet. In its continuation towards the Atlantic is the Serra d'Estrella, 7524 feet high; and even the Serra do Junto, not far from its termination at Cabo da Roca, is 2319 feet above the sea.

The Sierra Morena, which divides the basins of the rivers Guadiana and Guadalquivir, forms the southern boundary of the table-land. It does not however rise much above it, the mean elevation of this range varying between 3000 and 4000 feet. South of the Sierra Morena the country sinks considerably to the valley of the Guadalquivir, which, in its upper part is only about 1000 feet above the sea, and in its lower course traverses an extensive level plain, which, near the sea, is covered with swamps.

This valley is divided from the Mediterranean by a long chain of mountains running east and west, a considerable part of which is always covered with snow, and has therefore received the appropriate name of Sierra Nevada. The highest summits occur between 3° and 4° W. long., and are the Cerro de Mulhacen (11,660 feet high), Cerro de Machos (11,096), Cerro de Veleta (11,387), Cerro de Caldera (10,793), and Cerro de Fajos Altos (10,778). Many other summits exceed the snow-line, which, in this latitude, is about 9000 feet above the sea.

The country between the plain of the Garonne and the valleys of the Rhone and Rhine presents a different character. It contains also an elevated region, rising to between 2000 and 3000 feet above the level of the sea. But this region is of comparatively small extent, being included between 44° and 46° N. lat., and between 1° and 4° E. long. On its surface rise three chains of mountains, which enclose the valleys of the Allier and of the Upper Loire. The most western part is called the mountains of Auvergne, the middle the mountains of Forez, and the eastern range the Cevennes. The mountains of Auvergne, which exhibit unequivocal signs of volcanic origin, rise in Mount Cantal to 6090 feet, in Mont d'Or to 6200, and in Puy de Dôme to 4840 feet. The country west of them continues high and hilly, but gradually declines in elevation as far as the source of the Charente, from which point to the sea it extends in a low and level plain. The mountains of Forez rise in the Pierre Haute to 6200, and in the Mount Magdalene to 4800 feet. The two chains terminate about 46° N. lat., near the town of Moulins, on the Allier: the country extending to the north and north-west of them has an undulating surface, resembling that of the southern counties of England; it varies from 200 to 300 feet above the level of the sea, and does not exhibit ranges of hills, except in the south of Normandie and in Bretagne, where the hills rise from 1000 to 1500 feet above the sea.

The Covenues, which separate the valley of the Upper Loire from that of the Rhone, rise in Mount Mezin to 5820 feet, in Mount Pilate to 3516 feet, and in Mount Tarare to 4756 feet. South of 47° N. lat. they sink down to the level country, and through the depression thus formed runs the Canal du Centre. North of this canal the chain rises again, but to a less elevation, and is here called the Côte d'Or, which, between 47° and 48° N. lat., terminates in a hilly plain, called the Plateau de Langres. On this plain, which may be about 1000 feet above the sea, several of the rivers of France take their rise, and among others the Seine. From the north-eastern part of this plain issues a chain of low hills, called Monts Faucilles, which, at 48° N. lat., extend eastward till they meet the higher range of the Vosges mountains, which rise in the Ballon de Sulz to 4560 feet. The chain of the Vosges runs parallel to the Rhine and terminates at a short distance from the town of Mayence, in the Mont Tonnerre, or Donnersberg, 2656 feet high. West of this chain, as far as the Côte d'Argonne (a range of high hills which issues from the western extremity of the Monts Faucilles, and separates the valley of the Meuse from the

sources of the eastern tributaries of the Seine), extends a rugged country, intersected by valleys and chains of hills, running in a northern direction, and terminating in the Ardennes and the Eifel, which are hilly and rugged plains, about 1800 feet above the level of the sea, occupying the space between the Meuse and the Rhine as far north as 504° N. lat. West of the Côte d'Argonne extend the dry chalk-plains of Champagne, which gradually subside in the level country which occupies the north of France (the departments of Seine and Marne, Aisne, Oise, Seine Inférieure, Somme, Artois, and Nord), and joins that of Belgium. On this plain only a few hills, and those of very moderate elevation, occur at considerable intervals.

We pass now to that portion of the south European mountain system which lies to the east of the valleys of the Rhone and of the Rhine. Here we find the mountain system of the Alps, which extend from the banks of the Rhone as far east as 18° E. long., and cover an immense tract of country, measuring on an average about 130 miles across. The Alps may be divided into the Higher and Lower Alps. The Higher Alps extend to about 15° E. long., and the Lower between 13° and 18°.

The Higher Alps have the form of a quadrant, beginning on the shores of the Mediterranean, and running first due north, but gradually declining to the east, until they run due east, in which direction about one half of their course continues. Their mean breadth does not exceed 100 miles. Many hundred summits, perhaps not less than a thousand, rise above the snow-line, which here is found at somewhat more than 8000 feet above the sea. The highest summits are Mont Blanc (15,748 feet), Mont Rosa (15,170), and Mont Cervin 14,778 feet above the sea. The valleys by which these mountains are intersected are narrow, and sink down to 2500 and 2000 feet, and still lower.

The Lower Alps do not rise to so great an elevation, few of the summits attaining the snow-line; the highest summit is Mont Terglou, near the sources of the Save, which is 9380 feet above the sea. But the space occupied by these mountains widens considerably as they proceed eastward; between 15° and 16° E. long. they are upwards of 200 miles across, and fill up the whole country between the Adriatic Sea and the Danube. They form also several chains running east and west, between which there are wide longitudinal valleys. East of 16° E. long., where they approach the mountain system of the Balkan, they narrow to about 80 miles, and continue to run along the Adriatic Sea.

The Alps descend with a rapid slope southward to the plain of Lombardy, which extends from the western part of the Higher Alps to the Adriatic. Its length is about 250 miles, with an average breadth of about 50. Its western and higher districts are about 400 feet above the sea, but it gradually subsides as it advances east, till it terminates in a low sandy shore. It is mostly a dead flat, of great fertility, and very well cultivated.

South of this plain extend the Apennines, a mountain-range which, at its western extremity, joins the most southern part of the Higher Alps, and runs in one chain eastward along the plain of Lombardy, from which it rises with a steep ascent. It afterwards turns south and traverses, in different chains, the peninsula of Italy, terminating at its most southern extremity, the Capo dell'Armi, on the straits of Messina, with the Monte Aspro, 5300 feet. The highest part of this range is between 43° and 42° N. lat., where the Monte Corno or Gran Sasso d'Italia rises to 9510, and the Monte Sibilla to 7200 feet. The valleys, which are included between its several ranges, are wide and fertile. In some places the mountains do not extend to the shores of the sea, but leave spacious plains, as is the case along the Adriatic, north of 44°, and again between 42° and 43°. The latter plain, called the Tavogliera de la Puglia, is a savanna, without trees, and of very indifferent fertility. Along the Mediterranean occurs the plain of Terra di Lavoro, in which the town of Naples and Mount Vesuvius are situated, one of the most fertile spots of Europe or the world. Many of the mountainous districts along the Mediterranean are covered with lava.

The Island of Sicily, which is separated from Italy by the strait of Messina, has a hilly surface. Along the northern coast there runs a chain of low mountains, which, in Mount Madonia, rise to 3788 feet. Unconnected with this chain is the volcano of Mount Etna, which attains an elevation of 10,800 feet above the sea. Between the hills, with which Sicily is studded, and sometimes on their very tops, there

are plains of moderate extent, which are sometimes nearly 1000 feet above the sea.

The island of Sardinia consists of two chains of mountains running north and south, and an elevated valley between them. The eastern chain, which is the higher, rises in Mount Schimachiu to 6000, and in the Lyubarra mountains to 5768 feet. The western chain probably does not exceed 3000 feet in elevation. Along the coast there are some low swampy tracts.

The island of Corsica is still more mountainous. If a few small tracts along the eastern shores are excepted, which are covered with swamps, it is everywhere studded with high hills and ridges of mountains. Some of the summits attain a great height. Monte Rotondo is 9060, and Monte Paglia Orba 8691 feet above the sea. The valleys are numerous but very narrow, and of indifferent fertility.

Passing to the countries north of the Alps we find that this great mountain-system, at its western extremity, is bounded on the north by the river Rhone, from the point where it issues from the lake of Geneva to its junction with the river Saone. Immediately north of the Rhone there rises another chain of mountains, different in character and in elevation, called the Jura. This chain extends from the banks of the Rhone, in a north-east direction, to the river Rhine, on whose banks it terminates between the mouth of the river Aar and the town of Basel. Its length may be about 160 miles, and its width less than 20 on an average. It consists of a number of parallel ridges, rising 1000 feet and more on a base which is nearly 3000 feet above the sea. Some of the summits exceed 5000 feet in absolute elevation. The highest are towards the southern extremity of the range. The Pré des Marmiers attains 5640, Reculet 5619, and the Dôle 5500 feet.

Along the south-east side of the Jura, and between it and the Alps, extends the plain of Switzerland, beginning on the shores of the lake of Geneva and terminating on those of the lake of Constance. This plain is between 1250 and 1350 feet above the level of the sea. At each extremity some hills rise to a considerable height, but the central districts exhibit only a strongly undulating surface. Its length may be about 180, but its width does not exceed 20 miles.

Opposite the northern extremity of the Jura, but on the northern banks of the Rhine, rises the Black Forest, a mountain-range, about 20 miles across, which runs parallel to the Rhine, and whose western sides approach the river sometimes within three or four miles. It terminates on the banks of the river Neckar. Its length may be between 130 and 140 miles. The upper part of this range extends in wide plains more than 3000 feet above the sea; the number of summits which rise above these plains is not great. The Feldberg attains 4912 feet, and the Kandel 4160 feet above the sea. The Odenwald, which extends between the Neckar and Mayn, in the same direction, may be considered as its continuation, but it does not attain an equal elevation, its highest summit, the Katzenbuckel, rising only to 2000 feet.

Between the Black Forest and the Odenwald on the east, and the Vosges mountains on the west, lies the valley of the Rhine, which is about 20 miles in width, but the length from Basel to Mayence is not less than 200 miles. At its upper extremity it is 800 feet, but at its lower hardly more than 400 feet above the sea. This valley presents a level surface of great fertility.

The Rhine, below the great cataract of Schaffhausen, is not more than 1000 feet above the level of the sea; but the Danube, at Danauesingen, nearly under the same meridian, is 2200 feet above it; yet between both rivers no mountain-range occurs. With only a hilly surface, and in an extent of hardly 15 miles, the country rises more than 1200 feet. This hilly country may be considered as the commencement of the elevated plain of Bavaria, which extends from the foot of the Alps (about 47½° N. lat.), between the Black Forest and Odenwald on the west and the Böhmerwald (forest of Bohemia) and Fichtelgebirge on the east, to the Thüringer Wald and the Rhöngebirge (51° N. lat.). The length of this plain is about 180 miles, and its breadth about the same. The western part of the plain, which joins the Black Forest, is hilly, and intersected by a mountain-ridge, called the Raube Alp, which runs along the northern bank of the Danube for 70 or 80 miles, with a mean width of about 16 miles. South of this ridge the country is nearly 2000 feet above the sea, but north of it less than 1000 feet. The eastern part of the plain, south of the Danube, is nearly a level, which sinks gradually and almost imperceptibly

from the foot of the Alps towards the river. The town of Munich, which nearly occupies its centre, is 1664 feet above the sea, and Ratisbon, on the Danube, more than 1000 feet. That part of the plain which lies north of the Danube has an undulating surface, upon which some hills rise towards the banks of the river Mayn. From the banks of the Danube the country rises slowly, but hardly more than 150 feet above the river, when it forms the water-shed between the Danube and Mayn, and begins to subside towards the bank of the last-mentioned river, where it is only from 600 to 800 feet above the sea.

The elevated plain of Bavaria does not extend far enough north to reach the Great Plain, being divided from it by a mountain-region which extends between 50½° and 52° N. lat. over the whole of Germany, from the very banks of the Rhine to the Fichtelgebirge and Erzgebirge. This region, which has a width of about 100 miles, contains a great number of ridges, bearing different names. Their mean elevation is about 3000 feet, and the highest summits attain upwards of 4000. The most northern of these ridges is the Harz. For a more peculiar account of them we refer to GERMANY.

The countries which we have hitherto considered are to the north of the Higher Alps. To the north of the Lower Alps, and divided from them only by the narrow valley of the Danube, is another system of mountains, which encloses, in the form of a quadrilateral figure, the kingdom of Bohemia, and might therefore be called the Bohemian mountains. The several ridges of which it consists have different names. They attain a mean elevation of 3000 or 3500 feet above the sea; their highest summits rarely exceed 5000 feet. The great valley of Bohemia, which is enclosed by these ridges, is subdivided into numerous smaller valleys by the lower ridges, which advance into it from those which surround it. Near the higher ridges the surface of these valleys is 1500 feet and upwards above the sea, but they subside rapidly towards the middle of the great valley, where they are not more than 700 and 900 feet above the sea. Where the Elbe carries off the waters of Bohemia it is somewhat less than 400 feet above the sea.

At the eastern extremity of this mountain-system, where the rivers Oder and Morava take their origin, the Carpathian Mountains commence. They run first due east, then decline to the south-east, and when in that direction the range has passed 26° E. long., it turns suddenly to the west, and having proceeded in that direction to 23° E. long. it gradually declines to the south, and terminates on the banks of the Danube on both sides of the meridian of 22°. The length of this range does not fall much short of 800 miles; its breadth is not very considerable, in a few places only exceeding 70 or 80 miles. Its mean elevation, may be between 3000 and 4000 feet; but in two places it rises much higher: Tatra Mount, which is intersected by 20° E. long., is an enormous mass of rock, about 50 miles long and 30 wide in the central parts, whose surface is about 7000 feet above the sea. Above this huge mass there rise about ten peaks which exceed 8000 feet. The highest is the Peak of Lomnitz, which rises to 8675 feet above the sea. The Peak of Eisthal (dale of ice) is 8640, and the Krywan 8150 feet high. Elevated summits occur again on the most southern part of the range, where the Buzesd attains 8700 feet, and Mount Surul 7572 feet. Towards the great plain, and on the north and east, the range sinks with gentle slopes, forming no offsets, except a few short ones at the sources of the rivers Pruth, Serith, and Suezava, between 47° and 48½° N. lat. But some considerable offsets occur towards the two extremities of the range. Four chains are detached from it between 18° and 20° E. long., which run southward and terminate not far from the banks of the Danube, after traversing the north-western part of Hungary: they are comprehended under the general term of Hungarian Ore Mountains, from their being rich in gold and silver ore. The valleys between them are wide and fertile. No considerable chain branches off from the middle part of the range, but from its eastern extremity four or five ridges issue: these ridges running in a western direction some hundred miles, traverse Transylvania, and render the whole of this country a succession of mountains and wide valleys, which are generally very fertile.

Between these offsets of the Carpathians on the east, the principal range, and the Hungarian Ore Mountains on the north, and the eastern termination of the Alps (16° E. long.), lies the plain of Hungary, the most extensive that is

included within the South European mountain-system. It extends from north to south about 300 miles, and its mean breadth is not less. The Danube traverses it. To the west of the Danube is a small range on the plain, the Bakony Mountains, which rise in their highest part somewhat more than 2000 feet; and farther south (near 46° N. lat.), the hills of Fünfkirchen occur: but both these ranges occupy only a small surface. The plain east of the Danube is a dead flat. That portion which lies west of the Danube is fertile, as well as that which skirts the Hungarian Ore Mountains, but by far the greatest part of it is either covered with sand or swampy, and affords only indifferent pasture. This great plain towards the south is only 300 feet above the sea, but towards the north it rises to 400 and 450 feet.

South of the Carpathian Mountains, and between them and the lower course of the Danube, extends the plain of Wallachia, 250 miles in length from west to east, and about 150 miles in breadth. It is generally level, but towards the mountains undulating; in its lower parts along the Danube it is only about 100 feet above the sea. It is of great fertility, but in many places swampy.

The third great division of the South European mountain-system is formed by the Balkan, which, with its numerous branches, traverses the most eastern of the three great southern peninsulas, which advance from the body of the continent into the Mediterranean Sea. The Balkan range is not disjoined from the Alps by any natural separation, but is so closely connected with them as to form a continuation of that mountain-system. Geographers have however assumed a dividing line about 18° E. long.

From this line the principal range of the Balkan runs in a south-east direction till it reaches 22° E. long., from which point it continues in a general due east direction till it terminates on the shores of the Black Sea in Cape Eminah. The length of this chain may be about 600 miles. Its elevation is considerable west of 24° E. long., especially between 22° and 24° E. long., where a great part of the chain, called here Shardagh (Scardus) and Egrisu Dagħ, is covered with perpetual snow, which shows that it must rise at least to 9000 feet. East of 24° E. long. it does not rise so high, and it is supposed that in this part its mean elevation varies between 3000 and 4000 feet. The extent of country covered with this range and its numerous branches is very great. West of 24° E. long., all the immense tract which lies between the Save and Danube on the north and the Adriatic as far south as Cape Linguetta or Karaburnu, presents nothing but a continuous succession of high mountains and generally very narrow valleys, and is probably the most rugged part of Europe, as it is certainly the least known. The country which lies between the great range and the Danube, east of 24°, is only mountainous near the foot of the range, for its offsets rapidly decrease in height, and subside as they approach the river, on the banks of which the country exhibits merely an undulating surface.

From the southern side of the Balkan three ranges branch off: the eastern, which leaves the principal range about 70 or 80 miles from the Black Sea, is called Strandja or Stanches Dagħ, and runs south-east, parallel to the Black Sea, but gradually approaching it. About 50 miles west of Constantinople, it turns to the south, and terminates at the mouth of the river Maritza. The latter portion is called Tekir Dagħ. Both parts are of moderate elevation. The second range branches off from the Balkan east of 24° E. long., and runs first south-east till it approaches the Ægean Sea, within 20 or 30 miles, when it turns east and terminates nearly opposite the Tekir Dagħ, on the banks of the Maritza. This chain, called Dispot-Dagħ, rises to a considerable elevation, though none of its summits seem to attain the snow-line.

The country between the Strandja Mountains, the Dispot Dagħ, and the Balkan is only mountainous towards the two last-named ranges; the greater portion of it rises only into hills, separated from one another by wide valleys, which in several places spread out into plains of moderate extent. This country possesses great fertility, and is one of the finest parts of Europe.

The third and most considerable range, which branches off from the Balkan on its southern side, since no modern name has been assigned to it, may be called by the ancient denomination of Pindus. It leaves the principal range near 22° E. long., and runs south, forming the watershed be-

tween the rivers which fall into the Adriatic and those which empty themselves into the Ægean Sea. It may be considered as terminating south of 39° N. lat. with Mount Veluchi (7657 feet high). The length of this chain is upwards of 200 miles; and the greatest part of the upper range is for eight or nine months, and some summits probably the whole year round, covered with snow.

The country between this range and the Adriatic is very mountainous: it generally consists of high ranges and deep and narrow valleys, though in some places there are elevated plains of moderate extent, as that on which the town of Joannina (or Yanina) is built, which probably is at least 1500 feet above the sea.

The countries to the east of the Pindus range are less mountainous. That portion which extends north of 40° N. lat. contains high summits and ridges near the great range; but as it approaches the sea the mountains subside into hills, and the valleys widen by degrees into plains. Mount Athos, or Hagion Oros, is an isolated mass which terminates the most eastern of three projecting tongues of land, and rises to the height of 6349 feet.

Near 40° N. lat. a lateral chain branches off from the Pindus range. It is called Volutza Dagħ and runs east, terminating near the sea in Mount Olympus, which attains the height of 6520 feet. Near 39° N. lat., between Mount Itamo (5789 feet high) and Mount Veluchi (7657), two lateral chains branch off to the east and terminate respectively on each side of the Gulf of Zeitoun. In the northern range, called by the Greeks that of Othrys, the Ieracovouni rises to the height of 5670 feet. In the southern range, known among the ancients by the name of Oeta, the Katavothron rises to 7070 feet. Between the Othrys, the northern of these two ranges, and the Volutza Dagħ is the plain of Thessaly, celebrated from the most remote antiquity for its beauty and fertility. Though it extends nearly 60 miles from north to south it is much narrowed by hills, which advance from the neighbouring ranges 15 or 20 miles into the plain, and on the sea side it is shut in by a barrier of mountains.

The country south of the Oeta range and the Gulf of Arta is mountainous in its western districts, but farther east it assumes a more undulating surface, though some of its numerous elevations rise to the height of mountains, at Mount Parnassus, which is supposed to rise to 6000 feet, and several others are perhaps not much lower.

Round the lake of Topolias, the ancient Copais, there is an extensive plain, whose surface is several hundred feet above the sea level and walled in on the east by the high mountains which line the western margin of the Euripus. Some of these mountains are above 2000 and others above 3000 feet high.

The peninsula of the Morea is united to the continent by a rocky isthmus which in one part contains a considerable depression, across which several attempts were made in ancient times to cut a canal. The Morea preserves the character of the countries which are dependent on the Balkan, being very mountainous, especially in its eastern parts, where several lofty ranges run in a south-eastern or southern direction. Mount Zyria, the Cyllene of the Greeks, seems to be the knot where the ranges unite. Cyllene is 7744 feet high, but the Pentedaktylon (Taygetus), in the southern part of the peninsula, rises to 7920 feet. The central districts of the peninsula contain some elevated plains which are probably as high as the interior of Spain. Tripolitza is 2224 feet above the sea, and Madrid, according to Bauza, is 2222 feet above the same level. In the western districts the mountains gradually subside into hills; and several plains of moderate extent occur along the bay of Koron and the banks of the Alpheius.

The mountains of the island of Eubœa, which lies parallel to the coasts of Attica and Eubœa, belong to the mountain system of Othrys and of Oeta, from which it is separated on the north and west by those prodigious fissures which form the sea-valleys or channels of Trikir and the Euripus.

The Great Plain.—Beginning at its western extremity, we find that between the mouths of the Schelde and the Elbe, the country hardly in any place rises to more than 100 feet above the sea. Its surface is covered with a succession of moors and heaths, ill adapted for agriculture, except in the alluvial tracts along the rivers. But this sterile country is surrounded by fertile marshes, which run along the shores of the North Sea, and are so low that it is

necessary to defend them by dykes from the invasion of the waves. The width of these marshes varies from one to four or five miles, except at the western extremity, where they occupy the whole of the province of Holland. Towards the banks of the Elbe the soil mostly consists of sand, but it begins here to be covered with forests.

The countries between the Elbe and the Vistula are more fertile, though the sandy soil prevails, especially towards the north; yet even here extensive tracts of fertile land occur. Towards the mountain region which borders on it on the south, especially in Silesia and the southern districts of Poland, the country may be considered as rather fertile. No marshes occur along the Baltic, but at the south-western extremity of this sea a series of small lakes begin which run parallel to the shore and follow its sinuosities. Their distance from the sea is about 50 miles, and they are situated on the highest part of the plain, perhaps at a mean elevation of 150 feet. They form the watershed between the small rivers which fall into the Baltic and those which run southwards into the interior of the plain.

That portion of the plain which we have so far noticed is drained by rivers which originate in the mountain-region south of it and traverse it in a north-western or northern direction. But east of the upper branches of the Vistula, the rivers originate in the plain itself which they drain. These rivers run either north-west and north to the Baltic and White Seas, or south and south-east to the Black and Caspian Seas. The watershed which separates their sources begins about 23° E. long. on the northern declivity of the Carpathian Mountains, in a range of hills which separate the Saan, a branch of the Vistula, from the sources of the Dniester. This range of hills runs in a north-eastern direction to the sources of the Bug, another tributary of the Vistula, where it turns north, and is lost in the plain. It is soon replaced by an immense swamp, the largest in all Europe. The principal body of this swamp covers nearly the whole basin of the river Priepet, which extends about 200 miles east and west, with an average breadth of 100 miles. It also continues northward, but with a much diminished width, between the sources of the Niemen, Beresina, and Vilia, and terminates on the banks of the Düna, south of Dünauburg and Polotsk. The surface covered by this swamp is perhaps not inferior to that of England. Some parts of it are wooded. We do not know what is the elevation of this swamp above the level of the sea, but we may conjecture that it is not less than 300 feet. Towards the northern extremity of the swamp the watershed turns due east, and is here formed by an undulating country which separates the upper courses of the rivers Düna and Dnieper. But where it approaches the sources of the Volga it turns first north-east and then north, and here it is overtopped by steep and rocky hills, called the Hills of Waldai, which rise highest in the neighbourhood of that town, where they attain an elevation of 1200 or 1300 feet above the sea. This seems to be the highest point of the watershed. It continues in a northern direction till it passes 60° N. lat. between the lakes of Onega and Bielo Ozero, and then turns south-east to the sources of the Suchona, the principal branch of the Dwina: thence it proceeds in an east-north-east direction to the sources of the Petshora, which falls into the Arctic Sea, and of the Kama, a branch of the Volga, where it terminates in the Uralian range. That portion of the watershed which is east of the hills of Waldai is covered with an immense forest, called the Forest of Volkhonsky.

The country north of the watershed is, in general, of moderate fertility; there are some districts which are covered with sand, while others have a rich soil. That series of small but very numerous lakes which we noticed in the western part of the plain continues in this at nearly the same distance from the Baltic, forming likewise a subordinate watershed. East of 22° E. long. however it stretches farther inland, approaching the northern extremity of the great swamp, and then continues north of it along the watershed to the hills of Waldai, and still farther in the Forest of Volkhonsky, where it terminates near 35° E. long.

The country north of 60° N. lat. is only in a few places fit for agriculture, partly on account of its cold climate, and partly on account of the sterility of the soil. That portion which lies west of the lake of Onega is rocky, and is mostly traversed by ridges of rocky hills, which lie in a north and south direction. These hills rise in some places to 500 or 600 feet above the sea. Most of them, as well as the level

country between them, affords excellent pasture ground. This region is remarkable for its numerous large lakes, which cover nearly one-fourth of its surface, and are connected by short natural channels. The largest of these lakes are the Ladoga, Onega, Saima, and Enara.

There are only a few lakes east of the lake of Onega. It appears that the watershed here rises to a greater elevation, and that the slope of the country is more regular. Its southern districts are still covered with forests, and a few spots are cultivated; but its northern districts extend in immense plains, covered with moss, which by attracting the water of the melting snow renders them impassable for the greatest part of the summer. A few rocky ranges of hills occur on this plain, but we are not acquainted with their direction and elevation.

By far the greater part of the Great Plain extends to the south of the watershed. Contiguous to its southern declivity extends a country of great fertility, from 300 to 400 miles in width. It begins on the west near the foot of the Carpathian Mountains, and terminates on the east where the Volga begins to run south-south-west. The parallel of 49° forms its southern boundary, as far east as about 40° E. long., whence it runs in a north-eastern line to the town of Simbirsk on the Volga. The town of Moskwa, situated nearly in its centre, is 480 feet above the sea. The country east of the Volga, as far as the Uralian range, is mostly covered with hills, and is even mountainous, being traversed by the offsets of the great range: it is of moderate fertility in the valleys, which are frequently wide. The hills and lower parts of the mountains are covered with forests.

To the south of this region extend the deserts which are called the Steppes. They may be divided into the Higher and Lower Steppes, the line of separation between them being the high ground which extends north and south between the Don and Volga. The Higher Steppes occupy the western part of the plain, extending south of the fertile region to the very shores of the Black Sea. Their elevation above the sea may be between 150 and 200 feet. They are without trees, produce only in some places a few shrubs, and are overgrown in the early part of the summer with a coarse grass, which affords very indifferent pasture. In the latter part of the summer and autumn their dry brown surface shows no sign of vegetation. Agriculture can only be carried on in the narrow bottoms along the rivers. The peninsula of the Crimea is connected with them by a low isthmus. Three-fourths of its surface resemble the Lower Steppes; but on its southern shores rises a mountain-range, whose highest summit, the Chatyr Dag, is 5040 feet. The valleys of this range are fertile.

The Lower Steppes are at the eastern extremity of Europe, extending between the southern extremity of the Uralian range and Mount Caucasus along the banks of the river Ural, and on both sides of the lower course of the Volga. They occupy a space more than twice as large as the area of the British Islands. The southern part is lower than the level of the sea, the Caspian Sea being more than 300 feet beneath it, and the adjacent country rising very little above its shores. The town of Saratov on the Volga, more than 300 miles from the Caspian, is not above the sea-level. We do not know how much higher the northern districts of these steppes rise, nor if their soil differs from that of the southern, which are covered with a fine sand, intermixed with shells, producing no trees nor shrubs, but at certain seasons a scanty grass. This soil is strongly impregnated with saline matter, and most of the lakes which occur here contain such a quantity of salt that it crystallizes in summer, and supplies the greatest part of the inhabitants of Russia. In no part of these steppes are any traces of agriculture visible except in the neighbourhood of Astrakhan.

We shall conclude this general survey of Europe by observing, that the Uralian range, which runs about 1500 miles, first south and then south-south-east, rises in its highest summit, the Pawdinskoi Kamen, to more than 6800 feet above the sea; that the Lower Steppes extend east of the river Ural far into Asia; and that Mount Caucasus, though only few of its summits attain the snow-line, rises in its highest summit higher than the Alps, Mount Elboor attaining an elevation of 16,800 feet.

Looking at the map of Europe we find that its coast-line is formed alternately by wide projecting promontories and deep bays, which divide them from one another. This peculiarity has led a large proportion of its inhabitants to a

sea-faring life, and as the winds and weather in the waters that surround this continent are not regulated by the seasons of the year, but are subject to continual changes, this circumstance has given to them that boldness in maritime enterprise which forms the most distinguishing feature in their character, and raises them above most other civilized nations of the globe.

Europe, in fact, considered by itself, is only a large peninsula, which is further cut up into a great number of smaller peninsulas by the interior seas and gulfs which penetrate far inland into the main mass of the peninsula; consequently, in proportion to its surface, it presents a much greater extent of coast than any other of the great divisions of the globe, as will appear by the annexed table, which however must be considered only as a rough approximation:—

| | Surface in square miles. | Coast-line. Miles. | Ratio of one mile of coast-line to area in square miles. |
|---------|--------------------------|---|--|
| Asia | 18,000,000 | 35,000; or including the islands, 40,000. | 500; or including the islands, 420. |
| Africa | 14,000,000 | 18,000 | 900 |
| Europe | 3,900,000 | 20,000 | 195 |
| America | 15,000,000 | 32,000 (without the coast of the Arctic Sea). | 470 |

The Atlantic Ocean, with which all the seas that wash the shores of Europe are connected, except the Caspian (and this is rather to be considered as an immense inland lake), forms the Bay of Biscay between Cape Finisterre and the island of Ushant; the English Channel between the northern coasts of France and the southern coasts of England; St. George's Channel, between Great Britain and Ireland; and the North Sea, which separates Great Britain from the Netherlands, Germany, Denmark, and Norway. The North Sea might be considered a closed sea, as it is united on the south to the great expanse of the Atlantic only by the straits of Dover, which, between the South Foreland in Kent and Cape Grisnez in France, is only eighteen miles wide, and by the comparatively narrow channel called the English Channel, if it were not on the north connected with the Atlantic by the open and wide expanse of sea which separates North Britain from Norway.

The close seas, which are united to the Atlantic by straits, are the White Sea, the Baltic, and the Mediterranean; with the latter the Black Sea and the Sea of Azof are connected.

The White Sea, the smallest of these inland seas, covers an area of only about 40,000 square miles. The strait by which it is connected with that portion of the Atlantic which is called the Arctic or Icy Sea, is about 200 miles long, and of considerable width, its narrowest part being from 30 to 40 miles across. This sea is entirely or partially covered with ice during four or five months of the year. Into its eastern part the Dwina falls; and into the wider part of the strait the river Mezen.

The Baltic is connected with the North Sea by a channel with about 80 or 90 miles of average width; this channel branches off from the North Sea in an east-north-east direction, but afterwards suddenly turns south. That portion which is connected with the North Sea and extends to the east-north-east is called Skagerack, or the Sleeve by the British sailors, and the other part, which lies south and north, the Cattegat. At the southern extremity of the Cattegat are the three straits by which the Baltic is entered like three gates. The Sound, between Zealand and Sweden, is the passage generally taken by vessels; it is at the narrowest place only about two miles wide. The Great Belt is in the middle between Zealand and Fünen, and eight miles across at the narrowest place. The Little Belt, which is only three-quarters of a mile wide where narrowest, separates the island of Fünen from the peninsula of Jutland. The Baltic forms three great gulfs—those of Riga, Finland, and Bothnia. Receiving, by the numerous rivers which fall into it, great masses of fresh water, it is less salt than the Atlantic. This circumstance, and the small depth of its waters, sufficiently explain why ice is formed nearly every year along its shores, and the navigation is interrupted for three or four months.

The Mediterranean is connected with the Atlantic by the strait of Gibraltar, which is about ten miles across. It is the largest of the close seas which wash the shores of

Europe, but it receives the drainage of a comparatively small portion of its surface; the number of rivers which fall into it is very considerable, but few of them run 100 miles. Evaporation carries off a larger portion of its waters than is supplied by the rivers which flow into it, and there is accordingly a strong current setting continually through the straits of Gibraltar. A motion of its waters towards the east is proved by vessels requiring a greater time to sail from the coast of Syria to Gibraltar than from Gibraltar to Scanderoon. Its waters are saltier than those of the Atlantic. It also forms several large gulfs; as, on the European side, the Bay of Lyon, that of Genoa, the Adriatic, and the Ægean Sea, or Archipelago. By means of this sea the Straits of the Dardanelles (one mile across where narrowest), the Sea of Marmara, and the channel of Constantinople (six furlongs across at the most narrow place), the Mediterranean is united to the Black Sea, from which a constant current pours through the narrow straits into the Ægean. [EUBŒA.] The Black Sea is connected by the strait of Yenikale with the Sea of Azof. It is less salt than the Mediterranean, and its northern shores in winter are frequently fringed with ice.

The Caspian Sea, whose north-western shores only are included in Europe, is the largest of the numerous seas without an outlet which occur in the north-western regions of Asia. Ice is formed every winter along its northern shores. Its waters are salt, but only in a slight degree.

| Seas. | Extent, sq. miles. | Specific gravity of its waters. |
|--|--------------------|---------------------------------|
| Mediterranean | 760,000 | 1.0293 |
| Black Sea and Sea of Azof | 190,000 | 1.0142 |
| Caspian | 180,000 | |
| Baltic | 160,000 | 1.0400 |
| White Sea | 40,000 | 1.0190 |
| Atlantic Sea, in the northern hemisphere | | 1.0283 |

When we consider these seas as the receptacles of the drainage of the adjacent countries, we find that those towards the east have the most extensive basins. The basin of the Caspian Sea, though it is only drained by two large rivers, the Volga and the Ural, occupies a surface of 850,000 square miles, as far as it belongs to Europe, and runs with its northern boundary along the parallel of 60° N. lat. The basin of the Volga, the largest of the rivers of Europe, contains an area of above 750,000 square miles. The basin of the Black Sea is somewhat larger. Its south-western boundary is formed by the principal range of the Alps; its north-western by a line drawn from Switzerland to Moscow; and another line from this city to the mouth of the Volga, forms its north-eastern border. Its area in Europe is rather more than 900,000 square miles. The countries which are comprehended in the European part of its basin are drained by the Danube, Dnieper, Dniester, Don, and Kuban, and their tributaries. The basin of the Baltic is nearly equal in extent, including the Cattegat and Skagerack, being on all sides surrounded by countries which belong to Europe; their basin extends over a surface of nearly 900,000 miles, though perhaps none of its rivers rise more than 350 miles from its mouth in a straight line. The great rivers which fall into the Baltic are the Oder, Vistula, Niemen, Düna, Nawa, and the numerous rivers descending from the Scandinavian range, as the Tornea-elf, Calix-elf, Lulea-elf, Pitea-elf, Scatele-elf, Umea-elf, Angerman-elf, Indals-elf, Liunga-elf, Ljusna-elf, and Dal-elf; and likewise the Götha-elf, and Glommen, which fall into the Cattegat and Skagerack. The basin of the White Sea is drained by the Dwina, the Mezen, and Petshora, and some other smaller rivers, and occupies a surface of about 400,000 square miles. Though the coast-line of the Atlantic from Cape North Kyn to Cape Tarifa, comprehends the whole of the shores of the western declivity of Europe, including the British islands, its basin probably does not much exceed 600,000 square miles. No considerable river flows into the Atlantic between Cape North Kyn and the mouth of the Elbe. Into the North Sea there flow the Elbe, Ems, the Rhine, Schelde, and of the rivers of Great Britain, the Spey, Tay, Forth, Humber, and Thames; into the English Channel, only the Seine; into St. George's Channel, the Severn; into the Bay of Biscay the Loire and Garonne; and immediately into the Atlantic the Clyde, the Shannon, the Duero, Tajo, Guadiana, and Guadalquivir. The basin of the Mediterranean, including the Archipelago, is by far the

smallest of all those which belong to the inland seas of Europe, comprehending only about 250,000 square miles. The largest of its rivers, the Rhone, flows only 500 miles, including its bends. The other rivers, which are of a considerable length, are the Ebro in Spain; the Po and Tiber in Italy, and the rivers of Albania and the Maritza in Turkey. All the rivers which drain the basins of the Mediterranean and Atlantic Sea rise in the South European mountain region; those which fall into the Black Sea rise within the Great Plain except the Danube and its tributaries, which drain about one-third of the mountain region. The rivers which run to the Caspian rise partly on the watershed of the Great Plain, and partly in the Uralian range; and the same is the case with those that drain the basin of the White Sea. The rivers which flow from the east into the Baltic rise on the Great Plain; those which flow into it from the south rise on the edge of the mountain region; and those which fall into it from the north descend from the Scandinavian range.

Climate.—The climate of Europe presents great differences, if we compare it with that of those countries in other divisions of the globe, which lie within the same parallels. It is a well-established fact, that the eastern coast of North America is much colder than the western coast of Europe, under the same latitudes. This difference is in some places equal to 10° of latitude. Thus we find that the mean annual heat of London (51° 31' N. lat.) is nearly 50° Fahr., while at Quebec (46° 48' N. lat.) it hardly exceeds 42° Fahr. At Lisbon (38° 43' N. lat.) it is 61½° Fahr., and at Williamsburg in Virginia (37° 5' N. lat.) only 56° Fahr. It is however worthy of remark, that the eastern countries of Europe, especially those north of the Black Sea, are much colder, and approach in climate those of the eastern coast of America. At Moscow (55° 47' N. lat.) the mean annual heat is not quite 38° Fahr., whilst at Edinburgh (55° 58' N. lat.) it exceeds 47° Fahr.

This difference in the climate of Europe may perhaps be explained by the circumstance that this continent is enclosed on most sides by seas whose water is warmer than that of the ocean at large. The water of the Mediterranean is from 4° to 5° Fahr. warmer than the ocean without the straits. Between America and Europe the warm water of the gulf stream, which exceeds the heat of the other water of the Atlantic by 8° or 10° Fahr., covers a surface not inferior to that of the Mediterranean, and the exhalations of this immense expanse of warm water are carried by the prevailing western and south-western winds to the western shores of Europe. Besides this, the water in the sea between Spitzbergen, Greenland, and the coast of Norway indicates a higher degree of temperature when drawn from some depth under the surface of the sea than on the surface itself. This has been proved by the experiments of Sir John Franklin and Captain Scoresby, though the contrary is the case in all other seas, as far as we know.

Dr. Brewster however thinks that there are two frigid poles in the northern hemisphere, and that the degree of warmth increases with the distance from the meridian in which these poles are situated. By comparing the few exact meteorological observations which have been made in remote countries, he is induced to infer that these meridians are about 90° from the western countries of Europe, and hence he presumes we may account for the greater mildness of the climate in these regions. The observations which the latest traveller through the north of Asia, Dr. Erman, has made in those remote countries, seem rather to confirm than to contradict the theory of Dr. Brewster.

With respect to climate, Europe may be divided into three zones, the northern, the central, and the southern. These zones may be separated from one another by two lines, of which the northern begins near 60° N. lat., on the western coast, and terminates between 55° and 54° N. lat. on the Uralian range on the east; the southern commences about 48° N. lat. on the west, and terminates on the east at the mouth of the Danube (45° N. lat.). In the northern zone only two seasons occur, summer and winter, the former lasting about three months (June, July, and August), and the latter nearly nine months. These seasons are separated by a spring and autumn of a few days, rarely two weeks' duration. In summer the heat is very great, and the vegetation inconceivably rapid. The winter is severe and boisterous, and brings down immense quantities of snow. In the central zone the four seasons are distinct, and the passage from heat to cold and *vice versa* is very gradual. The heat is less than in the northern zone, and so is the

cold during the winter; still frost prevails during two, three, or four months, and snow is common except on the coasts. In the southern zone frost is either not felt at all or only during a few days; and snow is of rare occurrence, or it does not lie on the ground for more than a few days. Vegetation accordingly is very little interrupted. But the countries within this zone have abundant rains during the last three months of the year, and are subject to great and long droughts in summer. These droughts frequently continue for four or five months, and in some places occasionally for eight or nine months.

IV. *The Man of Europe.*—Nearly the whole population of Europe belongs to that race which is comprehended under the name of the *Caucasian* race; but along the Uralian range, and at the most northern extremity of the continent, a few nations occur which belong to the *Mongolian* race; to which must be added the *Magyars*, who inhabit nearly the centre of Europe (Hungary).

The inhabitants of the Caucasian race may be divided into three great branches and several smaller ones, if we consider them with reference to their language. The first division comprehends those languages which are derived from the Latin and an admixture of the languages of the ancient aborigines and of the later destroyers of the Roman empire. These languages are spoken in the peninsulas of Italy and Spain and in the countries west of the valley of the Rhine. They are the Italian, Spanish, Portuguese, and French languages. In some districts of the countries where these languages are spoken there still exist the languages of some of the aboriginal inhabitants of Europe. On both sides of the western extremity of the Pyrenean mountains, south and west of the river Adour, the Basque language is spoken by a population not exceeding 600,000 souls, according to the most exact computation. The Cymric language is spoken in Wales, and also in the interior districts of the most north-western peninsula of France, which is called Bretagne (Little Britain), by a population amounting to about 2,000,000 individuals. The most extensive of these languages is the Celto-Gaelic language, which is still prevalent in the greater part of Ireland, and in some of the northern districts of Scotland. The number of the individuals who speak it perhaps does not fall short of 7,000,000. Many persons think that the Cymric and Celto-Gaelic languages ought to be considered only as dialects of the same original language.

The second great branch of the languages is formed by those of Teutonic origin. These languages are spoken by the inhabitants of England, a great part of Scotland and Ireland, Iceland, Norway, Sweden, Denmark, Germany, and the Netherlands. In every one of these countries a peculiar dialect is spoken, though the affinity of all these languages cannot be questioned. It would seem as if these languages had been introduced into these countries by their first inhabitants, or aborigines, as at present no other language is spoken in any of these districts (with the exception of the British islands), nor do we find any mention in historical records of such other languages ever having existed.

The third great family of languages is comprehended under the name of Slavonian. The most western tribes that speak these languages are found in the eastern districts of Germany. The Czecks inhabit Bohemia, and the Wendes the north-western part of the Prussian province of Silesia. In the south-western part of the same province Polish is spoken. Between Vienna and Trieste is another Slavonian tribe, also called Wendes, or Windes by the Germans; but they call themselves Slovenzi. Towards the south the Slavonian language extends to the very summit of the Balkan, the inhabitants of Dalmatia, Croatia, Slavonia, Bosnia, Servia, and Bulgaria, speaking dialects of that language. From these extreme points the Slavonian language is spoken over the whole of the great plain of Europe to the borders of Asia, on the Uralian range, and on the river Ural. The most extensively spoken languages of this family are the Russian and the Polish.

In the immense tract of country in which the Slavonian language may be considered as prevalent, some extensive districts are occupied by nations who speak different languages. We shall first notice the tribes of Mongolian origin, who form three different groups. The most numerous tribe are the *Magyars*, who inhabit the greatest part of the Hungarian plain, especially that part on which lies east of the Danube, from the banks of which river they extend to the foot of the Carpathian mountains, where they

are on every side surrounded by Slavonian tribes. The second group of nations of Mongolic origin occupy the countries between the Scandinavian Peninsula on one side, and the White Sea and the three great lakes of Ladoga, Onega, and Peipus on the other side. The Laplanders inhabit the country between the northern extremity of the Gulf of Bothnia and the White Sea; the Finns occupy the country farther south, as far as the Gulf of Finland. At the most eastern part of this gulf live the Inghers, and south of it the Estonians and the Livonians, who extend to the southern part of the Gulf of Riga. All these nations speak dialects of the same language, which is said to have a great resemblance to the language of the Magyars. The third group of the Mongolian tribes occupy the countries along the Uralian range, and between the rivers Ural and Volga. The most northern tribe are the Samoyedes, who occupy the eastern portion of the government of Archangel, between the river Metzén and the Uralian range. South of them, in the eastern districts of the government of Wologda, are the Siryanes, who also occupy the northern part of the government of Perm. In the southern districts of this government are the Permiens, the Wogules, and Wotyakes. Here are also a few families of the Mordwines, Cheremisses, and Chuwasches, who are dispersed over the surface of the governments of Viatka, Kasan, Simbirsk, and Pensa, where they inhabit an extensive district on the western side of the Volga. Their neighbours on the other side of the Volga are the nomadic tribes of the Calmucks and Kirghises. The former occupy the countries contiguous to the Volga, on its eastern bank; but the Kirghises inhabit those between the rivers Ussén and the river Ural. The two latter tribes are Bhuddists. To these tribes are still to be added the Bashkirs, who, in their stature, and the conformation of their face, evidently show their Mongolian origin, though they speak a Turkish dialect. They inhabit the most eastern part of Europe, the northern portion of the government of Orenburg, and some districts of that of Perm, on both sides of the Uralian range.

Different both from the Mongolian languages, and those of the Slavonian tribes, are the languages spoken by the Lithuanians and Courlanders, two small nations who inhabit the countries between the rivers Niemen and Dúna, and extend over the northern districts of eastern Prussia and the Russian governments of Grodno, Minsk, Wilna, and Mitau.

The Vlaches, or inhabitants of Wallachia and Moldavia, speak a peculiar language, with which a great number of Latin words are mixed up. Hence it is inferred that their ancestors inhabited these countries when they were subject to the Roman empire.

The eastern peninsula of southern Europe is inhabited by nations who speak three different languages. The most numerous are those who speak the Turkish language, which is used by the Osmanlis or Turks, and the Tartars. Some tribes of the latter nation are also dispersed among the Slavonian nations, on the northern shores of the Black Sea,

where they are known by the names of the Nogai Tartars and Meshtcheryakes. They are most numerous in the Crimea, and along the northern declivity of the Caucasus. The Osmanlis form the bulk of the population in those parts of Turkey which lie between the Balkan and the Volutza range. The mountainous countries west of the Pindus range are inhabited by the Albanians, who speak a peculiar language, and are considered as the descendants of the Illyrians, the aborigines of these countries. The most southern part of the peninsula is inhabited by the Greeks, who form the bulk of the population in Greece, and also in that portion of Turkey which lies between the Volutza and Othrys ranges. Their language does not differ substantially from the ancient Greek, of which it is a corrupted form, mixed up with some Latin, Italian, Turkish, and other foreign words.

The population of Europe is calculated to amount to about 230 millions in round numbers. The Christian religion is that which generally prevails. The Catholic faith is nearly exclusively professed by the inhabitants of Portugal, Spain, and Italy, and also by the majority in France, Austria, Bavaria, Poland, Belgium, and Ireland. Catholics are also numerous in some cantons of Switzerland, and some provinces of Prussia and of Russia. The whole number of the adherents of this faith is calculated to amount to 112 millions. To the Greek church belong the Russians and the Greeks; and a great number of the members of this church are dispersed over different parts of Turkey: they amount altogether to about 54 millions. The inhabitants of Sweden, Norway, and Denmark are nearly exclusively Protestants; and the various sects of Protestants form the great majority in England, Scotland, Holland, Switzerland, Prussia, and the northern and western states of Germany. In France, Austria, Ireland, Belgium, and some provinces of Russia, Protestants are numerous. The whole number is about 52 millions. There are Armenians in Russia, Austria, and Turkey; about 200,000 in all.

The Turks and Tartars, with some of the small tribes of Mongol origin along the Uralian Mountains, are Mohammedans. Their number is supposed not to fall much short of six millions. Among the Laplanders and Samoyedes there are still some who have not embraced Christianity. The Calmucks and the Kirghises are mostly Bhuddists. At Astrakhan there are a few Hindoos. The Jews are most numerous in some parts of Russia, Poland, Austria, and Turkey. Their number cannot be accurately estimated. In the south-eastern countries of Europe there is a considerable number of gypsies: it is doubtful what their religion is.

The following is a tabular view of the sovereign states of Europe in 1837. The areas and population are given from the latest and best authorities, and, wherever they could be got, from official documents. It is hardly necessary to observe that these figures must be considered only as approximations with respect to several of the states of Europe, such as Turkey and Greece, for instance.

Those thus marked * are states which are members of the Confederation of Germany.

| States. | Form of Government. | Area. Sq. miles. | Population. |
|--|---|---------------------|-------------------------|
| ANDORRA (Pyrenees) | Republic, with two syndics and a council | 190 | 15,200 |
| * ANHALT-BERNBURG | | 336 | 45,600 |
| * COETHEN | Duchies, with states having limited powers | 310 | 36,400 |
| * DRESDEN | | 357 | 57,500 |
| * AUSTRIA, Empire of { 1, in Germany, Hun- gary, &c.; 2, in Italy | Absolute monarchy, with the exception of Hungary and Transyl- vania, which have legislatures | 237,334 17,892 | 29,600,000 4,500,000 |
| * BADEN | Grand duchy; limited sovereignty, with legislature of two chambers | 5,712 | 1,240,000 |
| * BAVARIA | Limited monarchy; two chambers | 28,435 | 4,300,000 |
| * BELGIUM | Do. | 12,569 | 4,230,000 |
| * BREMEN | Republic; senate and convention | 67 | 57,800 |
| BRITAIN, GREAT, Ireland, and settlements and islands in Europe | King and two houses of parliament | 116,700 | 25,800,000 |
| * BRUNSWICK | Duchy; limited sovereignty, with one chamber | 1,525 | 250,000 |
| CHURCH, States of the, or Papal States | Absolute and elective sovereignty | 17,048 | 2,590,000 |
| CRAKOW | Republic; senate and chamber of representatives | 490 | 134,500 |
| DENMARK, Continental Islands | Absolute monarchy, with provincial states having limited powers | 21,472 38,290 | 2,040,000 57,400 |
| FRANCE | Limited monarchy; two chambers | 202,125 | 33,600,000 |
| FRANKFORT (on the Main) | Republic; senate and legislative body | 91 | 56,000 |
| GREECE | Absolute monarchy | 10,396 | 810,000 (a) |
| * HAMBURG | Republic; senate and common council | 149 | 153,000 |
| * HANNOVER | Limited monarchy; two chambers | 14,600 | 1,679,000 |
| * HESSE-CASSEL, or Electorate of Hesse | Limited sovereignty; one chamber | 4,386 | 699,000 |
| * HESSE-DARMSTADT, or Grand Duchy of Hesse | Do. two chambers | 3,198 | 765,000 |
| * HESSE-HOMBURG | Landgraviate; absolute sovereignty | 154 | 34,000 |
| * HOFENZOLLERN-HECHINGEN | Principality; limited sovereignty, with one chamber | 136 | 21,000 |
| * SIEMERINGEN | Do. do. | 383 | 42,800 |
| HOLLAND (including Duchy of Luxemburg) | Limited monarchy, with two chambers | 13,890 | 2,830,000 |

(a) The area is assumed from the President's decree of the 25th of April, 1838. Balbi and others carry it above 15,000. The population according to Klade's Almanac for 1837, is 996,000, besides 13,236 troops.

| States. | Form of Government. | Area. Sq. miles. | Population. |
|---|---|---------------------|----------------|
| IONIAN ISLANDS | { Free state; with council and one chamber, under British protec- tion | 998 | 242,000 |
| *LIECHTENSTEIN | Principality; limited with one chamber | 52 | 5,800 |
| *LIPPE-DETMOLD | Do. do. | 432 | 79,000 |
| *LÜBECK | Republic; senate and common council | 142 | 46,500 |
| LUCCA | Duchy; limited sovereignty, with a senate | 410 | 145,000 |
| MARINO, SAN | Republic; with senate and council of ancients | 31 | 7,500 |
| *MECKLENBURG-SCHWERIN | Grand duchy; limited sovereignty, with one chamber | 4,701 | 472,300 |
| *STRELITZ | Do. do. | 1,034 | 85,300 |
| MODENA and MASSA | Duchy; absolute sovereignty | 2,073 | 390,000 |
| MONACO | Principality; absolute sovereignty | 50 | 6,700 |
| *NASSAU | Duchy; limited sovereignty, with two chambers | 1,736 | 379,780 |
| *OLDENBURG | Grand duchy; absolute sovereignty | 2,470 | 260,000 |
| PARMA | Duchy; absolute | 2,184 | 440,000 |
| PORTUGAL | Limited monarchy; with chamber of representatives | 34,500 | 3,400,000 |
| *PRUSSIA | Absolute monarchy, with provincial states having limited powers | 186,302 | 18,800,000 |
| *REUSS, Principalities of | Limited sovereignty, with one chamber | 588 | 83,400 |
| RUSSIA, Empire of—Russian Dominions | Absolute monarchy | 1,994,139 | 47,000,000 (a) |
| Kingdom of Poland | Do. do. | 47,670 | 4,100,000 |
| SARDINIA | Do. do. | 28,830 | 4,500,000 |
| *SAXONY | Limited monarchy, with two chambers | 5,705 | 1,680,000 |
| *SAXE-ALTEMBURG | Do. with one chamber | 491 | 113,700 |
| *SAXE-COBURG and GOTHA | Do. do. | 790 | 132,000 |
| *SAXE-MEININGEN-HILDBURGHAUSEN | Do. do. | 880 | 146,400 |
| *SAXE-WEIMAR-EISENACH | Do. do. | 1,403 | 243,000 |
| *SCHWARZBURG, Principalities of | Do. do. | 756 | 118,500 |
| *SCHAUMBURG-LIPPE | Do. do. | 905 | 96,000 |
| SICILY, The Two | Limited monarchy, with a council (consulta) | 41,521 | 7,650,000 |
| SPAIN | Do. with legislature | 179,480 | 11,965,000 (b) |
| SWEDEN and NORWAY | Do. with diet and storting | 284,530 | 4,150,000 |
| SWITZERLAND | Confederation of republics, with diet | 17,208 | 2,116,000 |
| TRKEY, Empire of (including Wallachia, Moldavia, and Servia) | Absolute monarchy | 183,140 | 12,000,000 |
| TUSCANY | Grand duchy; absolute sovereignty | 8,302 | 1,330,000 |
| *WALDECK | Principality; limited sovereignty, with one chamber | 455 | 56,000 |
| *WÜRTTEMBERG | Limited monarchy, with two chambers | 7,568 | 1,610,000 |
| | | 3,708,871 | 233,884,803 |

Zoology of Europe.—In giving a general view of the animals of Europe, it will be found that the number of wild quadrupeds at present existing (many species having become extinct from the progress of civilization), is too small to exhibit many characteristic peculiarities in their geographical distribution and local adaptation; and the close connexion of this continent with that of Asia makes it very difficult to draw any exact line between their productions. Many of the animals of the south of Europe are also common to the north of Africa; and most of the quadrupeds inhabiting the northern parts of our continent are found in the corresponding latitudes of Asia and America. But though the zoology of Europe does not possess much interest from the number, size, or peculiarity of its animals, this is in some measure compensated by the intimate acquaintance which we possess with the habits and manners of many of the smaller species, whose natural history has been carefully investigated by many able and industrious naturalists.

In the following table the mammalia which are found in Europe are arranged according to their position in the orders of the Cuvierian system; those which are peculiar to this continent, and those which are common both to it and other parts of the globe, are placed in separate columns.

| ORDERS. | Whole No. of known species. | Whole No. of European species. | No. of species peculiar to Europe. | No. of species common to Europe and other Continents. |
|-------------------|-----------------------------|--------------------------------|------------------------------------|---|
| I. Quadrumana | 186 | 1 | 0 | 1 |
| II. Cheiroptera | 192 | 27 | 18 | 9 |
| III. Carnivora | 320 | 50 | 17 | 33 |
| IV. Marsupialia | 67 | 0 | 0 | 0 |
| V. Rodentia | 295 | 35 | 12 | 23 |
| VI. Edentata | 23 | 0 | 0 | 0 |
| VII. Pachydermata | 30 | 1 | 0 | 1 |
| VIII. Ruminantia | 157 | 8 | 1 | 7 |
| IX. Cetacea | 76 | 28 | 10 | 18 |
| Total | 1343 | 150 | 58 | 92 |

We here see the relative number of European mammals placed according to their organization, in different groups or orders; and we may remark that no animal is found in Europe belonging to the Marsupialia and Edentata, while of the Quadrumana and Pachydermata two species only inhabit our continent, one belonging to each order, the Barbary ape (*Inuus sylvanus*) and the wild boar (*Sus scrofa*). The former is found among the precipices of the

rock of Gibraltar, and thus enters into the geographical limits of Europe.

The domesticated quadrupeds occupy a much more important station among the animals of our continent than any of the wild species: under this head we shall mention the horse, ass, goat, sheep, ox, hog, dog, and cat, and in the more northern parts of Europe the rein-deer may be added.

No wild races of horses at present exist which have not descended from domesticated varieties; but it seems probable that they were aboriginal in Tartary, and most likely in other parts of Asia. From the former country it is conjectured that they were originally imported into the north and east of Europe; while in the southern and western parts of the continent they were probably derived from Barbary and Arabia; but this of course must be mere conjecture, as we cannot name any time within historical limits when these animals were not spread over all or the greater part of Europe. The horses of Spain were celebrated in the time of the Romans, after which they were probably crossed with the Barbary and Arab breeds during the Moorish dynasty. They may be considered as the lightest and fleetest of the old European breeds, and the nearest approaching to the Arab; but they have fallen off greatly during the last century, little care having been bestowed in keeping up the more noble breed. The best Spanish horses are generally about four feet six or eight inches high, and closely resemble the beautiful Arabians of Barbary called Barbs: those of Andalusia, Granada, and Estremadura are the best. The heaviest horses in Europe come from the shores of the North Sea, and the smallest from the north of Sweden and from Corsica. Those of Germany and Italy are of little note. Switzerland produces good draught horses, and those of Holland are noted for the same qualities. The French is a useful and hardy race, and will endure greater fatigue, though it is not possessed of the size and beauty which now characterize the English horses: the native breeds have been much improved lately by crossing with English stallions. Greater attention is paid to the breeding of horses in England than in any other country except Arabia; but while the Arabs only endeavour to preserve their breed in its original purity, we have improved upon it by crossing with other varieties, till the English horses both exceed the Arabian in size and fleetness, and equal them in many instances in symmetry, though they are not quite their match in powers of endurance. The English horses have been divided into four principal classes—the racer, the hunter, the carriage-horse, and the dray-horse.

The ass in Europe holds a very inferior place to the horse.

(a) Including the governments of Perm, Viatka, Kasan, Simbirsk, Pensa, Saratof, Astrachan, and part of Orenburg, 452,390 square miles.
(b) According to the Appendix to a decree in the 'Madrid Gazette' of August, 1836.

It is generally an ill-used and neglected animal. Originally of Asiatic extraction, it does not accommodate itself so well to our climate as the horse; for it feels the effects of cold more, and degenerates in northern countries; a circumstance which partly accounts for the contempt in which it is held. In the southern parts of Europe it is a fine spirited animal, and approaches in appearance and usefulness to those of Western Asia and Egypt. The Spanish and Maltese are the finest breeds of asses in Europe. One principal use of this animal is for the breeding of mules, which are extensively used in the mountainous parts of Southern Europe as beasts of burden, where, from their possessing the sureness of foot of the ass, with greater size and strength, they are found exceedingly useful.

Sheep and goats, though placed in distinct genera, are so nearly allied, that the characters which distinguish them are very slight; and there are several races or species of wild sheep and goats very nearly approximated.

It is not easy to trace the present domesticated varieties of either of them to any species still existing in a wild state, for both goats and sheep were among the earliest animals domesticated by man. Cuvier imagined that all the present varieties of the domestic goat have arisen from the *Capra sagraos*, a wild species inhabiting the mountains of Persia, where it is called *Paseng* by the natives. He also states that this animal has been found on the Alps; but it has been supposed that this variety, which is met with there in a wild state, might have been a hybrid between the common goat and the *Ibex*. It seems probable that the goat preceded the sheep in domestication; at any rate it did so in the north and west of Europe for many ages. It is a hardier animal, and will live on the roughest fare, being an inhabitant of mountainous districts, where it is principally bred. The most numerous and finest varieties of domestic goats are in Asia. The Welsh breed is large, with fine long hair, generally white. In Sweden and Spain there are long-haired hornless breeds, with upright ears. The utility of goat's milk is well known; and though the flesh of the adult animal is not much valued, that of the kid is very palatable; the horns and hair are used in different manufactures; and the skin is formed into leather for making gloves, &c.

Sheep seem to have been originally derived from west ern Asia, whence they were imported into Africa, where they arrived at greater perfection than in their parent country. All the wild varieties of sheep have hair, and not wool: the change in the covering of the body seems to have arisen from the effects of cultivation and climate. The different kinds of domestic sheep are all supposed to have arisen either from the *Argali* (*Ovis ammon*), or the different varieties of *Musmon* (*O. musmon*), one of which is still found wild in some of the islands of Europe, as Candia, Sardinia, and Corsica. There seems formerly to have been a wild race of sheep in Great Britain, which was very large, with great horns and tail. Mr. Pennant observes (*History of Quadrupeds*) that such an animal is figured on a bas-relief taken from the wall of Antoninus, near Glasgow. Boethius says that a breed of sheep lived in St. Kilda which had horns as large as an ox, and reaching to the ground. The principal European breeds of domestic sheep are—1, the many-horned of Iceland; 2, the Cretan; 3, Wallachian; 4, Merino, or Spanish; 5, the English, of which there are many varieties. The most important among the continental races is the Merino, which differs from the English in bearing wool on the forehead and cheeks. The wool is of the finest quality for manufacturing cloth. This breed is extended over the greater part of Spain. But Great Britain possesses the most valuable race of sheep, taking every thing into consideration; for it produces the greatest quantity of the best wool, and the most delicate flesh.

The ox, which belongs to the largest tribe of ruminating animals, is eminently serviceable to man, though since the horse has come into such general use, oxen have been less employed in husbandry. It was first domesticated by the Caucasian nations of western Asia, and from thence is supposed to have found its way into Africa and Europe; but it has been imagined that the domestic varieties in our continent might have arisen from races which once existed in Europe, and even in Britain, in a wild state, the only remains of which is the wild bull of Scotland (*Bos Scoticus*), still preserved in one or two parks in the North. This is most probably the species which was named *Urus* by

Cæsar, and other ancient writers; but what makes it improbable that this was the parent of our domestic oxen is the fact, that several important anatomical differences, principally as to the shape of the skull, are discovered between the Scotch bull and the domestic ox. Numerous specimens of fossil skulls, found in the more recent formations, which are supposed to have belonged to the ancient *Urus*, present also the same differences. The largest European breeds of cattle are those of Podolia, and the Ukraine, of Turkey, Hungary, and the Roman states. The Roman variety is supposed to have been introduced by the Goths, as all the representations of oxen found among old sculptures seem to denote a smaller race, more resembling that which is now seen in Tuscany, of a fine form, and pure white colour. There is a large breed of oxen in Denmark, which is the origin of the Dutch and Holstein varieties, the latter is the parent of the English unimproved breeds.

The hog occupies a low place in the scale of domestic animals, though its flesh forms an exceedingly good article of diet, and one much used by the peasantry in Christian countries. One of its most valuable qualities is that of preserving exceedingly well with salt, without becoming dry and hard, and losing its nutritive properties. The common wild boar (*Sus scrofa*) of Europe is no doubt the original parent of our domestic varieties. It was once indigenous over the whole of the old world, though now exterminated from some countries, as for instance Great Britain. The English breed of pigs is the finest in Europe, and some of them are fattened to an enormous size. In Ireland every cottager keeps his pig as a regular part of his establishment; and the salting of pork for exportation is a considerable article of trade in that country. There is a peculiar long-legged race of swine in Portugal and Spain. The pigs of Poland and Russia are of a reddish colour, and very small.

The dog claims our attention, not for his use as a beast of burthen, or in providing food for our tables, but for the attachment which he shows to man, becoming his companion and friend, assisting him in his pleasures, and protecting his property and home.

M. F. Cuvier has divided the different varieties of dogs into three primary types; the first has the jaws and muzzle elongated, and we may remark that all the wild species, as the Dingo of New Holland, &c., belong to this group, and more resemble the wolf and fox: this therefore may be considered as the most natural type. The second group has the jaws shorter than in the first, though longer than in the last division. The principal varieties of dog found in Europe belonging to the first group are—1, the *Albanian*, mentioned by the oldest historians and poets; 2, the *French mastiff*, which is considered by the writers of that nation as the most important of the canine race, and the ancestor of many others; 3, the *Irish Greyhound*; 4, the *great Danish Dog*; 5, the *common Greyhound*. The second group of dogs includes the most intelligent and useful kinds, as the spaniels, hounds, shepherd's, and wolf dogs; and we may here mention as belonging to this section the Alpine spaniel, or Mount St. Bernard dog, a variety of the Spanish breed, which is a beautiful and intelligent animal, kept by the monks at the monastery, from whence it derives its name, for the preservation of unfortunate travellers, who are often lost in the snows of this inhospitable region. Two of them are said to be sent out together, one carrying a cloak, and the other a basket of provisions and cordials: thus provided, they often discover, and are the means of saving persons who would otherwise perish with cold and fatigue. In the last group, which have the muzzle very short, are placed the *mastiff*, *bull-dog*, *pug*, &c. Our English breeds of mastiffs were once so celebrated that the Roman emperors appointed an officer in the island, whose business it was to send these dogs to Rome to fight in the arena; and in later times, when in our own country savage conflicts between dogs and wild beasts were a fashionable amusement, great care was bestowed on the breeding of bull-dogs and mastiffs.

There has been considerable diversity of opinion respecting the origin of the domestic cat, and the part of the world from whence it originally came. It has been thought by some that it must have been an inhabitant of warm climates, as it is a chilly animal, and always creeps as near to the fire as possible. Cuvier believed that it was a native of our European forests, and was the same species as the wild cat at present found, having been only altered by the effects of domestication. In support of this opinion, it is

asserted that cats in some places, near woods or forests, will stray away and return to a savage state, when they assume very much the characters and appearance of the wild cat. According to Bewick (*History of Quadrupeds*), wild cats are found with little variety in most climates. The domestic cat is very useful in destroying vermin, as rats and mice, and is a favourite pet, though it is not capable of much attachment.

The reindeer, which is naturally wild in the north of Europe, becomes, when tamed by the Laplander, of the greatest value to him. It serves him for food, clothing, and as a beast of burthen; by its organization it is formed for crossing the snowy wastes, which without this animal would be impassable: it will draw a great weight when attached to a sledge, and go with amazing swiftness. The riches of a Laplander are estimated by the number of reindeer which he possesses: during the winter season when the ground is covered with snow, and the ox and horse would starve, the reindeer finds plenty of food in a peculiar lichen (*Cladonia rangiferina*), which grows in the greatest abundance, and often covers the soil in sterile places for miles, affording nourishment for vast herds of reindeer, which root for this vegetable under the snow like swine in a pasture. Attempts have been made to domesticate this animal in England, but hitherto they have not succeeded. The reindeer is not adapted to our climate, and does not seem likely to be of much use in any point of view even if the experiment should succeed.

The whole number of wild European mammalia at present met with is only 150, which includes 28 belonging to the whale tribe, and 8 species of plocids or seals, among which the morse or walrus (*Trichechus rosmarus*) is placed: these being deducted, the number of land animals is reduced to 114, a proportion very small when compared with the three other great continents: of these seventy are also found out of Europe, most of them being common to Asia; there only remain therefore forty-four quadrupeds which are now peculiar to Europe.

We have already mentioned the only quadrumanous animal found within our limits, the Barbary ape, or magot, which, though now naturalized, is probably not an aboriginal inhabitant of Gibraltar.

Of the *Chiroptera* twenty-seven species are found in Europe, most of which belong to the genus *Vespertilio*, a small and harmless race of bats. The most common and best known species is the *V. murinus*, the flitter-mouse of the English, which lives in caves, ruined buildings, church towers, the roofs of houses or churches, and hollow trees, where it hibernates during the whole winter, snugly wrapped up in the wing-membranes, and suspended by the hind feet. There are two or three or perhaps more European species of the genus *Rhinolophus*, commonly called horseshoe bats, and one species of *Plecotus* has been described as found in Europe. As many as sixteen bats have been enumerated by Jenyns as inhabitants of Britain.

Most of the *Carnivora* of Europe are very insignificant animals by the side of their congeners of Asia and Africa. The only formidable beasts of prey now found within the limits of our continent are the bear, the wolf, and the lynx; but it seems probable that the lion was once met with in the south of Europe. Herodotus says that it was found in Greece between the rivers Nestus and Achelous (vii. 125); and he mentions the circumstance of the army of Xerxes being annoyed by lions on its march from Acanthus to Therme [Arnos]. The fact of these animals having inhabited our continent is also confirmed by Aristotle, Pliny (unless he is merely copying other writers), and Pausanias. Of the genus Bear there are two species in Europe, the common brown bear (*Ursus arctos*), and the polar bear (*U. maritimus*): the former was once general over the whole continent, and is now found widely diffused in the most solitary districts from the arctic circle to the summit of the Alps and Pyrenees. It is a lonely animal, hibernating during the winter in the hollow of a tree or a cavern, where it remains till the spring without taking any sustenance. It is supposed to be nourished during that time by the fat which accumulates beneath the skin in great quantities in the summer. Cuvier describes a black bear peculiar to our continent, differing from that of America: however, as he never saw but one living specimen, and did not know its habitat, it was probably only a variety of the former species. The polar bear is almost confined to the frozen regions surrounding the north pole, but a solitary individual is occa-

sionally drifted as far south as Iceland, or even the northern extremity of Norway and Lapland. The wolf and fox, the latter under different varieties or species, appear generally distributed over Europe: the former is even now not uncommon among the wooded and mountainous districts of France: when pressed by hunger, it will descend to the farms, and even attack the inhabitants. The lynx, once common in central Europe, has for some time been extirpated, except from some parts of Spain, the Apennines, and the northern parts of the continent: it is about twice the size of the wild cat, which is still said to be a native of Britain. The common glutton or wolverine (*Gulo arcticus*) is a native of Denmark. It is one of those animals whose history is obscured by fable: it feeds principally on dead carcases, though it will kill prey of the smaller kinds, as mice, marmots, &c.; but the stories of its falling from the boughs of trees on to the backs of deer and other large animals, and maintaining its hold there till they drop with fatigue and loss of blood, are doubtless entirely fabulous, as it is a most cowardly animal, and may be easily killed with a stick.

Of small carnivorous quadrupeds there are several species; as many as eight Mustelids, or weasels, inhabit different parts of Europe, which are particularly destructive to birds.

Few of the *Rodentia* of Europe require particular notice. The beaver was formerly recorded as a British animal; at present it is found in the neighbourhood of the Rhone, the Danube, the Rhine, and other large rivers on the continent. The porcupine (*Hystrix cristata*) is said to be occasionally met with in Italy, and other parts of the south of Europe. The flying squirrel (*Pteromys volans*) is an inhabitant of Denmark and Lapland, as well as one or two species of lemming (*Georychus*). The different kinds of rats and mice, of which seventeen species have been described, arranged in different genera, form an important feature in European zoology. One species of Hamster (*Cricetus vulgaris*) is distributed over central and northern Europe; and two marmots (*Arctomys marmotta* and *Bobac*); and the *Spermophilus Citillus*, or Soulsk of the Germans, occurs in the same region.

The *wild boar*, the only aboriginal pachydermatous animal in Europe, was formerly an inhabitant of the forests of Great Britain, and was one of the noblest and most favourite objects of the chase; it is still found on the continent.

The number of *Ruminants* found wild in Europe is very limited, there being only eight species. Of these five are deer, all of which are also inhabitants of other continents, viz., the elk or moose-deer, the rein-deer, the fallow-deer, the red-deer, and the roebuck, which are severally described in the article DEER. The three remaining animals of this order are the ibex, the chamois, and the musmon. The first (*Capra ibex*) is found, though rarely, in the Alps, still more rarely in the Pyrenees, and it is said in some other mountainous parts of Europe and Asia: it lives only in the most lofty and inaccessible places, and is sought for at the extreme peril of the hunter. The chamois inhabits also the wildest and most precipitous regions in the mountains of Europe, though it scarcely ascends to the same heights as the ibex; it is placed in the same group with the antelopes, though by some naturalists it is considered that it should form an intermediate genus between those animals and the goats. The musmon (*Ovis musmon*), the only ruminating quadruped which appears confined in its range to Europe, we have already mentioned as being the supposed parent of our domestic sheep; it has disappeared from the continent, though there is no reason for believing that it formerly existed on the mountains of Spain.

The *Cetacea* are a tribe of animals of which little is known. Their habitation being in the deepest recesses of the ocean, it is impossible to learn much of their habits and characters; and hardly any species can be said to be peculiar to one continent more than another, for the same whale may be met with on the coast of Europe at one time, and on that of America at another. A great many species frequent the shores of Europe, principally on its northern part, and the Greenland fishery is an important branch of European commerce.

The *birds* of Europe are much more numerous than the mammalia. Above 400 species have been described as regular inhabitants of our continent, and a good many more are occasional visitants; but we must confine our notice to a few of the more remarkable and typical species. In the northern or arctic regions very few birds are met with, and

most of them belong to the wading and swimming orders; to whose nourishment and increase the arctic solitudes are particularly congenial. Almost all these species are found also in the northern parts of Asia and America; and the largest proportion occur in southern latitudes, extending even to the shores of the Mediterranean. One of the most characteristic birds of arctic Europe is the great snowy owl (*Strix nyctea*), which preys chiefly on the ptarmigans and grouse, which frequent these northern regions in great numbers. Two other formidable rapacious birds frequent the northern countries, particularly Lapland: the Iceland falcon (*Falco Islandicus*), which rarely wanders to more genial climes, and another gigantic owl (*Strix lapponica*), which is a peculiar inhabitant of the dreary solitudes of Lapland. As we proceed to warmer latitudes, and vegetation acquires a more decisive character, the number and species of birds subsisting on the produce of the earth and on insects greatly increase. Several woodpeckers are met with in the pine forests of Norway, one of which (the *Apternus tridactylus*) is remarkable for having only three toes on its feet. Among the noblest and most formidable birds of central and southern Europe may be mentioned the golden and imperial eagles; the former (*Aquila chrysaetos*) is an inhabitant of the wildest parts of Scotland and Ireland, and rocky places among the higher mountains on the continent. The latter (*A. imperialis*) is chiefly found in the southern countries. Four species of vulture are met with on the Alps, two of which are found in the north of Africa and the western part of Asia. The bearded vulture (*Gypætus barbatus*), which is almost peculiar to the Alps, is a noble bird, partaking more of the characters of the true falcons, being very courageous and sanguinary; it is above four feet and a half long, from the tip of the bill to the extremity of the tail, and will attack sheep and goats, and it is said that even the ibex and chamois are sometimes killed by it. The great-eared owl represents in central Europe the snowy species of the arctic regions; it is common in the German and Hungarian forests, and is sometimes, though rarely, met with in England. The Gallinaceous genera are few and widely dispersed. The great bustard (*Otis tarda*) ranges from the western extremity of central Europe to the confines of Asia. The red grouse (*Lagopus Scoticus*) is the only bird peculiar to Great Britain. This race of birds seems to occupy an intermediate station between the centre of Europe and the confines of its polar extremity: the largest species is the famous cock of the woods (*Tetrao urogallus*), once an inhabitant of the Scottish forests. The rocky and uncultivated tracts of Spain and Turkey are inhabited by two species of rock grouse (*Pterocles*), of a genus different from those belonging to northern latitudes. On the shores of the Mediterranean there is a union of the ornithology of Europe, Africa, and Asia: the pelican, the spoon-bill, and the flamingo are there met with, though not now very plentifully. Few of the birds of Europe are remarkable for that brilliancy of plumage which is so splendid a characteristic of the birds of tropical climates, but this is, in many instances, more than compensated by their sweetness of voice. The nightingale, the best songster in the world, is common in England and other European countries, though not confined to our continent; it visits us in the breeding season, along with numbers of other warblers, or small insectivorous birds, which enliven our woods and hedges during the spring and summer. The melody of the blackbird and thrush is too well known to require any eulogy. But Europe is by no means destitute of birds characterized by the beauty of their colours, though they are chiefly confined to its southern boundaries: the wall-creeper with its bright rosy wings is common in Italy; while the golden oriole, the European bee-eater, the hoopoe, and the roller are met with in abundance in the two Sicilies during the spring and autumnal migrations; and a modern author says that 'they may occasionally be seen hanging in the poultryers' shops in Naples and Palermo.'

The reptiles of Europe are few, and generally harmless. The common viper is almost the only venomous serpent. Numerous little lizards are common in the houses in the southern parts of the continent, as in Italy; but most of them are not peculiar to Europe, being also found on the opposite shores of the Mediterranean. An excellent edible species of turtle inhabits this sea, which resembles in appearance the logger-head of the West Indies, but is much more palatable when dressed. The most remarkable and curious reptile in Europe is the *Proteus anguinus*, which

somewhat resembles a water lizard in shape, or an eel with very imperfect legs: it is found in the lake Zirknitz, in Carniola, and more often at the bottom of the grotto of the Maddalena at Adelsberg. It was conjectured by Sir H. Davy and others not to be a natural inhabitant of the surface of the globe, but to be forced up from a subterranean lake through some crevices in the rocks. It was also doubted whether this was a perfect animal or only the larva of some other, but it has been proved to be furnished with both gills and internal lungs; its eyes are quite rudimentary and situated beneath the skin.

Insects and other annulose animals are very numerous in Europe, but few of them possess sufficient interest to require any notice in this general sketch. The scorpion is frequently found in houses in Sicily, though fortunately unknown with us. The common gnat is one of our most troublesome insects, and in warm shady places, where there is much stagnant fresh water, it will cause almost as much annoyance to some people as the mosquito of hot climates, which it closely resembles. In Sweden and other northern countries, where the summer though very short is proportionably hot, it is said that true mosquitos are more numerous than in the woods of tropical America.

Many of the fish which frequent the shores of Europe are very important in an economic point of view. We may particularly mention the herring, the anchovy, and the tunny, whose capture and preparation employ a great number of men, and which are also important articles of diet. Herrings (*Clupea harengus*) arrive in great shoals on the western coasts of Europe towards the end of the summer for the purpose of depositing their spawn, and at that time immense numbers are caught, particularly on the British coasts, where they abound. It was supposed by the older naturalists (and among others even by Cuvier) that the herrings migrated from the Northern Ocean in the spring, and returned there after depositing their spawn; but it is the more recent opinion (which is supported by the authority of Mr. Yarrell) that these fish inhabit the deep waters round our coasts, and only approach the shore for the purpose of spawning, and then retire again to the depths of the ocean, where they remain during the winter and spring. The pilchard (*C. pilchardus*), which belongs to the same genus as the herring, is caught only on the coast of Cornwall, where it makes its appearance in July: it goes away in the autumn, and returns in the beginning of January. The anchovy (*Engraulus encrasicolus*) is principally met with in the Mediterranean, which sea it enters in enormous shoals by the Straits of Gibraltar in the spring for the purpose of breeding, after which it retires again to the depths of the Atlantic. The most productive fishery is off Gorgona, a small island west of Leghorn, where it is carried on during the months of May, June, and July. The anchovies are fished for only during the night, and are attracted round the boats by means of fires kept burning in them. Their principal use is for forming a sauce, which is very generally known, and esteemed as a condiment.

The tunny (*Scomber thynnus*) is also an inhabitant of the Mediterranean. It was a fish well known to the ancients, and made a considerable branch of commerce: the time of its arrival in the Mediterranean from the ocean was observed, and stations for taking it established in places which it most frequented. (Strabo, p. 225.) It is in the interior of the Mediterranean that this fishery is now principally carried on, particularly along the shores of Catalonia, in Provence, in Liguria, in Sicily, and in Sardinia. These fishes frequent the coasts of Britain, but not in shoals like the tunny of the Mediterranean.

The salmon (*Salmo salar*), which is one of our most valuable and finest fishes, is found in all the seas on the north of Europe, Asia, and America, but it has never been met with in the Mediterranean. According to Cuvier it comes from the Arctic seas, whence it enters in large shoals the rivers of northern countries in the spring for the purpose of spawning. In temperate climates it is towards the end of winter that the salmon quits the sea: in the more northern regions it enters the rivers when the ice begins to melt on the shores of the ocean. Though the salmon is principally confined to the more northern regions, it has not been clearly ascertained how far south it extends, but probably not much beyond the 45th degree of latitude. It occurs, though not plentifully, in the rivers on the western coast of France.

The pike (*Esox lucius*), which is a palatable and whole

some fish, is exceedingly destructive and voracious; it has been called the fresh-water shark. It is found in almost all the fresh waters in Europe, though more plentifully in the northern than the southern parts. It sometimes grows to a very large size.

EUROPE, BOTANY OF. This continent in its most southern limits exhibits a strong resemblance to the vegetation of Africa and its adjacent islands. In Sicily, for example, along with the vine, grow, in the more sterile situations, the poisonous leafless *Euphorbia Canariensis*, an inhabitant of the Canaries, and its congener *E. balsamifera*. *Euphorbia dendroidea*, a fine globular shrub, is also met with in company with the castor-oil plant (*Ricinus Africanus*), and the *Solanum sodomæum* of Egypt. The Date, the Pisang (*Musa Paradisiaca*), and the Prickly Pear (*Cactus Opuntia*), ripen their fruit abundantly; *Agave Americana*, the American aloe, darts up its gigantic flower-stem from the midst of huge horny leaves; rice is grown; the sugar-cane is cultivated at Avola; the cotton-plant (*Gossypium herbaceum*) yields produce of the finest quality on the banks of the Simeto; while the great Italian reed (*Arundo Donax*) supplies the place of the bamboo, and furnishes the long stakes on which the vine is trained. Many parts of the south of Spain partake of this character. The *Smilax aspera* loads the bushes with its fragrant snow-white clusters, maize and Guinea corn are common articles of cultivation, the Peruvian Cherimoyer ripens its fruit in the gardens of Grenada, and the delicate melons of Valencia are as common an open crop as in the fields of Persia. At Barcelona, in the neglected botanic garden, were still found, a few years since, the Sappan tree of Brazil (*Coralpinia Sappan*), the *Schinus Molle* of Peru, and other trees from similar climates flourishing as if in their native air. In Portugal the laurel (*Ceranus Lusitanica*) seems almost identical with the Hixa of the Canaries, while the Coral trees at Lisbon unfold their noble leaves and gorgeous blossoms with all their native South American vigour. In Italy arborescent Endogens extend as far as Nice in the form of the dwarf Palmetto; and the Victor's laurel (*Laurus nobilis*), a common evergreen, is a European representation of the laurels of the Canaries. Along all these latitudes the fig, the olive, the orange, the vine, and the maize find a climate congenial to their southern constitutions. Even in valleys the olive will not exist higher than $44\frac{1}{2}^{\circ}$ N., nor the vine produce good wine beyond 48° , except in a few sheltered places.

About the northern limits of the olive, that is to say, in the parallel of the south of France, a marked change occurs in vegetation; most of the southern equinoctial forms of vegetation either disappear or become uncommon. The *Quercus Cerris*, so common in Italy and Turkey, is hardly found; evergreen oaks (*Quercus Ilex*), common oaks (*Q. veluticulata* and *sessiliflora*) supply its place. Cluster pines and Scotch firs (*Pinus pinaster* and *sylvestris*) and other species, especially *Pinus halepensis*, grow along the sea-coast and occupy the position held by the more southern stone-pine (*Pinus pinea*); while *Juniperus Phænicea* and *oxycedrus*, on the branches of which its peculiar mistletoe is sometimes met with, sweet chestnuts (*Castanea vesca*), the narrow-leaved ash (*Fraxinus oxyphylla*), the flowering ash (*Ornus Europæa*), mastich-trees, and Phillyreas increase the catalogue of trees, no vestige of which is to be traced much higher in a wild state. Still more to the north, where the vine begins to languish, its place in better occupied by broad plains of wheat and other corn; the hardy trees of England, elms, limes, oaks, ashes, alders, beeches, birches, willows, and poplars are found everywhere, with rich pastures and verdant fields, unknown in the land of oranges and myrtles. At last, in the more northern districts of the continent, aspens (*Populus tremula*), bird-cherries (*Prunus Padus*), birches, lime-trees, alders, junipers, spruce-firs, and pines are the principal trees that remain; barley and oats are the only corn-plants, but potatoes continue to be reared in the short cold summer.

Among plants less conspicuous than these and less popularly known, changes occur between the north and south of Europe not less striking to the eye of a botanist. In Sicily occurs a *Stapelia*, a form of vegetation so African, that Arabia Felix and Abyssinia are the nearest points where a parallel can be found. Mandrakes (*Mandragora autumnalis*) cover whole tracts in Turkey and Sicily in the autumn with their sky-blue flowers. Quantities of labiate plants, Boraginaceæ and gay Liliaceæ, Medicagæ in abun-

dant variety, an endless host of *Cistus* and *Helianthemum*. Narcissi, Tulips, many species of *Ophrys*, and numerous kinds of *Genista* and *Cytisus* mark a zone of vegetation corresponding very much with the distribution of the olive. To the north of this limit such plants either disappear or diminish essentially in number and variety. Apiaceous and Brassicaceous species become predominant, fungi swarm in the autumn, turnips and buckwheat (*Polygonum fagopyrum*) are cultivated advantageously, as also are hemp, flax, hops, carrots, parsnips, common clover, beans, vetches, and lucerne, as common field-crops. But in higher latitudes the predominant forms of herbaceous vegetation are numerous species of *Ranunculus*, *Potentilla*, *Saxifraga*, *Arenaria*, *Primula*, Mosses, and Lichens; and there also occur abundance of stunted or pigmy trailing shrubs, such as bilberries and whortleberries (*Vaccinium Myrtillus* and *uliginosum*), *Salix herbacea*, *Arbutus Alpina*, *Arctostaphylos Uva Ursi*, crowberries (*Empetrum nigrum*), and the like.

These changes take place if we merely look to the districts of the plains. In Europe, as in other parts of the world, similar alterations in vegetation occur as we ascend into the atmosphere. In Sicily for instance, with an almost tropical vegetation in the valleys, there is a transition to the middle forms of European vegetation midway on the mountain side, and then to the most northern flora at its summit, 9000 feet above the sea [Ætna]; and so with other mountains as we advance to the south, till at last on Suli-telma, in Lapland, not a trace of vegetation can be discovered above the height of 3640 feet.

EURYALE. [STELLERIDEANS: MEDUSA.]

EURYBIA. [MEDUSA.]

EURYDICE (Zoology). [ISOPODA.]

EURLAIMUS. [MUSCICAPIDÆ.]

EURYMEDON. [ANATOLIA, vol. 1., p. 494.]

EURYNOME, a genus of brachyurous crustaceans established by Dr. Leach, and forming the second genus of the *Parthenopians* of M. Milne Edwards, who remarks that it establishes the passage between *Parthenope* or *Lambrus* and the other *Oxyrhynchi*. The general form of the body and aspect approximates these crustaceans to *Parthenope*, whilst the disposition of their external antennæ is similar to the conformation in *Maia*. The carapace is nearly in the form of a triangle with a rounded base, and is strongly tuberculated and covered with asperities. The rostrum is horizontal, and divided into two triangular horns. The eyes are small; the orbits deep, their upper border very much projecting and separated from the external angle by a slit. The internal antennæ are bent back longitudinally, and the first joint of the external antennæ terminates at the internal angle of the orbit. The epistome is nearly squared, and the third joint of the external jaw feet strongly dilated externally. The sternal plastron is nearly oval, and its median suture occupies the two last thoracic rings. The feet of the first pair are scarcely longer than the succeeding ones; in the male they are rather long, whilst in the female they are very short, but less than those of the second pair; the succeeding feet diminish progressively in length. Abdomen consisting of seven articulations in both sexes.

Example, *Eurynome aspera*. Length about half an inch; colour lively red with bluish tints. Locality, the coasts of Noirmoutier and the Channel (La Manche), at rather considerable depths. (Leach; Milne Edwards.) [PARTHENOPÆ.]

Eurynome Aspera.

EURYPŌDIUS. [LEPTOPŌDIUS; MACROPŌDIANS.]
EURYSTOMIDÆ. [ROLLERS.]

EUSEBIUS PAMPHIL. bishop of Cæsarea, in Palestine, the friend of Constantine, and one of the most distinguished among the earlier Christian writers, was born in Palestine towards the end of the reign of Gallienus, about A.D. 264. He passed the earlier part of his life at Antioch, and acquired a great reputation for learning: it was said of him 'that he knew all that had been written before him.' He became intimate with Pamphilus, bishop of Cæsarea, who suffered martyrdom under Galerius in the year 309, and in memory of whose friendship he added to his name that of Pamphilus. In 313 he was himself raised to the see of Cæsarea, which he filled until his death. He attended the great council of Nicæa, A.D. 325, where he joined his brethren in condemning the tenets of Arius; but he is said to have raised some objections to the word 'consubstantial with the Father' as applied to the son, in the Nicæan creed. His intimacy with his namesake Eusebius, bishop of Nicomedia, who openly espoused the cause of Arius, led him also to favour the same, and to use his influence with the emperor for the purpose of reinstating Arius in his church, in defiance of the opposition of Athanasius. [ARIUS; ATHANASIUS.] The party to which he attached himself were called Eusebians, from their leader Eusebius of Nicomedia; and they seem to have acted in great measure from hostility against Athanasius and his supporters, as they did not as yet openly advocate the objectionable tenets of Arius, who had himself apparently submitted to the decrees of the council of Nicæa. In 331 Eusebius attended a council at Antioch, consisting of prelates of this party, who deposed, on some insidious charge, the bishop Eustathius, a zealous supporter of the Nicæan doctrine, and offered the see of Antioch to Eusebius of Cæsarea, which he declined. At the council of Tyre, A.D. 335, Eusebius joined in condemning and deposing Athanasius on the charges of disobedience to the emperor in not reinstating Arius, want of respect to the council, and an alleged desecration of some sacred vessels. Eusebius was deputed by the council to defend before Constantine the judgment which they had passed against Athanasius; and he appears to have used his influence with the emperor to have Athanasius banished. The part which he took in this unfortunate controversy caused him to be stigmatized as an Arian, though it appears that he fully admitted the divinity of Christ; and all that his accusers can prove is, that he believed that there was a certain subordination among the persons of the Trinity. (Mosheim, *Ecclesiastical History*; and Schoell, *History of Greek Literature*, and the notes and references therein.) Eusebius of Nicomedia afterwards openly advocated the Arian doctrine under the reign of Constantius, especially at the council of Antioch, A.D. 341. Eusebius of Cæsarea died A.D. 340.

Eusebius was possessed of most extensive erudition, sacred as well as profane, and he was one of the warmest defenders and expounders of Christianity. His principal works are—1. 'The Ecclesiastical History,' in ten books, from the advent of our Saviour to the defeat of Licinius by Constantine, A.D. 324. Eusebius has been styled the father of ecclesiastical history. He is silent on the subject of the Arian controversy, although it had begun at the time when he ends his narrative. Upon the whole, his history is written with considerable discrimination and impartiality. 2. 'De Præparatione Evangelicâ,' in fifteen books. In this work he examines the various systems of theosophy and cosmogony of the ancient philosophers, the purest part of which, he maintains, was borrowed from the Jewish sacred writings. Among the writers whom he quotes, and whose works are now lost, are the Phœnician Sanchoniatho and the Egyptian Manetho. From the aberrations of the heathens and the speculations of the philosophers he draws arguments in favour of the truth of the Christian doctrines. This work of Eusebius was followed by another—3. 'De Demonstratione Evangelicâ,' in twenty books, of which only ten have come down to us. It consists of further proofs of the truth of the Christian faith, chiefly directed against the Jews, being drawn from the books of the Old Testament. 4. The 'Chronicle or Universal History,' was only known by fragments until it was lately discovered entire in an Armenian MS. version, found at Constantinople, and published by Zohrab and Mai at Milan in 1818. The work is divided into two books; the first, entitled 'Chronography,' contains brief separate sketches of the history of the various nations and states of the old

world, from the Creation till the year 325 of our æra. The author gives extracts from Berosus, Alexander Polyhistor, Abydenus, Cephalion, Manetho, and other lost writers. The second book consists of synchronical tables, with the names of the contemporary rulers of the various nations and the principal occurrences in the history of each, from the age of Abraham till the time of Eusebius. The author has made use of the works of Africanus, Josephus, and others. The discovery of the Armenian copy of Eusebius has been a valuable acquisition, as it serves to correct several errors and to supply many deficiencies in chronology and ancient history. The other works of Eusebius are—5. 'Onomasticon Urbium et Locorum Sacrarum Scripturæ.' 6. 'The Life of Constantine,' in four books, a piece of panegyric biography. 7. A Life of his friend Pamphilus, of which only a fragment remains; and other minor works.

EUSTACHIAN TUBE. [EAR.]

EUSTA'CHIUS. Bartolomeo Eustachio, or Eustachius, was one of the distinguished band of Italian professors to whom we owe the restoration of anatomy and much of its advancement in modern times. He was born in the early part of the sixteenth century at San Severino, in the marquisate of Ancona. Having accomplished himself in the classical and Arabic languages, he studied medicine at Rome, and afterwards settled there with a view to practise as a physician, under the patronage of the celebrated cardinal Borromeo. The interest he could thus command and his unusual talents were sufficient to elevate him to the chair of medicine in the Collegio della Sapienza; yet he never obtained any degree of professional success, and after a long struggle with poverty and sickness, died in great indigence about 1574.

It is not surprising that Eustachius should have failed as a practical physician, for the exclusive devotion with which he pursued his favourite study must have left him little time for the cultivation of the lucrative branches of his art; but the complete failure as a teacher, of a man of so much genius and enthusiasm, is remarkable. It may be attributed perhaps to the ascendancy of the rival school of Padua, supported by the wealth of Venice, and illustrated by the established fame of Vesalius and his successors; and may be due in part to a defective temper, of which some indications may be observed in his writings, and to the jealousy with which he concealed his discoveries. Eustachius published little in his lifetime, though he lived long and laboured much; yet his treatises, short and few as they are, and composed when anatomy was yet an infant science, are of high authority even at the present day, and bear witness to the accuracy and extent of his researches. They are all in Latin, and are nearly all collected in his 'Opuscula Anatomica,' published in 4to. at Venice in 1564, by himself, and again by Boerhaave, Leyden, 1707, in 8vo. He also published an edition, with annotations, of Erotian's 'Lexicon Hippocraticum.' His principal work, 'On the Disputed Points of Anatomy,' upon which he evidently intended to rest his fame, was unpublished to the time of his death, although announced in the 'Opuscula,' probably for want of means; it was then lost, and has never been recovered; but thirty-nine copper-plates, engraved as early as 1552, and intended to illustrate the text of this work, were found at Urbino in 1712, and given to the world two years afterwards by Lancisi, with the aid of Morgagni, Pacchioni, and other anatomists of distinction. Several editions of them have since appeared with voluminous commentaries; the best is that of Albinus, published at Leyden in 1744, in folio, and reprinted in 1762. The importance attached to these plates, after so long an interval of oblivion, shows how much Eustachius must have preceded his age; and they prove that many facts of great importance in anatomy were accurately known to him, the partial re-discovery of which had shed lustre on a century and a half of subsequent inquiry.

Haller declares it to be impossible without writing a treatise on the subject to particularize the discoveries and corrections that Eustachius introduced into anatomy. The tube leading from the ear-drum to the throat, and a certain valvular membrane in the heart which bear his name are among the former.

EUSTA'THIUS, archbishop of Thessalonica in the latter part of the twelfth century, was one of the most learned scholiasts of his age. He wrote a Commentary upon the 'Iliad' and the 'Odyssey,' which is a mine of ancient erudition, and contains extracts from the older commentators, such as Apollonius, Heliodorus, Demo-

thenes of Thrace, Porphyrius, and others. It was first printed at Rome in the edition of Homer, 4 vols. fol. 1542-48; the latest edition is that of Leipzig, 1827. Eustatius wrote likewise a Commentary on Dionysius Periegetes, or the Geographer, which was published by Robert Estienne, 1547, and often reprinted since. He also wrote a Commentary on Pindar, which is lost. There are letters of Eustathius existing in MSS. in several libraries; but they have never been published. The novel of 'Hysmine and Hysminias,' published at Paris, 1618, has been also attributed to Eustathius, but, as it is now proved, erroneously.

EUSTATIUS, or EUSTATIA, St., in 17° 33' N. lat., and 63° 3' W. long., one of the Leeward islands in the West Indies, is a small rocky island, about 25 miles in circumference, rising from the sea, in the form of a truncated pyramid, or sugar-loaf, terminating in a plain surrounded with woods, having a hollow in the centre, which is now a vast den for numerous wild beasts, and is perhaps the crater of an extinct volcano. The climate is in general healthy, but the island is frequently visited by those dreadful thunder-storms and hurricanes which have so repeatedly ravaged the West Indies. These hurricanes have usually occurred in August and September. The extraordinary fertility of the soil, aided by the industry of the Dutch, who have cultivated the island to the very summit, have rendered it one of the most flourishing and wealthy of all the Caribbee islands. The principal article of cultivation is tobacco, but they grow likewise sugar, indigo, and cotton. The island has great abundance of hogs, goats, rabbits, and poultry of all kinds, not only for the consumption of the inhabitants themselves, but for the supply of the neighbouring colonies, with which they are said to carry on a profitable contraband trade, the situation of the island being remarkably convenient for that purpose. This may be one ground of the very jealous policy of the Dutch, which is far more strict than that of the other European nations who possess any of the islands. The only landing-place, naturally difficult of access, is further guarded by a fort, and fortified so as to render it impregnable; nor has any thing been neglected to render every part of the island equally so. Strangers therefore being nearly excluded, have little knowledge of the internal affairs of the island and of the riches with which it abounds.

St. Eustatius became the property of the Dutch by the right of first occupancy; the States-General granted it to some merchants at Flushing, and it was first settled about the year 1600. In 1665, when the English were at war with the Dutch, the latter were dispossessed by an armament sent from Jamaica. In the sequel France and Holland having formed an alliance, St. Eustatius was reconquered from the English by a combined force, and the French kept a garrison in the island till the treaty of Breda, when it was restored to the Dutch. Soon after the revolution of 1688, the French expelled the Dutch from St. Eustatius, but were obliged to capitulate to Sir Timothy Thornhill, who granted them only their lives and baggage, and left a small English garrison for the protection of the Dutch, who again recovered the entire possession of the island by the peace of Ryswick. They kept it till 1781, when it was taken by the English, but restored at the peace in 1783. The English again took it in 1801, and gave it back to the Dutch in 1814.

EUSTYLE, [CIVIL ARCHITECTURE.]

EUTOCIUS, a Greek mathematician of Ascalon, in Palestine, who flourished about A.D. 550. He was pupil of Isidorus, the architect who designed and chiefly built the celebrated church (now the mosque) of St. Sophia at Constantinople; and he became ultimately one of the most distinguished geometers of his time.

It was the general custom of mathematical and philosophical authors, during the decline of learning, to give their views and their discoveries, where they made any, in the form of commentaries on some earlier writer. Eutocius, like Proclus and others, delivered his views in this way; and like them he furnishes some valuable contributions to the history of mathematical science amongst the Greeks.

The commentaries of Eutocius on the works of Archimedes and Apollonius are the only works by which he is known to modern readers. His commentaries on Apollonius were published in Halley's Oxford edition of the works of that author, 1710; and those on Archimedes in various editions, from that of Basil, 1544, to that of Oxford, 1792.

Of the commentaries of Eutocius, those on the treatise of Archimedes 'On the Sphere and Cylinder' are most valued; and chiefly for his account of the various modes of solving the Delian problem of the Duplication of the Cube. All of them, however, though of less value both as to historical and geometrical matter, are still interesting to every one who takes a pleasure in investigating the history of pure science.

The commentary on the 'Measurement of the Circle,' by Archimedes, was translated into German, together with the text of Archimedes to which it refers, by J. Gutenäcker, Würzburg, 1825 and 1828, 8vo.

EUTROPIUS, FLAVIUS, was a Latin historian of the fourth century. Little is known of his life; he was secretary to the Emperors Constantine and Julian, and accompanied the latter in his unfortunate Parthian campaign. He is believed to have been of senatorial rank. He is known as the author of a compendium of Roman history, in ten books, from the foundation of the city down to the accession of Valens, A.D. 365, which, being short and easy, has been much used as a school-book. Meagre as it is—for it might be contained in 100 common-sized octavo pages—it is still of some use towards filling up those gaps in history which are left in consequence of the total loss of some writers and the imperfect condition in which others have come down to us. The best edition is said to be that of Haverkamp, Leyden, 1729, 12mo., improved by Verseik, Leyden, 1762, 2 vols. 8vo.

EUTYCHIANS, a sect of Christians which began in the East in the fifth century. Eutyches, its reputed founder, though the opinions attributed to him are said to have existed before (*de Eutychianismo ante Eutychen*, by Christ. Aug. Selig, and also Assemani, *Bibliotheca Orientalis*, tom. i., p. 219), was a monk who lived near Constantinople, and had a great reputation for austerity and sanctity. He was already advanced in years when he came out of his retirement, A.D. 448, in order to oppose the Nestorians, who were accused of teaching 'that the divine nature was not incarnate in, but only attendant on, Jesus, being super-added to his human nature after the latter was formed;' an opinion however which Nestorius himself had disavowed. In his zeal for opposing the error ascribed to the Nestorians, Eutyches ran into the opposite extreme of saying that in Christ there was 'only one nature, that of the incarnate Word,' his human nature having been absorbed in a manner by his divine nature. Eusebius, bishop of Dorylæum, who had already opposed the Nestorians, denounced Eutyches before a council assembled at Constantinople by Flavianus, bishop of that city. That assembly condemned Eutyches, who, being supported by friends at the court of Theodosius II., appealed to a general council, which was soon after convoked by the emperor at Ephesus, A.D. 449, under the presidency of Dioscorus, bishop of Alexandria, and successor to the famous Cyril, who had himself broached a doctrine very similar to that of Eutyches. The majority of the council tumultuously acquitted Eutyches and condemned Flavianus; the bishops opposed to him were obliged to escape, and Flavianus was cruelly scourged by the soldiers; it was in short a scene of disgraceful violence, which earned for the council of Ephesus the name of 'a meeting of robbers.' Flavianus appealed to Leo the Great, bishop of Rome, who, in his answer, condemned the doctrine of Eutyches, but could not obtain of Theodosius the convocation of another council. After the death of that emperor, his successor, Marcianus, convoked a council at Chalcedon, A.D. 451, which is reckoned as the fourth œcumenical council of the Church, and which the pope's legates attended. By this assembly the acts of the council of Ephesus were annulled, Dioscorus was deposed and banished, and Eutyches, who had already been banished by the emperor, was again condemned, and deprived of his sacerdotal office. The doctrine was at the same time expounded that 'in Christ two distinct natures are united in one person, and that without any change, mixture, or confusion.' Eutyches died in exile; but several monks, especially in Syria, continued the schism, and having found a protectress in the empress Eudocia, the widow of Theodosius, who was living in Palestine, they became more daring, and excited the people against the partizans of the council of Chalcedon, whom they stigmatized as Nestorians. The emperor was obliged to send troops to repress these disorders. The doctrine of Eutyches was perpetuated in the East under certain modifications, or rather quibbling of words, which caused the sect to be divided under various names

all however comprehended under the general name of Monophysites, or believers in one nature. (Assemani, 'de Monophysitis,' at the beginning of vol. ii. of his *Bibliotheca Orientalis*, and Albutarragius's *arguments* in favour of that doctrine in the same vol., pp. 288,9.) In the sixth century a fresh impulse was given to the Eutychian doctrine by one Jacob, a monk, surnamed Baradaeus, who reconciled the various divisions of the Monophysites throughout the East, and spread their tenets through Syria, Armenia, Mesopotamia, and Egypt, found supporters among several prelates (among others in the bishop of Alexandria), and died himself bishop of Edessa, A.D. 588. He was considered as the second founder of the Monophysites, who assumed from him the name of Jacobites, under which appellation they still constitute a very numerous church, equally separate from the Greek, the Roman or Latin, and the Nestorian churches. The Armenians and the Copts are Jacobites, and so are likewise many Syrian Christians in contradistinction to the Melchites, who belong to the Greek church. Jacobite congregations are found in Mesopotamia.

The Monothelites who appeared in the seventh century have been considered as an offshoot of the Eutychians or Monophysites, though they pretended to be quite unconnected with them. They admitted the two natures in Christ, explaining that after the union of the two into one person there was in him only one will and one operation. This was an attempt to conciliate the Monophysites with the orthodox church, and it succeeded for a time. It was approved of by many eastern prelates, and even by Pope Honorius I., in two epistles to Sergius, patriarch of Constantinople, which are found in the Acts of the Councils. But the successors of Honorius condemned the Monothelites, and Martin I., in a bull of excommunication, A.D. 649, consigned them and their patrons (meaning the Emperor Constans, who protected them) 'to the devil and his angels.' Constans, indignant at this, caused his exarch in Italy to arrest Martin, and send him prisoner to the Chersonesus. At last, under Constantine, who succeeded Constans, the council of Constantinople, which is the sixth oecumenical council, A.D. 680, condemned the Monothelites, and with them Pope Honorius himself. (Mosheim, *The Acts of the Councils*; and Bossuet, in his *Defence of the Declaration of the Gallican Clergy*, 1682.)

EUXINE. [BLACK SEA.]

EVA'GORA. [MEDUSA.]

EVA'GRIUS, born at Epiphania, in Syria, about the year 536, practised as an advocate at Antioch, where he acquired a brilliant reputation. He was afterwards appointed quaestor, and filled other public offices. He wrote an ecclesiastical history in six books, beginning with A.D. 431, about the period where the histories of Socrates and Theodoretus terminate, and continuing to the year 593. His work is spoken of favourably by Photius. Evagrius, though not always to be trusted implicitly, yet shows greater discrimination than Socrates; he consulted the original documents, and appears to have been tolerably impartial. He was well acquainted with profane, as well as ecclesiastical history. His work was published by Robert Estienne, and afterwards by Valois, Paris, 1679, in an improved edition founded upon two different MSS. It was published again with notes at Cambridge, 1720.

EVALD, JOHANNES, the most distinguished poetical genius produced by Denmark in the eighteenth century, was born at Copenhagen, November 18th, 1743. His father, who was a clergyman in that city, possessed considerable theological attainments, but was prevented by ill health from acting as preceptor to his sons. Johannes, therefore, the second and most gifted of the three, was shortly before his father's death (1754) sent to Slesvig, where his tutor left him entirely to his own choice of books for his leisure reading. Among these were translations of 'Robinson Crusoe' and 'Tom Jones,' the former of which so captivated his imagination that he proposed its hero as a practical model to himself, and when no more than 13 years old, eloped with the view of making his way to Holland, and there get on board ship for Batavia; but he was overtaken, and his project frustrated. He was still, however, left as before to inflame his fancy with romantic reading and with legendary lore, including that of saints and martyrs, as well as of northern fable and mythology. In reading the classics it was the adventurous part that chiefly engaged his attention: indeed he had at that time no reliance whatever for the beauties of the Roman poets, as he him-

self has acknowledged in his fragmentary autobiography. Notwithstanding he was of exceedingly weak frame of body, he longed to devote himself to a military career, and the war then carried on between Prussia and Austria afforded an opportunity; but his mother would not consent to his entering the army. Soon after, his thoughts were for a while diverted from such views by a very different object. He suddenly became violently enamoured with a young lady, a relation of his step-father's, for his mother was now married again, whom he has celebrated under the name of Arense, and his passion for whom he has described in the most glowing colours; a passion which, although hastily conceived was lasting in its effects, and which, although the source of heartfelt bitterness to him—since Arense bestowed her hand upon another—while it cast a shade of melancholy over his whole life, had a favourable influence on his poetical talent, producing in him that depth of feeling and pathos which discovers itself in his 'Balders Död' (Death of Balder). At this period, however, poetry, at least authorship, formed no part of his plans. Dissatisfied with being beneath his step-father's roof, he joined with his elder brother in the scheme of entering the Prussian service as hussars. The latter returned after reaching Hamburg, but Johannes proceeded to Magdeburg, where he enlisted, but was received only as a foot-soldier. In consequence of this disappointment he deserted to the Austrians; served in Bohemia; and was at Dresden when that capital was besieged by the Prussians. On his return to Denmark he applied himself to the study of theology, with the view of settling in that profession and marrying, when his hopes of the latter were frustrated, as already noticed. He now regarded with indifference all schemes of earthly felicity; and it was in this frame of mind that he took up his pen and produced his 'Lykken's Temple' (The Temple of Fortune, a vision), which at once stamped his reputation. This was succeeded by his 'Adam and Eve,' a dramatic composition replete with poetical energy, yet in many respects defective and anomalous. Conscious of its imperfections, he devoted two years entirely to the study of poetry and the best models, in order to prepare himself for some more finished undertaking. Having made himself master of the English language, he carefully perused Shakspeare, with whom he was before acquainted only through Wieland's translation. Ossian was likewise a favourite with him, and when he again took up his pen, he composed his 'Rolf Krage, a tragedy strongly tinged with Ossianic taste. It was first given to the public in 1770; about which time he was attacked with a most painful disorder in his limbs, that continued to afflict him with little intermission during the rest of his life. Notwithstanding his severe sufferings, he not only pursued his literary occupations, but wrote his comedy of 'Harlequin Patriot,' a masterpiece of its kind, abounding with pleasantry and satire chiefly directed against pseudo-reformers. In the following year, 1773, he executed his literary chef-d'œuvre, 'Balders Död,' a drama of extraordinary poetical beauty, and greatly superior to anything of the kind that had then appeared in the Danish language. Yet although well received, its merits were not so well appreciated by its author's contemporaries as they have been since. Although it is on this and his other poetical works that his reputation chiefly rests, Evald produced several things in prose, some of which—as his 'Foralg om Pebersvende' (Project respecting Old Bachelors), are replete with shrewd satire and strong comic humour, notwithstanding they were written when he had to contend both with ill-health and distressed circumstances. Their liveliness forms a strong contrast to the seriousness and even melancholy that pervade his other writings; in which respect he presents a parallel to the author of 'John Gilpin.' There is likewise another point of resemblance between Evald and Cowper; each in his affliction met with generous sympathy and succour from a female friend. What Mary Unwin was to the one, Madame Skou was to the other; and it was beneath the hospitable roof of the latter that the Danish poet breathed his last, on the 17th March, 1781, after being confined during two years to his bed or arm-chair, and almost deprived of the use of his limbs. The two poets may further be likened to each other for the high moral tone of their writings, vividness of conception, and happiness of expression.

EVANGELIST is the Greek appellation *Euangelistos* (εὐαγγελιστής, from εὖ and ἄγγελος), which signified a messenger of any good news, as in Isaiah xli. 27, of the Ser-

tuagint version. In the first ages of Christianity it was a general name of all those who, either by preaching or writing, announced the 'glad tidings' of the Christian revelation. The learned Hooker, in his 'Ecclesiastical Polity,' b. v. § 78, says that 'Evangelists were presbyters whom the apostles sent forth, and used as agents in ecclesiastical affairs.' They were similar to the class of ministers who in modern times are known as itinerant preachers. The deacon (subordinate minister) Philip is called an evangelist (*Acts* xxi. 8: see Grotius on the passage); so Ananias, Apollos, Timothy, and several others. St. Paul, in his epistle to the Ephesians (iv. 11), places evangelists in the third rank of ecclesiastical officers; thus, apostles, prophets, evangelists, pastors, teachers. The use of the term is now confined to the four writers to whom the canonical gospels are attributed, Matthew, Mark, Luke, and John, and the gospels themselves are not unfrequently, though incorrectly, called the Evangelists. St. Jerome states that the symbols of the four evangelists are a man, a lion, a calf, and an ox; but St. Augustine declares them to be a lion, a man, an ox, and an eagle. (*Ezekiel*, i. 5-10; *Rev.* iv. 7.) Dr. Campbell, in his 'Dissertation on the Gospels' (vol. i. p. 126, &c.), gives a variety of learned and critical remarks on the word *εὐαγγελιστῶν* as the translation of the Hebrew *בשר* *bashar*, 'læta annunciare,' 'to announce good tidings.' (See the word in Rose's ed. of Parkhurst's *Gk. Lex. of the N. T.*, and a list of works on the Evangelists in Watt's *Bibliotheca Britannica*, and Horne's *Introduction to the Bible*.) General histories of the four Evangelists have been written by Kirstenius, Spanheim, Mollerus, Florinus, Schröder, &c.

EVAPORATION. [HEAT.]

EVECTION. [LUNAR THEORY.]

EVELYN, JOHN, author of 'Sylva,' 'Memoirs,' &c., was the second son of Richard Evelyn, Esq., of Wotton, in Surrey, and was born at that place October 31, 1620. He received his education at Lewes' free school and Balliol College, Oxford. In 1641 he went abroad, and served for a short time as a volunteer in Flanders. Instead of taking arms in the royalist cause, as his family politics would have inclined him, he went abroad a second time in 1644, with the king's permission, and spent, with one interval, the next seven years on the continent, diligently employed in studying natural philosophy, cultivating his taste in the fine arts, and acquainting himself with such particulars of manners, trade, and manufacture as were most worthy of notice. In June, 1647, he married the daughter of Sir Richard Browne, the royalist ambassador at Paris, and in right of his wife became possessed of Sayes Court, near Deptford, where he fixed his abode on returning to England in 1652. He lived in privacy and study till the Restoration; after which, being much esteemed by the king and of some weight by family, fortune, and character, he was often withdrawn from his retirement and engaged in many capacities in the public service. He was appointed a commissioner to take care of the sick and wounded, on the Dutch war breaking out in 1664, commissioner for the rebuilding St. Paul's, a member of the Board of Trade on its first institution, &c. He was also one of the first members of the Royal Society, and continued through life a diligent contributor to its 'Transactions.' His most favourite pursuits were horticulture and planting, upon which he wrote a variety of treatises, which are collected at the end of the fifth edition (1729) of his 'Sylva, or a Discourse on Forest-trees and the Propagation of Timber in his Majesty's Dominions,' first published in 1664. The object of this, the best known and chief of Evelyn's works, was to encourage planting, both as a matter of national interest and of private adventure. It sold largely, and, as Evelyn himself says, had no small effect. In the same year he published the first 'Gardener's Almanac,' containing directions for the employment of each month. This was dedicated to Cowley, and drew forth one of his best pieces, entitled 'The Garden,' in acknowledgment.

Mr. Evelyn's works on the fine arts are: 'Sculpture,' 1662, a history of the art of engraving, in which the first account is given of Prince Rupert's new method of mezzotinto engraving: 'A Parallel of Antient and Modern Architecture,' 1669: 'Numismata, a Discourse upon Medals,' 1697. All these, though long superseded, were much esteemed, and were in fact valuable additions to the then existing stock of literature.

By the death of his brother, in October, 1699, Mr. Evelyn

succeeded to the family estate at Wotton, where he died, February 27, 1706, full of honour as of years. He was a diligent and successful labourer, in that age of discovery, in the subordinate departments of science; a valuable pioneer, as he used to call himself, in the service of the Royal Society. Besides this, he was a model for the character of a gentleman. A friend of the learned and the good, devoid of jealousy, pious, beneficent, intellectual, delighting in the occupations of his station, yet always ready to quit them for the public service: he was respected even by the court profligates to whom his example was a daily reproach. To the present age he is best known by his *Memoirs*, a journal extending nearly from his childhood to his death, which contains much curious matter relative to his travels, and to the manners and history, political and scientific, of the age. Many of his letters, and the private correspondence of Charles I. with Secretary Nicholas, and Clarendon with Sir R. Browne, are subjoined to these memoirs, which were first printed in 1818. (*Kippis, Biog. Brit.; Preface and Appendix to Memoirs.*)

EVERGEM, a town and commune of East Flanders, in the district of Ghent, about three miles north of the city of Ghent, in 51° 8' N. lat. and 3° 44' E. long. The canal of Sas-de-Gand, which connects Ghent with the Scheldt, passes Evergem, the little river Caele runs on the south of the town, on the south-west is the Ghent and Bruges canal, and on the west the Liève, which rises in the north-east quarter of West Flanders and joins the Bruges canal near Evergem. The population of the town is 7790; it contains establishments for cotton-printing and dyeing, breweries, distilleries, and a salt-refinery. Cotton and linen weaving give employment to many of the inhabitants. In 1832 the town contained a communal and six private schools: in the former 57 boys and 49 girls were taught, and in the latter 261 boys and 211 girls.

(*Vandermaelen's Dictionnaire Géographique de la Province de la Flandre Orientale.*)

EVERGREENS, in horticulture, are plants which shed their old leaves in the spring or summer after the new foliage has been formed, and which consequently are verdant through all the winter season; of this nature are the holly, the laurel, the ilex, and many others. They form a considerable part of the shrubs commonly cultivated in gardens, and are beautiful at all seasons of the year.

The principal circumstances in which evergreens physiologically differ from other plants are the hardness of their cuticle, the thickness of the parenchyma of their leaves, and the small number of breathing pores formed on the surface of those organs. These peculiarities, taken together, enable them to withstand heat and drought with more success than other plants, but are often not sufficient to protect them against such influences in excess. Hence we find them comparatively uncommon in those parts of the continent of Europe where the summers are hot and dry, and most flourishing in a moist insular climate like our own. This is rendered more intelligible by a comparison of the proportions borne by their evaporating pores, or stomates, and those of deciduous plants. As far as this subject has been investigated, it appears that their leaves are usually altogether destitute of such organs on the upper side, and that those of the lower are mostly fewer in number and much less active than in deciduous plants.

The greater part of evergreens are raised from seed; some are propagated by cuttings or layers, and the variegated varieties by budding and grafting. The soil in which they succeed best differs with the kinds; American evergreens, such as rhododendrons, kalmias, &c., grow best in equal quantities of peat earth, sand, and vegetable mould; European sorts grow in their greatest vigour in a fresh hazely loam, but will thrive in almost any kind of soil.

The operation of transplanting evergreens may be performed with success at almost all seasons of the year. *Mid-summer planting* has even been recommended; it however is a work of necessity rather than propriety, because its success depends entirely upon the nature of the weather after the operation; if it be cloudy and wet for some time they may succeed; but if, on the contrary, it be hot and dry, they are sure to suffer: for this reason, if the practice may be adopted, it is not to be recommended. The common holly however has been often known to succeed when planted at this season, either for hedges or as single plants. The hollies in one very remarkable case, were carefully dug up in the cool of the evening and removed to large trenches

which had been prepared for their reception; a quantity of water was then poured upon the roots, and the soil thrown upon the top of it, which of course was carried down and deposited in all the crevices in the trench, rendering the plants perfectly firm. In the instance alluded to the weather was very favourable for a considerable period after the operation was performed.

Autumn and spring are much better seasons for work of this kind; the plants are not so liable to suffer from the intense heat of the sun, and are more likely to be benefited by dews and frequent rains.

But, according to the most experienced cultivators, the winter months (that is, from October to February) are decidedly the best time for transplanting evergreens. Mr. McNab, who is one of the greatest authorities upon this subject, says—"I have planted evergreens at all seasons of the year with nearly equal success, except from the middle of June to the middle of August, and even during this period I have planted some; but unless the weather is very dull and moist, it is difficult to prevent the plants suffering considerably, and in many cases it is years before they recover. Although, however, I have planted evergreens ten months out of the twelve with little difference of success, yet one season has a preference over the others with me, and when there is the power of choice I would recommend late in autumn, winter, or early in spring; that is, any time from the middle of October till the middle of February; and, in general, the beginning of this period is the best; that is, from the middle of October till the middle of December; always providing that the weather and the ground are favourable; that is, supposing there is no frost, no drying wind, nor much sunshine, and that the ground is not too much saturated with wet, either from continued rain, or from the nature of the soil. One of the principal things to be attended to in planting evergreens is to fix on a dull day for winter planting, and a moist day for spring and autumn planting."

It is of great importance to keep a number of the more tender sorts of evergreens in pots, in order to send them to a distance if required; and if they are to be transplanted at home their roots are not so liable to be injured as when they are dug from the ground. The more tender species of the following genera should be treated in this way:—*Arbutus*, *Cupressus*, *Daphne*, *Erica*, *Juniperus*, *Laurus*, *Mag-nolia*, *Phyllirea*, *Pinus*, *Quercus*, *Rhamnus*, *Thuja*, &c.

In lifting evergreens particular care should be taken of the young rootlets, as upon their preservation the success of the operation, in a great measure, depends; especially if the specimens have arrived at any unusual size. Small evergreens are planted like other things; but the following precautions should be observed in all cases where individuals of any great size are the subject of the operation.

When the plant has been lowered into the hole dug for its reception, the soil must be thrown in loosely around it (not trod in), and a basin made to hold a quantity of water, which must be filled several times until the whole is completely saturated; this will convey the particles of soil down to the roots of the plant, and render it much more firm than any other method. By this treatment we have seen plantations of evergreens formed without a single failure, which, when finished, appeared to have been growing for many years.

It matters little what size the plants have attained, if they can only be lifted without injuring the small fibres of the roots: they have been moved, from ten to twenty feet high and otherwise large in proportion, with complete success. Should, however, the roots be unavoidably injured in transplanting, the branches must be closely pruned and shortened in proportion; so that when they begin to draw upon the roots for support they may not require more nourishment than the latter can supply.

Considering the great importance of evergreens in a climate like that of Great Britain, where they flourish in such unrivalled beauty, and form so much natural protection to bleak exposed situations, they cannot be too extensively planted. The following lists will furnish information as to the principal kinds to be procured in the nurseries.—

I. *Evergreens whose beauty depends exclusively upon their foliage.*

TREES.

Abies. All the species, where the soil is light enough to suit them, particularly *A. Douglasii*, *excelsa*, the Norway

Spruce, *Deodara*, the Cedar of India, *Cedrus*, the Cedar of Lebanon, and *Larix*, the common Larch, together with *balsamea*, the Balm of Gilead, *picea*, the Silver fir and *Webbiana*, the Silver fir of the Himalaya mountains. [ABIES.] The Cedar of Lebanon will grow well in a swamp.

Araucaria imbricata, the glory of the mountains south of Chili: it will hardly succeed north of the midland counties.

Cunninghamia lanceolata, the Chinese fir; very handsome, but only suited to the south of England.

Cupressus sempervirens, the common cypress, and *C. horizontalis*, the spreading cypress, are quite hardy: and the latter, if to be procured, forms a tree much more ornamental than the other with its formal shape. But the nurserymen almost always sell a slight variety of *C. sempervirens* for it.

Cupressus lusitanica, the Cedar of Goa, is a beautiful tree, but only suits the climate of southern counties.

Ilex Aquifolium, common Holly: the nurseries contain endless varieties of it, both green and variegated. The latter are not to be compared with the others for beautiful effect.

Juniperus. The *J. excelsa* forms a fine tree; *J. Virginiana*, the common Virginian Cedar, is less handsome: but both are quite hardy. [JUNIPERUS.]

Pinus. All the species where the soil is light and steril enough, with that proportion of decayed unfermented vegetable matter which this genus delights in. The finest, as ornamental plants, are *P. pinaster*, *taurica*, *Pinea*, the stone pine, *nigricans*, *halepensis*, and *Pullasiana*, which will grow in any soil that is not stiff and swampy in winter. *P. sylvestris* and *nigricans* are the hardest.

Quercus. The *Ilex*, or Evergreen oak, of which there are many varieties; *austriaca*, of which the Lucombe and the Fulham oaks are possibly domesticated forms; *Tur-neri*, *Suber*, the cork-tree, and *gramuntia*, the Bellota, or Spanish oak with sweet acorns, are all fine species equally handsome when young as bushes, and when old as trees. [QUERCUS.]

Taxus baccata, the common Yew, and *fastigiata*, the Irish Yew.

Thuja occidentalis, the American, and *orientalis*, the Chinese Arbor Vitæ.

SHRUBS OR BUSHES.

Aristotelia Maqui, a Chilean broad-leaved shrub, quite hardy.

Abies Clanbrasiliana, a curious dwarf fir, only suited to plant singly upon grass.

Cunninghamia lanceolata, the Chinese fir, rarely grows beyond the size of a bush.

Arbutus Andrachne, the Oriental Strawberry tree, and *hybrida*.

Aucuba Japonica, a Japanese spotted-leaved bush.

Buxus sempervirens, the tree box; will succeed in light, especially sandy, sterile soil; prefers chalky downs; will not thrive in stiff wet soil.

Juniperus communis, the common juniper; *Suecica*, the Swedish juniper, much less handsome; *Sabina*, the Savin bush, excellent for undergrowth and ornamental as a single bush upon lawns.

Laurus nobilis, the sweet bay, quite hardy, though a native of 'the warm south'; its aromatic leaves employed in confectionary, pickles, &c.

Ligustrum vulgare, the common privet; excellent for hedges and for undergrowth, especially the *evergreen* variety.

Phyllirea. Every variety of this valuable genus should be cultivated; *obliqua* and *latifolia* as large species, *media* as a middle-sized one, and *angustifolia* as a graceful bush.

Pinus pumilio or *Mughus*, the alpine pine tree.

Rhamnus alaternus, of which there are several varieties and *R. Clusii*; hardy bushes, which bear pruning or cutting down to the ground remarkably well.

TWINERS.

Hedera. Many varieties of the common ivy; *Cunariensa*, the Irish ivy; and *chrysocarpa*, the golden-berried.

II. *Evergreens whose flowers have a conspicuous appearance*

TREES

Andromeda arborea requires peat; grows 40 feet high in North America.
Arbutus Unedo, the common strawberry tree; of this there is a beautiful variety with deep red flowers, and another with double flowers, much less handsome than either.
Acacia affinis grows without protection near Edinburgh; *dealbata*, *lophantha*, and several other New Holland species, will flourish without protection in the southern counties.
Eucalyptus perfoliata, *pulverulenta*, exist in the open air near Edinburgh; they and other species will thrive in the South and West of England.
Ligustrum lucidum, the wax tree, a Japanese plant.
Magnolia grandiflora, with many varieties; they are scarcely hardy enough to live in this country away from the shelter of a wall, except quite in the south; unprotected specimens exist, however, near Edinburgh.

SHRUBS OR BUSHES.

Andromeda. The handsomest species are *A. Catesbaei*, *angustifolia*, *Mariana*, which is rather tender, *pulverulenta*, *speciosa*, and *floribunda*. Require peat soil.
Areostaphylos Uva Ursi, a trailing plant.
Ammyrsine Lyoni, a beautiful little American bush, requiring peat.
Berberis aquifolium, *fascicularis*, *repens*, *Asiatica*, *aristata*. [BERBERIS.]
Bupleurum fruticosum stands the sea-breeze well upon chalky cliffs.
Cistus, all the species. They are quite hardy if planted where wet cannot lodge in winter, and exposed to the full sun in summer.
Colletia spinosa.
Cotoneaster microphylla and *rotundifolia*, small bushes.
Cytisus scoparius, common broom; there is a double variety; *albus*, the Portugal white broom.
Daphne. All handsome, the following the most so. *Lauricola*, the spurge laurel, grows well beneath trees; *pontica*, with pale green fragrant flowers; and *Cneorum*, or Garland flower, one of the most lovely and sweetly perfumed plants in the world, but not to be cultivated except in a dry peaty soil and a well ventilated situation; late spring frosts injure it so much that it is not worth cultivating in valleys.
Duvaua dependens, and some others.
Erica Australis, *carnea*, *stricta*, *Mediterranea*, *codonodes*. [ERICA.]
Escallonia rubra, *illinita*, *montevideensis*, handsome South American shrubs. Bees take great delight in the blossoms of the last: the second species smells very strongly of melilot.
Garrya elliptica, with long pendulous catkins of a yellowish green colour.
Gemista tinctoria, the dyer's broom, with a few others.
Helianthemum of all kinds, to cover rockwork, or ground where the wet does not lodge in winter.
Kalmia latifolia, *angustifolia*, especially the first; require peat.
Lavandula spica and *latifolia*, common lavender.
Ledum latifolium, or Labrador tea, and *palustre*, low bushes requiring peat.
Menziesia polifolia or Irish heath; there is a white variety.
Myrtus communis, and its varieties; lives out of doors south of London.
Prunus Laurocerasus, the common laurel; *astanica*, the Portugal laurel.
Pittosporum Tobira, quite hardy south of London; sweet-scented.
Rosmarinus officinalis, common rosemary.
Rhododendron. Numerous varieties are to be procured; those of *ponticum*, *maximum*, and *cataubiense* are the most robust; *hybridum* obtained between the Indian and American species is less hardy; *ferrugineum* and *nirsutum*, dwarf alpine species; *campanulatum*, a North Indian species.
Spartium Junceum, Spanish broom; and *acutifolium*, a Turkish broom.
Tiburnum. Of the Laurustinus, one of the prettiest of all evergreens, there are three species; *V. Tinus*, the common Laurustinus, the hardiest; *V. lucidum*, with shining leaves, rather larger and more delicate; *V. strictum*, with

upright shoots, more hairy, and the least hardy of the three.

Ulex Europæus, the common furze; a double variety, which is particularly handsome; and *U. strictus*, the Irish furze, a smaller species, which does not flower abundantly.

Yucca. Several species quite hardy. They only require to be grown in places where water does not stagnate in winter; *Y. gloriosa*, *filamentosa*, *Draconis*, *flaccida*, and *superba*, are the handsomest species.

TWINERS OR CLIMBERS.

Bignonia capreolata, with dull brownish-red trumpet-shaped flowers; rather tender.

Caprifolium flexuosum, *græven*, *japonicum*, *sempervirens*, all handsome honeysuckles.

Jasminum revolutum and *officinale*, the common white jasmine.

Vinca major and *minor*, the larger and smaller periwinkle; trailers.

EVERLASTING FLOWERS. This name is popularly given to certain plants whose flowers have the property of retaining their brightness and colour for many months after being gathered. They owe this quality to a hardness of their tissue, which has exceedingly little moisture to part with, and which, consequently, does not collapse or decay in the progress of acquiring perfect dryness. It is generally in the scales of the involucre of composite plants or in the bracts of others that this property resides. Those who wish to possess such plants will easily find the following in the gardens of this country.

Hardy annuals. *Helichrysum bracteatum* (yellow), *Xeranthemum annuum* (purple or white).

Hardy perennials. *Antennaria dioica* (pink), *tripplinervis* and *margaritacea* (white). *Ammobium alatum* (white). *Gnaphalium stæchas* and *arenarium* (yellow).

Tender annuals. *Rhodanthe Manglesi* (red), *Morna nitida* (yellow), *Gomphrena globosa* (purple).

Greenhouse shrubs or herbaceous plants. *Astelma eximium* (crimson), *Helichrysum argenteum* (white), *ericoides* (pink), *sesamoides*, *proliferum*, and others (purple).

EVESHAM, a borough and market-town, having separate jurisdiction, locally situated in the hundred of Blackenhurst, in the county of Worcester, 15 miles south-east from Worcester, and 96 north-west-by-west from London. Evesham was formerly called 'Eovesham,' or 'Eovesholme,' an appellation derived from 'Eoves,' a swineherd of Egwin bishop of Wicci, who was superstitiously supposed to have had an interview with the Virgin Mary on this spot. It owes its importance to an abbey that was founded here in 709, and dedicated to the Virgin.

The abbot and the convent received numerous grants of land, as well as ecclesiastical and temporal privileges from various kings and other benefactors. The last abbot but one was Clement Lichfield, who built the isolated tower, now almost the only relic of this once celebrated abbey. This tower, called the Abbot's Tower, is a beautiful specimen of the pointed architecture of the period immediately preceding the Reformation: it is supported by panelled buttresses, adorned with windows having rich ogee mouldings, and surmounted by open embattled parapets and eight pinnacles. It was originally intended for a campanile, to which purpose it was converted in 1745. The tower is 110 feet in height, and is 22 feet square at the base.

A battle was fought near Evesham on the 4th of August, 1265, between Prince Edward (afterwards Edward I.) and Simon Montfort, earl of Leicester. Leicester placed King Henry III., whom he had made prisoner, in the van of his army, hoping that he might be killed by his son's troops, who were fighting for his release. However, the king was recognised nearly at the first onset by the prince, who rushed through the thickest of the battle to the assistance of his father, and soon placed him in safety. Leicester's defeat was complete, and he himself, as well as his son, fell in the field of battle.

The corporation claim prescriptive rights and privileges, but they were all confirmed by charter in the 3rd year of the reign of James I. They had the power of trying and executing for all capital offences, except high treason; and as late as 1740 a woman was burnt for petty treason. A court of record is held every Tuesday for the recovery of debts to 100*l.*; a court of session is also held for the borough on the Friday after the county quarter-sessions. The borough returned two members to parliament in the 23rd of

Edward I., and again in the reign of James I., since which time it has continued to do so. In 1831 there were 3991 inhabitants the number registered is 359. Evesham is one of the few municipal boroughs the boundaries of which were not altered by the Reform and Municipal Corporation Acts. The town is pleasantly situated on the banks of the river Avon, over which is a stone bridge, which connects it with the parish of Bengworth, which is within the boundaries of the borough. The two principal streets are wide and clean, and the town has a cheerful appearance. The Vale of Evesham is famous for the richness of its soil; and large portions of land near the town are laid out in gardens, which supply the neighbouring towns and villages with vegetables and fruit. There are also some corn-mills, and a linseed-oil mill. The market-day is Monday. Fairs are held on the 2nd of February, the Monday after Easter, Whit-Monday, and the 21st of September: the latter is famous for cattle and horses.

The borough comprises the parishes of All-Saints, St. Lawrence, and Bengworth, in the archdeaconry and diocese of Worcester. The living of All-Saints is a vicarage, which, with the curacy of St. Lawrence, is of the clear annual value of 208*l*. The church is said to have formed part of the abbey; it is in the later style of English architecture, and has a tower, spire, and a handsome porch. The church of St. Lawrence is now quite in ruins, and forms a beautiful specimen of the ornamented Gothic. In the south aisle is the chapel of Clement Lichfield; it is only 18 feet by 16, but is (as Tindal says) of such elegance and delicacy of construction as a verbal description would but very imperfectly convey to the reader's imagination.

There are places of worship for Baptists, Quakers, Wesleyan Methodists, and Unitarians. The free grammar-school, endowed originally by Abbot Lichfield, was re-founded by Henry VIII., and again re-modelled by James I. The master receives 10*l*. per annum from the crown, a house, and some other emoluments. At Bengworth there is a school, founded by John Deacle in 1709, for poor children of that parish. There are also several donations to the poor, and for apprenticing children.

In the parish of Bengworth was a castle belonging to the Beauchamp family, but it was destroyed by Abbot William D'Andeville in 1169, and the site was converted into a burying-ground, for which we believe it has continued to be used down to the present day. (For a full account of the abbey and antiquities, see Tindal's *History of Evesham*.)

EVIDENCE (Judicial). Evidence, in jurisprudence, denotes the means by which facts are ascertained for judicial purposes. The practical importance of the subject is obvious from this definition; and it has accordingly not only attracted much attention from judicial writers, but has formed a prominent part of the systems of jurisprudence of most civilized countries, though the particular rules of evidence adopted have varied according to the constitution of the tribunal by which judicial truth is to be ascertained. Thus the Roman law, in which facts are ascertained for judicial purposes by professional judges, contains (so far as we now know it) few regulations respecting evidence, the whole subject being comprised in one short chapter of the Digest, which lays down several positive rules for the exclusion of witnesses within prescribed degrees of consanguinity to the litigant parties. In the common law of England, where facts are ascertained by juries, the body of rules and restrictions denominated the law of evidence has been gradually established within the last two centuries. Previously to that time, in the infancy of the trial by jury, as we understand that institution, the only positive rules respecting evidence were those which related to the two witnesses in treason required by statutes passed in the reign of Edward VI. This fact of the gradual development of restrictions upon the admission of testimony seems to show that, in this country at least, the tendency of civilization has been to contract and not to enlarge (as some writers have supposed) the rules of judicial evidence. The accounts of our earlier judicial proceedings contained in the State Trials sufficiently prove that it was the practice formerly to admit without scruple or question every species of testimony; whereas the present law of evidence is almost wholly composed of restrictive rules.

In giving a compendious view of the principles of the English law of evidence (which are the same at equity as at common law, and in criminal and civil proceedings) it is proposed—1. To enumerate the limitations which it pre-

scribes to the competency of witnesses; 2. To give a brief summary of the principal rules by which the reception of oral evidence is governed; and 3. To state the principal rules which relate to written evidence.

I. Of the competency of witnesses.—The general rule of English law upon this subject is, that all persons may be witnesses in courts of justice who have sufficient understanding to comprehend the subject of their testimony, and sufficient religious principle to ensure a right sense of the obligation of an oath to speak the truth. Thus very young children are admissible as witnesses, if they have a competent knowledge of the nature of an oath, and a religious apprehension of the consequences of falsehood. All testimony, by the law of England, must be given under the sanction of an oath; but the form of the oath is immaterial, and nothing is required beyond a persuasion upon the mind of the witness that in swearing to the truth of what he states he is appealing to a Divine Being able to punish him for falsehood.

To the general rule of the admissibility of all persons of sufficient intellect and religious belief there are several important exceptions. In the first place, a husband cannot be a witness for or against his wife, nor a wife for or against her husband; a rule which is said to arise from the identity of interest subsisting in such a connexion. However, in criminal prosecutions founded upon personal violence committed by either of these parties upon the other, such testimony is admitted upon the ground of necessity. Secondly, in actions at the common law, a party to the suit cannot be examined as a witness; but in courts of equity defendants in a cause may be made witnesses upon a special application for that purpose; and in those courts, if a plaintiff consents to be examined as a witness his evidence may be admitted. Thirdly, a person cannot be a witness who has been convicted of treason or felony, or of any offence which involves the *crimen falsi* (such as perjury or cheating), or which is liable to a punishment which the law considers infamous, as whipping, branding, or the pillory. This principle of exclusion, which is derived from the Roman law (*Digest*, lib. ii., tit. *De Testibus*), is now of little practical importance, as the recent statutes have enacted that a pardon in felons, or the actual endurance of the punishment in felony or misdemeanour, excepting perjury or subornation of perjury, shall have the effect of restoring the competency of the party as a witness. Fourthly, the law of England excludes the evidence of those who have a direct interest in the result of the proceedings in which they are called to testify. The indefinite state of the rule respecting the nature of the disqualifying interest has led to much perplexity in its practical application.

The principle however which is illustrated by a great variety of cases, is, that, in order to disqualify a witness on the ground of interest, he must either be directly and immediately benefited by a result of the proceeding favourable to the party who calls him, by exonerating himself from a liability to costs or to some process founded upon the decision of the cause in which he is called to testify; or he must be in such a situation as to be able to avail himself of the decision of the cause, by giving it in evidence in support of his own interest in some future litigation. The first of these alternatives is, in fact, nothing more in principle than a part of the same proposition which excludes the parties to a suit from being witnesses; for where the determination of the suit in one way directly affects the witness in interest, he is in a certain sense a party to it, and would, in fact, be testifying in his own cause. The second section of the rule which is peculiar to the law of England, and first appeared in practice about fifty years ago, is of more doubtful expedience. It is much more exclusive in its operation than the former, and is objectionable and inconvenient in practice by introducing into the question of the competency of a witness in a particular action the complicated and embarrassing process of considering his position in every supposable litigation which may afterwards affect him as arising out of that action. With the view of removing the practical difficulties arising from this objection, it was enacted by the stat. 3 & 4 Will. IV., c. 42, § 26, that 'if any witness shall be objected to as incompetent, on the ground that the verdict or judgment in the action on which it shall be proposed to examine him would be admissible in evidence for or against him, such witness shall nevertheless be examined; but in that case a verdict or judgment in that action in favour of the party on whose behalf he shall have

been examined, shall not be admissible in evidence for him; nor shall a verdict or judgment against the party on whose behalf he shall have been examined be admissible in evidence against him. By the 27th section, it was enacted that the name of every witness objected to as incompetent, on the ground that the verdict or judgment in the cause in which he is examined would be admissible in evidence for or against him, shall, at the trial, be indorsed on the record on which the trial shall be had, together with the name of the party on whose behalf he was examined, and shall be afterwards entered on the record of the judgment; such indorsement or entry to be sufficient evidence that such witness was examined in any subsequent proceeding in which the verdict or judgment shall be offered in evidence.

II. *The principal general rules by which the reception of oral evidence is regulated.*—The first general rule which applies equally to written as to oral testimony) is that all evidence produced must be relevant to the point at issue between the parties. The object of special pleading by the common law is to reduce controversies between parties to particular issues, or propositions of fact affirmed by one and denied by the other, which are to be decided by the jury; and the rule of evidence, that the proofs in the cause must be strictly confined to these issues, is founded upon obvious reasons of justice as well as convenience. Secondly, the affirmative of every issue is to be proved; that is, the party who asserts the affirmative of a proposition is to bear the burthen of proving it. This principle is taken from the civil law; '*Ei incumbit probatio qui dicit, non qui negat.*' Thirdly, in proving a fact, the best evidence of it must be given of which the nature of the thing is capable. Thus, a party is not permitted to prove the contents of a deed by a copy, and still less by oral testimony, where the deed itself may be produced; nor to prove the execution of a deed by any other person than a subscribing witness, when he is living and producible. This rule is justified by the presumption which the offer of secondary evidence raises, that the production of the best evidence might have prejudiced the party in whose power it is, had he produced it. This rule is not, however, to be understood as requiring that all the evidence which can be given upon the fact in dispute should be produced; as, for instance, if there are several attesting witnesses to a deed or other contract, it is not necessary that more than one should be called. Fourthly, hearsay testimony, which is a statement on oath of what an absent person has said respecting a fact to be proved, is, in general, excluded both on the ground that the witness to the actual fact does not declare his knowledge upon oath, and also because he is absent from the cross-examination of the party who is to be affected by what he states. To this rule, however, there are the following exceptions:—1. The declarations of persons who are in imminent danger and under the apprehension of immediate death, and who are therefore considered to be speaking under as powerful a religious sanction as the obligation of an oath; 2. The declarations of deceased persons, and made against their interest; as, for instance, charging themselves with the receipt of money on account of third persons, or acknowledging the payment of money due to themselves; 3. The declaration of deceased persons respecting rights of a public nature, such as the boundaries or general customs of a manor or district; 4. The declarations of deceased persons on questions of pedigree, or family occurrences of antient date before the memory of living witnesses, such as births, deaths, or marriages. With respect to the two last exceptions, however, evidence of declarations of this kind is inadmissible, if they have been made *post litem motam*, that is, after the matter to which they relate has become the subject of litigation.

III. *Written evidence consists of records, documents under seal, as charters and deeds, and writings not under seal.*—Acts of parliament are records of the highest nature, being the memorials of the legislature; but a distinction is made with respect to evidence between public and private statutes. A public statute requires no express proof in courts of justice, every one being presumed to know the law which he is bound to observe; as to them, therefore, the citation of the statute itself is in all cases sufficient. But private acts of parliament are considered as documents relating to individuals, and must therefore be proved by copies compared with the original roll of parliament. A second and inferior species of records is the proceedings of courts of justice, which are proved by exemplifications, sworn

copies, and office copies. Exemplifications are transcripts of the records of different courts, accredited by having the seals of such courts attached to them. Sworn copies are transcripts made by individuals who authenticate them upon oath, when they are produced in evidence. Office copies are copies certified to be true and accurate by an officer expressly entrusted for that purpose by an officer of the court to which the records belong. Charters and deeds are proved by the production of the instrument and proof of the execution by the party to be charged with it; but where the document is more than thirty years old, the execution need not be proved. The general rule is that the original deed must be produced, on the principle already alluded to of its being the best evidence; but this is subject to the following exceptions:—1. Where it has been lost or destroyed by accident; 2. Where it is in the possession of a party to a suit against whom it is sought to be produced, and who refuses to produce it: in either of which cases the contents of the document may be proved by a copy, or if no copy exists, by oral testimony. Deeds attested must, in general, be proved by one at least of the subscribing witnesses; but if the attesting witnesses be dead, or are not to be found after a diligent search, or are infamous, or for any other reason incompetent by law to give evidence, the execution of the deed may be proved by proof of the hand-writing of the party. The proof of hand-writing, by the law of England, is peculiar. The testimony of persons skilled in hand-writing is wholly excluded, comparison of hands being inadmissible for the purpose. The course is that a witness acquainted with the writing of the individual in question, and who has seen him write, or who has had a written correspondence with him, shall testify to his belief that the document to be proved is in his hand-writing.

From the above summary of the principal rules of evidence existing in the English law, it will be observed that the system is extremely exclusive. Upon the subject of interested witnesses, the law does not merely caution and restrict the amount of credit to be given, but entirely rejects them from being heard wherever a pecuniary interest in the result of the cause, however small, is shown to exist. So also with respect to the reception of secondary and hearsay evidence, it sanctions no degree or kind of testimony at second-hand (except in the cases above enumerated), but excludes it under all varieties of circumstances. That the statement of an interested person is always to be received with caution, often with suspicion, and often with disbelief, may be readily admitted; that it should be always peremptorily rejected as unworthy to be heard is a different and much more questionable proposition. Again, it is true that we ought not to attach so much weight to hearsay evidence as to direct testimony, because it is beyond all doubt that the certainty of obtaining the truth is diminished, and that the means and causes of error are multiplied, in proportion as you remove from the actual observer and add links to the chain of testimony. 'Any testimony,' says Mr. Locke, in his chapter on the Degrees of Assent, 'the further off it is from the being and existence of the thing itself, the less force and proof it has. A credible man vouching his knowledge of it is a good proof; but if another, equally credible, do witness it from his report, the testimony is weaker; and a third that attests the hearsay of an hearsay is yet less considerable. So that, in traditional truths, each remove weakens the force of the proof; and the more hands the tradition has necessarily passed through, the less strength and evidence does it receive from them.' Admitting the justice of this objection to the effect of hearsay evidence, it may still be questioned whether its absolute and unconditional rejection for judicial purposes is justifiable. So also with respect to the mode of proving hand-writing, it might be unsafe wholly to rely upon the evidence of comparison of hands by persons of experience in that occupation, but there seems no good reason why such proof should not be admissible in aid of the present vague and unsatisfactory mode of proof by the general belief of a witness.

The most plausible reason for the exclusiveness of the English law of evidence is derived from the nature of the trial by jury, with reference to which it is contended to be safer to withdraw doubtful evidence altogether from their consideration, than to leave it to persons who are often uninstructed, and incapable, of drawing correct distinctions upon the subject of testimony to form a proper estimate of its credibility. But this reason is founded upon an assumption not justified by the fact, namely, that the means of

proof actually legalized are infallible guides to truth; whereas, the truth is that many of them are quite as liable to lead to a false conclusion as those which are excluded. In this state of things, therefore, there seems no good reason why all practicable means of attaining to truth, however various in their degrees of effectiveness, should not be committed to juries. This seems indeed to be the growing impression in the profession; the inclination of the courts of late years being to let in as much light to a cause as possible, and to regard objections to evidence rather as matters of *credibility* upon which juries may exercise their judgment, than of *competency* to be wholly withdrawn from their consideration.

In the article *EQUITY* a reference is made to the present head of *EVIDENCE*, and we shall accordingly briefly state the manner of ascertaining facts in courts of equity, which differs from the practice in courts of law, where the witnesses are produced and examined orally before the court.

Witnesses in proceedings in equity are examined upon written interrogatories before the examiner of the court or before commissioners in the country, both examiner and commissioners being sworn to secrecy. The answers of the witnesses to these written interrogatories, or their depositions, as they are called, are taken down in writing, and form the only evidence for the plaintiff and defendant (except the defendant's answer, if the plaintiff chooses to avail himself of it), which is admitted at the hearing of a cause.* The interrogatories are drawn by counsel, according to the instructions which he receives as to the facts which a witness is considered able to prove; but it frequently happens that the instructions are very defective, and the counsel is obliged to frame his interrogatories as well as he can, in order to elicit the proof of facts favourable to the party for whom he is employed. Though each several interrogatory, when well drawn, is framed for the purpose of establishing some single and distinct fact, written interrogatories cannot from their nature be otherwise than long and somewhat difficult to comprehend. In the oral examination of a witness, it necessarily happens that several questions must be asked consecutively for the purpose of completing the investigation into and the establishment of every important fact to which the examination is directed. Written interrogatories must be framed on the same principle, and therefore every subsequent part of an interrogatory must be framed on the supposition of every previous part being answered in some way; and consequently, it is hardly possible in written interrogatories to avoid what is called making them *leading*, and at the same verbose and cumbrous. These long interrogatories, it is proved by experience, are often imperfectly comprehended by the witnesses, and consequently their evidence is to some intents either incomplete or inaccurate, or both. The interrogatories which either party proposes to his witnesses are not known to the adverse party until the examination of all the witnesses on both sides is concluded, when *publication* is passed, as it is termed, and copies of all the depositions are delivered to the litigating parties under an order of the court.

Under this system, there is of course no cross-examination, in the proper sense of the term; for one party does not know what the witnesses examined by the opposite party have deposed, and cannot therefore effectually examine them, as in a court of common law, where the cross-examination of a witness follows and is founded upon what the witness has stated in his examination in chief. If a party to a suit in chancery will cross-examine a witness who is produced by his adversary for examination, he must examine him on written interrogatories, without knowing what interrogatories have been proposed to him by the opposite party, and without knowing what he has said in his depositions in chief. Such a cross-examination must be in general altogether useless, and often dangerous to the interest of the party making it; unless his object is to ascertain that the witness is an incompetent witness, or unless the witness is one whom he would himself have examined in chief. Under the 32nd Order of the 21st of December, 1833, the last interrogatory before that date commonly in use is in future to be altered as follows: 'Do you know or can you set forth any other matter or thing which may be of benefit or advantage to the parties at issue in this cause, or either of them?' &c. A party however is not bound to insert

this interrogatory; and indeed no great harm will result if it is never used. Owing to various causes, such as disinclination on the part of a witness to give himself further trouble, particular affection to one of the litigating parties, or forgetfulness, it might have been anticipated that this general interrogatory would fail in its object; and so far as it has been used, such is said to be the case.

This mode of ascertaining facts in suits in equity is evidently very defective, and has been the subject of considerable complaint and of lengthened inquiry; but hitherto nothing has been done to amend the system.

(See *Minutes of Evidence taken before the Chancery Commissioners, annexed to their Report of 1826*; and a recent pamphlet (1837) by W. A. Garratt, entitled *Suggestions for Reform in Proceedings in Chancery*.)

Those who may be inclined to follow this subject further will find it discussed at great length and with much acuteness in Bentham's *Rationale of Judicial Evidence*. The full development of the English law of evidence is contained in the treatises of Mr. Phillips and Mr. Starkie.

EVIL EYE. It was an antient superstition that certain persons were endued with the power of injuring those on whom they cast a hostile or envious look. The eyes of such persons were supposed to dart noxious rays on every object on which they were fixed. This power of injuring with the eye was called *Bascaria* (*Baskaria*) by the Greeks, and *Fascinatio* by the Romans. Several writers who have collected the testimonies of the antients concerning it (as Potter, *Archæologia Græca*, lib. ii. c. xviii., and Alesius, 'de Fascino,' *Grævi Antiq. Rom.*, tom. xii. p. 885), may be consulted for particulars. Those who enjoyed great prosperity, or met with any extraordinary good fortune, and such as were too much elated by praise and flattery, were more particularly liable to the effects of fascination. Hence when the Romans praised any thing or person, they used to add, *Præflectini* or *Præflectine dixerim*, to avert any fascination that might ensue, and to prove that their praise was sincere.

It is remarkable that the same superstition prevails to the present day in several parts of the world, even in the northern part of our island, and in Ireland. In Greece it is at present called *kato mati* (*case pare*), and its effects are averted by spitting, in the same manner as was practised by the antients against fascination (Theocr., *Idyl.* vi. 39) and ill omens of every kind. In Italy it is called *mal-occhio*, and among the lower orders of people its effects are supposed to be very powerful and fatal. When praise is bestowed on beauty, riches, or any other advantages, the person praised immediately exclaims, 'se mal-occhio non vi fosse,' from an apprehension that the praise may not be sincere, but proceeds solely from a malicious intention to injure. This exclamation is accompanied with a sign of the hand, or by holding up pieces of coral, shells, or various kinds of stones worn as amulets.

The belief in fascination is extremely antient, and in the opinion of some is connected with the story of Medusa and the Gorgons, whose eyes caused immediate destruction. From this source the superstition of the evil eye is probably derived.

Virgil alludes to this superstition in his third Eclogue:—

'Nescio quis teneros oculos mihi fascinant agnos.'

Scot, in his 'Discovery of Witchcraft,' has one or two passages relating to it. He says, p. 35, 'The Irishmen affirm that not only their children, but their cattle are (as they call it) *eye-bitten* when they fall suddenly sick.' It is likewise mentioned in Martin's 'Description of the Western Islands of Scotland,' in Heron's 'Journey,' vol. ii. p. 228, and in several volumes of the 'Statistical Account of Scotland,' as still believed there.

'Nothing,' says Dallaway, in his 'Account of Constantinople,' 4to. Lond. 1797, p. 391, 'can exceed the superstition of the Turks respecting the Evil Eye of an enemy or infidel. Passages from the Koran are painted on the outside of the houses, globes of glass are suspended from the ceilings, and a part of the superfluous caparison of their horses is designed to attract attention, and divert a sinister influence.'

(Millingen's *Observations on an Antique Bas-relief, on which the Evil Eye, or Fascinum, is represented*; *Archæolog.* vol. xix. p. 70—74; Brand's *Popular Antiquities*, 4to. edit. vol. ii. p. 400—403.)

EVIL KING'S. [SCROFULA.]

EVILMERODACH [BABYLON HISTORY.]

* The execution of written instruments, not wills, may be proved at the hearing by an attesting witness; & where the instrument is not attested, the handwriting of the party may be so proved also.

EVOLUTE. [INVOLUTE and EVOLUTE.]**EVOLUTION. [INVOLUTION and EVOLUTION.]**

EVOLUTIONS, MILITARY, are the movements made by any body of troops either acting by itself or in conjunction with other bodies, for the purpose of arriving at or of retiring from a field of battle, or of placing itself in a position to act offensively or defensively against an enemy.

The circumstances attending the great movements of armies along their lines of communication, and the dispositions of the troops on the field of battle, are developed under the words **STRATEGY** and **TACTICS**. The present article will therefore comprehend merely a description of the manner in which the principal evolutions of a battalion of infantry, a regiment of cavalry, and an entire army, are performed; and will conclude with a short account of the movements of light troops in the field.

Evolutions of a Battalion.—When a battalion formed in line has to march in that order towards the front or rear, in order to ensure exactness in the movement three directing sergeants post themselves a little way in front of the centre of the line, and observing some object in the required direction, they advance directly towards it, the battalion following and keeping itself perpendicular to the line of march. While the battalion is thus moving in line, the two flanked companies are wheeled backwards, and made to march in files perpendicularly to the line of the battalion, in order to cover it; and on a halt being ordered, they face towards the enemy.

This order of march can of course only take place where the country is open; when partial obstacles occur, the troops near them necessarily form in file till they have passed them, and afterwards they wheel into the line; but when the obstacles are of great extent, and occur frequently, it is evident that the march of the battalion should be in column.

Columns formed for this purpose are designated columns of companies, of subdivisions, and of sections, according as their breadths, or the extent of their front, is equal to that of a whole, a half, or any portion of a company; and they are said to be at open order, at half, or at quarter distance, according as the intervals between the companies or their divisions are equal to the whole, to one-half, or to one-quarter of the breadth of the column. The order is said to be close when the several divisions are at the distance of one pace only from each other in the length of the column.

The wheel from line into column, and the converse, when the battalion is at a halt, must obviously be performed by causing the divisions to describe a quarter of a circle on their respective pivots. But when a battalion in column is on the march, and it is required to change the route, should the divisions be at the full distances from each other, that is, at intervals equal to the length of a division, it is necessary that the first division, after having described on its pivot an angle equal to that which the new direction is to make with the former, should march forward as soon as the wheeling pivot of the next division has arrived at the like pivot of the first division: the second division then wheels and marches in like manner, and so on. The same rule may be followed when the divisions are at less than full distance, provided the angle which the intended direction of march makes with the former is sufficiently obtuse to allow the divisions to describe the required angle without interfering with one another, otherwise the wheeling must be made by parts; the first division describing a portion of the angle corresponding to the required change of direction, then marching forward a few paces, and completing the wheel, the other divisions doing the same in proportion as they arrive at the ground where the preceding division performed the evolution. The wheelings may be made upon either extremity of a company or subdivision, and they may take place either forward or backward, according to circumstances; occasionally also a company is required to perform a wheel upon its centre, in which case one-half wheels backward, and the other half forward; but in all cases the wheeling pivots are to remain dressed, or in one line.

When a battalion is formed into a column for the purpose of an attack, it is called a column of manœuvre; and when so formed in order to move along a road or through a defile, a column of route. In either case the column may be in open order, at half, or at quarter distance, or in close order; and in the first formation the column of course

occupies in length an extent of ground equal to that which it occupies in line, minus the length of the first division. Columns at half, or at quarter distance, or at close order, have the convenience of moving upon less space than the open column, with equal capacity of forming in any manner that may be required for resisting an attack; and their compact order enables them to avoid the evils attending the loss of distances which may occur with an open column, from the inequalities of the ground.

The battalion in line may be formed into a single or double column: the former upon or in rear of either flank company, and the latter upon the two centre companies or the two centre subdivisions. In either case the column is equally fit for its purpose, and the preference of one to the other must depend upon the ground or upon the point to which the movement is to be directed: the single column, however, can always be diminished to the smallest degree, according to the breadth of the defile; whereas the double column, if much diminished, may be in danger of becoming disordered by the intermixture of the files. For an attack, the column formed on the centre of a battalion can be more rapidly brought to bear upon the required point than a column formed on one of the wings, seeing that the divisions in line have but half the distance to march through in order to arrive at their places in the column, and a corresponding advantage is enjoyed when the battalion has to deploy from column into line.

It is to be observed that the front of a column should never be unnecessarily contracted, and battalions should be so instructed as to render it indifferent whether the first or second rank is in front, or whether the right or left flank division (of the line) is at the head of the column; but occasions may occur in which the order of battle is to be reversed, and then the divisions must necessarily change their positions by countermarching.

A battalion in column at open order is formed in line by merely causing the divisions to wheel upon their respective pivots; but a close column of companies, having its head already in the alignment, is deployed by causing the several divisions to move out by files to the right or left parallel to the alignment; each division having got beyond that which was in front of it halts, and then marches up to its place in the line. The deployment may take place upon any one of the companies, which then remains at rest.

Echelon movements are performed when it is required to advance or retreat obliquely, and when a change is to be made in the position of a line, corresponding to a wheel of the whole about some given point: the movements are made to the front when an enemy's flank is to be turned, and to the rear when it is required to cover the flank of the line itself. Echelon movements are the safest that can be adopted by troops in presence of the enemy, as they have the advantage of preserving a general front during the march. A direct echelon, as it is called, may be formed by the different companies or subdivisions marching from their position in the line towards the front or rear, keeping parallel to that position, and halting successively when arrived at the required distances. The oblique echelon is formed by causing the different companies or subdivisions to make a wheel upon their pivots through any angle less than a right angle, but generally not more than one eighth of it; the parallelism of the divisions being ensured by causing a non-commissioned officer of each division to place himself, as the case may require, before or behind some given file, suppose the eighth, from the pivot, and to take a given number of paces on an arc of which that pivot is the centre; the division is then to wheel up to the place where he halts.

An important evolution of a battalion is that of placing itself in a square or oblong form, with the men on the four sides facing outwards, so as to be enabled to resist an enemy who may attempt to surround them. This figure is always formed hollow, or so as to enclose a space in which baggage or treasure may be placed for security; if otherwise, it is evident that great numbers of the men would be useless, since they could not use their fire-arms.

When a battalion in line is to form a hollow square, the manœuvre may take place upon any given company, or upon one formed of the two contiguous subdivisions of two companies, which then for the moment remain at rest; while the other companies break out of the line and march, some to the front and some to the rear of the troops who are stationary, so as to form with them a column of companies at quarter distance. The second division in the

column closes up to the first, and these two form the front of the square; the two rear divisions then face outwards, the last but one closes up to the last, and these two form the rear of the square. The remaining divisions wheel outwards, and constitute the two sides of the square or oblong, which is thus formed four deep. If the square is to resist an attack of cavalry, the two front ranks kneel and slope their firelocks outwards till, at the word of command, they fire a volley: the men in the two standing ranks fire by files, or independently of one another. It is said that Bonaparte, while in Egypt, formed his infantry in squares whose sides were six ranks deep, in order to resist the Mameluke cavalry.

When several battalions form themselves into squares, they dispose themselves either en echelon or in two lines, each square in the first line being at some distance in front of the interval between two squares in the second line; by which means the fire of one square may defend the face of another.

Squares may be reduced to columns, and these to line, by reversing the processes above mentioned. One square consisting of several battalions is not recommended, as much time would be spent in its formation, and the safety of the troops might be endangered should they be attacked while so occupied.

A battalion in column may be obliged to engage in a street or narrow pass where deployment is impossible. In this case, if the column is advancing, the two front companies or divisions fire, the first kneeling and the other standing; after which, on a favourable occasion presenting itself, the whole column moves forward: if the column is to retire, the first division, after firing, faces outwards, half to the right and half to the left; these subdivisions file away to the rear, where they re-load; the second division fires, then files to the rear in like manner, and so on.

Evolutions of a Regiment of Cavalry.—The movements of cavalry on a field of battle, like those of infantry, consist of marches to the front or rear, in line or en echelon; deploying from open or close columns into line, and the converse.

If it be required to form a line for attack from an open column of divisions upon any particular division, those divisions which are in front make a wheel forward equal to three-eighths of a circle, and those which are in rear wheel forward one-eighth; all the divisions being thus parallel to each other, they march in this order up to the alignment on the division which remained stationary, wheeling into it as they arrive. On the contrary, if the column be in retreat, and it be required to form a line on the defensive from an open column of divisions, suppose on the first division of the first or leading squadron, all the divisions are to make a wheel equal to one-eighth of a circle, and in this order march up and wheel into the alignment. It must be observed that the line first formed in these cases is to be at the distance of two horses' length in rear of the intended alignment, in order to allow the officers in front of each squadron to dress the troops, which they can do more correctly than the officers of divisions who are in the line itself.

To deploy in line to the front from a close column of squadrons for an attack, suppose on the second squadron; all the squadrons except this break into divisions by threes, as it is called (that is into divisions consisting of three horses in each of the two lines); the divisions of the first squadron wheel a quarter circle to the right, and march in that order till they get beyond the squadron on which the line is to be formed; the third and fourth squadrons also break into divisions in like manner, wheeling to the left, and marching till they get opposite their respective places in the intended line, which is supposed to be in front of the ground occupied by the first squadron, and into this line all the squadrons now march. But if the line be required to be formed on the rear of the regiment when in retreat, for the purpose of defence, suppose on the fourth squadron, this squadron must then change its front by a counter-march, the others break into divisions, wheel a quarter circle, and march to the left till they come opposite their proper places in the intended alignment, into which they then march as before.

The evolutions are made as above stated when the regiment is in column with its right in front; but it is easy to apply the precepts to the contrary case.

The reason why the squadrons are made to break into

divisions by threes is that, since the breadth of three horses is about equal to the length of one, each division of three can wheel within a space equal to that which it occupies in line: the practice however has been objected to on account of the extension of the files which is produced when marching in this order. Movements by the usual divisions or sub-divisions have been preferred on this account, but the former method prevails.

Evolutions of an Army.—The general principles upon which the evolutions of armies, divisions, or brigades are performed, correspond nearly to those of single battalions. When a whole line has to advance parallel to itself, one of the battalions is considered as the regulator, and all the others should conform to its movements. The commander of this battalion must therefore devote his whole attention to the preservation of the direction which has been indicated by the general commanding the army, while the flank officers of the other battalions must endeavour to preserve the regularity of their own battalions by the line of the colours.

Columns of route or manoeuvre are formed of any number of battalions, each in column of companies or of sub-divisions, in rear of one another; and if the columns are at close order, the interval between every two battalions is only six paces, or the same as if all the troops were drawn up in line. If the distances of the companies are equal to one quarter of the length of their front, the intervals between the battalions are twelve paces; but when the columns are at open order, the intervals of the battalions should be equal to the breadth of the column, together with the six paces which should be the intervals between the battalions in line. Such columns as the last can instantly be thrown into line by each company making simply a wheel on its proper pivot. When one general column is required to form into what is called a line of columns, the heads of all the columns must be placed in one alignment, but the distances of the several columns from one another in the direction of the line may, according to circumstances, be of any extent, from six paces (in which case the columns are said to be contiguous), to the proper distance for deployment, that is, a distance equal to the length of a column.

A column whose divisions are either at quarter distance from each other, or in close order, can always wheel into a line of columns, because each battalion, in performing the wheel, leaves room for the wheel of that which is in its rear; but a line of contiguous columns, when the depth of each battalion exceeds the extent of its front, cannot for want of room be wheeled into a single column. When such a manoeuvre becomes necessary, the line of columns must open out to the right or left far enough to allow the wheel to be performed. When a line of columns is required to be changed into one column, for the purpose of performing a march towards either flank, the most convenient disposition would be that in which all the columns in the line stand with their right wings in front, if it is intended that the march should be towards the right; and the contrary, if it is to be towards the left, for then a simple wheel to the front brings the divisions into the alignment in their proper order.

When a column is on a march, the baggage should be in the rear; or if, on any account, it is placed within the line, it should be, together with the artillery which accompanies the column, in the intervals between brigades, and never between the battalions of a brigade. The preservation of the original extent of a column in front is of importance, and defiling, in order to pass an obstacle, should be avoided if possible, on account of the loss of time which it occasions in fact, it will frequently happen that, on arriving at a stream, a ditch, or a bank, the obstacle will be more conveniently passed by extending than by contracting the front.

Echelon movements of an army are almost always those which are made when in presence of the enemy, the inequalities of ground generally preventing large bodies of troops, if it were otherwise advisable to do so, from acting against one another in continuous lines. Like the echelon movements of battalions, those of an army may be either direct or oblique: the former are executed by advancing brigades, battalions, or companies parallel to and at unequal distances from their front; and this advance may be made from the centre of the line when it is intended to refuse both wings to an enemy, or from one flank when it

is intended to turn that of the enemy. The direct echelon may also be produced by posting columns in proper situations, ready for deployment, parallel to the enemy's position: the distances between the battalions in echelon should be sufficient to allow them to form squares chequerwise, so as to flank one another.

Oblique echellons of an army are formed by wheeling, and then marching in the new directions so as to gain ground obliquely towards a flank; each of the several bodies performing the manœuvre should not exceed a company, as it might be hazardous to present one flank of a large body towards an enemy in position, and thus expose the line to be enfladed. And, as the enemy would endeavour to counteract the intended project of outflanking him, should he observe it, advantage ought to be taken of the localities to conceal some of the divisions, and to gain points of support for the bodies placed in advance of the rest of the army. When it is intended to refuse one wing, the battalions of that wing may retreat en echelon as far as necessary, and the artillery of that part of the line which is stationary should be ready to enflade the enemy on his advance towards the retiring divisions. Movements of attack may be made in columns, which should deploy in line at from 1200 to 1400 paces from the enemy; the destructive effects of an enflading fire preventing a nearer approach in column.

Generally speaking, the most convenient order for an army, whether on the offensive or defensive, is in column, provided the columns can be covered by the ground from the enemy's artillery; since it may be readily moved up to any given point of attack, while the enemy has few means of judging where that point of attack will be.

Changes in the front of a position, when under fire, are best effected by an echelon march of companies; but when the line is extensive, the battalions which are most remote from the new alignment, and which may be attacked by cavalry during the movement, should be marched up in columns of battalions, the divisions being at quarter distances from one another.

The retreat of a line is accomplished by causing each alternate battalion to retire, perpendicularly to the front, to a certain distance towards the rear, not exceeding 200 yards, that the divisions may be able to support each other by their fires; the remaining battalions protecting the retreat of the others, and then retiring as far as the intervals between the former battalions, who then retreat still further, and so on. The intervals in the lines should be occupied by light infantry; and if the enemy should press closely, the second line of the army, after the first battalions have passed through it, must contribute by its fire to the defence of the intervals in the first line.

This retreat by alternate battalions, or by half-battalions, is indispensable when it is made over a plain; and if the retreat is to be continued, defiles and commanding spots of ground must be occupied and defended as long as possible; by degrees the bodies may diminish their fronts and form themselves into columns of march.

If a gradual retreat of the whole line is not intended, on a flank of the army being attacked, that flank only may be retired in direct echelon by alternate battalions or half-battalions, beginning with that which is at the extremity of the flank attacked; the remaining battalions then retire, still en echelon, thus keeping the menaced flank refused to the enemy, taking care that the distances between the corps are not so great as to render it impossible for them to defend each other by their fire. Each body must repel an attack, if made upon it by infantry, by a counter-attack; if by cavalry, it may dispose itself in a square; or a new line may be formed in the oblique position, if it be thought best thus to resist a general attack of the enemy.

The movements of the second line of an army should correspond exactly to those of the first; the two lines always preserving their parallelism and distance. The second is however frequently kept in a line of columns of battalions, and is made to move in that order even when the first line is deployed.

The most proper stations for cavalry are on the wings of an army, because troops of this class are unfit for resisting an attack; and should they be compelled to retire when placed in the centre, there would be left an interval which the enemy might immediately occupy, and from thence enflade the wings. This false disposition was made by the French at the battles of Hochstet and Minden, and was

the cause of their defeat in those actions. Cavalry are generally employed in the operation of turning a line; and it is evident that this manœuvre must be more readily made from the nearest wing than from the centre.

Manœuvres of Light Troops.—To the light infantry and riflemen, or troops acting as such, are entrusted the guard of the encampments or cantonments. When an army is on the march they reconnoitre the country, repel any parties of the enemy which might get between the columns while advancing; and they check the pursuit of the enemy in a retreat.

When a battalion is employed as light infantry, not more than one-third of the men should actually engage as skirmishers; these extend themselves in line, in two ranks, to the right and left, from some given file, at any distance which may be appointed; or, if no order is given, at the regulated distance of six paces. The rest of the battalion is divided into parties, as supports, of which one is usually in rear of the centre, and another is towards each flank; and when the skirmishers have advanced about one hundred paces to the front, these supports follow them, and are themselves followed by a general reserve. Each of the supporting bodies and the reserve should be kept in compact order; and when the skirmishers retire upon their support, they form in sections in its rear. The skirmishers advance or retire, as the case may be, in one general line, and they should avoid standing exposed if any cover, as that of a hedge, ditch, or copse, can be obtained on the ground: for this reason, when obliged to cross an open plain, their line should make a simultaneous rush towards the spots where they may fire under cover. On open ground, they fire kneeling or lying down, the front rank man discharging his piece first, then retiring in rear of the second rank and loading: as soon as he has loaded he gives the word, ready, in a low voice, when the second rank man fires and loads, care being taken that the muskets of both ranks are not unloaded at the same time.

On the appearance of cavalry the nearest supporters and the reserve move towards the threatened part, and form squares; the skirmishers at the same time run to any cover from whence they may aid the supports by a cross fire.

When light troops have to advance across a bridge, or through a short defile, on arriving at the bank of the river, or at the entrance of the defile, the skirmishers lie down in line and fire; the supports, strengthened by the reserve, charge the enemy on the bridge, or in the defile, drive him back, and then form an extended line as skirmishers, while the former skirmishers pass the bridge or defile, and now constitute the supports and reserve. In retreating the supports pass first over the bridge or through the defile, covered by the skirmishers, and immediately deploy, in order to act as skirmishers themselves; the former skirmishers then rapidly pass, followed by the supports, and the whole form in column in rear of the present skirmishers, who then, by their fire, protect the retreat if it is to be continued.

EVORA, the principal town of the province of Alentejo, in Portugal, is built upon an eminence in the midst of a fine open country, which produces wine, oil, and corn, and is south-west of the Serra de Osa, which forms part of the range which crosses Alentejo from east to west. Evora is an archbishop's see, has a college, two female houses of education, several good buildings, and a fine aqueduct, attributed to Sertorius, who for a time made this town, then called Ebora, his residence. Julius Cæsar, after his Spanish campaign, made Ebora a municipium, with the name of Liberalitas Julia. There is now at Evora a handsome temple of the Roman period, supposed to have been dedicated to Diana: the front presents an hexastyle of the Corinthian order, the columns remain, and the capitals are of very delicate workmanship, but the entablature is gone, and has been replaced by a rubble work with pinnacles in the Moorish style. (Murphy's *Travels and View of this Temple, with Copies of Roman Inscriptions found at Evora*.) Evora has about 12,000 inhabitants, some manufactures of hats and leather, and a considerable inland trade. It suffered greatly in the French invasion of 1808, for having attempted an insurrection against the invaders; many of the inhabitants were put to death. (Southey's *History of the Peninsular War*.) Evora lies on the road from Lisbon to the Algarve, and is about 80 miles south-east of Lisbon, 30 miles north of Beja, and 50 miles west by south of Badajoz.

EVREMOND. CHARLES de St. Denys, Seigneur de St. Evremond, was born April 1, 1613, at St. Denys le Guast, near Coutances, in Normandy. He entered the army early, and by his literary talents and sprightly wit, as well as bravery, acquired the friendship of Turenne, Condé, and other of the most distinguished men of that brilliant epoch. Condé made him lieutenant of his guards, for the sake of his society; and he fought with that great commander at the bloody battles of Roerui and Nordlingen. But the prince, though fond of raillery at the expense of others, could not bear it levelled against himself; and St. Evremond, by an imprudent exercise of his satiric humour, lost his patron and his lieutenantcy in 1648. In the wars of the Fronde he espoused the royal cause, and was rewarded with promotion and a pension. He incurred a three months' imprisonment in the Bastille by making too free with Cardinal Mazarin; but found means to reinstate himself in the minister's favour. Another indiscretion in ridiculing the treaty of the Pyrenees (unless, as has been said, there was some secret cause for his disgrace, and this was only a pretext), led to a second order for his arrest in 1661. He received timely notice, and fled, first to Holland, then to England, in which two countries the rest of his long life was spent. Louis XIV., though solicited by his most favourite courtiers to pardon St. Evremond, remained inflexible till 1689, when he granted the exile a tardy permission to return. But it was then too late for St. Evremond again to change the scene; and though in banishment, his life had all that he required for happiness. He was a favourite with Charles II., who gave him a pension of 300*l.*, and his society was courted by the most distinguished wits and beauties of that reign; nor was he less fortunate in possessing the regard of William III., who had known him in Holland, and took much pleasure in his company. Devoted to the enjoyment of the present, and availing himself moderately of every source of social pleasure, he retained his faculties, mental and bodily, to the last, and died in his 91st year, September 20th, 1703.

St. Evremond was one of those who, aiming chiefly at success in society, leave no memorials sufficient to sustain the reputation which they have enjoyed in life. He possessed however extensive reading and an independent and acute judgment, as well as wit. His verses are deservedly forgotten; but his treatises on Roman literature and on the modern drama are ranked among his best works. His letters are among the most brilliant specimens of that style of composition in which the French have excelled. He appears to have been a disbeliever in revealed religion, but he was not a scoffer, and he checked wanton insult to religion in others. Neither was he, as has been said, an atheist; but some atheistical books were falsely published under his name long after he was dead. He never derived profit from the sale of his works, nor authorized their being printed; so that the earlier editions, which were all pirated, contain much that was foisted in by the booksellers to profit by his popularity. The first correct edition is that of Des Maizeaux, 3 vols. 4to., Lond., 1705, with a life prefixed, from manuscripts revised by the author and editor jointly, shortly before the death of the former. Des Maizeaux also translated the whole into English. (*Biog. Univ.*; see also Des Maizeaux's *Life* and Grammont's *Memoirs* for scattered notices of St. Evremond.)

EVREUX, a city in France, capital of the department of Eure, on the little river Iton, a feeder of the Eure, 51 miles in a direct line west by north of Paris.

Evreux is mentioned by Ptolemy and by Ammianus Marcellinus, in the Itinerary of Antoninus and in the Theodosian Table. It bore the name of Mediolanum, and was the capital of the Aulerici Ebuovices. The name Ebuovices was afterwards applied to their chief city, and in the middle ages appears under the corrupted Latin forms of Ebroicæ and Ebroga, from which is derived Evreux. It has been matter of dispute whether the old Mediolanum was on the site of the present city or at a village in the neighbourhood known by the name of Old Evreux; but the remains of a theatre and of several antiquities which have been discovered may be considered as showing that Mediolanum was close to, if not on the site of, the present city. Evreux came into the hands of the Normans, but the duke of Normandy, Richard I., severed it from the duchy and erected it into a distinct county in favour of his second son, from whose descendants it afterwards passed to the house of Montfort. In the beginning of the twelfth century

(in 1119) it was burned by Henry I. king of England; and toward the close of the same century (in 1194 and 1199) it was twice destroyed by Philippe Auguste, king of France, who shortly afterwards acquired permanent possession of it. The county of Evreux was bestowed as an apanage on a branch of the royal family of France, which subsequently acquired the throne of Navarre; but on the death of Charles le Mauvais, king of Navarre, it reverted to the French crown. In the wars of the English in France, under Henry V. and VI., Evreux was repeatedly taken and retaken: the last time was in 1441, when it was captured, after a vigorous resistance, by the French, from whose hands it has never since passed away.

A great proportion of the inhabitants (who in 1832 were 7988 for the town, or 9963 for the whole commune) are persons of independent property. The houses are for the most part built of wood and clay or plaster. The streets are broad and beautifully neat. The city stands in the midst of gardens and orchards in a fertile valley watered by the Iton, which divides into two branches before reaching the town, and flowing on each side, under or near the walls, and afterwards reuniting, renders the position of the city insular. Part of the waters of the Iton are conducted through the city by means of a canal.

The principal edifice is the cathedral, which was rebuilt by Henry I. of England, after he had burned the former one with the rest of the town: the nave alone retains any vestiges of early architecture: its massy piers and semicircular arches are evidently of Norman origin, and are probably part of the church erected by Henry. All the rest is comparatively modern. The interior is adorned with some elegant carving, both in stone and wood: there are some good specimens of painted glass.

The church of St. Taurinus (formerly attached to the Benedictine abbey of St. Taurinus, founded in the seventh century) contains some valuable specimens of Norman architecture: the interior has been modernized. A portion of the monastic buildings serves as a seminary for the Catholic priesthood. The church of St. Gilles, now converted into a stable, presents some antique features worthy of notice.

Among the other remarkable buildings are the episcopal palace, the hospital, a fine new building, the office of the prefect, formerly the hospital, and the prisons. There are some handsome public walks.

The manufactures of Evreux are woollen cloth, woollen and cotton yarn, bed-ticking, calico, cotton velvet, hosiery, leather, paper, wind musical instruments (flutes, clarinets, &c.), and ivory and box-wood combs. Trade is carried on in these articles, and in grain, brandy, cider, perry, and linseed oil. There are seven annual fairs; the most important, that of St. Taurin, lasts eight days. There are a subordinate court of justice, 'une chambre consultative des arts et manufactures,' a central society of agriculture, sciences, arts, medicine, surgery, and pharmacy; a high school; a public library of 6000 volumes; and a botanic garden, at which courses of lectures on botany are delivered.

In the neighbourhood of Evreux, about a mile and a half from the town, is the Château de Navarre. Jeanne, daughter of Louis Hutin, king of France and Navarre, in which latter kingdom she succeeded her father, married the then count of Evreux, and built a château, which she called the Château de Navarre: this structure was, in 1686, levelled to the ground by its possessor, the duke of Bouillon, who erected the present building. Upon the emigration of his descendants, it became national property, and was given by Napoléon to the Empress Josephine, who resided here for a time. The house, which is of stone, is formal and ill proportioned; but the woods around are beautiful, the avenue noble, and the sheets of water extensive. The château is now deserted. Old Evreux appears to have been the site of a Norman and previously that of a Roman fortress. There are some remains of a Roman aqueduct and Roman medals in gold, silver, and bronze have been dug up.

The arrondissement of Evreux contains 11 cantons or districts under the charge of a justice of the peace; two of these are in the town of Evreux. It comprehends 287 communes, and had, in 1832, 118,397 inhabitants. The diocese comprehends the department of Eure: the bishop is a suffragan of the archbishop of Rouen. The foundation of the see is ascribed to the third century. (Dawson Turner, *Tour in Normandy*; Dulaure, *Histoire des Environs de Paris*; *Dictionnaire Géographique Universel*, &c.)

EX. [DEVONSHIRE.]**EXAMINATION. [EVIDENCE.]**

EXANTHEMATA (*Exanthematous diseases*), *ἐξάνθημα*, an *efflorescence*; a term under which are comprehended the eruptive fevers, or the diseases commonly termed rashes. Rashes are superficial red patches, variously figured, and diffused irregularly over the body, leaving interstices of a natural colour, and terminating in cuticular exfoliations. Fever is an essential element in the definition of an exanthematous disease, as this term is usually employed by nosologists; but the writers on cutaneous diseases give to it a modified signification, and comprehend under it only those diseases which are properly termed rashes, whether those rashes are attended with fever, and whether they are contagious or not. Thus Dr. Bateman comprehends under the order Exanthemata measles, scarlet fever, nettle-rash, roseola or the rose, purpura, and erythema.

EXARCH was the title of the governor of Italy under the Byzantine emperors, established by Justinian after the reconquest of Italy from the Goths in the sixth century. The first exarch appointed was Longinus, A.D. 568. The residence of the exarch was at Ravenna, then a sea-port town, and the great entrepôt between Greece and Italy. The exarchs, who were generally chosen among the officers and favourites of the Byzantine court, were of course removable at the pleasure of the emperor, but several of them remained in their office to the end of their lives. Their administration was often marked by acts of oppression and treachery, the results of Byzantine corruption as well as of the peculiar difficulties of their situation. They were engaged in frequent hostilities against the Longobards who had invaded the greater part of Italy, and were also not unfrequently at variance with the popes, and their authority was often confined within the walls of Ravenna. At last, in the year 752, Ravenna being taken by Astulf or Astolphus, king of the Longobards, the exarchate, as well as all dominion of the Byzantines over North Italy, was at an end; but the Greek emperors still retained possession of parts of Apulia and Calabria, where Bari became the residence of the catapan or Byzantine governor. (See *Chronological Series of the Exarchs* in Petau, *Rationarium Temporum*.)

EXCAVATIONS. [FOUNDATIONS.]**EXCENTRIC. [PTOLEMAIC HYPOTHESIS.]**

EXCENTRICITY, a term applied to the ratio which the distance between the centre and focus of an ellipse or hyperbola bears to the whole semiaxis. [*ELLIPSE; HYPERBOLA.*] With regard to this word, it should be noted that in the older writings on conic sections it was not the *ratio* of these two lines, but the former of them, namely the distance between the centre and focus, which was called the eccentricity.

Let a be the semimajor axis of an ellipse or hyperbola, b the semiminor axis, and e the eccentricity; then

$$\text{in the ellipse } e^2 = 1 - \frac{b^2}{a^2}$$

$$\text{in the hyperbola } e^2 = 1 + \frac{b^2}{a^2}$$

EXCESS. For a peculiar mathematical use of this term, namely, the *spherical excess*, see *SPHERICAL TRIANGLE*.

EXCHANGE. The term exchange is commonly employed by merchants to designate—first, the written instrument by which the debts of persons residing in different countries or in different parts of the same country are brought to a condition for final liquidation; and, second, the varying price of such negotiable instruments in the market.

The first division of the subject is discussed under the title *BILL OF EXCHANGE*; the following article will comprise the second, and will include an investigation of the principles on which exchange transactions are based.

International, or, as it is commonly called, foreign trade, arises out of the unequal or exclusive capacity of different countries to produce the various objects of desire. One country, for instance, has abundance of coal and iron; another enjoys a climate especially adapted to the culture of the vine; whilst a third possesses some peculiar advantages for the growth of wheat. If interchange were not restricted by legislative enactments, if trade were perfectly free, the first country would supply the other two with iron wares,

taking from the second wines, and from the third wheat; whilst the two last would in like manner exchange their respective productions with each other.

Peculiarities of soil and climate, abundance and cheapness of land or of labour, the exclusive presence of certain animals, vegetables, or minerals, all give rise to interchange between nation and nation. Every country has some peculiarity which gives it an advantage with respect to that peculiarity over all other countries: it is by means of interchange that such advantages are shared equally among all.

In the article *BILL OF EXCHANGE*, already referred to, we have explained how this mode of settling accounts between parties in different countries arose; and the various legal rights of the parties to a bill of exchange are also in that article fully explained.

In investigating that part of the subject which belongs to the present article it is necessary to bear in mind that different countries make use of different coins—different in denomination, in weight, and consequently in value. The pound, for instance, is the money of England, the franc that of France, the dollar that of America. These several coins contain very different quantities of the precious metals. The dollar, for instance, contains about five times as much silver as the franc, whilst the guilder contains only twice as much. The value of a currency depends on the quantity of pure metal contained in the coin which forms its legal tender, alloy being left wholly out of the account.

In the language made use of by merchants, the existence of a *par of exchange* is usually assumed. Between two countries making use of the same metal a par may exist; but between two countries one of which makes use of gold and the other of silver an invariable par cannot exist.

The following is a statement of the contents, in pure silver, of the several coins forming the money of account of the several countries specified:—

| | Grains. |
|---------------------------|---------|
| Franc of France . . . | 69·4 |
| Mark of Hamburg . . . | 105·15 |
| Florin of Amsterdam . . . | 146·8 |
| Dollar of America . . . | 370·1 |

Hence the mark is worth, in Paris, 1·515 francs; in Amsterdam, 14 stivers 5 pennings; and in New York, 28·2 cents.

Gold is now a legal tender in America, and the sovereign is by law worth 4·87 dollars, making the eagle of 10 dollars worth 21. 1s. 0½d.; the dollar (of gold), 4s. 1½d.; and the 100l. sterling equal to 487 dollars; all of which are different expressions for the *par* between England and the United States—both being gold-using countries.

We have said that a par of exchange cannot exist between two countries making use of different metals as the standard of their respective currencies; we shall now explain the reason. Gold is the standard in England. The silver coin of England possesses a conventional value independent of the market value, and the latter may fluctuate without affecting the former. Foreign coins, the franc or the guilder for instance, possess no such conventional value. They are merely a commodity liable to fluctuation with the varying price of silver.

Within the last ten years the price of silver in the London market has varied from 4s. 10½d. to 5s. 1d. per ounce of 444 grains pure, the medium price being 4s. 11½d. to 5s. The extreme prices give the following results:—

| Price of Silver per oz. | Value of Franc. | Value of £1. |
|-------------------------|-----------------|--------------|
| s. d. | d. | f. |
| 4 10½ | 9½ | 26·30 |
| 5 1 | 9·54 | 25·15 |

Thus making a fluctuation in the so-called par of exchange of rather more than 4½ per cent.

The assumption of a par of exchange where no par can exist is likely to lead at times to great inconvenience. Suppose, for instance, that the par between Paris and London be assumed at 25·58fr., which is about the medium. Suppose further that exchange is quoted at 26·30fr.; what would be the inference? Why that exchange was 2·8 per cent. in favour of England, and (the cost of transmission being much less than the above difference) that consequently bullion was about to pour into London. But sup

pose that at the same time the market price of silver had declined in London to 4s. 10½d. per ounce, and gold in Paris had advanced in a like ratio, what would be the effect? Why the supposed premium in favour of England would vanish, and the par, for the time being, would be brought to coincide with the actual rate.

Though there exists no invariable par of exchange, it is extremely useful to the merchant to know the average value of the currency of every country with which he trades, in order to ascertain what may be called the *approximate par*, which must be the pivot around which fluctuations will necessarily turn. This approximate par (a term which we make use of for the sake of conforming, as nearly as truth will permit, to the language familiar to merchants) should be grounded on the average value of a currency taken on a period sufficiently long to include fluctuations from highest to lowest. To the approximate par so taken will be the tendency of the rate of exchange to conform.

The approximate par of exchange will be liable to be affected by four pairs of circumstances, in addition to a rise and fall in the price of the precious metals. These are—

1. Changes made by the supreme authority in the quantity of the pure metal contained in the coin by way of increase or diminution.

2. Depreciation from the use of paper money, and restoration.

3. Clipping, and restoration.

4. Wear and tear, and restoration.

1. *Legal Changes in the Coinage.* Governments have not unfrequently found the diminution of the quantity of the metal contained in the current coin an easy way of getting rid of improvidently contracted debts. The English pound was once a troy pound of silver; it is now about four ounces. The French livre, once probably the same quantity, is now less than a *seventieth* part of a lb. By what a succession of frauds must this change have been brought about!

A government having borrowed so many pounds of its subjects would find it a very convenient thing, when the day of payment should come round, to call ten or fifteen shillings 'a pound;' and as it would have all the debtors in the kingdom on its side, popularity would be divided on the measure. But although creditors at home may be compelled to submit to this robbery, creditors abroad cannot. Their contract is to receive a given sum of the money of their own country, and the only effect of any debasement will be that the foreign debt will require more of the debased money to liquidate it; in other words, exchange will fall in the ratio of the debasement. Thus suppose the sovereign to be reduced in weight 10 per cent., exchange on the Parisian Bourse, if at 25·58f., would fall to 23f. 2c. If, on the other hand, the franc were reduced, exchange would rise.

We can illustrate this by two historical facts. Formerly the Spanish dollar contained as much silver as 4s. 6d. sterling, and consequently the average value of 100l. was 444 dollars 44 cents. The weight of the dollar however has been since reduced, and it now contains only as much silver as 4s. 2d. sterling, so that that the average value of 100l. sterling is now 480 dollars; the difference being 8 per cent. The old language of quotation however has never been wholly abandoned by the American merchants. They still assume the old par, so that when exchange is quoted at 10 or 11 per cent. premium—a premium which, as we shall presently see, could not be maintained for an hour—it is in fact at 2 or 3 per cent. only (the remaining 8 per cent. being nominal); and when it is quoted at 6 or 7 per cent. premium, it is in fact at 1 or 2 discount. The other fact to which we allude is the recent adoption of a gold standard in the United States, at a rate, compared with silver, to render the American currency practically debased.

Before the introduction of the Gold Bill the average value of 100l. sterling, as we have seen, was 480 dollars; by the new standard, the quantity of gold contained in 100l. is now coined into 487 dollars, being a difference of 1·45 or nearly 1½ per cent. Thus the par between England and America is now 487 d. = 100l., or adhering to the old (erroneously assumed) par, a nominal premium of 9·45 per cent.

2. *Paper Money.* One of the evils to which paper money is liable is depreciation from excess. The market price of money, like that of every thing else, varies in the inverse ratio of its quantity. If it be scarce it will be dear; in other

words, all other things will be cheap. If, on the other hand, money be in excess, it will be cheap; in other words, much of it will be given in exchange for other things. To say that prices are advancing, is equivalent to saying that money is getting cheaper and cheaper. The effect of issuing paper money in excess is, then, to make money, both metallic and paper, cheap. Being cheap, it becomes desirable to export it; but paper money is not available for this purpose, and hence metallic money is alone exported. Bullion in the uncoined state would, under such circumstances, advance in price, but the sovereign would be still a sovereign; hence there would exist a motive to convert coined money into bullion, or to export it. Bullion however would not be exported, except when it was really cheaper than in other countries.

During the Bank restriction the depreciation reached 27·9 per cent. Gold was then worth 5l. 8s. per ounce, and silver 6s. 11d. estimated in paper money. But at these nominally high prices the proportion between gold and silver was precisely the present average proportion, namely, 1 to 15·52; or, gold at 3l. 17s. 10½d., and silver at 4s. 11½d. The Parisian par was then 18·43f. per l. sterling (instead of 25·58f.), so that although *coin* might be sent away as a cheaper mode of conversion than melting, bullion would not necessarily be an article of export, unless when exchange was really, and not merely nominally, against us.

We have seen that the present average value of the dollar is 4s. 2d.; when silver was at 6s. 11d. the value would be 5s. 9½d. in the depreciated English money. Hence a debt in London of 100l. could be discharged with 346 dollars 18 cents, whereas now it would require 480 dollars. The dollars remained unchanged, but 100l. of 1813 was worth only 72l. 2s. in gold.

As the par of 4s. 6d. was then, as now, retained, the depreciation was met by a heavy nominal discount of 27½ per cent. It is unnecessary to pursue these calculations to other countries: the same principles apply to all countries.

It is scarcely necessary to observe, that in the process of restoration the phenomena are reversed. A restoration of the English currency, for instance, would be similar in its effects to a depreciation of the currencies of all other countries.

3. *Clipping the Coin.* In some countries the practice of clipping the coin still continues, and it is likely to continue just so long as people will take clipped coin. If people would take shillings clipped into polygons, they would be so clipped in less than twenty-four hours.

The effect of clipping on the exchange is precisely similar to the two cases we have already examined. If the silver coin of France were clipped to the extent of one-tenth of its weight, exchange would be affected to that extent. Instead of requiring only 25·58f. to purchase 1l. sterling on the Parisian Bourse, it would require 28·14f. Restoration would be equivalent to clipping the coins of other countries.

Some of the continental states in which clipped coin circulates have adopted an expedient to keep up the character of their money of account. This expedient is to transact all their dealings with other nations in what they call *Banco*, which may be defined money as it ought to be, to distinguish it from the current or clipped money, which may be called *money as it is*. The merchants keep their bank accounts in *money as it ought to be*, paying in the clipped money, or *money as it is*. They are charged with the depreciation, which is known by the term *Agio*. This is purely an arrangement of convenience.

4. *Wear of Coin.* The case of a worn coinage is precisely similar to that of a clipped coinage, except that the latter is sudden in its effects, the former gradual. Hence depreciation from wear is much more likely to deceive than that which arises from clipping. Restoration by means of a new issue reverses all the effects.

We have now enumerated the principal circumstances affecting the value of a currency. Fluctuations in the rate of exchange proceeding from an alteration of the value of the medium in which price is quoted are purely *nominal*; and so they are usually designated. They are alterations proceeding from the altered quantity of the article purchased, and are analogous to an alteration of the price of wheat from an alteration in the capacity of the imperial quarter.

What is usually called the *real* exchange is the actual market-price, determined by the same law as the price of

sugar, corn, or broad-cloth: namely, the existing proportion between supply and demand.

The demand for bills of exchange arises out of the necessity of paying for importations. The supply arises out of the practice of drawing for the amount of exportations. If the supply and demand be equal—if for every pound's worth of goods imported there be exactly a pound's worth of exported goods to be drawn for—there will be no real exchange: that is, the real exchange, however much the nominal exchange may alter, will be at par.

When, however, the importations are not precisely equal to the exportations, exchange can no longer remain at par. An excess of importation would cause exchange to advance against the importing country. Let us suppose a case. Let us suppose that an actual or anticipated advance in the price of wheat causes the transmission of extensive orders to the north of Europe. This would produce a sudden demand for bills of exchange—not perhaps to the extent of the orders; for in all probability goods adapted to the markets of the wheat-growing countries would be sent in part payment—but, at all events, to a considerable amount. There would accordingly be an advance in the rate of exchange, first on the wheat-shipping ports, and next on all other countries. Thus, England imports wheat from Danzig, and exchange on Danzig rises. But exchange on Amsterdam is at par, as it is also at Amsterdam on Danzig. Hence the wheat-importer would buy a bill on Amsterdam, and with the proceeds would there buy a bill on Danzig. But the buyer of exchange on Amsterdam cannot go into the market without causing an advance in the rate. In this way the advance becomes general.

The real exchange, however, is subject to a limit beyond which it cannot advance. This limit is the cost of transmitting the precious metals. A debtor to a foreign country—say the importer of wheat—can liquidate his debt by the transmission of bullion as well as of a bill of exchange; and he will be determined in his choice by the comparative cheapness of either mode. The cost of transmitting specie is, let us assume, 2 per cent.: so long as exchange continues below 2 per cent. the debtor will continue to purchase it; but the moment the drawer demands more than that rate, the exportation of bullion will be resorted to, and bills of exchange will cease to be demanded. The cost of transmitting bullion, including the cost of collecting it at the port of shipment, is therefore the limit beyond which the real exchange cannot advance.

But an advance in the rate of exchange, even up to this point, cannot long be maintained. The tendency in an advance in the rate is to check importation and stimulate exportation. Articles which would only just pay with exchange at par would pay a profit sufficient to induce exportation where the exporter could secure 1 or 2 per cent. more for his draft. Thus, by the stimulus to exportation, the supply of bills would be increased to meet the demand, and *pro tanto* to check the advancing rate of exchange. On the other hand, an imported article which was only just paying when exchange was at par would cease to pay when it should cost the importer 2 per cent. more to make his remittance. Thus, whilst the cost of exporting the precious metals is the immediate check upon an advancing rate of exchange, the effect of the real exchange in stimulating or checking importation or exportation, as the case may be, is to work its own remedy. The real exchange is, in fact, continually gravitating towards par, though at times superior forces may overcome that perpetual tendency.

Most of the errors which prevail in relation to the subject of exchange arise out of confounding the real with the nominal exchange. For the purposes of general reasoning, it is well to know what is the average value of the currencies of the several nations with which we have commercial relations; but for practical purposes the actual par for the moment should be rigidly calculated. Unless this be done, the practical merchant will be liable to continual error. For farther information on the subject, the reader may consult Mill's *Elements of Political Economy*, chap. iii. sec. 16, p. 182; Ricardo's *Principles*, chap. vii., *On Foreign Trade*; article *Exchange* in the *Encyclopædia Britannica*; and Tooke's *High and Low Prices*, passim.

EXCHANGE, ROYAL. [GRESHAM.]

EXCHEQUER COURT is a superior court of record established by William the Conqueror as part of the *Aula Regis*, and reduced to its present order by Edward I.

It is the lowest in rank of the four great courts which sit at Westminster Hall, although in ancient times one of the first in importance, as all causes relating to the rights of the crown were there heard and determined, and the revenues of the crown were supposed to be received there. Perhaps the inferiority in point of precedence of this court may be attributed to its having been originally erected solely for the king's profit, which was considered an object inferior to the general administration of justice to the subject.

Etymologists have exhausted much research in ascertaining the origin of the name: some assert that it is derived from the old French word *Eschequier*, a kind of abacus or table; or the German, *Schatz*, 'treasure.' The Latinized form of the word is *Scaccarium*. Camden says it was so called from the covering of the table at which the barons sat being partly-coloured or *chequered*, and on which, when certain of the king's accounts were made up, the sums were marked and scored with counters.

The judges of the court of exchequer are the chancellor of the exchequer for the time being, the chief baron, and four other barons, who are created by letters patent, and are so called from their having been formerly chosen from such as were barons of the kingdom, or parliamentary barons. (Selden's *Titles of Honour*.)

The court of exchequer was formerly held in the king's palace. Its treasury was the great deposit of records from the other courts; writs of summons to assemble the parliaments were issued by its officers; and its acts and decrees, as they related almost entirely to matters connected with the king's revenue, were not controlled by any other of the king's ordinary courts of justice.

It now consists of two divisions, one of which exercises jurisdiction in all cases relating to the customs and excise, and over revenue matters generally. The other division is subdivided into a court of common law, in which all personal actions may be brought, and a court of equity, where suits in equity may be commenced and prosecuted.

A plaintiff, when bringing an action in this court, previously to the Act for Uniformity of Process in personal actions (2 Will. IV. cap. 39), fictitiously alleged himself to be the king's debtor, in order to give the court jurisdiction in the cause; but since the passing of that act it is no longer necessary to resort to this fiction in order to bring an action on the plea side of the court of exchequer, as that statute assimilates the practice of all the common law courts, and the operation as well as the name of the processes issued from them are the same.

The number of officers on the plea side of the court of exchequer, and their several duties, are regulated by the 2nd and 3rd Will. IV. cap. 110. By 3rd and 4th Will. IV. cap. 70, a great number of old offices are abolished.

When the court sits in equity the chancellor of the exchequer has a voice (although now very rarely exercised) in giving judgment. The last case in which the chancellor was required to sit, owing to the barons being equally divided in opinion, was that of *Naish* against the East India Company, Michaelmas Term, 1735, when Sir Robert Walpole was chancellor, and his decision in a question of very considerable difficulty was said to have given great satisfaction.

An appeal lies from this court by writ of error to the justices of the courts of king's bench and common pleas sitting in the exchequer chamber, who alone have power to review the judgments of the barons; and from their decision a further appeal may be brought before the house of lords.

The Court of Exchequer chamber was first erected in England by stat. 31 Edward III., to determine causes upon writs of error from the common law side of the court of exchequer. The judges of the three superior courts occasionally sit here to hear arguments in important criminal cases, and upon causes of great weight and difficulty, in which the judges of the court below have not given their judgment.

As a court of error, the court of exchequer chamber underwent considerable alterations by the passing of the 11th Geo. IV. and 1st Will. IV. cap. 70., and its constitution is now regulated by that statute. [Courts.]

The Court of Exchequer in Scotland was established by the 6th Ann. cap. 26. The judges are the high treasurer of Great Britain, with a chief baron, and four other barons. By a recent act (3 and 4 William IV. c. 13) the powers

of the barons of the Scotch Exchequer as to the duties and revenues, &c., mentioned in the act have ceased, and are vested in the Commissioners of the Treasury: and the collection and management of the assessed taxes and land-tax of Scotland are transferred to the Commissioners for the Affairs of Taxes, but the judicial powers of the barons are specially saved.

The Court of Exchequer in Ireland was established by the 40 Geo. III. cap. 39, and consists of the chief justices, chief baron, and the rest of the justices and barons, or any nine of them.

EXCHEQUER BILLS form the principal part of the unfunded public debt of this country. These bills are issued under the authority of parliament for sums varying from 100*l.* to 1000*l.*, and bear interest. They were first issued in the reign of William III.; and although their amount has since varied greatly at different times, the convenience which they afford to individuals and their advantage to the public have been such as to cause their constant issue. Their convenience to individuals arises from the circumstance of their passing from hand to hand without the necessity of making a formal transfer, of their bearing interest, and of their not being subject to such violent fluctuations as sometimes occur in the prices of the funded debt. This comparative steadiness in value is caused by the option periodically given to the holders to be paid their amount at par, or to exchange them for new bills to which the same advantage is extended; besides this, when a certain limited period has elapsed from the date of their first issue, they may be paid to the government at par in discharge of duties and taxes. The amount of premium that may have been paid at the time of purchase is consequently all that the holder of an exchequer bill risks in return for the interest which accrues during the time that it remains in his possession. The advantage to the public consists in the lower rate of interest which they carry compared with the permanent or funded debt of the nation, to which, however, they must in this respect bear some certain proportion. When the price of the public funds is high, the interest upon exchequer bills will be low; and if, through any public or commercial derangement, the funds should fall in price so as to afford a much more profitable investment than exchequer bills, the rate of interest upon these must be raised in order to prevent their payment into the exchequer in discharge of duties, a thing which would embarrass the financial operations of government. When first issued in the reign of William III., the interest borne by exchequer bills was 5*d.* per 100*l.* per diem, being at the rate of 7*l.* 12*s.* 1*d.* per cent. per annum. In the same reign the interest was afterwards lowered to 4*d.* per 100*l.* per diem, or 6*l.* 1*s.* 8*d.* per cent. per annum; and in the following reign the rate was still further reduced to 2*d.* per diem, or 3*l.* 0*s.* 10*d.* per cent. per annum. During the greater part of the war from 1793 to 1814, the rate of interest upon these securities was fixed at 3*d.* per cent. per diem, or 5*l.* 6*s.* 5*d.* per cent. per annum. Since the last-mentioned year the rate has been progressively reduced to 2*d.*, 1*d.*, and 1*d.* per 100*l.* per diem, at which latter rate they were in the market at the time of the derangement of the currency which was experienced in the beginning of 1837. Under these circumstances, it was considered important as far as possible to relieve the Bank of England, by which establishments a very large proportion of these securities were then held, and to place it in the most favourable position for affording relief to the commercial classes; and accordingly the rate of interest upon exchequer bills was raised to 2*d.* per cent. per diem, at which rate they are still current (August, 1837), although the high premium which they bear in the market—48*s.* per cent.—leads to the supposition that it will be soon again reduced.

In periods of commercial pressure arising from causes which are believed to be temporary, it has sometimes been considered advisable by parliament to make advances to merchants upon the security of goods; these advances have been made by the issue of exchequer bills, which have been cancelled when the exigency that called for them has passed away. A more permanent occasion for their issue, apart from the immediate wants of the government, has been the desire of aiding individuals or private associations in the prosecution of works of public utility, such as canals, roads, &c. In these cases the rate of interest charged to the borrowers is somewhat greater than that borne by the

bills, and the difference has been applied to defray the expense of management on the part of the public.

The amount of exchequer bills 'outstanding and unprovided for' at the end of each of the last ten years was as follows:—

| | £. | | £. |
|----------|------------|----------|------------|
| 1827 . . | 27,546,850 | 1832 . . | 25,696,000 |
| 1828 . . | 27,657,000 | 1833 . . | 28,384,700 |
| 1829 . . | 25,490,550 | 1834 . . | 28,521,550 |
| 1830 . . | 25,609,650 | 1835 . . | 29,007,950 |
| 1831 . . | 25,351,350 | 1836 . . | 28,155,150 |

EXCISE DUTIES, the name given to taxes or duties levied upon articles of consumption which are produced within the kingdom. This description, which has usually been given of excise duties, is more strictly applicable now than it was formerly, when the commissioners of excise revenue were also charged with the collection of duties upon various articles imported from foreign countries. Among these foreign articles were wine, spirits, tobacco, glass, and tea. The last named of these was the last that was withdrawn from the management of the Excise and transferred to the Board of Customs. There are still, it is true, certain duties to which the name of excise is applied which can hardly be called duties upon consumption, although they are accessory to it, such as the duty on sales by auction and the sums charged for licenses to permit parties to carry on certain trades.

Excise duties are said to have had their origin in this country in the reign of Charles I., when a tax was laid upon beer, cider, and perry of home production. The act by which these duties were authorised was passed by the long parliament in 1643. This act contains also a list of foreign articles, and among others tobacco, wine, raisins, currants, and loaf sugar, upon which excise duties were imposed, in addition to duties of customs already chargeable. This act was adopted and enforced under the protectorate of Oliver Cromwell; and by the statute 12 Charles II. c. 24, the duties of excise were granted as a part of the revenue of the crown.

For a long time this class of duties was viewed with particular dislike by the people, on account of its inquisitorial interference with various industrial pursuits, and it certainly forms a very strong ground of objection against excise duties, that the security of the revenue which they yield is held to be incompatible with the perfect freedom of the manufacturer as to the processes which he may apply in his works. In every highly-taxed country where consumption duties form part of the public revenue, it would seem however to be hardly possible to avoid the adoption of this class of duties. If, taking for our example an instance which is now exercising an injurious effect in a neighbouring country, it is found expedient to impose a customs' duty upon the consumption of foreign-made sugar, it is clearly necessary for the protection of the revenue that an excise duty should be imposed upon sugar of domestic production, otherwise the community at large is made to bear the load twice, once in the form of some other tax, and again to the producer of indigenous sugar, who will charge the consumer nearly as much as he would pay to the importer of foreign sugar, including the amount of the duty. By such means a branch of industry would be fostered, unprofitable to the country at large, and profitable only to the few persons by whom the indigenous sugar is produced, but whose profits will not long continue greater than the usual profits upon the employment of stock obtainable in the same country from other branches of industry. An attempt has been lately made to set up a beet-root sugar manufactory in England, but parliament having imposed an excise duty upon the produce equal to the customs' duty charged upon colonial sugar, it does not appear probable that the attempt can be successful, or indeed that it can be persevered in, which indeed is little to be regretted, for the reason already assigned.

Excise duties are liable to this among other very serious objections, that the regulations under which they are collected are made, perhaps unavoidably, to interfere with processes of manufacture, so as to prevent the adoption of improvements which would be beneficial first to the manufacturer and afterwards to the community at large, which must always be interested in their adoption, because of the greater excellence or cheapness of the products which it is the object of the experimenter to attain. It will give some idea of the

extent to which this interference is injurious, if we state, on the authority of a gentleman conversant with all the details of the art of calico-printing, that upon the same premises, with the same capital, and employing the same amount of labour, double the quantity of cloths are now printed which could have been printed previous to the repeal of the duty, and to the consequent withdrawal of the excise-officers from the works. Another great objection that may be urged against excise duties is, the facilities which they offer for the commission of frauds against the revenue, an offence which, in the eyes of many persons, is of a venial kind, but which too often ultimately demoralizes those by whom it is committed. In the Seventeenth Report of the Commissioners appointed to inquire into the management and collection of the excise revenue it is stated as a striking proof of the extent to which frauds are committed by manufacturers of soap, that 'there are in England fifty that take out licenses, for which they pay 4*l.* per annum, each of which makes, or rather brings to charge, less than one ton of soap per annum, from which it is obvious that as the profits of such a sale would not pay for the license, the entry is made in order to cover smuggling.' With regard to malt, another article of great consumption which is subject to excise duties, the commissioners state it to be their opinion, founded upon the evidence given by several respectable maltsters, 'that malt is sold throughout the season, and in large quantities, for a price that is insufficient to pay the expense of making it and duty; and that the duty is evaded to a great amount.' A strong presumptive evidence to this effect is contained in the fact that the average number of bushels of malt brought to charge in each of the ten years from 1725 to 1734 was 26,177,330, while in the ten years from 1825 to 1834, that is, after the lapse of a century, the number of bushels so brought to charge was 29,572,380; although during that time the population had been more than doubled, and the habits of the people not altered in any way that should lead to the supposition of any decreased consumption of the products of malt.

The articles now subject to excise duty are:—auctions; bricks; glass; hops; licenses; malt; paper; soap; spirits (British); vinegar.

In addition to the foregoing, excise duties were collected in 1797, under the following nineteen heads, viz.: * starch; * stone bottles; * sweets and mead; tea; * tiles; * candles; * coaches; * cocoa; * coffee; * cider; * perry; * hides and skins; pepper; * printed goods; * salt; spirits (foreign); tobacco and snuff; wine; * wire.

Of these nineteen articles the duties have been repealed upon the twelve to which an asterisk is prefixed; the collection of duties on the remaining seven articles has been transferred to the Customs department.

The following table states the amount of payments made into the Exchequer on account of excise duties in England, the charges of collection and the rate per cent. on the collection calculated on the gross revenue in each year from 1797 to 1835.

| | Net Receipt. £ | Charges of Collection. £ | Rate per cent. £ s. d. |
|------|-------------------|--------------------------------|---------------------------|
| 1797 | 9,452,887 | 411,696 | 3 14 4 |
| 1798 | 9,872,025 | 409,357 | 3 10 11 |
| 1799 | 11,429,523 | 425,174 | 3 3 7 |
| 1800 | 10,198,749 | 432,329 | 3 12 1 |
| 1801 | 10,529,110 | 557,766 | 4 9 2 |
| 1802 | 13,774,158 | 520,022 | 3 7 0 |
| 1803 | 16,889,374 | 525,583 | 2 17 9 |
| 1804 | 19,448,143 | 557,470 | 2 13 1 |
| 1805 | 21,015,539 | 564,594 | 2 10 0 |
| 1806 | 21,739,067 | 579,940 | 2 9 6 |
| 1807 | 22,087,226 | 648,756 | 2 14 6 |

| 1816 | 21,553,638 | 928,659 | 3 13 2 |
| 1817 | 18,396,400 | 992,744 | 4 13 10 |
| 1818 | 21,330,746 | 953,869 | 3 19 7 |
| 1819 | 21,492,839 | 951,431 | 3 19 10 |
| 1820 | 24,742,242 | 958,124 | 3 10 7 |
| 1821 | 24,781,957 | 964,515 | 3 10 4 |
| 1822 | 24,022,441 | 950,644 | 3 10 7 |
| 1823 | 22,375,780 | 933,815 | 3 13 9 |
| 1824 | 23,498,903 | 923,864 | 3 10 0 |
| 1825 | 18,055,446 | 889,994 | 4 1 8 |
| 1826 | 16,158,649 | 857,310 | 4 12 10 |
| 1827 | 15,446,801 | 846,591 | 4 13 5 |
| 1828 | 16,718,861 | 829,162 | 4 4 10 |
| 1829 | 15,761,547 | 822,070 | 4 10 11 |
| 1830 | 14,747,976 | 840,101 | 4 16 5 |
| 1831 | 12,411,676 | 797,298 | 5 11 3 |
| 1832 | 12,909,188 | 762,863 | 5 6 2 |
| 1833 | 12,846,800 | 750,982 | 5 5 1 |
| 1834 | 11,061,893 | 748,724 | 6 1 8 |
| 1835 | 9,518,688 | 738,812 | 6 16 0 |

The gross and net receipt, charges of management, and the rate per cent. for which the gross revenue of excise in England, Scotland, and Ireland respectively, were collected for the year 1835, were as follows:—

| | Gross Receipt. £ | Net Receipt. £ | Charges of Management. £ | Rate per cent. for which the Revenue was collected. £ s. d. |
|----------|---------------------|-------------------|--------------------------------|---|
| England | 10,861,182 | 10,255,486 | 738,812 | 6 16 0 |
| Scotland | 2,456,705 | 2,232,961 | 150,530 | 6 2 6 |
| Ireland | 1,911,464 | 1,906,150 | 183,049 | 9 11 6 |

The gross receipt, as stated in the foregoing abstract, was collected on the different articles subject to excise duties in the following proportions:—

| | England. £. s. d. | | | Scotland. £. s. d. | | | Ireland. £. s. d. | | | United Kingdom. £. s. d. | | |

EXCITANTS. [STIMULANTS.]

EXCOMMUNICATION. From *Excommunicatio*, is the highest ecclesiastical censure which can be pronounced
P. C. No. 609.

by a spiritual judge. The person against whom it is pronounced is for the time being excluded from the communion of the church. This punishment, as well as many others, springing from ecclesiastical jurisdiction, according to some opinions, had its origin in the advice given by St. Paul when reproving the early Christians for scandalizing their profession by prosecuting law-suits against each other before heathen judges; and the apostle accordingly recommended them to leave all matters in dispute between them to the decision of the Ecclesia, or the congregation of the faithful. This advice was soon followed, and heathen tribunals were seldom afterwards occupied by the controversies of the Christians.

The bishop and his clergy, and afterwards the bishop alone, became sole judge in these disputes; but possessing no coercive powers to enforce their decrees, they were obliged to adopt the only means of which they could avail themselves, to bring the refractory to submission, namely, by excluding them from the rites of the Church, and warning other Christians from their company and presence. A Christian thus shut out from the fellowship of his own brethren could not do otherwise than submit unconditionally.

This censure, although instituted by the primitive church as the means of preserving its purity, and of enforcing obedience to its just laws, was afterwards used for the promotion of ecclesiastical power, and was converted into an engine of the greatest oppression in those countries which were most subject to ecclesiastical rule. (Robertson's *History of Charles V.*, vol. ii. p. 109.)

In England excommunication became at a very early period the instrument of punishment under the authority of the bishops, and others possessing ecclesiastical jurisdiction. It was divided into the greater and the less excommunication. The latter only removed the person from a participation in the sacraments, and is what was most commonly meant by the term excommunication; the other was called anathema, and not only removed the party from the sacraments, but from the Church and all communication with the faithful, and even deprived him of Christian burial. Subjects were absolved from their allegiance to an excommunicated prince: indeed they were forbidden to obey him. Gregory V. was the first prelate who ventured to excommunicate a reigning prince in the case of Robert, king of France, in 998. John and Henry VIII. are well-known instances in English history. The latest instance of all was Napoleon, in 1809, by Pius VII.

Excommunication sometimes followed immediately upon the commission of an offence, and was then called canonical, to distinguish it from that which did not depend upon any established canon, but upon the sentence of a judge.

The following offenders were punished with the greater excommunication: diviners, heretics, their receivers and comforters; simoniacs; violators and plunderers of churches; those who spoiled clerks going to Rome; the plunderers of the property of a bishop who ought to go to his successor; those who gave aid, favour, or counsel to excommunicated persons; those who laid violent hands on clerks or religious persons, or commanded others to do so.

Those punished with the less excommunication were persons committing any mortal sin, as sacrilegious persons; those who received a church from lay hands; notorious offenders; those who talked with, saluted, or sat at the same table with, or gave anything in charity to persons excommunicated by the greater excommunication, unless they were familiars or domestics.

Excommunication was also pronounced for other matters which belong to ecclesiastical jurisdiction, as adultery, incontinence, fornication, &c., or for contempt of any ecclesiastical order or sentence. A sentence of excommunication was preceded by three monitions at due intervals, or one peremptory, containing the legal space of time, with a proper regard to the quality of the person and the nature of the offence. But, as Blackstone remarks, 'heavy as the penalty of excommunication is, considered in a serious light, there are, notwithstanding, many obstinate or profligate men, who would despise the *brutum fulmen* of mere ecclesiastical censures, especially when pronounced by a petty surrogate in the country, for railing or contumelious words, for non-payment of fees or costs or other trivial causes. The common law therefore compassionately steps in to the aid of the ecclesiastical jurisdiction, and kindly lends a supporting hand to an otherwise tottering authority.' This was effected by the writ 'de

excommunicato capiendo,' or for seizing the excommunicate. But before the writ for taking the excommunicated person could be granted the contumacy and contempt of the party were to be certified by the bishop to the court of Chancery by letters under his seal; and by 5 Eliz. c. 23, the writ was made returnable into the King's Bench. By the statute just cited the cause of excommunication was to be stated in the writ, in order that the court might judge as to the justice of the case. The sentence of excommunication might be revoked by the judge who passed the sentence, or upon appeal the party might be absolved. Absolution generally belonged to the same person who passed the sentence, unless in some particular cases, which were referred to the pope or a bishop. (Reeves' *Hist. of English Law*; Sullivan's *Lectures*.)

By a sentence of excommunication, both greater and less, those denounced were excluded from the right of Christian burial, from bringing or maintaining actions, from becoming attornies or jurymen, and were rendered incapable of becoming witnesses in any cause. But since the 53rd Geo. III. c. 127, excommunication cannot now be pronounced in England, except in certain cases (as spiritual censures for offences of ecclesiastical cognizance); and by the 3rd section of that statute 'no person who shall be pronounced or declared excommunicate (pursuant to the second clause of this statute) shall incur any civil penalty or incapacity, in consequence of such excommunication, save such imprisonment, not exceeding six months, as the court pronouncing or declaring such person excommunicate shall direct.' The proceedings in those cases, in which excommunication may still be pronounced, are the same, as to the issuing and return of the writ, as they were before the act of 53 George III. By the same act (53 George III. c. 127), in all cases cognizable by the laws of England in ecclesiastical courts, when any person shall refuse to appear when cited by such court, or shall refuse to obey the lawful order or decree of such court, no sentence of excommunication, except in the cases above alluded to, shall be pronounced; but a writ 'de contumace capiendo' shall issue, which in effect is the same as the old writ 'de excommunicato capiendo' was. Thus the various difficulties are now obviated which formerly existed in courts of law with respect to excommunication.

EXECUTION is the effect given to the judgments and other proceedings analogous to judgments of courts of law and in civil suits. This term denotes the process by which a party is put into the actual possession of that to which by the proceedings of a court he appears to be legally entitled.

As a judgment of a court of common law ascertains that the party is entitled to the possession of some subject of a real or personal nature; or to recover damages in respect of property withheld or injuries done, so the execution founded upon such judgment will be framed with a view to putting the party in whose favour the judgment is given either in the actual possession of the thing in dispute, or to enable him to obtain pecuniary compensation.

For this purpose a written command issues in the name of the king or other lord or owner of the court, to an officer of the court: when the judgment is in one of the king's superior courts at Westminster, the officer of the court for this purpose is the sheriff of the county in which the property is situate, or, in the case of pecuniary compensation, the sheriff of the county in which the party from whom such compensation is due is supposed to reside; which, until the contrary is shown, is taken to be the county in which the litigation was carried on.

Where lands or other corporeal hereditaments are recovered, the process of execution varies according to the nature of the interest recovered. If a right to a freehold interest has been established, the writ commands the sheriff to give the recoverer seisin of the lands, &c., and is called *habere facias seisinam*. [*HABERE FACIAS SEISINAM*.] If a chattel interest only is recovered, the writ does not affect to authorize the sheriff to intermeddle with the freehold, and directs that officer merely to give possession of the land, &c. This is called an *habere facias possessionem*. [*HABERE FACIAS POSSESSIONEM*.]

A judgment in the action of detinue [*DETINUE*] establishes the right of the recoverer to the possession of a specific personal chattel, and the writ of execution called a *distringas* ad deliberandum issues, requiring the sheriff to coerce the defendant by his *distringas* (distresses) to restore the specific chattel or its value.

A judgment for the defendant in replevin [*REPLEVIN*]

establishes his right to the possession of the personal chattel which formed the subject of the litigation. In the ordinary case of an action of replevin after a distress, the right of the defendant in respect of the chattel distrained is merely to hold it as a security for the payment of the debt or duty, the payment or performance of which is sought to be enforced by the coercion of a distress. [*DISTRINGAS*.] The writ of execution requires the sheriff to cause the chattel to be restored to the possession of the defendant. This is called a writ *de retorno habendo*, and in case the sheriff is unable to find the chattel, further process issues commanding him to take other chattels of the plaintiff as a substitute for that which is withheld, by a writ called a *capias* in withernam.

The most ordinary cases of execution are those in which pecuniary compensation is to be obtained, but in these cases the sheriff is not authorized directly to take money from the party by whom it is to be paid. Formerly the only mode of obtaining this compensation was by process of *distringas* or distress. And this is still the case in inferior courts; but in the superior courts execution of judgments or other records establishing pecuniary claims may be had by a writ of *fieri facias* [*FIERI FACIAS*] affecting the personal property; by writ of *elegit* [*ELEGIT*], affecting both real and personal property; and by *capias* ad satisfaciendum [*CAPIAS*], by which compliance with the pecuniary demand is enforced by detention of the person of the defaulter in prison until the claim be satisfied, or the adverse party consents to his discharge.

A subject is not entitled to pursue all these remedies at once; but in the case of the crown, the right to obtain satisfaction from the goods, lands, and person of its debtor may be enforced simultaneously, by writ of *capias*, and *extendi facias*, or extent. [*EXTENT*.]

EXECUTION is also the term applied to denote the giving effect to the sentence of a court of criminal jurisdiction. In this sense it is most commonly used with reference to the execution of sentence of death. [*SHERIFF*.]

EXECUTOR. An executor is he to whom another man commits by will the execution of that his last will and testament. He answers in some degree to the *heres designatus*, or *testamentarius*, in the civil law, as to the debts, goods, and chattels of his testator; but the origin of executors seems to be properly traceable to a constitution of Manuel Comnenus (*περί διοικητῶν τῶν διαθητῶν*). All persons who are capable of making a will, and some others besides, as married women and infants, are capable of being made executors; but infants are by statute rendered incapable of acting in the execution of the will until they attain the age of twenty-one.

An executor can derive his office from a testamentary appointment alone, though it is not necessary that he should be appointed by express terms; any words of the testator indicating an intention to make the appointment are sufficient: in this case he is usually called 'executor according to the tenor.' If no executor is appointed by the will, administration is granted by the ordinary, with the will annexed, in which case the administrator is bound to obey the directions given by the will. An executor may renounce probate; but having once acted, he cannot divest himself of the office or its liabilities; nor can an administrator who has accepted the office, get rid of his responsibility.

An executor may do many acts in execution of the will, even before probate, as paying and receiving debts, &c., but he cannot, before probate, sustain actions or suits. An administrator can do nothing till the letters of administration are issued; for the former derives his power from the will, and not from the probate: the latter owes his entirely to the appointment of the ordinary. If an executor die before probate, administration must be taken out to his testator, with the will annexed; but if an executor, having proved the will, die, his executor will be the executor and representative of the first testator, unless, before proving the will of the second testator, he expressly renounces the execution of the will of the first. If the executor dies intestate, his administrator is not the representative of the testator, but an administrator *de bonis non* of the testator must be appointed by the ordinary. If there are several executors, the office survives, and is transmitted ultimately to the executor of the surviving executor, unless he dies intestate. Executors have a joint and entire interest in the effects of their testator; any one of them is capable of acting by himself; and the receipt of a debt, or the transfer of property by one, is as valid as if it had been done by all.

If a stranger takes upon himself to act as executor without any authority, as by intermeddling with the goods of the deceased, he is called an executor *de son tort* (of his own wrong), and is liable to all the trouble of an executor without any of the advantages attached to the office. He is chargeable with the debts of the deceased, so far as assets come to his hands; and is liable not only to an action by the rightful executor or administrator, but also to be sued as executor of the deceased by his creditors and legatees. The only advantage which an executor derives from his office is the right to retain any debt due to him from the testator, as against creditors of equal degree, and this privilege is allowed him, because he cannot take any legal steps to recover payment. This, though practically a privilege, is in reality only a provision of the law that he shall not be prejudiced by his appointment; otherwise as a man cannot sue himself, all the other creditors would, by instituting a suit against the executor, gain priority over him in respect of their debts.

The duties of executors and administrators are in general the same, the only essential difference between them being, as before mentioned, the mode of their appointment. Their duties are to bury the deceased, to prove his will in the proper Ecclesiastical Court, to collect and get in his goods and chattels, to pay his debts in the order appointed by law, and also his legacies, if he has bequeathed any, and to dispose of the residue of his goods and chattels in the manner by the will directed, or according to the statutes for the distribution of the effects of intestates, if there should be a total or partial intestacy. Executors and administrators are liable to an action at law, and also to a suit in equity, for the payment of the debts and liabilities of their testator or intestate; and to a suit in equity and the Ecclesiastical Court for the legacies bequeathed by him, and the due administration of his estate: but no action at law lies for a legacy, at least not until after the executor has assented to it, as it is called, that is, has acknowledged the sufficiency of the assets after providing for the payment of the debts. [LEGACY.]

It appears to have been a subject of much controversy whether the probate of wills was originally a matter of exclusive ecclesiastical jurisdiction, but whatever may have been the case in earlier times, it is certain that at this day the Ecclesiastical Courts are the only courts in which, except by special prescription, the validity of wills of personality can be established or disputed. If all the goods of the deceased lie in the diocese or jurisdiction within which he died, the probate is made before the bishop or ordinary of that diocese or jurisdiction; but if he had *bona notabilia* (that is, goods and chattels to the amount of 5*l.*) within some other diocese or jurisdiction than that in which he died, then the will must be proved before the archbishop or metropolitan of the province by special prerogative; and if there be *bona notabilia* in different provinces, there must be two prerogative probates. A will should be proved within six months after the death of the testator, or within two months after the termination of any dispute respecting the probate. (See 55 Geo. III. c. 184, sec. 57.)

Executors and administrators are treated by the courts of equity as trustees for the creditors, legatees, and next of kin of their testators or intestates. They are bound to administer the assets according to their due order of priority and to pay the debts of the deceased in like manner; and though the ecclesiastical courts will entertain suits for the payment of debts or legacies and the due administration of the assets, yet, where there is any trust to be executed, or any charge on real estate to be established, a court of equity will interfere by injunction or prohibition; for the constitution of the ecclesiastical courts is not adapted to the administration of trusts, and over real estate they have no jurisdiction. The probate is exclusive evidence of a will of personality; but courts of equity assume the jurisdiction of construing the will in order to enforce the performance of the trusts by the executor: hence they are sometimes styled courts of construction, in contradistinction to the ecclesiastical courts, which, although they also are courts of construction, are the only courts of probate. Formerly, the personal estates only of persons deceased were liable for the payment of their simple contract debts; but now, since the statute 3 and 4 Wm. IV. c. 104, real estates are liable for the payment of debts of that nature; and it may be broadly stated that all the real and personal estates of the deceased are assets for the pay-

ment of his debts. The personal estate is liable in the first instance, unless the testator direct otherwise. Estates descended are applied before estates devised; and in other respects the estates of the deceased are administered in the order laid down by the courts.

The debts are also payable in a certain prescribed order.

1. The funeral expenses, the expenses of probate, and the costs of a suit for the administration of the estates, if any be instituted.
2. Debts due to the crown on record or specialty.
3. Certain debts, which by statute are to be preferred to others, as poor-rates, by stat. 17 Geo. II. c. 38, &c.
4. Debts of record, as judgments, statutes, and recognizances.
5. Specialty debts, *i. e.*, debts due on bonds or instruments under seal.
6. Simple contract debts, as upon bills of exchange and ordinary verbal engagements.

It seems that in this class debts due to the crown and the wages of domestic servants are entitled to priority.

A mortgage made by the testator must, if there be no specified direction in his will, be paid out of the personal assets, if there be sufficient to pay the other creditors and legatees; it is, in fact, considered as the personal debt of the testator: though, if he did not create the mortgage himself, but took the estate subject to the mortgage by purchase, inheritance, or devise, the debt, not being his personal engagement, must be borne by the estate itself. The executor must pay the debts in the order mentioned; for if he apply the assets in payment of those of a lower degree, he will be personally answerable, to the extent of the assets misapplied, to the creditor of the higher degree. He may, however, pay a debt of an inferior degree before one of a superior, provided he has no notice of the latter and a reasonable time has elapsed after the testator's death; except in the case of debts of record due to the crown, of which the executor is bound to take notice. An executor or administrator may also retain his own debt as against creditors of an equal degree; and he may pay any one or more debts to creditors of equal degree, although thereby he may exhaust the assets, unless a suit or action be commenced against him; and even in that case he may, by confessing a judgment, enable a creditor to obtain priority. But notwithstanding an action or suit be commenced, he may pay a creditor of a higher degree than the one proceeding against him; save only where the suit is for a general administration of the estate, when the executor should not make any farther payments.

The debts being all paid, the next duty of an executor or administrator is to pay the legacies, and distribute the personal estate to the next of kin of the testator if there be any overplus; but where the testator has made a residuary legatee, he is entitled to the surplus. If the assets are not sufficient for the payment of the legacies, the executor must pay to each legatee an equal proportion of his legacy, unless the testator has directed the order of payment, in which case the legacies must be paid in full in the prescribed order, and the whole loss must fall upon the last in order. Specific legatees, *i. e.* persons to whom a specific fund or article of property is given by the will, are not liable to abatement of their legacies, but receive the fund or article whether the assets are or are not sufficient to pay the other legatees; though if the fund is changed, or the article sold, or from any other cause is not in existence at the death of the testator, the legacy fails, or in technical language, is said to be adeemed. Executors and administrators cannot be compelled to pay legacies or distribute the personal estate before the expiration of a year after the decease of the testator; and not even then, if notice has been acquired or there is reasonable ground to suspect the existence of debts and liabilities. Indeed, unless the assets are of ample amount, the executor or administrator should not pay within the year, even though the testator has directed it to be done; for it has been held that such a payment affords no defence against a creditor, and the testator or intestate may be bound by covenants upon which subsequent liabilities may accrue; or he may have been a trustee, and some maladministration of the trust estate may be discovered after the lapse of many years. In these and many other cases, executors and administrators should not part with the assets until all chance of liability is at an end, or security be given by the parties receiving them to refund in case of need. This last course will sometimes be directed by a court of equity in a suit for a legacy; for though an executor or administrator may recover from the legatee or next of kin to whom he has handed over the assets in

case of subsequently-discovered debts of the deceased, it is obvious that this is a very insufficient and uncertain security. Where a legatee is an infant, or the testator has directed his executors to invest any portion of his estate in the funds, or has provided for some future payment to be made, or from any other cause, an investment by the executors becomes necessary, they are, in the absence of any express direction to the contrary, bound to make such investment in the Three per Cent. Consols, that fund being considered by the Court of Chancery as the most desirable for the purpose of investment. The rule is inflexible, and an executor who should disregard it would run great risk of having to pay the costs of a suit to compel him to place the money in that fund, and to make good any loss which might occur through the change of securities.

Full information upon these subjects will be found in the works of Williams, and Toller 'On Executors,' and Wentworth 'On Administrators.'

EXE'DRA (*ἑξιδρα*), a name given to certain open recesses in the buildings of the ancients. There were numerous exedræ in the baths. Vitruvius says the spacious exedræ of the Greek palaestra were furnished with seats. The exedræ were placed in the three porticos of the palaestra. (Vitruvius, v. c. 9.) Sometimes in houses a covered hall, and of a square form, was called exedra. (Vitruvius, vi. cap. 5.) In the disposition of the Greek house the exedræ were placed looking to the west. (Vitruv. vi. cap. x.)

EXERCISE. [ANALEPTICS.]

EXETER, a city and a county of itself, locally in the hundred of Wonford, in the southern division of the county of Devon, of which it is the chief town; 44 miles north-east from Plymouth, and 174 west by south from London.

Exeter is supposed to have been a settlement of the Britons before the Roman invasion. It was then called 'Caer-Isc' and 'Caer Rydh,' the former derived from its situation on the Ex or Isc, the latter from the red soil on which the castle is built. By the Romans it was called *Isca Dumnoniorum*, to distinguish it from the *Isca Silurum* in Wales. From the number of coins, small bronze statues (evidently Penates), tessellated pavements, and other Roman antiquities discovered near the walls and in the neighbourhood of the city, it must have been a Roman station of some importance. It is uncertain how long Exeter retained its appellation of *Isca Dumnoniorum*, but in the reign of Alfred it had acquired that of *Exan-Cestre* (castle on the Ex), whence its present name.

In the reign of King Stephen, Baldwin Rivers, earl of Devon, fortified Exeter on behalf of the Empress Maude, and did not yield till reduced by famine after a long siege. It was besieged in the 12th year of the reign of Henry VII. by Perkin Warbeck, and again by the rabble of Devonshire and Cornwall in 1549.

The city of Exeter was formerly surrounded by walls and strongly fortified. Leland, in speaking of it, says, 'The town is a good mile and more in cumpace, and is right strongly waulled and maintained. Ther be diverse fere towers in the town waul bytwixt the south and west gate. There be four gates in the town, by names of Est, West, North, and South. The Est and the West Gates be now the fairest, and of one fasion of building: the South Gate hath been the strongest.' Situated on a high eminence, on the north side of the town, are the ruins of the castle, called 'Rougemont.' When this castle was first erected is unknown; but it was either rebuilt or much repaired by William the Conqueror, who bestowed it on Baldwin de Brion, husband of Albrina his niece, in the possession of whose descendants it remained till the 14th year of the reign of Henry III., who then took it into his own hands. It was completely dismantled during the civil war, and has never since been rebuilt. In the area of the castle-yard a session-house has lately been erected, which is a neat-looking building, faced with Portland stone, and contains, in addition to two good-sized courts, a grand-jury room, magistrates' room, &c. In front is a fine open space, where county, election, and other meetings are held. To the north of the castle is a delightful walk, shaded by fine old elm trees, called Northernay. Nearly in the centre of Exeter is the guildhall, where the assizes for the city (which is a county of itself) are held, as well as the sessions, elections, and other business relative to the city alone. The building contains several valuable portraits, amongst others, those of Henrietta Maria, Charles the First's queen, of her daughter Henrietta duchess of Orleans, and of General

Monk. The only other antient building of any importance at Exeter is the cathedral. It is uncertain when the present edifice was begun, but probably it was soon after the see of Devon was transferred to Exeter from Crediton, which was its locality till the year 1049. At all events it was considerably altered and enlarged by Warlewast, third bishop of Exeter, who was a Norman, and came over with the Conqueror. It then assumed its present cruciform shape, but underwent numberless alterations and additions during the thirteenth and fourteenth centuries. It now consists of a nave, 76 feet in width and 175 in length, with aisles on each side; two short transepts, formed by two Norman towers 130 feet in height; a choir of the same width as the nave, and 128 feet in length; ten chapels or oratories, and a chapter-house. The whole building from east to west (including St. Mary's Chapel) is 408 feet in length. The western front is highly decorated with a profusion of niches and elegantly carved figures, and presents one of the richest façades of any building in Europe. The towers are highly interesting to the antiquary as specimens of Norman architecture. The interior is also exceedingly fine; the vaulted roof of the nave is supported by clustered columns, surmounted by fine pointed arches; as is also that of the choir, which is separated from the nave by a screen of exquisite workmanship. The chapter-house is a beautiful edifice, with a handsome oak roof: it was used as a stable by Cromwell and his soldiers, but has since been thoroughly repaired, as other parts of the building also have lately been.

In the north aisle are the splendid monuments of Sir Richard and Bishop Stapleton. The organ, with the exception of the one at Haerlem, is perhaps the largest in Europe: the large pipes are nearly twenty-three feet in height, and four feet in circumference. (For a further account of this truly magnificent building we must refer the reader to Risdon; Oliver; Britton's *Cathedral Antiquities*, &c. &c.)

The city was antiently held in demesne by the crown; its earliest charter was granted by Henry I., and confirmed by Henry II. and Richard I. The governing charter was granted by George III. in 1770. The corporation hold a court of quarter-sessions, and the assizes are held by the judges of the western circuit twice a year for the county of the city at the guildhall, and twice a year for the county at the session-house. There is also a county court, and a court of requests for the recovery of debts under 40s., the former held every Tuesday, the latter once a fortnight. Petty sessions are held before the magistrates of the county every Friday at the session-house; and some magistrate of the city sits every day at the guildhall. Under the Municipal Act, Exeter is divided into six wards, with twelve aldermen and thirty-six councillors.

Exeter has returned two members to parliament ever since the reign of Edward I. At the first election after the passing of the Reform Act, there were 2952 registered voters. The population of the city and borough is 28,242, of whom 15,559 are females. There are not many manufactories, and the population is chiefly employed in handicraft and the retail trade.

The city of Exeter comprises the parishes of Allhallows, Allhallows on the Walls (the church of which has been demolished), St. Edmund, St. George, St. John, St. Kerrian, St. Lawrence, St. Martin, St. Mary Arches, St. Mary Major, St. Mary Steps, St. Olave, St. Pancras, St. Paul, St. Petrock, St. Sidwell, St. Stephen, and the Holy Trinity, and the parochial chapelries of St. David and St. Sidwell, and the extra-parochial precincts of the Cathedral Close and Bedford Chapel, all in the archdeaconry and diocese of Exeter. There are besides these several other chapels, as well as places of worship for Baptists, Quakers, Independents, Wesleyan and other Methodists, Unitarians, Catholics and Jews.

The town is pleasantly situated on a steep acclivity on the river Ex, over which a handsome stone bridge was erected in the year 1778, at an expense of about 20,000*l.*, a little above the site of an antient bridge originally built in 1250. The streets, with the exception of the High Street and Fore Street, are generally narrow, but there are some handsome squares and terraces in Northernay, Southernay, &c., which contain many well-built houses. The town is lighted with gas, and well supplied with water by waterworks erected in 1794. The subscription ball-room is one of the finest country ball-rooms in England; it measures eighty feet by forty, and is very handsomely fitted up. There

is a subscription library in Fore Street; and in 1813 the Devon and Exeter Institution was founded, for the promotion of arts, &c., the library of which contains about 10,000 volumes. The theatre is a neat building. To the north of the city are the cavalry barracks, and very near them is the new bridewell and the county gaol, both of which are judiciously planned, and contain the governor's residence, chapel, &c. There is also a city prison. The port of Exeter extends from the coast near Lyme Regis to the Ness Point. The trade principally consists in woollen goods and manganese; the imports are wine, hemp, tallow, &c. A branch bank has lately been established here by the Bank of England. The market day is Friday; but there is a daily sale of meat, vegetables, fish, fruit, &c. Fairs are held on the third Wednesdays in February and May, the last Wednesday in July, and second Wednesday in December. There is a great horse fair held at Alphington, about one mile from Exeter.

The free grammar-school was founded by the citizens in the reign of Charles I.; the sons of freemen are instructed gratuitously. There are fifteen exhibitions to either of the universities of Oxford or Cambridge, six of which are of 36*l.* each, the others are much less. The school-room is partly formed of the remains of an antient convent, of Augustine friars founded in 1239. There are no less than ten charity schools in Exeter, independent of Sunday-schools; amongst others are St. Mary Arches' school, founded in 1686, by W. Wootton, for the instruction on Dr. Bell's system of forty-four boys, of whom thirty are clothed; the Devon and Exeter Central School, founded in 1811, where about 430 boys and 270 girls are taught to read and write; and the Exeter British School, where about 130 boys and about the same number of girls are instructed, without regard to party or sect. The Devon and Exeter Hospital is supported by subscription, and has a considerable income arising from funded property: it now contains above 200 beds. There is a lunatic asylum admirably managed, as well as a dispensary, an eye infirmary, and an institution for the deaf and dumb. The workhouse forms a large range of buildings in the London road; it contains a governor's house, committee rooms, &c., and affords accommodation to several hundreds of the poor. A savings' bank was established in 1815, and a mechanics' institution, consisting of above 200 members, in 1825. Amongst other alms-houses and poor-houses are those respectively founded by Mr. John Stevens, Mr. John Palmer, Sir Thomas Lethbridge, and Mr. John Webb. There are also numerous private donations and bequests for the instruction and benefit of the poor.

Many eminent men have been natives of Exeter; among the most distinguished are Josephus Iscanus or Joseph of Exeter, a Latin poet of the twelfth century, Baldwin, archbishop of Canterbury, Sir Thomas Bodley, founder of the Bodleian Library, Lord Chancellor King, Lord Gifford, and Sir Vicary Gibbs.

EXETER or EXON DOMESDAY, the name given to a record preserved among the muniments and charters belonging to the dean and chapter of Exeter cathedral, containing a description of the western parts of the kingdom, comprising the counties of Wilts, Dorset, Somerset, Devon, and Cornwall; supposed, as far as it extends, to contain an exact transcript of the original rolls or returns made by the Conqueror's commissioners at the time of forming the General Survey, from which the Great Domesday itself was compiled. It is written on vellum in the form of a book of the small folio size, containing 532 double pages. The skins or sheets of vellum of which it is composed vary in the number of leaves which they comprise from one to twenty; the lands of each of the more considerable tenants beginning a new sheet, and those of almost every tenant a new page. The lands in the counties of Devon, Somerset, and Cornwall belonging to one tenant, are classed together, the counties following each other, though not always in the same order; and, in like manner, the summaries of property in Wilts and Dorset are classed together.

The manuscript begins with the 'Inquisitio Geldi,' or taxation of the hundreds of Wiltshire; of which it contains no less than three copies, the third seeming to be a corrected edition of the other two. The taxation of the hundreds of Dorsetshire follows, and after it those of Devonshire, Cornwall, and Somersetshire. The Inquisition for each hundred states—1. The total number of hides; 2. the number held by the king and his barons in demesne, with an enumera-

tion of those for which the tax was not paid; 3. the number of hides for which the tax was paid, and its amount; 4. the tax in arrear, and the reasons for its so remaining. Throughout, the geld or tax is computed at the rate of 6*s.* for every hide.

Upon collating the returns of lands which form the great body of the Exeter Survey with the Exchequer Domesday, they have been found, with a few trifling variations, to coincide; one entry of property alone being discoverable in the Exeter which is omitted in the Exchequer Domesday, relating to Sotrebroc in Devonshire. The Exeter manuscript, however, is not complete in its contents. There are considerable omissions of lands in Wiltshire, Dorsetshire, and Devonshire; but these have evidently been cut out and lost. In Cornwall every manor mentioned in the Exchequer occurs in the Exeter Domesday. One leaf of this record was accidentally discovered in private possession within these few years, and has been restored to the manuscript. In the spelling of the names of places and persons there is a remarkable difference between the two records. Rilehetona, in the Exon Domesday, fol. 101, is Chichetone in the Great Domesday, tom. i., fol. 120. Modiforda, Exon, fol. 116, is Mundiforda in Domesday, tom. i., fol. 87. Pillanda, Exon, fol. 127 *b.*, is Welland, Domesday, tom. i., fol. 102 *b.* Illebera, Exon, fol. 139 *b.*, is Lilebere, Domesday, tom. i., fol. 88. There are also many observable differences in the names of persons, as Ulwardus Wite, mentioned in the Exon Domesday, fol. 116, is Vliwardus Albus in the Exchequer Domesday, tom. i., fol. 87. The Abbot of Battle in Sussex is called Abbas de Prelio in the Exon Domesday, fol. 195; but in the Exchequer Domesday, Abbas de Labatallge. Abbas de Aliennia, Exon, fol. 280, is Abbatis de Adelungi in Domesday. Adret, Exon, fol. 488, is both Eldred and Edred, Domesday, tom. i., fol. 118. Willielmus Capra of the Exon, fol. 398, is Willielmus Chievre in the Great Domesday. The names of tenants in King Edward's time are far more numerous preserved in the Exon than in the Exchequer Domesday. In the systematic arrangement of the subject matter the Exchequer Domesday bears unquestionably a decided preference over the Exon Domesday. Occasional insertions in the margin of the Exon Survey are entered in the text in that of the Exchequer. The lands of the great barons also in the Exon Survey are in a few instances intermixed. In folio 161 of the Exon, although the title of the lands described is 'Terra Abbatis Glastingheberiensis in Devenecira,' yet in fact there is only one of the manors in that county; the rest are all in Somersetshire, and are entered as such in the Great Domesday. On the contrary, in fol. 194 of Exon, the 'Terra Ecclesiarum quæ datæ sunt Sanctis in Elemosina,' from all that appears on the face of the record are in Somersetshire; whereas they are really in Devonshire, and are so placed in the Exchequer Domesday.

The most striking feature however of the Exeter Domesday, in which it uniformly supplies us with additional knowledge to that in the Exchequer Survey, is the enumeration of live stock upon every estate; there is an account of the number of oxen, sheep, goats, horses, and pigs, exactly in the same manner as it is given in the second volume of the Great Domesday. The reason for omitting this enumeration in the abbreviated entries of the first volume of the Great Survey is self-evident. The live stock was altering every day and year; the enumeration of it therefore could be of no further use than for the exact time when the survey was made. A comparison of this part of the Exeter with the second volume of the Great Survey tends greatly to corroborate the notion that the returns of the counties of Essex, Norfolk, and Suffolk, were transcribed in full from the original rotuli, in the same manner as the Exeter Domesday. The difference between the two surveys as to diction, when they agree in sense, is likewise remarkable; as for instance,

Exchequer Domesday.

The utility of this record for the purpose of comparison with the Exchequer Domesday is obvious. The Exeter Domesday was published with several other surveys nearly contemporary, by order of the Commissioners upon the Public Records, under the direction of Sir Henry Ellis, in a volume supplementary to The Great Domesday, folio, London, 1816. Our account of this record is chiefly derived from the Introduction to that volume.

EXETER COLLEGE, OXFORD, was originally founded in 1314, by Walter de Stapledon, bishop of Exeter, and some time lord high treasurer of England, and was then called Stapledon Hall. The bishop removed hither his scholars from Hart Hall, and made a foundation for a rector and twelve fellows. Of these thirteen he directed that eight should be elected from the archdeaconries of Exeter, Totness, and Barnstaple; four from the archdeaconry of Cornwall; and that one should be nominated by the dean and chapter of Exeter, from any place they might deem most fit, provided that he was in priest's orders. In 1404 Edmund Stafford, bishop of Exeter, added two fellowships from the diocese of Salisbury, and obtained leave to give the college its present name. In 1565 Sir William Petre, knight, secretary of state, and privy counsellor to Henry VIII., Edward VI., Queen Mary, and Queen Elizabeth, added eight fellowships for the counties of Devon, Somerset, Dorset, Oxford, Essex, and any others in England in which he or his heirs might have lands or possessions. These counties at present are Norfolk, Suffolk, Middlesex, Hampshire, and Kent. Charles I., in 1636, annexed one fellowship for the islands of Jersey and Guernsey, the candidates for which are nominated by the dean and jurats of one of these islands alternately. Lastly, Mrs. Shiers, who died in 1700, left certain rents, out of which two fellowships were founded for the counties of Hertford and Surrey, to which the five senior fellows alone elect. The candidates for all fellowships in this college are required by the statute to be, at least, *Generales Sophistæ* in the university. The day of election is the 30th of June, except for the Hertford and Surrey vacancies, when it is on St. Stephen's day. The present foundation consists of a rector and twenty-five fellows, besides whom there are numerous scholarships and exhibitions: and among these, three Eton Collegers, appointed by the provost and fellows of Eton; three from Exeter school, nominated alternately by the dean and chapter and chamber of Exeter; two from Truro school, nominated by the trustees of that school; and two from Exeter school. Two scholarships have been more recently founded by a bequest of the late William Gifford, for natives of the county of Devon, with a preference to candidates from the school of Ashburton.

Among the eminent men who have received their education here may be enumerated John de Trevisa, Sir John Fortescue, Sir John Doddridge, Sir William Noy, Joseph Caryl, Anthony Ashley Cooper, Lord Shaftesbury, Maundrell the traveller, John and Charles Wesley, Toup, Tindal the continuator of Rapin, and Dr. Kennicott.

The front of the college, which is opposite Jesus College, extends two hundred and twenty feet, with a large central gateway, consisting of a rustic basement, from which spring four pilasters of the Ionic order, supporting a semi-circular pediment, crowned by a balustrade. The greater part of this front was renewed in 1835 with Bath stone. The hall was erected by Sir John Acland in 1620. The

chapel, begun in 1622-3, was completed by Dr. George Hakewill, afterwards rector. The library was erected in 1778, after a design of the late Rev. W. Crowe, public orator.

On the 31st December, 1836, there were 304 members upon the college books. There are twelve benefices in the patronage of this society, one of which, the vicarage of Kidlington, in Oxfordshire, is annexed to the rectorship. The bishop of Exeter is the visitor of this college.

(Chalmers's *Hist. of the Colleges and Halls of Oxford*, 8vo., Oxf., 1810, vol. i., p. 62-76; *Oxford Univ. and City Guide*, 8vo.; *Oxford Univ. Calendar*, 1837.)

E'XODUS, THE BOOK OF, is the second of the Pentateuch, or Five Books of Moses, and derives its name from the principal event recorded in it, namely the departure of the Israelites from the land of Egypt, which, in the Greek Septuagint translation, is expressed by the word *éxodos* ('Éξοδος), that is, the going out. In the original Hebrew it is named, according to the usual Jewish mode, from the initial words, שמות ואלה שמות, or, as read with the Masoretic points, Ve-aleh Shemoth, 'These are the names.' This book records the slavery and cruelty endured by the descendants of Israel (Jacob) under the kings of Egypt; the birth, exposure, and preservation of Moses; his flight into Midian; his divine mission to Pharaoh (at the age of 80: vii. 7); the miracles performed by him and his elder brother, Aaron; the ten plagues inflicted on the Egyptians: the institution of the Passover; the departure of the Israelites from Egypt; their miraculous passage across the Red Sea; the destruction of the Egyptian army; the journeyings of the Israelites in the Arabian desert; their murmurings against God and Moses; their resumption of the Egyptian worship of the calf under the direction of Aaron, and their consequent punishment; the promulgation of the law from Mount Sinai; and the erection of the tabernacle, or portable temple. The king, Pharaoh (a general Egyptian appellation of royalty), for whom the Israelites built the treasure cities, and by whom their male children were ordered to be drowned (chap. i.) is usually considered by the commentators to be Rameses, the eldest son of Sesostris and the Pharaoh whose army perished in the Red Sea (xiv. 27) is supposed to be his son and successor, Amenophis the Second, or according to others, the Third. Le Père Pezron says he was Pharaoh Alisphragmuthosis, by whom the Hyksos, or Phœnician Shepherds, were expelled from Lower Egypt, whence the Israelites departed. The same chronologist makes the establishment of the Shepherd dynasty at Heliopolis coincident with the appearance there of Joseph from Canaan. (See the *Dissertation of Perizonius on the identity of the Hyksos and the Hebrews*.) The Mosaic exodus is noticed by several ancient writers, but with brevity and apparent contempt. The Egyptian historians, Manethon and Chæremon, as cited by Josephus (*Against Apion*, l. i., c. 9, 11, 12), state that 250,000 leprous people, and others afflicted with contagious diseases were banished from Egypt (*Exod.* xii., 39, 'they were thrust out of Egypt') by king Amenophis; and that their chief was a priest of Heliopolis named Moses, who furnished them with a system of religion and laws. (See a similar account in Josephus, *Hist.*, l. v. c. 34; Tacitus, *Hist.*, l. v. c. 3; Diodorus Sic. in *Photii Biblioth.*, l. xxxiv.; Justin, l. xxxvi. c. 2.)

The period over which the history in the book of Exodus extends consists of 145 years, that is, from the death of Joseph (B.C. 1635) to the formation of the tabernacle in the desert of Arabia (B.C. 1490), one year after the exode in the year B.C. 1491. Mr. Horne, in his 'Introduction to the Bible,' adopts the general opinion of commentators that the book was written by Moses, yet he thinks that it cannot be determined at what time of his life; but, as it is stated (xvi. 35) that 'the children of Israel did eat manna 40 years until they came unto the borders of the land of Canaan' that is, on the banks of the Jordan, opposite Jericho, when

and where Moses died (*Gen. xxxiv.*), and, 'as things cannot be historically related,' as Mr. Horne observes, 'until they have actually taken place,' it is evident that, if Moses is the author, he must have written it immediately before his death (B.C. 1451). It must be observed however that, among biblical critics and chronologists a great difference of opinion exists as to what date should be assigned to the departure of the Jews from Egypt, and as to the book of Exodus being written by Moses. In chronological works the exodus forms the fourth grand epocha in the ancient history of the world: thus, 1. The creation of Adam. 2. The Deluge of Noah. 3. The call of Abraham (his emigration from Chaldaea into Canaan). 4. The Departure of the Israelites from Egypt. This last event, according to the Hebrew text of the Scriptures, took place B.C. 1491; but according to the Samaritan text, which is the primitive Hebrew (Dr. A. Clarke) it occurred 267 years earlier, that is, B.C. 1758. The learned Pezron ('*Canon Chronologique*,' in his '*Défense de l'Antiquité des Temps*,' 4to, 1691) adopting, with improvements, the chronology of the Alexandrine version, or Greek Septuagint, which adds 1500 years to the Hebrew age of the world, determines the exodus to have taken place A.M. 3953, and B.C. 2019. Whiston, Kennicott, Jackson, Brett, Hay, Geddes, and other divines, adopt the Greek chronology. Archbishop Usher ('*Annales Vet. et Nov. Test.*') prefers that of the Hebrew text. Dr. Andrews, in his '*Heb. Dict. and Chronol.*' 1823, puts the exodus B.C. 1677. (See Dr. Hales's '*Analysis of Chronology*;' Sir John Marsham's '*Chronicon Egyptiacum*,' Ed.; Simson's '*Chronicon Catholicum*,' Lugd., fol. 1752; J. G. Frankius, '*Novum Systema Chronol.*,' Götting., fol. 1778; R. C. Benningse, '*Biblische Zeitrechnung*,' Leips., 1763; Walker's '*Analysis of Time*,' 1796; '*Remarks on the Bible Chronology*,' 1830; '*Criteria for determining the accuracy of Scripture Chronol.*,' by J. Cullimore, 1830, p. 13.)

Moses, according to St. Justin, Tatian, Clemens Alexandrinus, Tertullian, Julius Africanus, and other Christian Fathers, as well as Josephus, Justus, Manethon, Ptolemæus of Mendes, Apion of Alexandria, Porphyry, and others, is supposed to have been contemporary with Inachus, whom the chronologists place from 270 to 450 years earlier than the birth of Moses according to the Hebrew text. (Du Pin, '*Biblioth. Univer.*;' Du Fresnoy, '*Chronol.*') In the chronicon of Eusebius, the author of the Pentateuch is made contemporaneous with Cærops, who became king of Athens (*Arund. Marb.*) 11 years before the birth of Moses (*Heb. text.*), and, according to Pezron, 130 years after the death of Moses. (*Heb. text.*)

That the Pentateuch is not the production of Moses has been the opinion of many learned critics, both Christians and Jews, as Aben Ezra, Maimonides, Le Clerc, Dr. Middleton, Newton; and in Germany it is generally prevalent among the philosophical theologists of the *rational* school of Eichhorn. Dr. Geddes, who was deeply imbued with the German rationalism, makes the following statement in the preface to his new translation of the Bible from the Hebrew in 2 vols. 4to. :—'From intrinsic evidence three things to me seem indubitable. 1. The Pentateuch in its present form was not written by Moses. 2. It was written in the land of Canaan, and most probably at Jerusalem. 3. It could not be written before the reign of David, nor after that of Hezekiah. I would refer it to the reign of Solomon.' That is, about B.C. 1000, in or near the age of Homer and 500 years after that of Moses. Eichhorn (*Einleitung in das Alte Test.*, vol. ii. p. 245.) believes the first two chapters of Exodus to have been taken from the historical documents out of which the book of Genesis apparently was compiled. (See Astruc, '*Conjectures sur les Mémoires originaux dont il paraît que Moïse s'est servi pour composer la Genèse*,' 12mo. Brussels, 1753.) By the Jews the Book of Exodus is divided into 11 parashas, or chapters, and 22 siderim, or sections. In English Bibles it is comprised in 40 chapters. Various passages and expressions in Exodus involve apparent difficulties which have exercised the critical skill of every commentator. All chronologists agree that from the time of the immigration into Egypt of Israel and his family (70 persons, chap. i.) to the exodus, was only 215 years; the 430 years mentioned xii. 40 signifying this period and a previous one of 215 years to the call of Abraham. The numeral increase of the children of Israel is therefore considered to be very unusual, since, in xii. 37, 38, it is said there were 600,000 men on foot, besides children and a mixed multitude, the total number, as computed by

Dr. Adam Clarke in his Commentary, being 3,263,000. They are said to have been 'more and mightier' than the Egyptians, 'very mighty' (i. 9, 20), to have gone out with their 'armies' (xii. 51) 'harnessed,' that is, accounted for battle (xiii. 18); and 'with a high hand' (xiv. 8), 'with flocks, and herds, and very much cattle' (xii. 38), but as they are also said to have been slaves to the Egyptians, who 'made them serve with rigour and hard bondage, in mortar, brick, and all manner of service in the field' (i. 14)—to have been led out of their nearest way to Canaan, lest, on seeing war with the Philistines, they should repent, and return to Egypt (xiii. 17), and to have been 'sore afraid' at the sight of the Egyptians marching after them (xiv. 10), some commentators understand the word עֲרֻמִּים *pmshim*, to mean not harnessed, but slung together five in a string. Concerning the criminality of the Israelite women in borrowing and appropriating jewels and raiment of the Egyptians by the divine direction (iii. 21, 22, and xi. 2), and God's hardening the heart of Pharaoh (iv. 21), see *Explanations of Scripture Difficulties*, compiled by W. Carpenter, p. 35, &c. In xvi. 15 it is stated that the Israelites, when they first saw the manna, said one to another, 'It is manna, for they wist not what it was;' and in xxxviii. 8 of the English translation, it is said that the laver of brass was made of the looking-glasses of the women who assembled at the door of the tabernacle. These inconsistencies are avoided by Dr. Geddes; and he observes that the word כְּרָמִית *mrath*, translated looking-glasses, occurs in a hundred other places, but in no instance signifies the ancient metallic mirrors. The ten miraculous plagues inflicted on the Egyptians are described in the following places:—1. Water turned into blood, vii. 14—25. 2. The land covered with frogs, viii. 1—15. 3. The dust of the land turned to lice, viii. 16—19. 4. The swarms of flies, viii. 20—32. 5. The murrain and death of all the cattle. 6. Ashes produce boils and blains on man and beasts, ix. 8—12. 7. The storms of devastating hail, rain, and fire, ix. 13—35. 8. All the land covered with locusts, x. 1—20. 9. Three days of darkness which might be felt, x. 21—27. 10. The death of all the first born of man and beast, xi. 5—7 and xii. 29, 30. The learned writer in the '*Universal History*,' vol. 3, p. 374, shows that the Egyptian magicians and sorcerers were permitted to exhibit the power of the devil for the sake of exposing his comparative impotence; thus, although 'they did in like manner with their enchantments,' (vii. and viii.) in making their rods become serpents, in turning the Nile into blood, and in covering the land with flies, yet, they could not, as Aaron did, turn the dust of the land into lice (viii. 18.) Jacob Bryant in his '*Treatise on the Ten Plagues*,' 8vo, 1810, explains their adaptation to the peculiar character, habits, and notions of the Egyptian people, so as to cause the greatest possible aggravation of suffering and misery. The latter half of the 40 chapters of Exodus are occupied in announcing the civil, moral, and ceremonial law, and in describing the numerous articles of furniture, utensils, and sacerdotal raiment, for the celebration of sacrificial service in the tabernacle, or moveable temple, erected as a tent in the desert. The value of the gold appropriated to the vessels and ornaments of the adytum, or holy place, is stated in xxxviii. 24 at 29 talents and 730 shekels of gold. Each of the former being 5464*l.* 5*s.* 8*d.*, and each of the latter 1*l.* 16*s.* 5*d.*, they amount to 159,793*l.* 11*s.* 3*d.*, that is, nearly 160,000*l.*

Many learned men, in observing the similarity of the Mosaic and Egyptian ritual and religious institutions as described in various ancient writings, have assigned a greater antiquity to the latter, and contended that the former were a mere imitation. Dr. Geddes asserts that Moses made a selection and judicious composition from the ancient Egyptian institutions. (See especially Spenser, '*De Legibus Hebraicorum*;' Sir John Marsham's '*Chronicon Egyptiacum*;' Jablonski's '*Pantheon Egyptiorum*;' Ikenius, '*Dissertatio de Institutis et Ceremoniis Legis*.) Plutarch (*De Iside*) and other ancient authors prove that Jehovah or Jao was the sacred name of God among the Egyptian priests; and that it was not known to the Israelites before their residence in Egypt is stated in *Exod.* vi. 3. The 'I AM' of chap. iii. 14 is compared with the Egyptian inscription on the personification of the universe, 'I am all that is.' (See Plutarch, *περί τοῦ ἑνὸς ἀελοῦς*.) Aaron's oracular breast-plate (xxviii. 15—30) is thought

to be identical with that of the Egyptian chief judge, as described by Diodorus Sic. l. i. c. 2, sec. 26.

The learned Huet, Vossius, and others give curious parallels of the birth, life, and deeds of Moses with the primitive Egyptian Bacchus, but this is not more strange than the statement of Origen, who says in his 'Homily on Exodus' that Pharaoh is the devil, his daughter the church, and the two midwives (i. 15) are the 'Old and New Testament.' (See *The Scholia* of Dathe, Rosemüller, Schulz, Bauer, and Eichhorn; Willet's *Hexapla or Sixfold Comment on Exodus*; *Translations and Comments*, by Ainsworth, Hopkins, and Bishop Kidder; Dr. A. Clarke's *Bible*; Horne's *Introduction*, and list in Watt's *Bibliotheca*.)

EXOGENS, the largest primary class in the vegetable kingdom, are so named in consequence of their woody matter being augmented by additions to the outside of that which is first formed near the centre. As long as they continue to grow they add new wood to the outside of that formed in the previous year, in which respect they differ essentially from Endogens, whose wood is constructed by successive augmentations from the inside. [**ENDOGENS.**] All the trees of cold climates, and the principal part of those in hot latitudes, are exogenous. In many cases they are easily recognised by the wood of each different year forming a distinct zone, so that a section of their wood exhibits a number of concentric circles; but there are so many exceptions to this rule as to render it necessary to consider this character as by no means essential to them.

The nature of the exogenous mode of growth will be best compared with that of an Endogen, if we pursue the same mode of illustration as in the article which treats of the latter form. We will therefore proceed from an explanation of the typical mode of growth in a common Exogen to such remarks as we may have to offer upon deviations from it.

In an Exogen of ordinary structure the embryo consists of a cellular basis, in which there is usually no trace of woody or vascular tissue; but as soon as germination commences fine ligneous cords are seen proceeding from the cotyledons towards the radicles from the opposite sides of the young stem, meeting in the centre of the embryo, and forming a thread-like axis for the root.* As the parts grow the ligneous cords are increased in thickness and number, and having been introduced among the cellular basis of the embryo, are separated from each other by a portion of the cellular substance, which continues to augment both in length and breadth as the woody cords lengthen. By degrees the plumule or rudimentary stem becomes organized, and having lengthened a little, forms upon its surface one, two, or more true leaves, which gradually expand into thin plates of cellular substance traversed by ligneous cords or veins converging at the point of origin of the leaves. If at that time the interior of the young plant is again examined, it will be found that more ligneous cords have been added from the base of the new leaves down to the cotyledons, where they have formed a junction with the first wood, and have served to thicken the woody matter developed upon the first growth. Those ligneous cords which proceed from the base of the leaves do not unite in the centre of the new stem, there forming a solid axis, but pass down parallel with the outside, and leave a small space of cellular tissue in the middle; they themselves being collected into a hollow cylinder, and not uniting in the middle until they reach that point where the woody cords of the cotyledons meet to form the solid centre of the root. Subsequently the stem goes on lengthening and forming new leaves: from each leaf there may be again traced a formation of woody matter disposed cylindrically as before, and uniting with that previously formed, a cylinder of cellular substance being left in the middle; and the solid woody centre of the root proceeds in its growth in a corresponding ratio, lengthening as the stem lengthens, and increasing in diameter as the leaves unfold and new woody matter is produced: the result of which is, that when the young Exogen has arrived at the end of its first year's growth it has a root with a solid woody axis, and a stem with a hollow woody axis surrounding cellular tissue, the whole being covered in by a cellular integument. But as the woody cords are merely plunged into a cellular basis, the latter passes between them in a radiating manner, connecting the centre with the circumference by straight passages, often imperceptible to the

naked eye, but always present. The following diagram illustrates this:—

Root.

Stem.

Here we have the origin of *pith* in the central cellular tissue of the stem, of *wood* in the woody axis, of *bark* in the cellular integument, and of *medullary processes* in the radiating passages of cellular tissue connecting the centre with the circumference.

The woody axis is not however quite homogeneous at this time. That part which is next the centre contains great numbers of vessels of different kinds, particularly dotted vessels (vasiform tissue); the part next the circumference is altogether destitute of vessels, and consists of woody tissue exclusively: of these two parts that with the vessels belongs to the wood, properly so called, and serves as a mould on which future wood is added; the other belongs to the bark, separates under the form of liber, and in like manner serves as a mould upon which future liber is disposed.

At the commencement of a second year's growth the liber separates spontaneously from the true wood, a viscid substance called *cambium* is secreted between them, and the stem again lengthens, forming new leaves over its surface. The ligneous cords in the leaves are prolonged into the stem, passing down among the cambium, and adhering in part to the wood and in part to the liber of the previous year, the former again having vessels intermingled with them, the latter having none. The cellular tissue that connected the wood and liber is softened by the cambium, and grows between them horizontally while they grow perpendicularly, extending to make room for them, and consequently interposed between the woody cords of which they each consist, forming in fact a new set of medullary processes terminating on the one hand in those of the first year's wood, and on the other in those of the first year's liber. This addition of new matter takes place equally in the stem and in the root, the latter extending and dividing at its points, and receiving the ends of the woody cords as they diverge from the main body. The following diagram illustrates this, and shows, when compared with the last, what difference there is in the appearance of the stem of an Exogen one and two years old.

Root.

Stem.

And thus, year after year, the Exogen goes on, forming zone upon zone of wood, which is permanent, and zone within zone of liber, which perishes as the stem increases in diameter. [**BARK.**]

If this account is compared with that already given of Endogens, it must be obvious that the stem of these two great classes is formed from the very beginning in an essentially different manner. Endogens have no cylindrical column of pith; their woody arcs are never collected into a cylinder, through the sides of which the cellular tissue passes in the form of medullary processes; and the woody matter of their bark, so to call their cortical integument, is not parallel with that of the wood and spontaneously separable from it; not to speak of important anatomical differences, or of the concentric arrangement eventually assumed by the wood of Exogens. The only points in which the growth of the stem of Exogens corresponds with that of Endogens are the following: in both classes the woody

* In the article **ENDOGENS** the reader is requested to make the following correction in the early part of the fourth paragraph:—for (fig. A. p. 396) read (A); and twenty lines farther on, 'or (fig. A) read (A).

matter is connected with the leaves; in both a cellular substance is the basis of the whole structure, and extends horizontally wherever it is necessary to do so; and in certain Exogens woody arcs, stated to be like those of Endogens, are found in the pith. These cases properly belong to anomalous forms, but nevertheless may be noticed here, in consequence of their direct connection with this branch of the subject. One case is that of *Zamia*: but as that genus now belongs to the new class of Gymnosperms and not to Exogens proper, it need not be considered here. The other cases are *Piper*, *Nyctaginaceae* plants, and some others. Professor Schultz states (*Natürliches System des Pflanzenreichs*, p. 320, &c.) that in *Piper*, *Mirabilis*, and *Boerhaavia*, the central part of the stem consists of cellular tissue, amongst which cords of spiral vessels and woody tissue are placed either without order, or (in *Boerhaavia*) in a cruciate manner as in tree-ferns, and that on the outside of this the woody bundles are arranged circularly into a cylinder. A similar statement had long previously been made by Mirbel, who ascribes to *Mirabilis* and some Umbelliferous plants longitudinal vessels in the pith (*Elém. de Phytol. Veget.* i. 112), and by Professor Meyer, who finds the pith of *Mirabilis longiflora* and *dichotoma*, *Boerhaavia scandens*, and *Oxybaphus Cervantesii* abounding in many large bundles of spiral vessels within the woody radiated zone. (*De Houttuynia atque Saururets*, p. 40.) This, if correctly described, only shows that in certain Exogens a portion of the central tissue is placed at first in a confused manner, and that the wood does not assume a definite circular disposition till afterwards; that it does assume it eventually is admitted. We find in *Piper nigrum* and *Lonchitis* that from the beginning the woody bundles are placed circularly, but they are separated by a good deal of cellular tissue, and do not assume in the first zone the wedge-like or triangular form which is most common in Exogens, and which they themselves at last take on. In *Boerhaavia repanda*, a specimen of which is now before us, we find the wood regularly disposed in two zones, and instead of spiral vessels a very singular structure in the pith, which is filled with fistular passages of lax soft spheroidal cellular tissue surrounded by smaller, harder, and more cubical cellular tissue which passes off into the medullary processes. It is in such plants as *Piper incanum* that the organization of Exogens most nearly approaches that of Endogens; but in the first place the whole race of *Pipers* forms a sort of transition from Exogens to Araceous Endogens; and secondly, it is probable that when they are most endogenous in appearance they are not really so in regard to the final development of their woody tissue.

Let it however be admitted that in certain cases Exogens are, in the centre of their stem, organized less regularly than usual; this will offer no argument in favour of their analogy with Endogens. In all such cases it will be found that they eventually assume their typical conformation. We are acquainted with some striking proofs of this. Among twining plants of tropical countries, we occasionally find instances like the following—

Beneath a most irregularly compressed and lobed bark there lies a mass of wood, apparently so confused and irregular in its arrangement in the centre, that nothing symmetrical can be made out by the most acute observer; but it will be seen that towards the circumference it distinctly assumes the radiated appearance of an Exogen. In other cases, where the structure is sufficiently regular, this circumstance is still more distinctly illustrated.

It is however more commonly at the centre that we look for typical structure, and at the circumference that we find irregularity; as if Exogens usually commenced their growth

according to the plan to which nature has subjected them, and only deviated from it under the influence of unknown

causes coming into operation and controlling their development after they have advanced to a certain stage in their growth. Thus in the singular instances shown in cuts D, E, F, and G, the principal part of the stem is so confused and irregular as to look more like an Endogen than an Exogen, and a fragment might easily be mistaken for the former; nevertheless in a young and tolerably regular shoot (D) the radiated appearance is sufficiently well marked; and in two others, irregular and distorted as they are (E and G), the central pith is visible, although far out of the centre; and in the fourth (F) the centre has not only pith, but a radiated structure that is quite regular.

By far the most singular case of this sort is in an unknown twining plant in our possession from the Malayan Archipelago, of which the cuts H and I are representations. In old stems of this plant a section exhibits a most irregular combination of wood, looking like palm wood, broken up into lobed cords lying amongst still more irregular cellular

tissue, and inclosed in a common bark; so that we doubt whether it would be possible to tell to which class it really belongs, if it were not for its young shoots and the pith of the old ones. The latter may be seen lying quite out of the centre towards one side (near the bottom of our figure, a little to the right); and in the former (H) the pith is found with wood radiating around it, although still with sufficient irregularity.

The cases already given are evidences of exogenous wood being sometimes extremely different from the condition in which we see it in Europe, and attest the necessity of forming our ideas of its nature from a more extended examination than that which is commonly given to it. Several curious cases have been previously published by the author of this article (*Introduction to Botany*, edition 2, p. 77, &c.), and others have been noticed by other writers, but the subject has been so little investigated that we gladly avail our

selves of the present: opportunity of making known some additional facts.

Irregularity in the structure of exogenous wood is usually owing either to a confused disposition of the tissue at some particular period of the growth, or to some derangement of the medullary processes, or to the absence of concentric circles, or to the formation of a deep zone of cellular tissue alternately with each zone of wood; or, finally, to the production of wood within the bark instead of beneath it. The first cause has been already sufficiently illustrated.

The sinuosity and partial obliteration of the medullary processes is a principal cause of the anomalous appearances at *figs. D, E, F, G*, where they are reduced to fine lines only visible beneath a microscope, and not radiating from the centre, but disposed in no certain manner, sometimes even transversely, owing to the excessive disturbance of the wood itself. In *fig. I*, the singularity of structure is owing in part to the excessive irregularity with which the wood has been developed, and in part to the looseness and irregular shape of the medullary rays, which seem huddled as it were round the woody cords; the latter are moreover extremely variable in size, some of them being as much as half an inch in diameter, and others so small as to consist of no more than a single vessel with its usual coating of woody tissue.

The absence of concentric circles is an extremely frequent occurrence in the wood of tropical countries, and it is almost certain that many families of Exogens never form them visibly under any circumstances. We say visibly, because in fact they must be annually formed in all cases, although we do not see them. The reason why Exogens have their wood marked by concentric circles is, that the ligneous tissue formed at the end of a season is more compact than that formed at the beginning, and hence, as the two are in juxtaposition, the difference in their density distinctly separates the one from the other. But if, from any cause,—whether proper to plants as species or owing to the external influence of an equable climate—the tissue of wood formed at all seasons is exactly alike, no zone will be visible, although in fact the formation of the wood is exogenous in the most regular manner. Such cases are seen at *figs. K, L, S*, and elsewhere in the illustrations of the present article.

It is not a little remarkable however that while the wood in some cases has no trace of zones, the bark should show them most distinctly, as in the instance of *fig. K*.

When a deep zone of cellular substance is formed between each zone of wood, a curious banded appearance is produced, as in the singular Indian climber marked *N M O P Q*, where extremely excentric growth is combined with this peculiarity. At *N* we have the stem two years old, the second

zone passing pretty regularly round the first and cut off from it by a broad deep band. At *M* the specimen is of the same age, but the second zone is formed on one side only

At *O* the specimen is two years old, with the first zone perfect, but the second broken up into a number of unequal irregular pieces, and it would seem as if a third growth commenced on one side (to the left of the cut). At *P* growth is of three zones, both the second and third being much lobed, and the third only extending three quarters round the second. Finally, at *Q*, where the irregularity is the greatest, there is a growth of four zones, the first symmetrical, the second very much deeper on one side than the other, the third but half surrounding the second, and fourth formed only along two ridges on the third.

If it happens that, in addition to the presence of a cellular layer between each zone, the medullary processes are also very thick, an appearance still different from the last is produced, as at *fig. R*.

That wood is sometimes formed in the bark itself has been long since shown by Mirbel, in the case of *Calycanthus floridus*, where four additional woody columns appear distant in the bark, without any separate pith, but radiating from their first line of origin. We are now acquainted with many such cases. In *fig. T* are the commencement of such columns at *a* on one side; but in that specimen further indication of such a structure is visible; but at *U* which is the same plant at a more advanced stage of growth, four such columns on one side and one on the other, acquired considerable size, and each radiates towards the circumference of the stem. As in the *Calycanthus* in these and in all the other instances of the same kind, which these cuts represent (see *F, K, and S*), the columns of the bark are destitute of pith.

Perhaps what we have called the separation of zones

wood at N M O P Q R, by thick layers of cellular tissue, are rather to be considered as other instances of wood formed in bark, but in a regular and uniform manner. We are

however uncertain how this may be, and prefer allowing the statement to stand in its present form until some one shall have examined such plants in their native forests at Singapore.

In addition to such anomalous kinds of structure as those now described, Exogens, like Endogens, contain species, the organization of whose stem is so imperfect as to be reducible within no certain rules. Not to speak of *Callitriche*, *Ceratophyllum*, or *Myriophyllum*, wherein vessels are scarcely developed, and the woody matter merely forms a simple central axis of growth, we have in this class an exact parallel with *Lemna* among Endogens; some Podostemaceous plants have their leaves and stem completely fused together so as to resemble a *Marchantia* or an Alga. Such plants are to be regarded rather as instances of imperfect organization than as deviations from a typical form; and it is by no means a violent supposition to conclude that if their organization were more complete it would then become such as is characteristic of the class to which they belong.

From what has now been stated it will be obvious that the most essential features of exogenous vegetation are, not concentric circles in the wood, but an arrangement of the

woody matter in a circular manner round pith, its augmentation by external additions, and the universal presence of medullary processes which give the wood a radiated character. With endogenous vegetation it agrees principally in the existence of two systems of growth; one original, cellular, and capable of extending and increasing in all directions; the other perpendicular, capable of augmentation in a longitudinal direction only, and developed subsequent to the first.

In both Exogens and Endogens therefore, the one system, which we have elsewhere called the fibro-vascular, but which may also be termed the woody, lies across the other by which it is held together, as the threads of the warp in linen are held together by the woof, as the writer of this has long since pointed out in another place. (*Introduction to Botany*, book ii., chap. 3.) This appears to be the circumstance upon which the real explanation of all the phenomena of growth in stems must necessarily turn. We find it is adopted by M. Gaudichaud in his theory of the development of stems, of which a brief notice has been published in the '*Annales des Sciences*,' new series, vol. v., p. 24; and Mirbel, the reporter in the place referred to, calls it '*la pierre angulaire de la théorie*.' Connected with this, however, are two other facts that require also to be rightly understood; the one, that buds are emanations of the horizontal cellular system; and the other, that roots are elongations of the descending woody system. Unless these are coupled with the first-named fact there will be no solidity in the theory of growth now about to be explained.

Keeping in view all the phenomena above referred to, it will be obvious that the origin of wood is to be sought in the action of leaves, or of buds which are collections of leaves; and the theory of the formation of wood may be thus expressed:—

1. Wood is a collection of thick-sided tubular tissue, united in different ways in different species of plants. It is usually combined with vascular tissue, but does not necessarily include that kind of tissue.
2. It is always mixed with cellular tissue; through which it passes, and which in Exogens is arranged in the form of radiating plates.
3. It proceeds downwards from the leaves to the roots; either in parallel series, as in Exogens, or in curving and intersecting lines, as in Endogens.
4. It has the power of lengthening at its lower extremity as soon as it has once been generated, without any further impulse from the leaf from which it emanated. (This undoubtedly happens by the formation of new woody tubes at the points of those previously created.)
5. It is, in fact, the nutrient system of the leaves, and may be regarded as their roots.
6. The quantity of wood in a given plant will therefore bear a direct proportion to the quantity of leaves, or to their size and vigour.
7. In general its development takes place beneath the bark or cortical integument; but it may be found within the bark itself, in which case it continues to follow the order of development proper to it in its ordinary situation.

The woody part of bark is also derived from the leaves, and may be in like manner considered a state of their roots; but the office of its tubes is excrementitious rather than nutritive.

This view of the nature of wood is much the same as that first brought to the notice of modern botanists by Du Petit Thouars, an ingenious French physiologist, who, during many years, sustained the opinion in opposition to all his countrymen. It did not however originate with him, for it had been previously taken by others, who did not persevere like himself in maintaining it against the prejudices of their day, and who, moreover, did not possess the skill and extensive acquaintance with vegetable organization requisite to sustain a theory to which so many specious objections could readily be offered. The great error committed by Du Petit Thouars, in which it is probable that the slow progress of his opinions is really to be found, was his mixing up notorious errors with the truths of his theory. He insisted, for example, that the moment leaves begin to grow, wood is formed 'with the rapidity of lightning,' in continuous threads passing from the extremities of branches to the roots: this was anatomically untrue, for the woody tissue consists of tubes adhering end to end, and not continuous—and the rapidity assigned to their development was altogether imaginary. He next insisted that new roots could not

be developed till new leaves made their appearance this was disproved by the well-known fact that newly planted deciduous trees produce roots before their leaves appear. It may be doubted moreover whether he ever understood that buds originate exclusively from cellular tissue, and roots exclusively from fibro-vascular tissue; a fact, without attending to which, there is no possibility of explaining many common phenomena, but about which we conceive there is no sort of doubt.

It is not altogether a matter of theory that wood is formed of the roots of leaves imbedded in cellular tissue in a definite manner, according to the species: on the contrary, there are many curious facts to corroborate the supposition. The leaves of *Chianthus puniceus*, and many other plants, particularly *Gesneraceæ*, emit roots when cut off the stem to which they belong, and completely separated from the bud that is axillary to them. A knowledge of some such fact probably led to the absurd speculation, insisted upon by Bradley in the beginning of the last century, of forming plantations by sticking leaves in the ground. Du Petit Thouars found that the young leaves of *Dracenas* in the Isle of France root between the rind and old wood, forming rays of which the axis of the new shoot is the centre. The case of *Pandanus* we have adverted to elsewhere (*Introd. Bot.*, ed. 2nd, p. 262); and in the article Endogens of this Cyclopædia we have given a much more striking instance from *Barbacenia*. In that plant the cuts (which it should have been stated are representations magnified about three times) show that when undoubted roots proceeding from leaves are consolidated by passing down one above the other over the surface of the stem, precisely the appearance of palm-wood is produced. This we regard as conclusive as to the true nature of endogenous wood: and it would be unphilosophical to suppose that the wood of one great class of the vegetable kingdom is formed upon one plan, and of another class upon a totally different plan.

It must be highly satisfactory to those who have embraced

the opinions of Du Petit Thouars, as modified by the writer of this and by others, to find how nearly they accord with what Mirbel represents to be the ideas of Gaudichaud upon the same subject. M. Gaudichaud is one of the very few physiologists who has studied this question with reference to tropical forms of vegetation. Most others have drawn their ideas exclusively from common European trees; in doing which, with all respect be it spoken, they appear to us to have begun at the wrong end. This distinguished botanist and traveller, in an unpublished memoir for which the Montyon prize was awarded by the French Academy in 1835, is represented as having collected a great mass of admirable observations upon the embryo, the germination, the mode of growth, the stem of a considerable variety of plants, and to have particularly adverted to the important phenomena of barking, striking from cuttings, grafting, pruning, and other horticultural operations; from all which he has deduced a theory of growth which M. Mirbel states to be substantially the same as that above explained. Among other curious facts, he mentions that he possesses a specimen of a cutting of *Cissus hydrophora*, with a bud upon it from whose base proceeds a woody network which partially invests the lower portion of the old wood, and afterwards escapes on all sides as root. (*Ann. Sc. N. S.* v. 29.)

We have in the first instance stated in what manner wood is formed according to our own views of the subject. It is now requisite that we should add the views of those who differ from us. That wood derives its origin directly from the leaves in any way whatever, is denied by some, who believe that it is a superficial deposit from the previously formed wood. But as those who entertain this opinion do not explain how the *first* wood originated, that theory need not be discussed. Mirbel seems to consider that both wood and the woody part of bark are independent formations created out of the cambium; but there is no cambium when the *first* wood of Exogens is generated, and that substance never makes its appearance at all in Endogens, which ne-

EXOGENOUS VEGETATION.

vertheless form wood: we however think it may be doubted whether this is the present opinion of that great physiologist. De Candolle says, that the woody and cortical layers are formed laterally from the cambium supplied by pre-existing layers, and nourished by the descending sap; but we again say that this is inapplicable to Endogens; and moreover, that it is inconceivable upon such a theory how the first of the woody and cortical layers originated. Besides, woody matter appears before the new leaves can be supposed to have generated descending sap: it is not probable that so heterogeneous a formation as that of the wood is a mere superficial deposit, in which case it might be expected to be homogeneous; and finally, we do not know how, upon the supposition of De Candolle, to explain in any intelligible way why wood is found in pith, and in bark, as we have already shown that it often is. It would take us too far if we were to discuss this subject at greater length; the reader is therefore referred for further information to De Candolle's *Physiologie Végétale*, p. 146; Mirbel in the *Annales des Sciences* above quoted; Henslow in the *Magazine of Zoology and Botany*, vol. i., p. 32; and to our own *Introduction to Botany*, ed. 2nd, p. 256, &c.

The age at which Exogens may arrive is closely connected with their mode of development, as already shown in this work. [AGE OF TREES.]

If Exogens are distinctly known from Endogens by their peculiar manner of growth and by the arrangement of their woody matter, they are not less clearly defined by external marks.

Their *leaves* have the veins ramifying from the midrib, or ribs if there are several, in so intricate a manner as to give the appearance of irregular net-work. Their veins never run parallel with each other without ramifications; for if, as sometimes happens, they appear to do so, it will be found that the appearance is confined to the principal veins or ribs, and that the secondary veins between them ramify in the usual way. The leaves are moreover in most cases articulated with the stem, leaving behind them a clean scar when they die, not rotting away and hanging upon the stem in the form of a ragged sheath, as is common in Endogens. Moreover, they are frequently furnished with stipules, an unusual circumstance in Endogens.

The *flowers* of Exogens are usually constructed upon a quinary type, that is, they have five sepals, five petals, and five stamens, or some power of that number; now and then they vary to a type of four, or they exceed the number five; but we very rarely find the ternary structure of Endogens present in them. If, as in Anonaceæ, Berberaceæ, and other orders, the sepals and petals follow a ternary type, the number three is lost in the stamens or the ovary. The natural order Menispermaceæ is the only one among Exogens in which the ternary type regularly pervades all the parts of the flower.

In their manner of growth they rarely resemble Endogens. The consequence of the ramification of the veins is to give their leaves a broad and rounded figure, the effect of which upon their general appearance is to produce the rounded lumpish aspect that we recognize in all the trees naturally inhabiting this country. In no known instance does the stem grow by the development of a single terminal bud; so that we never find in this class the columnar aspect of palm-trees [GYMNOSPERMS], unless the genus *Theophrasta* be considered an exception. Consequently, a landscape consisting of nothing but exogenous plants would resemble the imaginary scene that forms the subject of the preceding cut.

The differences between Exogens and Endogens, thus strongly marked in the stem, leaves, and flowers, are connected with others in the *embryo*. In Exogens of the common kind this organ has two lobes, held together by a minute central body, the upper end of which, between the lobes, is the plumule or rudimentary stem, the lower the radicle or rudimentary root; the lobes themselves, or cotyledons, are rudimentary leaves. This structure is readily seen in a hazel-nut or a garden-bean; the deviations from it are few and unimportant as compared with those of Endogens. Three or a greater number of cotyledons may be present in a whorl, instead of two opposite to each other. Or one of the two cotyledons may be much smaller than the other, as in *Trapa*; or they may be deeply lobed, as in the garden-cress. But in all these cases the deviations are obviously reconcilable with the typical character of being *dicotyledonous*.

When the embryo of an Exogen germinates, the radicle

simply lengthens at its point, without having to break through the coat of the embryo; on this account Exogens have been named *exorhizæ*.

The result of this examination is, that the great class of Exogens has five important, and, in some measure, independent characters, by which its limits are settled.

1. The wood is exogenous.
2. The veins of the leaves are netted.
3. The fructification is formed upon a quinary or quaternary type.
4. The embryo is dicotyledonous.
5. The germination is *exorhizal*.

Hence Exogens have received two other names in allusion to such characters; they are commonly called *Dicotyledones*, and *Exorhizæ* is another but less common appellation. Moreover, they are the *Phanerocotyledonæ* of Agardh, the *Aniophytæ* and *Carpophytæ* of Oken's school, the *Dichorgana* of Schultz, the *Phylloblastæ* of Reichenbach; not to mention other names still more obscure.

In consequence of imperfect development, and the abortion or multiplication of parts, many deviations occur from the above characters. But as in Endogens, so in these, there is not in consequence any real difficulty in distinguishing Exogens from other plants. Suppose the stem to be so slightly formed, as in Podostemaceæ or the aquatic Haloragaceæ, as not to arrive at a state in which the exogenous arrangement is perceptible, we have the dicotyledonous embryo, and the typical number of the floral organs to guide us. Let the leaves appear as scales, as in *Lathræa*, *Orobanche*, and the like; still there is the embryo or again the floral proportions. If the fructification is absolutely ternary as in Menispermaceæ, the organization of the stem, leaves, and embryo reveals the true nature of such plants. Or if the embryo is undivided, as in *Cuscuta*, and at the same time the veins of the leaves deficient, and all this with an incomplete formation of woody matter, then the number of parts in the flower remains to prevent our falling into error. It is therefore always to be remembered, that the limits of this great class are not exclusively determined by one single character, but by a combination of five; a part of which may be occasionally exceptional or undiscoverable.

Like all other natural assemblages, Exogens have many analogies with other parts of the vegetable kingdom. We have already adverted to the Podostemaceæ order of this class representing distinctly the Pistiaceæ order, or at least Lemna among Endogens. In speaking of the latter class (vol. ix., p. 398) other cases have been noticed, and we now add that Piperaceæ are distinct analogies here to the Araceæ of Endogens, Chenopodiaceæ to Glumoseæ, and possibly Menispermaceæ to Smilacææ.

Whatever uses there may be in the vegetable kingdom are to be found in this class, which comprehends four-fifths of the natural orders, and probably not much less than the same proportion of species. Timber, in particular, is their exclusive produce, and if corn has no direct analogy in Exogens, at least a substitute for it is furnished by the potato and the cassava. To speak therefore of its useful products would be, in fact, to explain the utility of plants to man, and this we shall do in a more appropriate place. [PLANTS.]

Considering the very great numbers of Exogens,—they may be rated at 50 or 60,000 at a low computation,—it is not surprising that it should be here that the systematic botanist experiences his great difficulties. No embarrassment worth notice occurs in the arrangement of Endogens, as has already been shown; but in Exogens the difficulties are so great as to have hitherto baffled the most acute writers. We do not mean with regard to the natural orders themselves, for they are in general well understood and defined: our observation applies to a collocation of the orders, or, in other words, to the construction of groups of a secondary value which shall be as natural and as well defined as the orders themselves. In a recent enumeration we find no fewer than 231 orders of Exogens. It is obviously impracticable to study so large a number of combinations without breaking them into groups, and accordingly various methods have been proposed.

Jussieu, adopting, to a certain extent, the views of his predecessors, considered—1st, the separation of the petals; 2nd, their combination; or 3rd, their absence, of primary consequence; and adding to this, 4th, the separation of the sexes in flowers having no petals, he formed the four groups of—1st, *Polypetalous*; 2nd, *Monopetalous*; 3rd,

Apetalous; and 4th, *Diclinous* plants. The three first of these he again subdivided according as their stamens or their corolla grew under the ovary (hypogynous), upon the calyx (perigynous), or upon the ovary (epigynous); then the monopetalous epigynous group was subdivided into plants having united stamens and those having them distinct; the result being 11 classes, which were placed by Jussieu in the following order:—

| | | Class. |
|--------------|--|--------|
| Apetalous | { Stamens epigynous | 1 |
| | " perigynous | 2 |
| | " hypogynous | 3 |
| Monopetalous | { Corolla hypogynous | 4 |
| | " perigynous | 5 |
| | " epigynous { anthers united | 6 |
| Polypetalous | { Stamens epigynous | 8 |
| | " hypogynous | 9 |
| | " perigynous | 10 |
| Diclinous | | 11 |

This was, however, so artificial a distribution, that botanists soon found it as unsatisfactory as it was simple. Various changes have therefore been recommended from time to time, some of which are the following:—

In 1813, De Candolle, dropping the names of all Jussieu's classes, and abolishing many of them, proposed to arrange as follows the 113 orders of Exogens with which he was at that time acquainted.

| | Class. |
|--|--------|
| Polypetalous { Petals hypogynous (<i>Thalamifloræ</i>) | 1 |
| { Petals perigynous (<i>Calyctifloræ</i>) | 2 |
| Monopetalous { Corolla perigynous { <i>Corollifloræ</i> | 3 |
| { Corolla hypogynous | 4 |
| Apetalous { (<i>Monochlamydeæ</i>) | 5 |

Thus the classes were reduced from eleven to five, which was a defect; but those which remained were supposed to be more natural, which would have been an advantage. Five years afterwards, in his 'Regni Vegetabilis Systema Naturale,' he added the names inclosed within brackets, and he broke up the *Thalamifloræ* into five cohorts, but without stating what orders he arranged under them. We do not find that he ever pursued the subject farther. Since that period this great botanist has occupied himself with the special study of the natural orders, and the public has derived no advantage from his general views, which is much to be regretted.

In 1823, Professor Agardh of Lund, now bishop of Carlsbad, proposed a great change in the subordination of Exogens, retaining the principles of primary division recognized by Jussieu and De Candolle, but forming them into twenty subdivisions, defined by various characters analogous to those by which the orders themselves are circumscribed. This, we believe, is the first step of any consequence towards putting Exogens into a more natural grouping than that of Jussieu: in many respects the subdivisions are, as far as they go, unobjectionable; but they have excited scarcely any attention among systematic botanists. The necessity, however, of some better method of subordination than that of Jussieu and De Candolle has become evident to everybody; and attempts have been made to effect this by Drs. Bartling, Schultz, Von Martius, and others on the continent, and by the author of the present article; not to mention certain transcendental German writers, whose views, as we do not understand them, we will not attempt to explain. In our own arrangement the class is first broken into the Polypetalous, Monopetalous, and Incomplete subclasses; the latter are next distributed in groups; and finally, the groups themselves have a subordination of alliances, beneath which the orders are disposed in numbers varying from 1 to 8 or more, the general result being 17 groups or 80 alliances. The following table will show upon what principle the groups and alliances have been constructed. It will be remarked that the terminations of the names express their value; the groups or highest combinations end in *osæ*; the alliances, or combinations of a lower kind, in *ales*; the orders in *aceæ*; the suborders in *ceæ*.

EXOGENS.

Table of Groups.

Subclass 1. Polypetalæ.

Albumen very considerably larger than the minute embryo. **ALBUMINOSÆ.**

Albumen absent, or only forming a layer between the embryo and the seed-coat.

Ovary inferior (often with an epigynous disk). **EPIGYNOSÆ.**

Ovary superior. **PARIETOSÆ.**

Placentæ parietal. **PARIETOSÆ.**

Placentæ in the axis. **CALYCOSÆ.**

Calyx dislocated. **CALYCOSÆ.**

Calyx complete; its parts being all on the same plane.

Carpels united in a solid pistil, parallel with each other **SYNCARPOSÆ.**

Carpels oblique, upon a gynobase. **GYNOBASEOSÆ.**

Carpels disunited. **APOCARPOSÆ.**

Subclass 2. Incompletæ (or Apetalæ).

Calyx altogether absent. **ACHLAMYDOSÆ.**

Calyx present.

Embryo curved round albumen. **CURVEMBRYOSÆ.**

Embryo straight. **COLUMNOSÆ.**

Stamens monadelphous. **COLUMNOSÆ.**

Stamens distinct.

Calyx tubular, often resembling a corolla. **TUBIFEROSÆ.**

Calyx very imperfect. **RECTEMBRYOSÆ.**

Subclass 3. Monopetalæ.

Fruit consisting of but one perfect carpel. **AGGREGOSÆ.**

Fruit of several carpels.

Ovary inferior. **EPIGYNOSÆ.**

Ovary superior.

Carpels three or more. **POLYCARPOSÆ.**

Carpels only two. **NUCAMENTOSÆ.**

Fruit nucamentaceous. **NUCAMENTOSÆ.**

Fruit capsular. **DI-CARPOSÆ.**

The orders are disposed under their several alliances in the following sequences.

Table of Alliances and Orders.

Subclass 1. Polypetalæ.

Group 1. ALBUMINOSÆ.

Alliance 1. Ranales. *Herbaceous plants; either with the carpels more or less distinct, or, if that is not the case, with parietal placentæ.* Ranunculaceæ, Podophylleæ, Papaveraceæ, Fumariaceæ, Nymphaeaceæ, Hydropetideæ, Nelumbiaceæ, Cephalotaceæ, Droseraceæ.

Alliance 2. Anonales. *Woody plants, with distinct carpels, which are sometimes confluent. Anther-valves opening longitudinally.* Myristicaceæ, Magnoliaceæ, Winteraceæ, Anonaceæ, Schizandraceæ, Dilleniaceæ.

Alliance 3. Umbellales. *Flowers umbellate. Calyx superior. Carpels one-seeded. Stem hollow.* Apiaceæ, Araliaceæ.

Alliance 4. Grossales. *Flowers never in umbels. Calyx superior. Carpels many-seeded. Stem solid.* Grossulaceæ, Escalloniaceæ, Bruniaceæ.

Alliance 5. Berberales. *Anthers bursting by recurved valves.* Berberaceæ.

Alliance 6. Pittosporales. *Calyx inferior. Carpels consolidated; style single.* Vitaceæ, Pittosporaceæ, Olaceæ, Francoaceæ, Sarraceniaceæ.

Group 2. EPIGYNOSÆ.

Alliance 1. Onagrales. *Corolla not valvate. Placentæ central. Type of flowers binary throughout.* Herbs. Onagraceæ, Cistaceæ, Haloragaceæ, Hydrocaryæ.

Alliance 2. Myrtales. *Corolla not valvate. Placentæ central. Type of flowers not binary throughout. Shrubs or trees.* Combretaceæ, Alangiaceæ, Rhizophoraceæ, Memecylaceæ, Melastomaceæ, Myrtaceæ, Barringtoniaceæ, Lecythidaceæ, Philadelphaceæ.

Alliance 3. Cornales. *Corolla valvate.* Hamamelidaceæ, Cornaceæ, Helwingiaceæ, Lorumthaceæ.

Alliance 4. Cucurbitales. *Placentæ parietal.* Cucurbitaceæ, Loasaceæ, Cactaceæ, Hemslaceæ.

Alliance 5. Ficoidales. *Petals indefinite.* Mesembryaceæ.

Alliance 6. Begoniales. *Flowers unisexual. Placentæ central.* Begoniaceæ.

Group 3. PARIETOSÆ.

- Alliance 1. Cruciales. *Embryo curved. Albumen none.* Brassicaceæ or Cruciferae, Capparidaceæ, Resedaceæ.
- Alliance 2. Violaes. *Embryo straight. Stamens definite; none sterile.* Violaceæ, Sauvagesiæ, Samydaceæ, Moringaceæ, Frankeniaceæ.
- Alliance 3. Passionales. *Embryo straight. Stamens definite; the sterile ones in a separate ring.* Passifloraceæ, Papayaceæ, Flacourtiaceæ, Malesherbiaceæ, Turneraceæ.
- Alliance 4. Bixales. *Stamens indefinite; sterile none. Leaves dotted.* Bixaceæ.
- Group 4. CALYCOSÆ.
- Alliance 1. Guttiales. *Stamens indefinite. Albumen none. Petals and sepals equal in number.** Clusiaceæ or Guttiferae, Canelles, Rhizobolaceæ, Mægregariaceæ, Hypericaceæ, Ochrantheæ.
- Alliance 2. Theales. *Stamens indefinite. Albumen none. Petals and sepals unsymmetrical, passing one into the other.* Ternstroemiaceæ.
- Alliance 3. Acerales. *Stamens definite. Flowers unsymmetrical.* Aceraceæ, Sapindaceæ, Millingtoniæ, Esculaceæ, Polygalaceæ, Vochyaceæ.
- Alliance 4. Cistales. *Flowers symmetrical. Albumen present.* Elatinaceæ, Linaceæ, Hugoniaceæ, Chlenaceæ, Cistaceæ, Reaumuriaceæ.
- Group 5. SYNCARPOSÆ.
- Alliance 1. Malvales. *Calyx valvate. Carpels 4 or more. Stamens monadelphous more or less.* Sterculiaceæ, Malvaceæ, Elæocarpaceæ, Dipteraceæ, Tiliaceæ, Lythraceæ (?)
- Alliance 2. Meliales. *Calyx imbricated. Carpels 4 or more. Stamens usually monadelphous.* Meliaceæ, Cedrelaceæ, Humiriaceæ, Aurantiaceæ, Spondiaceæ.
- Alliance 3. Rhamnales. *Calyx valvate. Carpels fewer than 4. Shrubs.* Rhamnaceæ, Chailletiaceæ, Tremandraceæ, Nitrariaceæ, Burseraceæ.
- Alliance 4. Euphorbiales. *Calyx imbricated. Carpels fewer than 4.* Euphorbiaceæ, Empetraceæ, Stackhousiaceæ, Fouquieriaceæ, Celastraceæ, Hippocrateæ, Trigoniæ, Staphyleaceæ, Malpighiaceæ, Erythroxyleæ.
- Alliance 5. Silenales. *Embryo rolled round albumen; or joints of stem tumid; or leaves minute and scale-like.* Silenaceæ, Alsiniaceæ, Tamaricaceæ (?), Illecebraceæ.
- Group 6. GYNOBASIOSÆ.
- Alliance 1. Rutales. *Style single, or leaves marked with pellucid dots.* Ochnaceæ, Simarubaceæ, Rutaceæ, Zygophyllaceæ, Xanthoxylaceæ.
- Alliance 2. Geraniales. *Styles distinct. Ovary consolidated. Stamens hypogynous.* Geraniaceæ, Vivianiaceæ, Balsaminaceæ, Tropæoleæ, Oxalidaceæ, Ledocarpeæ.
- Alliance 3. Coriales. *Styles and carpels both distinct.* Coriariaceæ, Surianaceæ.
- Alliance 4. Flörkeales. *Styles single. Fruit lobed. Stamens perigynous.* Limnanthaceæ.
- Group 7. APOCARPOSÆ.
- Alliance 1. Rosales. *Albumen wholly absent.* Rosaceæ, Pomeæ, Amygdaleæ, Sanguisorbeæ, Fabaceæ or Leguminosæ, Cæsalpinieæ, Mimoseæ, Connaraceæ, Chrysobalanaceæ, Calycanthaceæ.
- Alliance 2. Saxales. *Carpels two, diverging at the end, many-seeded. Albumen present.* Baueraceæ, Cunoniaceæ, Saxifragaceæ.
- Alliance 3. Crassales. *Carpels several, distinct, continuous with the styles. Seeds indefinite. Albumen.* Crassulaceæ.
- Alliance 4. Balsamales. *Carpels neither two, nor divergent, nor numerous, with hypogynous scales. Leaves and bark balsamic.* Amyridaceæ, Anacardiaceæ.
- Sub-class 2. Incompletæ.
- Group 1. RECTEMBRYOSÆ.
- Alliance 1. Amentales. *Catkins. Carpels two or more, combined. Trees or shrubs.* Corylaceæ or Cupuliferæ, Betulaceæ, Scapaceæ.
- Alliance 2. Urticales. *Carpels solitary or syncarpous. Stems continuous, without sheaths. Never a cupule.* Garryaceæ, Hemsloviaceæ, Trewiaceæ, Urticaceæ, Ceratophyllæ, Ulmaceæ, Stilaginaceæ, Myricaceæ, Juglandaceæ.

- Alliance 3. Casuarales. *Carpels solitary. Stems jointed and with sheaths.** Casuaraceæ.
- Alliance 4. Datiscales. *Carpels several. Seeds numerous. Leaves alternate.* Datisceæ, Lacistaceæ.
- Group 2. ACHLAMYDOSÆ.
- Alliance 1. Piperales. *Carpels solitary or distinct. Flowers in spikes. Embryo minute, in the base of fleshy albumen.* Chloranthaceæ, Saururaceæ, Piperaceæ.
- Alliance 2. Salicales. *Flowers amentaceous. Fruit mostly many-seeded; when one-seeded, in globular heads.* Salicaceæ, Platanaceæ, Balsamaeæ.
- Alliance 3. Monimiales. *Flowers within an involucre. Sexes distinct.* Monimiaceæ, Atherospermeæ.
- Alliance 4. Podostemales. *Flowers solitary. Carpels two or three, combined. Seeds numerous and minute.* Podostemaceæ.
- Alliance 5. Callitrichales. *Carpels several, combined single-seeded. Floaters.* Callitrichaceæ.
- Group 3. TUBIFEROSÆ.
- Alliance 1. Santalales. *Calyx superior. Anthers opening longitudinally.* Santalaceæ.
- Alliance 2. Daphnales. *Calyx inferior, imbricated. Carpel solitary. Anthers opening longitudinally.* Elæagnaceæ, Thymelaceæ, Hernandiaceæ, Aquilariaceæ.
- Alliance 3. Proteales. *Calyx valvate. Stamens opposite its lobes. Fruit simple, follicular.* Proteaceæ.
- Alliance 4. Laureales. *Anthers opening by valves. Carpels solitary, superior, or inferior.* Lauraceæ, Illigeraceæ, Cassythaceæ.
- Alliance 5. Penæales. *Carpels several. Calyx imbricated or valvate.* Penæaceæ.
- Group 4. COLUMNOSÆ.
- Alliance 1. Nepenthales. *Dioecious. Ovary superior.* Nepenthaceæ.
- Alliance 2. Aristolochiales. *Hermaphrodite. Ovary inferior.* Aristolochiaceæ.
- Group 5. CURVEMBRYOSÆ.
- Alliance 1. Chenopodiales. *Albumen. Radicle next the hilum.* Amarantaceæ, Chenopodiaceæ, Tetragnoniaceæ, Phytolaccaceæ.
- Alliance 2. Polygonales. *Albumen. Radicle remote from hilum.* Polygonaceæ.
- Alliance 3. Petiveriales. *Albumen 0. Cotyledons spiral.* Petiveriaceæ.
- Alliance 4. Scleraleæ. *Tube of calyx hardened.* Scleranthaceæ, Nyctaginaceæ.
- Alliance 5. Cocculales. *Albumen. Flowers ternary. Calyx in two rows.* Menispermaceæ, Lardizabaleæ.
- Sub-class 3. Monopetalæ.
- Group 1. POLYCARPOSÆ.
- Alliance 1. Brexiales. *Albumen 0. Carpels five. Sterile stamens between fertile ones. Seeds indefinite.* Brexiaceæ.
- Alliance 2. Ericales. *Anthers porous. Carpels four, five, or more.* Pyrolaceæ, Monotropaceæ, Ericaceæ, Vaccinaceæ, Epacridaceæ.
- Alliance 3. Primulales. *Anthers opening longitudinally. Carpels four or five. Fruit often one-celled.* Primulaceæ, Myrsinaceæ, Sapotaceæ, Ebenaceæ, Styraceæ, Aquifoliaceæ.
- Alliance 4. Nolanales. *Fruit lobed.* Nolanaceæ.
- Alliance 5. Volvales. *Carpels two—four, combined. Anthers never porous.* Convolvulaceæ, Cuscutaceæ, Polemoniaceæ, Diapensiaceæ, Hydroleaceæ.
- Group 2. EPIGYNOSÆ.
- Alliance 1. Campanales. *Stipules none. Seeds indefinite.* Lobeliaceæ, Campanulaceæ, Sphenocleaceæ?, Belvisiaceæ, Columelliaceæ, Stylidiaceæ.
- Alliance 2. Goodeniales. *Stigma with an indusium.* Goodeniaceæ, Scævulaceæ.
- Alliance 3. Cinchonales. *Stipules between the leaves.* Cinchonaceæ, Lygodysoideæ.
- Alliance 4. Capriales. *Stipules none. Leaves opposite. Seeds definite.* Caprifoliaceæ.
- Alliance 5. Stellales. *Fruit didymous. Leaves whorled. Stipules none. Stem angular.* Galiaceæ, or Stellatæ.
- Group 3. AGGREGOSÆ.
- Alliance 1. Asterales or Compositæ. *Anthers syngenesious. Ovary inferior.* Cichoraceæ, Mutisiaceæ, Cichoraceæ, Asteraceæ, Cynaraceæ.

- Alliance 2. Dipsales. *Anthers distinct. Ovary inferior.* Dipsacæ, Valerianacæ.
- Alliance 3. Brunoniales. *Ovary superior. Stigma with an indurium.* Brunoniacæ.
- Alliance 4. Plantales. *Ovary superior. Stigma naked. Style single.* Plantaginacæ, Globulariacæ, Salvadoracæ.
- Alliance 5. Plumbales. *Ovary superior. Stigma naked. Styles five.* Plumbaginacæ.
- Group 4. NUCAMENTOSÆ.
- Alliance 1. Phaceliales. *Fruit capsular. Inflorescence gyrate.* Hydrophyllacæ.
- Alliance 2. Echiales. *Fruit nucamentaceous. Inflorescence gyrate. Flowers symmetrical.* Cordiacæ, Ehretiæ, Boraginacæ.
- Alliance 3. Labiales. *Fruit nucamentaceous. Flowers unsymmetrical.* Lamiacæ or Labiatæ, Verbenacæ, Myoporacæ, Selaginacæ, Stilbacæ.
- Group 5. DICARPOSÆ.
- Alliance 1. Bignoniales. *Flowers didynamous. Seeds winged. Albumen none. Calyx complete.* Pedaliacæ, Bignoniacæ, Cyrtandracæ.
- Alliance 2. Acanthales. *Flowers didynamous. Seeds adhering to hooks, not winged. Albumen none. Calyx dislocated.* Acanthacæ.
- Alliance 3. Lentibales. *Flowers subdidynamous. Fruit with a free central placenta.* Lentibulacæ.
- Alliance 4. Scrophulales. *Flowers didynamous. Albumen. Placenta parallel with axis.* Gesneracæ, Orobanchacæ, Scrophulariacæ.
- Alliance 5. Solanacæ. *Flowers symmetrical. Albumen. Placenta parallel with the axis.* Solanacæ, Cestracæ.
- Alliance 6. Gentianales. *Flowers symmetrical, tetrandrous or pentandrous. Placenta perpendicular to axis. Seeds often winged. Leaves opposite.* Gentianacæ, Spigeliacæ, Apocynacæ, Asclepiadacæ.
- Alliance 7. Loganiales. *Flowers unsymmetrical. Stamens never two. Leaves always opposite.* Loganiacæ, Potaliacæ.
- Alliance 8. Oleacæ. *Flowers regular, unsymmetrical, diandrous.* Oleacæ, Jasminacæ.

We shall not be restrained by false delicacy from criticising this arrangement freely, with reference to its merits as well as its demerits. We will therefore at once say, that in several respects it is a decided advance in the grouping of the orders. By abandoning the artificial distinction of perigynous and hypogynous insertion, many orders naturally allied are brought into contact. The great mass of Polypetalous Exogens is analysed with tolerable precision; a great many of the alliances are, as far as we can discover, unobjectionable; and we can state, from the experience of four years' personal use, that the scheme is of great utility to students, in consequence of the power it gives them of combining the orders. The albuminous group in particular, although incompletely made out, may be regarded as an important elimination of orders which often had no obvious relation to any with which they were previously associated. It cannot be considered otherwise than a striking physiological peculiarity, that while the greater number of Exogens have an embryo so robust as to be able to spring at once into existence, and from the very beginning of its life capable of trusting to the atmosphere and the earth for its support, there should be others, and many of them among the most highly organized races, which are so feeble and puny in the beginning as to require from nature a large and abundant store of nutritive matter upon which they may feed until strong enough to contend with the elements among which they must eventually live. These latter form the albuminous group. Albumen occurs very often in other groups; but in such small quantity that it may be regarded as a mere residuum of the nutrient mucilage in which the embryo was originally developed, rather than a store of food provided for the young plant when it enters upon its first stage of growth. Among the former the presence or absence of albumen is of little or no consequence; Fabacæ for example, and other equally well defined groups, possess it in some species, and want it in others. But in the orders collected in the albuminous group, its presence and its great disproportion to the embryo are identified with the reproduction of the species, and there is no instance known of its absence, except in Nelumbiacæ, in which, if they really belong to the group, it may be supposed that the

usual function of the albumen is performed by the excessively thickened cotyledons.

But, on the other hand, this system has defects in abundance; so many indeed, that we should say they outweighed its advantages, if they were not fully participated in by all other similar schemes; from a respect for which they have indeed been to a great extent produced. Among minor blemishes may be named the artificial collocation of the genera in some of the alliances, as, for example, the Passional, the Silenal, the Euphorbial, and the Primulal. In the next place, the alliances are excessively multiplied; as in the case of the Cinchonol, Caprial, and Stellal, of the Chenopodial, Petiverial, and Scleral, or of the Geranial and the Flörkeal; this however is a fault on the right side. Of much more consequence is the indefinite character of the Parietous and Gynobaseous groups. The first depends upon a distinction which sometimes exists in the fruit and not in the ovary of the same plant, and which may be destroyed by either the contraction or extension, in a slight degree, of the dissepiments: moreover, the orders collected under it, although to a certain extent naturally combined, yet in other instances, as Bixacæ, Turneracæ, Moringacæ, and the whole Crucial alliance, agree less with each other than with other parts of the system. The Gynobaseous group is much more natural; that indeed is its merit; but the gynobasic character, strongly marked as it is in Geraniacæ and many of the Rutal alliance, is, it must be confessed, too feeble to deserve to be considered of more than very subordinate importance; in fact, many of the Syncarpous group are gynobasic—Malva, for example. Then, among Monopetalæ, the Dicarpos and Nucamentous groups are not distinguishable, and should have been combined; each however is natural as far as it goes.

The great vice of the arrangement however is that which it owes to the adoption of the old practice of considering Polypetalæ, Monopetalæ, and Apetalæ, fundamental divisions. Every systematical writer at all known, down to the present time, has adopted them; so that their value has become a matter of prejudice, which it will be no easy task to remove from the minds of those who have all their lives been accustomed to look at botanical classifications in one and the same point of view. We will nevertheless attempt to show, firstly, that these divisions are essentially bad; and secondly, that a great advantage will be derived from their rejection. The Monopetalous sub-class depends entirely upon the circumstance of the petals adhering to each other by their edge; it has no accessory characters whatever to sustain it. Now the partial adhesion of contiguous organs is of no greater than ordinal importance when it takes place in other parts of the fructification, and is often not of so much. The sepals adhere or remain separate in the very same natural order, Urticacæ and Chenopodiaceæ for example. The stamens adhere into a tube, and this sometimes gives a character to certain orders, but more often is a mere distinction of genera, as in Euphorbiacæ, Iridacæ, Aristolochiacæ, &c. When the carpels unite and form a multiplex fruit, the ovaries, style, and stigma, being altogether consolidated, that character becomes of considerable value as contrasted with the complete or partial separation of the carpels, because it is found constant; and hence it has been employed by us as a distinction of a portion of the group of Polypetalæ. But we are persuaded that we have assigned it too high a value, and that it is only one degree better than an ordinal distinction. It is therefore improbable that the adhesion of the petals, organs not even essential to the fructification, but which may be wholly absent without the great functions of impregnation and reproduction being interfered with, should be of greater importance. The monopetalous corolla is not considered of any value in Endogens, even as an ordinal character, and nothing can justify our considering it of primary value among Exogens, except the constant and unvarying existence of that character throughout certain natural orders more nearly related to each other than to anything else. It will be found however upon strict inquiry, firstly, that the character is anything but constant, except in a portion of the Monopetalous sub-class; and secondly, that it combines dissimilar orders, separating them widely from their true affinities.

That the Monopetalous character is not constant hardly requires proof, so notorious is its instability. Pyrolacæ, Monotropacæ, Ericacæ, Myrsinacæ, Lobeliacæ, Campanulacæ, Plumbaginacæ, and Oleacæ, all offer instances of the polypetalous structure; and some Primulacæ, Ole-

aceæ, and Monotropaceæ, are even apetalous; while on the other hand Rutaceæ, Anonaceæ, Stackhousiaceæ, Fouquieriaceæ, Crassulaceæ, Loranthaceæ, Cucurbitaceæ, Cactaceæ, Papayaceæ, and many other natural orders, stationed in Polypetalæ, because of their affinity, are either partially or wholly Monopetalous. The Monopetalous character cannot then be defended because of its stability. Moreover, nothing can well be more arbitrary than the language of botanists in speaking of the corolla. In Delphinium, Trifolium, and many other plants, the corolla has all its petals in a state of adhesion; the same thing occurs in Loranthaceæ, and yet these are called Polypetalous. Still more strange is it that Malvaceæ, which have the petals adhering to the tube of the stamens, should be called Polypetalous, while Styraceæ, having precisely the same organization, are accounted Monopetalous.

It will also be found that the Monopetalous character is equally objectionable as a means of combining similar natural orders. So far is it, except in the case of the Dicarpaceous and Nucamentous groups, from complying with the conditions to be required of all characters employed for purposes of co-ordination, namely, combining genera more nearly allied to each other than to any thing else, that in fact it disunites plants closely akin, and interrupts series that would be otherwise as complete as series can be in the arrangement of living beings; as will be apparent from the following statement.

Pyrolaceæ and Monotropaceæ have a minute embryo, a large mass of albumen, a tendency to become leafless and parasitical, and in all their habits are at variance with the rest of Ericales.——The latter have no direct connection with any other Monopetalous order, but have all their affinities turning towards Rutaceæ, as is proved by Correa, Phebalium, and other genera.——Primulaceæ and Myrsinaceæ, with their large horny albumen, approach Cinchonales, and together with that, the Caprial and the Stellal alliances seem rather to belong to the Albuminous group.——Ebenaceæ and Aquifoliaceæ have an affinity with Myrsinaceæ. Dr. Royle has pointed out a connection between Ebenaceæ and Clusiaceæ; Adolphe Brongniart has shown that Aquifoliaceæ must stand near Ebenaceæ; and with regard to Styraceæ, Jussieu actually referred them to the polypetalous Meliaceæ, and De Candolle considers them nearly akin to Ternstroemiaceæ.——Whatever the affinity of the Nolanal and Volval alliances may be, it is clear that in taking away the orders already mentioned, they will remain isolated among orders to which they have no direct relation. It will be seen that they fall naturally into their places in a re-distribution of Exogens upon other principles.——Columelliaceæ must be looked upon as a monopetalous form of Onagraceæ, and will connect the Campanal and Goodenial alliances with the series to which Onagraceæ belong.——The Cinchonal, Caprial, and Stellal alliances, which ought to be combined, are so closely united with Apiaceæ among Albuminosæ, that they may be naturally transferred to that group. Even De Candolle has found it necessary to approximate them by stationing Apiaceæ near the end of his polypetalous sub-class, and Cinchonaceæ near the beginning of his Monopetalæ. The connection of Apocynaceæ with these plants is perhaps more apparent than real.——Asterales and Dipsales necessarily follow the affinity of the Campanal alliance.

——The Brunonial, Plantal, and Plumbal alliances may be considered more properly analogous than allied to Asterales, and have no affinity of an obvious kind with any other monopetalous orders.——All the other orders are well combined, with the exception of Orobanchaceæ; the affinity of that order with Scrophulariaceæ and the remainder of the dicarpous group is extremely problematical. It has not, so far as we are aware, been before observed that the carpels in that order are right and left of the axis, and not anterior and posterior; a very important circumstance, which so much weakens its supposed affinity with Scrophulariaceæ as to remove many objections to its separation into a distinct part of the system. But if on the other hand we look to the aristate base of the anthers in Orobanche, the extreme resemblance of that genus to Monotropaceæ in habit, and the remarkable similarity between its placentation and that in the upper half of the ovary of Monotropa, to say nothing of its capitate stigma and calyx, the number of whose parts is at variance with that of the corolla, we incline to think that these two orders are more closely allied than they are usually supposed to be.

P C., No. 511.

With regard to the Apetalous sub-class, it is even more objectionable than the Monopetalous. There is no end to the instances of Polypetalous orders being Apetalous; and in Thymelaceæ, Menispermaceæ, Polygonaceæ, and a few others, the denial of the presence of petals in particular genera is a mere arbitrary use of words. Many Apetalæ appear, in fact, to be imperfect forms of Polypetalous groups, and will naturally arrange themselves in the same series with what may be supposed to be their more perfect types. Piperaleæ seem a degraded state of Anonales, Penæales of Onagraceæ, Daphnaceæ and their allies of Rhamnaceæ. But a large proportion of the Apetalous orders undoubtedly require to be located separately. They have distinct sexes and a peculiar habit, and must be considered a quite distinct group, as Jussieu originally stated them to be.

Having thus shown how unsatisfactory are the principles hitherto employed for classifying Exogens, we next proceed to show in what way it appears to us they may be arranged in a more natural and precise manner; the Polypetalous, Monopetalous, and Apetalous sub-classes being altogether abandoned.

In the first place, there are the orders whose embryo is, as has already been stated, furnished with an excessive quantity of albumen. This, as a great physiological distinction, may be considered to supersede all others, and to establish an *Albuminous* group.——The remainder consists of orders in which some have the sexes in distinct flowers, others combined with hermaphrodite flowers. We know of no character intimately connected with the reproduction of the species which is upon the whole so important as this; indeed, if it were not for the frequent occurrence of polygamous flowers throughout hermaphrodite orders, we should assign it a higher place than even the albuminous character; but the constant tendency of hermaphrodite flowers to become polygamous leads us necessarily to look upon sexuality as a secondary character only, especially since, if it were taken as a primary one, it would have the unnatural effect of separating Myrsinaceæ and Schizandreeæ from Anonales. For this reason a *Diclinous* group may be formed, into which nothing should be admitted except plants without any tendency to hermaphroditism.——The hermaphrodite orders may be separated into those with the calyx, corolla, and stamens confluent at the base with each other and with the ovary, that is, having an inferior ovary, and those in which those parts are distinct, either altogether or at least from each other: the former will constitute an *Epigynous* group.——Finally, the remainder of the orders may be divided into those with a monopetalous corolla combined with an ovary upon a binary plan (*Dicarpous*), and those which, if monopetalous, have the ovary simple or complex (*Polycarpous*).

The following table will put this in a clearer point of view.

| | |
|---|-----------------|
| Albumen extremely abundant; embryo minute | 1. ALBUMINOSÆ. |
| Albumen absent, or in small quantity. | |
| Sexes in the same flower. | |
| Ovary inferior | 2. EPIGYNOSÆ. |
| Ovary superior | |
| Flowers, if monopetalous, not with a bicarpellary ovary | 3. POLYCARPOSÆ. |
| Flowers monopetalous, with a bicarpellary ovary | 4. DICARPOSÆ. |
| Sexes in different flowers | 5. DICLINOSÆ. |

Each of these groups will form a series by itself, the sequence of which ought to be natural, and to exhibit various lateral analogies with other groups. Possibly each group will comprehend within itself a maximum, a medium, and a minimum type of structure, the second being typical of the group, the first an exaggerated form of it, and the last a degraded form. This at least may be traced in the classes of Exogens, Endogens, and Acrogens; it frequently occurs in natural orders, is not uncommon in genera, and therefore may be expected in groups.

It is scarcely possible to undertake a more difficult task than that of disentangling and settling the perplexed and complicated web of natural affinities. Every order may be compared with so many other orders in one respect or another, and the value of characters is, as far as we yet know, so very unsettled, that the most skilful and experienced botanist is perpetually embarrassed at determining the fundamental question of which orders have more relation to each other than to anything else. Viewed in one direction, the subject has one aspect, from another position it often seems quite changed. We have no certain test by

which affinity and analogy can be distinguished; and moreover, it is a most difficult thing to divest the mind of the prejudices that inevitably result from a long habit of thinking erroneously.

Nevertheless, in spite of all such obstacles, Truth is surely to be found; and when found, she will prove most richly worth the labour bestowed in searching for her. One great and immediate advantage that may be expected from a discovery of the true method of arranging exogens according to their real affinities will be a great simplification of the subject; and the extent to which this seems to be effected by the plan now proposed is much in favour of its being at least an approach to a discovery of the secret we are in search of. We will not here undertake to re-arrange all the orders already named according to the method now suggested; but the following table will serve to show that each of the five groups now proposed does exhibit distinct lateral analogies between its own series of orders and those of the groups standing next it.

| ALBUMINOSÆ. | EPIGYNOSÆ. | DICARPOSÆ. | POLYCARPOSÆ. | DICLINOSÆ. |
|---------------|---------------|---------------|---------------|---------------|
| Anonaceæ | Myrtaceæ | | Chenopodiaceæ | Menispermaceæ |
| Schizandraceæ | Melastomaceæ | Asclepiadaceæ | Malvaceæ | Euphorbiaceæ |
| Cinchonaceæ | Columelliaceæ | Coriaceæ | Sapotaceæ | Cucurbitaceæ |
| Apiaceæ | Cornaceæ | Solanaceæ | Convolvulaceæ | Corylaceæ |
| Vitaceæ | Sesuviaceæ | Lamiaceæ | Rhamnaceæ | Urticaceæ? |
| Monotropaceæ | Loranthaceæ | Acanthaceæ | Polygalaceæ | Nepenthaceæ |
| Garryaceæ | Lobeliaceæ | Geraneaceæ | Resedaceæ | Datisaceæ |

| ALBUMINOSÆ. | EPIGYNOSÆ. | DICARPOSÆ. | POLYCARPOSÆ. | DICLINOSÆ. |
|-----------------|--------------|-------------|--------------|------------|
| Aristolochiaceæ | Valerianaceæ | Selaginaceæ | Polygonaceæ | Begoniaceæ |
| Piperaceæ | Santalaceæ | Oleaceæ | Thymelaceæ | Elmagnaceæ |
| Chloranthaceæ | Hippuridæ | ? | Krameriaceæ? | Salicaceæ. |

Of course it is to be supposed that many of the orders or alliances introduced into this table, are separated from those now placed next them by many, sometimes a great number of intervening orders, and that in fact what stands on paper as a series is an intricate combination of crossing and interfering analogies and affinities, which could only be expressed correctly by rays diverging from a common centre and intersecting or striking other rays of other centres, the points of intersection being what we call analogies. No diagram can exhibit these otherwise than very imperfectly; nevertheless, as it does show them better than mere lines of words, we have introduced into the following plan the analogous orders comprehended in the preceding table. The orders collected around the centre are all in close relation, and exhibit in their own series a degree of organization equivalent to what occurs at the same point in other series; those at the points of the rays of the diagram correspond in like manner with the other points; and the orders stationed along the sides of each ray are places at which the rays are laterally analogous; while the orders themselves are in direct affinity with each other through other orders not included in the diagram.

That these groups are all perfect in themselves, or nearly so, is sufficiently proved by Albuminosæ, the sequence of whose orders may be expressed as follows; the orders included in the diagram being marked with *.

- Anonales.** Magnoliaceæ
Winteraceæ
Dilleniaceæ
Berberaceæ
*Anonaceæ
Monimiaceæ
- Ranales.** Nymphaeaceæ
Atherosperma-
ceæ
Myrsinaceæ
*Schizandra-
ceæ

- Ranales.** Hydropelti-
deæ
Nelumbiaceæ
Ranunculaceæ
— Podophylleæ
Papaveraceæ
— Fumariæ
Francoaceæ (?)
Sarraceniaceæ
Cephalotaceæ

- 3 Primulales.** Primulaceæ
Myrsinaceæ
Ebenaceæ?
Aquifoliaceæ?
- 4 Gentianales.** Apocynaceæ
Spigeliaceæ
Gentianaceæ
- 5 Loganiæ.** Loganiaceæ
Potalliaceæ

If we should find it necessary to recur to this subject, we shall do so when speaking of NATURAL ORDERS.

EXORCISM, (*ἑκωρισμός*) the form of adjuration, or charging upon oath, by which evil and malignant spirits are subjected to command, or driven away: from the Greek *exorkizen* (*ἑκωρίζω*). See Joannis Wieri, *De Præstigiis Dæmonum et incantationibus ac veneficiis Libri* v., 8vo., Bas. 1566 and 1583; and the *Manuale Exorcismorum*, by Maximilian ab Eynatten, 8vo., Antw., 1619.

EXORHIZÆ. [EXOGENS.]

EXOTERIC and **ESOTERIC** (*ἑκωτερός* and *ἑσωτερός*), literally 'external' and 'internal,' were two terms used in reference to the writings and doctrines of many of the ancient Greek philosophers. The general distinction between the classes of works called by these respective names is this: the 'exoteric' were those writings which were in a more popular form; the 'esoteric' those which were written in a scientific and more exact form. The 'esoteric' would of course contain a true investigation of principles as then understood; the 'exoteric' would exhibit philosophical systems in such a form as the mass were able and willing to receive. The 'exoteric' writings consequently accommodated themselves to popular prejudices and superstitions, this being the only safe way in which a certain amount of philosophical truth could be conveyed to the vulgar. The 'esoteric' writings and doctrines were reserved for those who were far enough advanced to understand them, and to form a just notion as to the prevalent false opinions of the mass of the people. It is important to bear in mind this distinction between 'exoteric' and 'esoteric' doctrines in forming our judgment of the character and writings of the ancient philosophers. [ARISTOTLE, p. 334.]

EXPANSION. [HEAT.]

EXPECTATION OF LIFE, a term applied to the mean or average duration of the life of individuals of any given age. [LIFE, MEAN DURATION OF.]

EXPECTORANTS (from *ex*, out of, and *pectus*, the chest) are medicinal agents, which, in certain conditions of the system, will, either by promoting or repressing the secretion of the air-passages and of the lungs, facilitate its expulsion. The articles which bear this name differ considerably as to the means by which this end is accomplished. They are chiefly derived from the vegetable kingdom, some being gum-resins, or balsams, of a stimulating quality, while others are possessed of nauseating or sedative properties; vapours also are expectorants, and may be either simple, as that of warm water, or medicated with different impregnations. Vapours alone reach the organs to be affected, and are therefore the only *direct* expectorants; the others being taken into the stomach must operate by sympathy or some other obscure agency.

From the differences in the nature of the substances regarded as expectorants it is clear that they must operate in a very different manner, according to the state of the system, the pathological condition of the lungs, and the stage of the complaint. Great care is necessary in selecting the particular agent suited to each case, and in no set of diseases are greater errors committed by unprofessional persons by an injudicious employment of these agents, than in those of the lungs, from common colds to the more serious and fatal affections of these vital organs. The slight nature of many of the common maladies of the throat and lungs, and the fatality of consumption, which is generally though most erroneously regarded as an affection of the lungs themselves, while it is truly an affection of the whole constitution, have led to a degree of interference with the treatment of diseases of these organs not attempted in any other cases, as the multitude of popular remedies for *coughs, colds, and consumptions*, attest.

Those who regard their health and wish to prolong their

lives should beware of tampering with such important organs by means of any of the numerous *nostrums* vended to the public. To treat satisfactorily the diseases of the lungs it is necessary to know their structure, and the relations they have to the other parts of the body. The bronchia (or air-passages) and air-cells of the lungs are lined by a *mucous* membrane, and have of consequence relations of sympathy with the skin and intestinal canal more close than with any other part of the system. A vicarious discharge or secretion is thrown off by the internal (pneumogastric) or external surface (*i. e.* the skin), and any considerable diminution of this discharge on the part of either is in some degree compensated for by augmented secretion of the other. Hence when the insensible perspiration of the skin is suddenly checked by exposure to cold, a double duty is thrown upon the internal membrane, sometimes of the intestines, when diarrhoea may result, sometimes of the lungs, when catarrh (common cold), or pneumonia may ensue. This fact enables us both to comprehend the cause of some of the diseases in which expectorants are proper, and their mode of aiding the cure.

A certain exhalation from the internal surface of the lungs and air-passages constantly goes on in a state of health—any considerable diminution or augmentation of this secretion may require the assistance of medicines to raise it to the proper quantity in the one instance, or to evacuate the superfluity and repress the tendency to its excessive formation in the other. The chief causes which lead to diminished secretion are inflammation and spasm—hence at the commencement of inflammatory affections of the air-passages and of the lungs the inner membrane is dry, and by the stethoscope what is called the crepitating *râle* is heard; in asthma and whooping-cough, while the spasm lasts, there is an absence of secretion, which becomes abundant when the spasm yields.

To obviate these states very different means must be employed from what are necessary in the later stages of an inflammatory affection, or where there was extreme relaxation of the vessels of the lungs, and the exhaled fluid redundant in quantity. One of the terminations of inflammation being by effusion, when the increased action of the vessels has lasted for some time a state of the lungs occurs which is precisely the reverse of what it was before, and an extreme quantity of mucus obstructs the access of air to the blood circulating through the cells of the lungs: if this continue to accumulate, suffocation must follow. Too great an accumulation sometimes takes place, especially in elderly people, not from excessive secretion but from deficient absorption.

These are a few of the different states for which expectorants are used, but much circumspection is required to accommodate the means to the end. Where there is decided inflammation the best expectorants are those which lessen the inflammatory state, such as venesection and nauseating doses of tartaric acid or of ipecacuanha, and the inhalation of the vapour of warm water, simple or medicated, by means of Mudge's Inhaler. But as the use of any such instrument requires considerable exertion of the respiratory organs, where the inflammation is violent it is inadmissible, as the lungs must be kept in as tranquil a state as possible; but the head may be held over a basin of warm water, the vapour of which will be received by the lungs in the ordinary course of respiration.

When the inflammation has subsided, the more stimulating expectorants may be used. Where there is first spasm hindering secretion, and ultimately an excessive exhalation which must be cleared away, a combination of a sedative or antispasmodic medicine with the expectorant is best.

These are the principles which should regulate our choice in the more acute affections of the chest; but as no set of organs are so subject to chronic disorders as the lungs and their appendages, we frequently have recourse to expectorants to alleviate many of the symptoms attendant on them.

Lessening the tendency of blood towards the lungs, and directing it more towards the skin, is of service both in acute and chronic affections of the chest. Hence bathing the feet in warm water on the first feeling of an attack of cold, followed by antimonials or other diaphoretics, is of much utility, if the patient go into a warm bed immediately; while, on the same principle, the use of flannel next the skin is the best preventive, and is indispensable for all delicate persons, particularly if predisposed to diseases of the lungs.

EXPLANARIA. [MADREPHYLLEA.]

EXPONENT; EXPONENTS, NOTATION OF. In the algebraical expression a^x , x is called the exponent of a . If we were strictly to preserve the most ancient meaning of the term, x would be called the exponent of the whole symbol a^x ; but it is usual to call x the exponent of a , and the logarithm of a^x .

From the time of Descartes it has been usual to employ exponents in abbreviation of repeated symbols of multiplication: but this was only the beginning of a series of extensions which have made the theory of exponents a fundamental part of analysis. Beginning with the simple substitution of a^2 instead of $a \times a$, a^3 instead of $a \times a \times a$, and so on, we have a succession of new symbols suggested by the processes of algebra, namely, that a^1 should stand for

a , a^0 for unity, a^{-1} for the reciprocal of a , and $a^{\frac{1}{m}}$ for the m th root of the m th power of a . These conventions being made, the common algebraical theory of exponents is complete; and the student will find in works on algebra an account of the manner in which the necessity for these extensions appears. The theory of logarithms flows naturally from this notation and the binomial theorem.

Looking at the notation of exponents in another point of view, we see that a^1 , or a , signifying the performance of a certain operation on the unit, a^2 , or aa , signifies the repetition of the same operation upon a itself; a^3 denotes the repetition of the same operation upon a^2 , and so on. Hence by analogy, whenever, in the higher parts of analysis, ϕx signifies an operation performed upon x , $\phi^2 x$ signifies the repetition of the operation upon ϕx . Thus if ϕx signify $1 + 2x$, then

$$\phi^2 x \text{ is } 1 + 2(1 + 2x) \text{ or } 3 + 4x.$$

$$\phi^3 x \text{ is } 1 + 2(3 + 4x) \text{ or } 7 + 8x, \text{ \&c.}$$

It appears by reasoning analogous to that which establishes the meaning of exponents in algebra, that $\phi^0 x$ must stand for x itself. Also $\phi^{-1} x$ must signify the operation inverse to (or which destroys the effect of) ϕx ; thus if ϕx signify x^2 , $\phi^{-1} x$ must be \sqrt{x} . Also $\phi^n x$ means that operation which performed n times in succession, gives the same result as ϕx performed n times.

The Differential Calculus and the Calculus of Differences furnish striking examples of the notation of exponents. As soon as the student arrives at the higher parts of these subjects, he should pay particular attention to the structure of the notation, and in particular to the meaning of those theorems in which the symbols of operation are separated from those of quantity.

EXPORTS. [IMPORTS AND EXPORTS.]

EXTENT (Lat. *extenta*) is a writ of execution (sometimes called an *extendi facias*), which is directed to the sheriff against the body, lands, and goods, or the lands only, of a debtor; and it is also used as signifying the act of the sheriff or officer upon the writ itself.

The king by antient prerogative is entitled to this writ, either in chief or in aid for the purpose of obtaining satisfaction of debts originally due to him or assigned to the crown. The writ of extent in chief is an adverse proceeding by the king for the recovery of his own debt, and in which he is the real plaintiff. This writ is issued out of the equity side of the Court of Exchequer; and the sheriff, for the purpose of executing it, may break open the defendant's doors, when purposely closed, either to arrest him or to take his goods. If however the defendant cannot be found, or is not meant to be arrested, the sheriff impanels a jury to inquire as to the debtor's lands and tenements, goods and chattels; and after the inquisition is made, the lands then become bound to the crown until the debt is satisfied. The writ of extent in aid is also sued out at the instance and for the benefit of the crown against the debtor of a crown debtor: in this proceeding the king is the nominal plaintiff only. This writ is in effect an extent *pro forma* is sued out against the debtor to the crown, upon which an inquisition is taken; and if it be thereupon found that another person is indebted to him, the Court of Exchequer, on an affidavit to that effect, and also to the effect that the crown debt is in danger, will grant a fiat or warrant for an immediate extent in aid. Under this writ, the body of the defendant may in strictness be taken in execution as well as his lands, tenements, goods, and chattels, &c.; but where there are effects sufficient to satisfy the debt, the

court seems generally disposed to give the defendant his discharge.

On the return of the writ of extent in chief or in aid to the court from whence they are issued, an order is endorsed on the back of it, 'that if no one shall appear and claim the property of the goods, &c. mentioned in the inquisition, on or before that day se'nnight, a writ of venditioni exponas shall issue to sell the same.' If the produce of the goods sold be not sufficient to pay the debt, the court will make an order for the sale of the debtor's lands under the 25th George III., c. 35.

There are various means of resisting the execution of the above writs, on the ground of informality or want of title in the crown; which may be referred to in the second volume of Mr. Tidd's work on the practice of the superior courts.

The writ of extent for the subject is founded upon a recognizance at common law or by statute, or upon a judgment in an action of debt against an heir, on the obligation of his ancestor. It is very similar in its effects and mode of execution to the other writs of extent already specified. [ELEGIT.]

When lands are delivered over to a creditor upon an extent, a reasonable but not the real value is set upon them; and the effect is the same as if the creditor took a lease of the lands until his debt is satisfied. The time during which the creditor will hold the lands will of course be determined by a comparison of the value set on the lands with the amount of the debt. (Coke on Littleton; Tidd's Practice; Blackstone's Commentaries.)

EXTORTION; any oppression under colour or pretence of right. In its more common acceptation, extortion is applied to the unlawful taking by an officer, under colour of his office, of any money or valuable thing where none at all is due, or not so much is due, or before it is due. The officer is punished by fine and imprisonment, and by removal from office. Where no fee at all is due, the offence is more properly extortion—the distinction is thus made in the *Termes de la Ley*: 'Extortion is where an officer demandeth and wresteth a greater sum or reward than his just fee; and exaction is where an officer or other man demandeth and wresteth a fee or reward where no fee or reward is due at all.'

EXTRACTION OF ROOTS. [INVOLUTION AND EVOLUTION.]

EXTRACTS are medicinal preparations of vegetable principles, obtained in various ways. Sometimes they are merely the juices expressed from the fresh plants, brought by careful evaporation to the consistence of honey, and then more properly denominated *insipissated juices*; at other times they consist of certain principles of the fresh or dried plant extracted by some menstruum in which they are soluble, such as water, proof spirit, or vinegar, and afterwards evaporated, as in the former case. According to the nature of the menstruum employed the extract is called *watery*, *alcoholic*, or *acetous*. The objects proposed in such proceedings are, to ensure the preservation of the active principles of the plant by removing the fluid in which they are dissolved, or the materials with which they are associated, that have a greater tendency to fermentation or putrefaction; to bring the valuable portion into the smallest possible compass; and to facilitate the administration of them by thus rendering them capable of being made into pills, &c.

The preparation of extracts requires the greatest care. The plants must be in every respect of the best quality, as regards the place of their growth, season when collected, &c., and the evaporation must be conducted rapidly, yet at a low temperature. Orfila found that the excellence of preparations of this kind was always in the reverse ratio of the temperature employed to form them. Mr. Barry effected a great improvement in the mode of preparing extracts by evaporating *in vacuo*. During the preparation, and especially towards the end of the operation, frequent stirring the contents of the evaporating-pan is necessary to prevent burning or decomposition of any portion of the mass. Extracts may also be formed from dried plants, barks, roots, &c., by reducing them to fine powder and macerating it for 24 or 48 hours in sixteen times its weight of water. In general cold water is now employed, but in some cases it is proper to employ warm. The extract of cinchona, prepared with cold water, is less powerful than that prepared with warm.

Extracts are simple or compound, according as they are prepared from one plant or from several different kinds.

This mode of preparing vegetable principles is generally unsuitable where a volatile oil is the active agent, unless great care and a very low temperature be used.

A well-prepared extract should possess in a great degree the odour, and especially the taste, of the plant from which it is obtained; it should not have either an empyreumatic smell or taste, and it should have a proper and uniform consistence. It is necessary to preserve extracts in a dry situation: to assist in keeping watery extracts, it is customary to sprinkle a little alcohol over the surface before covering them up; but watery extracts, if made with cold water and due care, rarely require this precaution. It is proper to examine the condition of all extracts very frequently, both during very warm and very wet weather: any portion which seems spoiled should be immediately thrown out.

Formerly, from the careless or unskilful mode of their preparation, extracts were the most uncertain and useless form of vegetable remedies; but since competent practical and scientific chemists have given their attention to the subject, they are now, in many instances, the most valuable contributions which chemistry has made to practical medicine.

EXTRAVASATION (*extra*, without, *vas*, a vessel), in medicine, signifies the escape of any of the fluids from its natural reservoir or canal into some neighbouring cavity or texture. The term is nearly synonymous with effusion, but less comprehensive, as it does not include the case of fluids poured out by secretion, such as dropsies, or any of the products of inflammation. It is most commonly employed in designating effusions of blood or of urine; and we shall therefore confine what we have to say on the subject to a brief notice of the principal varieties of these accidents, referring the reader for more complete information to other parts of the work.

Extravasations of blood are always serious and often fatal when the larger vessels and more important organs are concerned in them. Thus if blood escape in consequence of the rupture of an aneurism of the aorta into the bag which encloses the heart, the circulation is immediately arrested, and sudden death ensues. Such an accident is said to be 'an extravasation of blood into or within the pericardium.' [**ANEURISM.**]

Blood is sometimes driven with great force from a ruptured or wounded artery into the loose spongy substance consisting of connected cells which surrounds and separates the various organs, and is found in great abundance in every part of the body. This is called 'extravasation of blood into the cellular tissue' of the part. In such cases, if the vessel be a large one, the extravasation may be so considerable as to occasion enormous swelling and distension of the contiguous parts; and it may be fatal from the amount of the hæmorrhage, or from pressure upon some vital organ, or from mortification. [**HÆMORRHAGE.**] This is a frequent source of danger in gunshot wounds. Fractures also are generally followed by considerable effusions of the same kind, which however are soon absorbed, and are not often attended with serious consequences, except in fractures of the skull: in that case they compress the brain, and produce the symptoms of apoplexy. [**HEAD, INJURIES OF THE.**] The *thrombus*, or swelling beneath the skin, so frequently observed after bleeding from the arm, is also formed by extravasation of blood into the cellular tissue. It arises from the puncture in the skin not corresponding with the opening in the vein, or not being sufficiently large. It soon disperses, and is of little importance. [**BLEEDING.**] Contusions are likewise followed by extravasation of blood into the cellular tissue under the skin and in the skin itself from the rupture of small vessels; and this is the reason of the dark colour assumed by the bruised parts, which often extends to a considerable distance from them; as in the familiar instance of a black eye. This superficial extravasation is generally called *ecchymosis*, a word of the same import.

Spontaneous extravasations of blood, allied to those last mentioned, frequently take place in the progress of various diseases, of which they may be causes or symptoms. The spots which appear under the skin and beneath the membranes which line the internal cavities and tubes, in plague, typhus fever, sea-scurvy, and other complaints, are of the symptomatic kind; and these as well as the discolorations after contusions are included in the general term

ecchymosis; they are also known by various other names, as *vibices* (wheals), *petechiæ*, and *purpura*. They are frequently attended with bleeding from the mucous membranes of the intestines and bladder, and of the nose; and they often occur, in the lower extremities especially, when the liver is enlarged, or otherwise diseased. They are supposed in general to indicate a want of tone in the system, and are attributed by some to a *dissolved* and semiputrescent condition of the blood; but they arise in some instances from a plethoric habit, and require bleeding for their cure.

One of the most common causes of apoplexy is an extravasation of blood in the substance of the brain, or between its membranes, from the simultaneous rupture of many minute arteries. It happens for the most part suddenly, when the vessels of the head are preternaturally distended, but yet not without some premonitory signs; and as the affection occurs most frequently at an advanced period of life, when the arterial system in general is disposed to disease, it is probable that the rupture is often preceded by some morbid change which renders the capillary vessels more than usually fragile. [**APOPLEXY.**] The term *apoplexy* has been extended by modern pathologists to similar extravasations occurring in the texture of other organs besides the brain; it may take place in the liver when the venous system of the abdomen is loaded with blood, and from other causes; and it frequently happens in the lungs when their circulation is either obstructed or too forcibly urged in various diseases of the heart. [**HEART.**] It likewise happens very commonly in the early stage of consumption, when the body is yet full of blood, and the substance of the lungs is rendered brittle and inelastic by the deposit of tuberculous matter. [**PHTHISIS.**] When it occurs in the lungs, the injury is attended with *hæmoptysis*, or spitting of blood. In this, as in many extravasations of the same kind, it is probable that the blood is effused rather in consequence of a *rent*, or breach of continuity in the structure concerned, than from what is implied in the common notion of the breaking of a blood-vessel.

The presence of extravasated blood does not in itself produce much irritation, and the coagulum is soon absorbed when the quantity is not very great, and the vital powers are not depressed by concomitant causes. Where pressure is applicable, the absorption is much quickened by a bandage put on after the immediate effects of the injury have subsided, as in sprains and bruises of the limbs: friction and embrocations have the same effect.

Extravasations of urine may take place in consequence of rupture of the bladder or urinary passages from ulceration, mechanical injuries, or any cause that produces distension to a great degree. If the fluid escape into the cavity of the abdomen, the result is uniformly and speedily fatal. If it insinuates itself into the cellular tissue in the neighbourhood of the neck of the bladder or the urethra, the accident is still a very serious one, though it generally admits of cure if the nature of it be immediately recognized. The fluid, which is highly deleterious, must be promptly evacuated by free incisions, and care must be taken to prevent further infiltration. If this be neglected, unhealthy suppuration is sure to take place, accompanied by fever of a typhoid character, and followed by extensive mortification.

The most common causes of infiltration of urine are abscesses of the prostate gland, and neglected or mismanaged strictures; and a very frequent consequence is the establishment of a urinary fistula in the perineum. [**URINARY ORGANS.**]

It may be remarked that the bile is sometimes extravasated in the same way from the gall-ducts or bladder. If it escape into the abdomen, it is followed by a similar fatal result from inflammation of the *peritoneum*. [**ABDOMEN: CALCULI, BILIARY.**]

EXUMA. [**BAHAMAS.**]

EYCK, JOHN VAN, the improver and supposed inventor of oil-painting, sometimes called John of Bruges from his having settled at that place, was born at Maaseyk as is generally said, in 1370, and studied with his elder brother Hubert (born in 1366), an artist of reputation, but now rarely mentioned except in conjunction with himself. There are however some reasons for supposing John to have been born much later than 1370. There are very contradictory accounts of his merits. Some extol him as a various and expressive designer; others say he had no claim to repute, except as a colourist; others again found his whole fame upon his discovery of the art of painting in

oil; and it was concluded by most, till lately, chiefly on the authority of Sir Joshua Reynolds, that Raspe the antiquary, in a treatise on the question, had deprived him even of this last remnant of his renown. Raspe certainly proved that he did not make the discovery; but he surmised, what Lanzi has since shown to be the probable conclusion; that although Van Eyck did not invent, he greatly improved the art of oil-painting, and brought it into general use. This was effected by his discovering the means of giving consistency to colours without drying them in the sun, and of adding to them clearness and brilliancy by a water-proof varnish. After having long resided in the rich and flourishing city of Bruges, the two brothers removed about 1420 to Ghent, where their greatest and most renowned work, the 'adoration' of the Lamb, was painted between the years 1420 and 1432. Some say it was painted for Todorús Wyts, a rich citizen of Ghent, while others affirm that it was by order of Philip, duke of Burgundy, count of Flanders, who came to the government in 1420. It is certain however that John Van Eyck was long attached to the brilliant court of Philip. This often described picture contains no fewer than 330 figures. It is with folding-doors, filling in all twelve panels. It was so highly prized that it was shown only on particular occasions. Philip II., king of Spain, thought of removing it to Madrid, but was prevailed upon to content himself with a copy by Michael Coxis of Malines. This copy has in our days found its way back to the Netherlands, and thence, as it should seem, to Berlin. The fate of the original is remarkable, and much to be regretted. It remained entire till the French, getting possession of Belgium, of course turned their eyes to so rich a prize. The clergy of the cathedral of St. Bavon succeeded however in concealing eight of the twelve panels, so that only four were taken to Paris, whence they were brought back in 1815. The clergy have since sold six of the panels which were concealed, and they are now in the Royal Museum at Berlin, where they are united with a part of the copy made by Coxis for Philip II. Hubert Van Eyck died in 1426. John is generally said to have died in 1441, but the date of his death is uncertain. (Raspe, Descamps, Lanzi, &c.)

EYE. The organs appropriated to the sense of sight are distributed very extensively, yet with that frugality which always regulates the operations of nature in the construction of animals. All the active species which live in the light are furnished with them; the rest are disqualified to possess as well as to profit by them, by their limited powers of locomotion, or by constant residence in the dark. In conformity with this rule, to which there are few, if any, exceptions, these organs are occasionally associated with the lowest types of animal development, and are sometimes absent in the highest. Thus some radiated animals, most of the articulated tribes, and many of the mollusca, have manifest organs of vision, and some of them are of the most curious and artificial construction; on the other hand, the mole and the shrew-mouse*, both vertebrate animals, and belonging to the highest order of that class, the mammalia, are blind. They have eyes, it is true; but those of the mole are not larger than the head of a pin, and are unprovided with optic nerves; and the equally imperfect eye of the shrew is covered with skin, from which hair grows as on the rest of the body. Hence, even in the absence of further evidence, we might conclude that if these animals have any perception of light, it can only be sufficient to warn them back to their haunts when by any accident they emerge to the day. But it is more probable that they do not see at all; and that these rudimentary organs, like the male nipple, exist only in conformity with the general model of vertebrate construction.

The structural peculiarities of the eye, as well as the presence of that organ, may be inferred with more certainty from the circumstances of an animal, than from the place it occupies in any zoological scale: in fact, no part has a closer relation to the habits and mode of existence. The eye may be simple or compound, single or multiplied, fixed or moveable: it may be encased in a hard transparent shell; or lie deeply imbedded within the protection of a bony socket; or project from the surface of the head at the extremity of a sensitive and retractile horn: it may be adapted for near or distant, oblique or direct vision; for seeing in a strong or a weak light, in a dense or in a rare medium; or it may be formed so as to accommodate itself

to each of these conditions in its turn: and these peculiarities will all be found upon examination to be in strict accordance with the exigencies of the animal. Mere difference in bodily size, and the proportionate reduction or increase in the bulk of the eye, is sufficient to constitute a reason for a difference in its structure, and may suggest an explanation when such discrepancies are observed to exist in animals otherwise alike.

Yet, with all the varieties in configuration to which we have alluded, it is rather in form than in substance that the eyes of animals differ from each other. The organ has always a common purpose, and is essentially the same in all cases: that is, we find an assemblage of the same fundamental parts, generally arranged in the same order, even when our powers of observation are assisted by the microscope, and until all traces of organization are lost in extreme tenuity of texture and the transparency which results from it. And although there are refinements in the structure of the organ of which we do not know the purpose, and certain delicate adjustments in the exercise of the faculty of which we do not know the instruments, yet upon the whole we can deduce the principles upon which the eye is constructed, and assign the uses of its several parts with great certainty from our knowledge of optical and physiological laws.

Having offered these prefatory remarks on the organ in general, we now proceed to the most interesting of its varieties—the human eye. We propose, in the first place, to describe its anatomical structure at some length, noticing as we proceed, or subsequently, some of the most remarkable peculiarities in the eyes of other animals. We shall then add a few observations on the physiology of vision, and complete our account of the organ with an outline of its most important diseases in the human subject.

The object, or what may be called the *general problem*, of the beautiful mechanism we have to consider, is to combine distinctness and extent of vision with the security and maintenance of the organ, and the utmost convenience in using it. The parts associated for these purposes are the *orbits*, or sockets, of the eye; the *optic nerve*; the *eyeball*, or globe, with its contents, and the external muscles which move and suspend it; the *eyelids*; the *lacrimal apparatus*; the nerves and vessels which supply these parts, and the mass of fatty and cellular substance which isolates and supports them. We shall describe these parts nearly in the order in which they have been enumerated.

Orbits.—The eyes with their appendages are lodged in two symmetrical roomy cavities in the skull, completed in front by the eyelids, but elsewhere entirely circumscribed by bone, the office of which, it need hardly be said, is to protect them from injury, and from any pressure that might embarrass the perfect freedom and precision of their movements. These cavities are called the *orbits*, *orbital fossa*, or sockets of the eye. Seven bones of the cranium or face, which we need not enumerate, enter into the composition of each. They are separated from each other in their whole depth, which is about two inches, by the posterior chambers of the nose. They are conical in shape, or, more strictly speaking, pyramidal, and obscurely quadrangular. The apex is directed backwards; the base, about an inch and a quarter in width, is directed forwards, with a considerable inclination outwards or towards the temple. The margin is less prominent at the outer side than elsewhere, so that when viewed laterally it presents a wide semicircular notch, with the concavity forwards. One object of the divergence of the orbits, and of this retreating curvature of the outer margin, is obviously to increase the extent of vision. If the point of the finger be held before the eye, and carried gradually back towards the ear, it will be observed that, in consequence of this arrangement, it can be seen long after it has got behind a vertical plane touching the front of both eyes, which, taken together, are thus enabled to sweep over an angle of about 320°, or 20° on each side behind the tangent plane. Above and below, the edge is undercut as well as prominent, and the socket is therefore a little wider within than at the margin itself, so that it slightly overhangs the eyeball at these points. The inner or nasal sides pass directly backwards and are parallel to each other, and the roof is horizontal; consequently the conical form of the cavity arises from the inclination of the outer side and floor. In the angle between these sides, and in that between the first and the roof, there are two long irregular slits. The former opens into the deep hollow between the

temple and the back of the upper jaw; it is called the *foramen lacrum inferius*, or *spheno-maxillary fissure*, and gives passage to a branch from the fifth pair of nerves, which piercing the bone, passes beneath the floor of the orbit, and emerges upon the cheek through a hole just beneath the lower edge of the orbit, about a third part from the inner angle of the eye. The other slit, which is called the *sphenoidal fissure*, or *foramen lacrum superius*, opens into the cavity of the head, and transmits another branch of the fifth pair, which passing within the orbit, along the roof, comes out through an opposite notch in its upper margin, and is distributed upon the forehead and upper lid. These branches of the fifth pair, called the *supra* and *infra-orbital* nerves, are the most frequent seats of that excruciating affliction the *tic-douloureux*. Through the sphenoidal fissure are likewise transmitted the ophthalmic veins, and all the other nerves except the optic destined to the eye and its appendages. A third opening, which is circular, called the *foramen opticum*, of the size of a large quill, and leading also from the cavity of the skull, gives passage through the sphenoid bone to the ophthalmic artery and the optic nerve. It is directed obliquely outwards and forwards, and is situated at the apex or back part of the orbit, in the angle between the nasal side, and the roof. In the same angle, close to the margin, that is just within the corner of the eye near the nose, there is a deep groove leading into the lacrymal canal, to which we shall have occasion to recur hereafter.

Optic nerves.—The optic nerves, arising at the back part of the brain, with which they have extensive and important connections, not only where they seem to originate, in the *corpora quadrigemina*, but throughout the whole of the first part of their course within the cranium, pass horizontally forward above the floor of that cavity, converging towards each other till they meet, when they become closely united. It is probable that they not merely meet, but cross each other, the greater part, if not the whole, of the nerve from the *right* side of the brain going to the *left* eye, and *vice versa*. It has been ingeniously supposed by Dr. Wollaston (*Phil. Trans.* 1824), in order to account for some singular phenomena of disordered and healthy vision, that this *decussation* or crossing takes place only with respect to those parts of each nerve which lie towards the other; so that each supplies the outer half of one eye and the inner half of the other. This he conceives would explain, among other things, the correspondence between the *homologous points* of the two eyes, which may be defined as those points which see the same object at the same time. It is scarcely possible to verify such speculations by dissection, from the softness and apparent homogeneity of the parts. In fish* the optic nerves cross each other entirely without touching; and in man, when the sight of one eye has been lost, the nerve beyond the point of union within the cranium has been observed to be wasted or diseased on the side opposite to that of the affected eye. [BRAIN; NERVE.] Beyond the point of junction the nerves again diverge from each other, and passing into the *optic foramen*, become invested in a tough, flexible, and fibrous sheath, which is a tubular production of the strong membrane called the *dura mater* which lines the cavity of the skull. The outer part of this sheath is reflected off as the nerve enters the orbit, and expanding, adheres to the bony surface of that cavity throughout, becoming its *periosteum*. The nerves, continuing to diverge, reach the eye-ball after a somewhat tortuous course of an inch in length. The curvature and laxity of the optic nerve give facility to the movements of the globe, and preserve the delicate structures within it as well as the nerve itself from the injurious effects of tension. Its length is such as to allow the eye-ball to project slightly beyond the edge of the socket in front and to afford space behind for the action of the muscles which move it, and a suitable distance between their points of attachment. Including the thickness of the sheath, it is about one-sixth of an inch in diameter. It does not consist, like other nerves, of a bundle of distinct fibres, but of a medullary pulp inclosed in minute transparent tubes. The sheath is pierced half an inch from the globe by a vessel called the *arteria centralis retinae*, which, accompanied by several small veins, reaches the axis of the nerve, and passes with it into the interior of the eye. The nerve

does not enter the back of the globe exactly in the axis of vision, but about the fifth part of an inch from it, in a horizontal line, on the inner or nasal side, and subtending an angle of about 23° at the centre of the eye. At this point the dimensions of the sheath are suddenly contracted, and it terminates in a thin cul-de-sac, pierced with minute holes or pores, hence called the *lamina cribrosa* (sieve-like plate). Through these pores the pulp of the nerve, divested of its tubular involucra, passes into the interior of the globe in divided portions; but immediately reuniting, expands at the back of the eye into a delicate cup-shaped membrane, with the concavity directed forwards. This expansion of the optic nerve is called the *retina*; it is the most important part of the eye, having a peculiar and exclusive sensibility to the impressions of light, of which immediate notice is conveyed from it along the collected nerve to the brain. All other parts of the mechanism of vision are subordinate to this; and their whole office, independently of the conservation of the organ as a part of a living body, is to regulate the quantity of light admitted into the eye, and to distribute it in such a way upon the surface of the retina, that the impression, which, if immediately received, would be confused and general, may be an exact counterpart of the visible surface of the object.

Mechanism of distinct Vision.—A specific account of the several provisions which conduce to this end will be more readily apprehended if the circumstances which make each of them necessary be first briefly passed under review, and the requisite parts be supposed to be added to the retina in succession.

The most elementary fact that we know respecting light is, that it proceeds in straight lines or rays from every point of a luminous or illuminated body. A sensitive surface or retina presented nakedly to such a body would therefore intercept innumerable cones or pencils of light, each diverging from a different point of the object. But each point of the retina must also be considered in that case as the apex of a cone of rays converging upon it from every part of the object; and it is manifest that the various impressions thus received upon the same point at the same time would be undistinguishable from each other. All therefore that we can conceive to be communicated to the mind by the sum of such indefinite impressions over the whole retina, is a knowledge of the prevailing colour of the object, and possibly a general idea of its direction. But if there were more objects than one, or that one had 'parts or magnitude,' even this inconsiderable addition to the mere sense of light and colour would be impossible. The confusion resulting from the simultaneous impressions of a multitude of pencils of light on the same surface would be partly removed if the seat of perception were placed at the bottom of a cavity capable of being turned to each object or each part of the same object in succession, inasmuch as this would prevent the interference of rays proceeding from parts not actually under contemplation; but an indistinctness would still remain in proportion to the magnitude of the field of view, only remediable by narrowing the cavity to a mere capillary tube, upon the inconvenience of which we need not enlarge.

Let us consider what would be the effect of a very simple addition to the cavity. We will suppose it to be closed in front by a dark screen, perforated with a small central hole as in the section represented in *fig. 1*.

In this case pencils of rays crossing each other from A and B, the top and bottom of an object, would impinge at a and b upon different parts of the retina. By this means the advantages of a large and a small field of view would be combined, a *distributed* impression of the object would be produced, and its several parts would be seen separately and in their proper relative situations. The effect may be easily shown by holding a card, pierced with a smooth circular hole, near a taper, and throwing the spectrum upon a wall at a little distance. Such a screen is termed the *iris*.

* Except in the haddock (*gadus morhua*), D. W. Soemmering. * Sect. Horst. Ocul. In this fish they do not cross each other, but pass to the orbit on the same side.

But still the rays from each point of the object would be diffused over a *space*, instead of being collected upon a separate *point* of the surface, and the impressions of contiguous pencils would in some degree overlap and confuse each other. This inconvenience might be lessened by contracting the opening, but another cause of indistinctness would then be introduced in the diminished admission of light.

Both evils might be avoided if a *lens* of a proper construction were fixed behind the screen (as in *fig. 2*). Pencils diverging from single points of the object would thus be admitted through the opening, which we will call the *pupil*, and would be made to *converge* to single points on the surface, and the impression would now be an exact counterpart of the object, A being distinctly seen in its true place and direction from *a*, and B from *b*.

But additional provisions would be necessary to bring this arrangement to the requisite degree of perfection. In the first place the retina must be adjusted to correspond in shape with the focal distance of the lens. This purpose might be accomplished, if the walls of the cavity were composed of flexible materials, by interposing a transparent fluid between the lens and the retina, which, by its uniform distension, would constrain the latter to take and retain the form of a portion of a sphere.

Again, although the diagram has been otherwise drawn for an obvious reason, our arrangement hitherto supposes the object to be very small, and to be seen directly in front of the eye; but if oblique as well as direct pencils are to be brought to a focus, that the lateral vision may be also *distinct*, a second refracting body, of a proper form, must be placed in front of the lens. This may be done very conveniently, with the further advantage of completing the cavity, by adding a transparent portion to its walls in front of the screen, to be likewise distended with fluid in order to keep it in the shape of a segment of a sphere (*fig. 3*).

It is also desirable that the back of the screen and the interior of the cavity should be blackened, that the rays may be extinguished after impact upon the retina, lest any internal reflection should interfere with the impressions on other parts. The expediency of this provision is always kept in view in the construction of optical instruments, and may be made evident by looking at a bright object through a polished metal tube. The colouring matter is called the *vimentum nigrum*, or, simply, the *pigment*.

The only remaining artifice to secure the perfection of the organ that need be mentioned in this synopsis of its most essential provisions, is to endow the pupil with the faculty of contraction and enlargement according to the quantity of light. If it were of a constant size, more light would be concentrated upon the retina from a bright or a near object than from one comparatively distant or faintly illuminated; and as the sensibility of the retina must remain the same, the disproportion would occasion dimness of sight in one case and dazzling in the other, and might even impair the nerve.

We have thus imagined all the parts to be built up in succession that are of primary importance (as far as we know) in the construction of an organ of *distinct vision*, and the figure to which we have arrived might pass as a tolerably correct diagram of the human eye.

The laws of light and sensation require that there should

be a general type in the structure of these parts, and a mutual relation among them as to density, form, and position. But this does not preclude much variety; a difference of position, for instance, may be, and frequently is, compensated by a corresponding difference in form or density either of the same or other parts. Hence the problem of distinct vision has many solutions, each perfect in its kind. In fact nothing can be more diversified in unimportant particulars, or more uniform in those which are essential, than the interior constitution of the eye in different animals: it is never precisely the same in any two species, however closely they may be allied; but we constantly find the retina, the lens, and the pigment, and generally the iris, enclosed of course in some kind of capsule, transparent in front, and partly occupied by complementary fluids. To this there are some exceptions, which however we believe to be only apparent. Thus the larvæ of many insects, the *cercarizæ*, and other microscopic animalcules, and some of the molluscs, have red or black spots upon their surface, which are undoubtedly eyes, and are thought by some to be little more than expansions of an optic nerve beneath a thin coloured membrane to absorb the light, and in some unknown way to distribute its impressions. But when observation fails us, our presumptions with respect to natural phenomena should be guided by analogy and accord with known principles; and as nothing that we know of light enables us to conceive how so inartificial a construction as this can account for the acute vision obviously enjoyed by some of these animals, we are disposed to adopt another view of such coloured points, and to consider them as a congeries of extremely minute but perfectly formed eyes of the usual construction, of which the pigment alone is visible from its opacity and abundance. The myriads of simple eyes observed under the microscope to be grouped together in the compound organs of the perfect insect and other articulated animals, as the scorpion and crab, afford strong analogical grounds for this opinion.

We now resume our account of the anatomical structure of the human eye.

Section of the spherical surfaces of the eye, twice the natural size; the circles completed in dotted lines.

a, Sclerotic. b, Cornea. c, Anterior surface of lens. d, Posterior surface of lens. e, Centre of the eye. f, Intersection of the axis of direct vision with the back of the eye. g, Entrance of the optic nerve.

Globe.—The globe, or eyeball, contains the parts immediately concerned in vision. It consists of very unequal portions of two spheres of a different size, which have a common circular intersection in a transverse vertical plane, much nearer the front than the back of the eye. The iris, or coloured screen, perforated centrally by the pupil, nearly occupies the situation of this imaginary plane, but is, strictly speaking, behind it. The posterior and larger portion is circumscribed by the sclerotic membrane, except in front, where it may be considered as bounded by the iris: it is rather less than an inch in diameter, and constitutes about five-sixths of the surface of the globe. (*Fig. 4, a*.) The included space is occupied by the choroid membrane and retina, the vitreous and crystalline humours, the ciliary body and processes, and a small part of the aqueous humour. The anterior portion, which forms about a quarter of a sphere, thirteen-twentieths of an inch in diameter (*Fig. 4, b*), and occupies the remaining sixth part of the surface of the globe, contains the rest of the aqueous humour, and is bounded in front by the transparent and slightly prominent disc set in the sclerotic like a watch-glass in its metallic rim, and known as the *cornea* from its horny texture. Its transverse chord, or the diameter of the circle of union be-

tween the cornea and sclerotic is nine-twentieths, or nearly half an inch in length.

The globe derives its firmness to the touch from the distension of the contained fluids: its capability to bear that distension, which insures the permanence of its shape, is due to the flexible but strong and inelastic outer covering or tunic, consisting as we have said of the sclerotic and cornea.

Section of the globe of the right eye through the optic nerve.

a, sclerotic; b, cornea; c, choroid; d, retina; e, vitreous humour; f, crystalline humour or lens; g, aqueous humour; h, iris; i, ciliary ligament; k, ciliary processes; l, ora serrata of the ciliary body; m, canal of Petit; n, foramen of Soemmering; o, sheath of the optic nerve; p, substance of the nerve; q, arteria centralis retinae.

Sclerotic. (Fig. 5, a.) The sclerotic membrane is so called from its toughness (*σκληρός*, hard, rigid). It may be considered as an expanded prolongation of the sheath of the optic nerve, which it resembles in its interwoven fibrous texture. Its inner surface is continuous with the lamina cribrosa already mentioned. Immediately around this part it is about an eighth of an inch thick, and gradually becomes thinner as it approaches the cornea, which it slightly overlaps. The two structures are not separated by an abrupt line, but are blended together, and adhere so closely that they cannot be torn asunder without great force. The thin glistening tendons of the muscles which move the globe, or rather their smooth outer laminae, are spread over and incorporated with the sclerotic in front, approaching each other till they unite near its junction with the cornea. They render it somewhat thicker in this situation than in the spaces between them or behind the line where they begin to be inserted. This front part of the capsule of the eye is called the *tunica albuginea*, from the whiteness characteristic of all tendinous parts.

Conjunctiva. The albuginea is defended from contact with the air by a transparent mucous membrane, continuous with that which lines the interior of the eye-lids. It is called the *conjunctiva reflexa* or *adnata*, to distinguish it from the *conjunctiva propria* of the lids. It is very loosely connected to the sclerotic at first to facilitate the movement of the globe: as it advances forward it becomes more closely attached to the albuginea; and hence extending to the cornea, adheres intimately to its margin and over its whole surface. The conjunctiva is the most sensitive external part of the body to all painful impressions, except cold, especially where it invests the cornea. The smallest particle of foreign matter in contact with it gives intolerable pain, and makes the act of winking to clear it away imperative on the will; and hence its chief and most essential use as part of the delicate organ of which it may be considered as the guardian. If the nerve which supplies it with sensibility be divided or injured, incidental causes of

irritation are suffered to produce their injurious effects unheeded, and the eye soon becomes inflamed, ulcerates, and is destroyed.

Cornea. (Fig. 5, b.) The cornea is somewhat thicker than the sclerotic except at the back of the eye, is equally tough though rather more flexible, and of a much closer and more even texture. Its inner surface is concave, and nearly parallel to its outer surface; it is however rather thicker in the middle than elsewhere, and the general statement that it has no share in effecting the convergence of incident rays on account of the parallelism of its surfaces is therefore not quite correct. It is covered externally, as we have already mentioned, by the conjunctiva, and is lined internally by a delicate elastic membrane. The bulk of the tunic, or cornea proper, consists of several layers which slide upon each other when the membrane is rubbed between the finger and thumb, and are separated in the natural state by a limpid fluid contained in a delicate cellular structure. This fluid gives plumpness to the outer surface, which is represented by some authorities to be not *exactly* spherical, but of that kind which would be formed by the revolution of an ellipse of small excentricity about its long axis.

The sclerotic part removed, and the rest turned back, showing the Choroid Coat and Iris.

Choroid or Choroid membrane. (Fig. 5, c, Fig. 6.) We have now to consider the internal tunics of the eye, the first of which is the choroid, or, more properly, *chorioid* membrane, so called from some resemblance in the flocculence of its outer surface to the *chorion*, or external investment of the ovum. This is a thin soft dark-brown structure in contact with or lining nearly the whole concave surface of the sclerotic. It may be said to originate around the entrance of the optic nerve, which passes through it before it expands into the retina; and it terminates in the posterior margin of the ciliary ligament or circle (fig. 5, i),—a flattened band of grey matter, about the seventh part of an inch in breadth, attached to the sclerotic internally near its junction with the cornea. In these situations the two membranes adhere with some firmness; they are elsewhere connected by vessels which pierce the outer and ramify upon the inner membrane, and by the filaments of a fine intermediate cellular tissue. But the connexion is so slight that it may be readily broken by gentle inflation with a blow-pipe insinuated through a puncture in the sclerotic, without injury to the fragile texture of the choroid. The choroid consists almost entirely of a multitude of minute vessels, curiously interlaced, and communicating freely with each other. It is supplied with blood by 15 or 20 branches of the ophthalmic artery, which pierce the sclerotic round the entrance of the nerve, and are at first distributed externally on the posterior part of the sphere; but they finally pass inwards, and terminate in a close and uniform vascular expansion over the whole concave surface. This is called the tunic of Ruyssch, who erroneously considered it as a distinct membrane. The innumerable veins of the choroid, or *venae vorticosae*, are arranged with great elegance and regularity in arched and drooping branches, like the boughs of the weeping willow; they are very conspicuous upon the outer surface, above the first exterior ramifications of the arteries. (Fig. 6.) They unite in four or five common trunks, which emerge through the sclerotic at equal intervals behind the middle of the eye-ball. The outer surface of the choroid is somewhat rough and flocculent; the inner surface, upon which the retina is expanded, is delicately smooth and even. Both are abundantly covered with the pigment, which is secreted by every part of the choroid, and pervades its loose and porous texture.

Pigment.—In man this matter is of a deep brown colour, in most other animals it is black, and hence is very commonly called the *pigmentum nigrum*. It appears under

the microscope to consist of hexagonal particles arranged side by side like the cells of a honeycomb. It adheres very loosely, so that when the surfaces covered with it are drawn to and fro in water, it becomes diffused, and may be washed off. The choroid thus treated is found to be of the same whitish or grey colour which characterizes the ciliary ligament. In the natural state of the parts, not only the choroid, but the cellular tissue on its external surface, and the inside of the sclerotic, are deeply stained by the pigment, which shows through, and occasions the bluish tint of the white of the eye in persons of delicate complexion. But on the inner surface of the choroid the pigment is retained by an expansion finer than a spider's web, yet of close texture, which may be called after its discoverer the membrane of Dalrymple. By this means the transparency of the retina is preserved. It is probable that this membrane of the pigment is of a *serous* kind, and that it is reflected at the optic and ciliary margins of the choroid, and passes over the whole posterior surface of the retina,—thus doubly defended from absolute contact with the pigment. The choroid is not the only part which secretes this coloring matter. It is found in equal or greater abundance upon the back of the iris, on the surfaces of the ciliary processes, and in fact wherever it is wanted to facilitate vision.

Tapetum Lucidum. In many animals, especially the nocturnal and carnivorous tribes, the pigment is deficient at the bottom of the eye, and the surface of the choroid in that situation presents a brilliant colour and almost metallic lustre. This is called the *tapetum* (tapestry of divers colours). It is of various shades of blue, green, and yellow; sometimes changeable like shot silk, and sometimes of a silvery whiteness. The tint occupies various proportions of the surface; it is most brilliant immediately opposite the pupil, and passes gradually into the dark hue of the pigment. There is no vestige of a tapetum in the human eye: the use of it is not well known. It probably causes the animal to see better in the dusk and less clearly in the day, by reflecting the rays a second time through the retina. This reflection from a very effective concave mirror produces a strong convergence of the rays which come back through the pupil, and is the cause of the well-known glare of the eyes of cats and other animals seen in an obscure light from that particular distance at which the emerging rays are most completely brought to a focus upon the eye of the observer. The breadth of this luminous appearance arises from the great dilatation of the pupil under the circumstances in which it is seen.

Retina. The optic nerve, having entered the interior of the globe through the sclerotic and choroid membranes, forms a slight prominence at the point of union of its several portions, and thence spreads out in the form of a fine transparent membrane over the whole concave surface of the choroid, embracing the translucent body called the vitreous humour. Towards the choroid it appears to consist of a mere homogeneous pulp not very different from the medullary matter of the brain; but it is undoubtedly most elaborately and minutely organized. Analogy would lead us to suppose it to have a fibrous arrangement, and recent observations of great nicety with the microscope appear to lead to the same conclusion.* Towards the vitreous humour it has the structure of a most delicate vascular web, consisting of innumerable ramifications of the central artery (which, as we have already mentioned, accompanies it into the interior of the globe) and of its associated veins. Its name may have been derived from the *net-work* formed by the visible branches of these vessels; at least it is not otherwise applicable to the structure of the membrane. The distribution of the central artery may be made visible to an observer in his own eye by a curious experiment first suggested by Purkinjé. One eye being steadily directed to a surface of some uniform dark or neutral tint, such as a wall painted of a lead colour, and the other eye closed by the hand, the flame of a small wax taper is to be slowly waved round and round, so as to be brought at every turn at a little distance over the front of the eye. The central artery will gradually come into view, at first obscurely, and afterwards more clearly. The experiment succeeds best after the experience of several trials on successive nights. The form is such as might be expected from a branching net-work of vessels: the lines are dark, with bright edges on a faintly illuminated ground. There are other modes

of making the experiment, which show the appearance more distinctly, but they are less simple. We shall offer an explanation of this experiment in treating on the physiology of vision. The retina terminates anteriorly in a thin scalloped edge, fitting into corresponding irregularities called the *ora serrata* in the posterior margin of the ciliary body. (Fig. 5, *l* and 9, *d*.) Exactly opposite the pupil there is a bright yellow spot, fading gradually off at the edges, and having a black point in the centre precisely where the axis of direct vision intersects the back of the eye. (Fig. 5, *n*.) This central point was believed by its discoverer, Soemmering, to be an actual deficiency of the substance of the retina; and it is generally called in consequence the *foramen* of Soemmering. But it is now known to be merely a central absence of the yellow colour of that part of the retina rendered conspicuous by the pigment seen through the ordinary transparent texture. These appearances are lost very shortly after death, and are replaced by a minute fold, into which the retina gathers itself, reaching from the place of the central point to the prominence which marks the union of the divided portions of the nerve.* The use of this yellow spot and central point, and of the tendency of the retina to assume a folded shape in this situation, is not understood. It has been suggested that the group of appearances is a rudiment of the yellow dye of the retina and of the *pecten* in birds, of which we shall give some account in a future part of the article. They are met with only in the eyes of man, the quadrumana, and some lizards. We have already described sufficiently the serous membrane which lines the posterior surface of the retina, supposed to be a reduplication of that which retains the pigment on the opposed surface of the choroid. Whatever may be the truth as to this supposition, there is no doubt of the existence of the retinal membrane, which was discovered by Dr. Jacob of Dublin, and has been named after him.

Vitreous Humour. (Fig. 5, *e* and 7, *d*.) The part next in order to be described is the vitreous humour, behind which the retina is disposed. It is a transparent fluid of semigelatinous consistence and high refractive power, constituting about five-sixths of the bulk of the globe. It consists of a fluid differing in no great degree from water, contained in a cellulated structure called the *hyaloid* membrane (*ballois, glass*), from its perfect translucency. The minute cells are connected together; for if the external part be punctured, the fluid contained in them gradually drains away. This cellular structure is so delicate and fragile that it is almost impossible to obtain it separately; but the membranous partitions are rendered slightly opaline by strong spirit or diluted acids, and may thus be

Fig. 7.

This figure, from the work of Zinn, represents the vitreous humour in its natural state. The lens, imbedded in its upper surface, is surrounded by the canal of Petit. The dark border beyond is the platted portion of the hyaloid membrane called the *zona of Zinn*, stained with the pigment left by the ciliary body, which in the natural state of the parts rests upon that portion of the surface of the hyaloid. The outer edge of the zone is marked by a wavy outline, corresponding with the *ora serrata* of the ciliary body. *a*, crystalline lens; *b*, canal of Petit; *c*, zone of Zinn; *d*, vitreous humour.

made evident. It is condensed into a membrane of a firmer consistence upon the surface, which serves the general purpose of a containing capsule for the vitreous humour, and is strong enough to cause it to preserve its shape in some degree when the stronger tunics of the eye are removed. There is a narrow tubular dimple of some depth in the vitreous humour opposite the entrance of the nerve, lined by a trumpet-shaped production into it of the external membrane, called the *hyaloid canal*. (Fig. 5. It serves to transmit a branch of the retinal artery and associated veins for the nourishment of the capsule of the

ens in the fetus, and perhaps also of the hyaloid membrane, and of the substance of the lens itself. There can be no doubt that the vitreous humour is secreted by the surfaces of the hyaloid cells, but this foetal artery is the only vestige of a vascular arrangement yet discovered in the part.

Fig. 8.

Magnified view of the lens, showing its laminated and fibrous structure, and the direction of its planes of cleavage.

Lens, or Crystalline Humour. (Figs. 5, f; 7, a; 8.) The crystalline (*κρυσταλλος*, crystal) is imbedded in a deep depression in the front of the vitreous humour, a little nearer the nasal than the temporal side of the globe. It has the form and function of a double convex lens. The surfaces may be considered as portions of two unequal spheres, the anterior being considerably flatter than the posterior. The diameter of the sphere of which the former is a segment is about eight-twelfths, of the latter five-twelfths of an inch. The thickness of the lens, measured in the axis of vision, is about the sixth part of an inch, and its transverse diameter is about twice that length. (Fig. 4, c, c, d, d.) In refractive power it is superior to the other transparent substances contained in the eye. Its consistence is gelatinous, increasing in density from the circumference towards a central nucleus, which has the tenacity of soft wax. It is composed of an infinite succession of thin concentric laminae, arranged with the utmost regularity one within another like the coats of an onion; and every such stratum or elliptic shell is made up of a series of exquisitely minute fibres laid side by side, forming three *septa* like the cloves of an orange, of which the bounding or cleavage planes diverge from the axis of the lens at angles of 120° in the manner represented in the annexed figure. (Fig. 8.) If the lens be hardened in strong spirit, the result of this curious arrangement is, that it partly cleaves into three portions made up of layers which may be peeled off one after another, each further separable to a certain extent into its component parallel fibres. The spirit not only hardens the crystalline humour, but renders it opaque; and the same effect is produced by plunging it in boiling water, as every one must have observed in the eyes of dressed fish. In fact it consists chiefly of the transparent substance called *albumen* found in eggs, and is coagulated by heat in the same way. The lens is similarly constructed in the eyes of other mammalia; and analogous, though not identical, arrangements are observed in other classes. In fish the fibres we have spoken of are curiously hooked together by fine teeth, resembling those of a saw. We chiefly owe the discovery of these facts respecting the intimate structure of the lens to the labours of Leeuwenhoek, Young, and Brewster, whose writings may be consulted for much further interesting information on the subject. The crystalline is enclosed in a transparent and highly elastic membranous capsule, represented in Fig. 5 by a white line, to the regulated pressure of which the preservation of its true shape, so important to the purposes of vision, is mainly attributable. There is no analogous structure in the body, except the internal lining of the cornea already mentioned, which closely resembles it in its function with reference to the surface of the aqueous humour. When the lens is hardened in spirit or boiling water, this capsule retains its nature; and if peeled off, shrivels up and curls upon itself. It may be easily detached with a pin from the hard spherical lens of a boiled fish, and will be found still possessed of its peculiar qualities of transparency and elasticity. The capsule is firmly attached to the hyaloid membrane behind, from which it is not easy to separate it neatly. Whether it has any further connection than that of mere contact with its own contents, is not easy to show, or to doubt; but the nature of that connection, if any exists, might be ex-

pected to be obscure, considering that both the parts are diaphanous, and one of them almost liquid at the surface of contact. Indeed it has been supposed that a small quantity of limpid fluid was actually interposed between the lens and its capsule, but this is now shown to be the result of imbibition after death.

Besides its posterior attachment to the hyaloid membrane, the lens, or rather its capsule, has connections with other parts which adjoin it laterally in front: the nature of these will be best understood if those parts be first briefly described. At present, we shall only remark upon it further, that the gradual increase in its density from the circumference to the centre is a provision for correcting what is called the *aberration of sphericity*, or that impairment of focalising power which results from the too great refraction of the lateral rays of a pencil of light in passing through a homogeneous medium, such as glass, if bounded by spherical surfaces.

Aqueous humour.—This fluid, in no respect distinguishable from water except in holding a minute proportion of several saline ingredients in solution, occupies the space between the lens and the cornea. The iris divides this space into two unequal portions called the *anterior* and *posterior chambers* of the eye, and so closely approaches the lens that near the margin of the pupil the two surfaces are separated by a mere film of aqueous humour. The cavity is lined throughout by a serous membrane which secretes and limits the fluid, and prevents it from acting injuriously upon subjacent parts of importance. At least a membrane of this kind may be peeled off in some animals; its existence in the human eye is rather a matter of inference than proof.

Several parts of much interest besides those we have already noticed are contained in the cavity of the aqueous humour, or form part of its boundaries. These are the iris, the ciliary body and processes, the zone of Zinn, and the canal of Petit.

Iris. (Fig. 5, h; 9, b.) In speaking of the choroid we have already adverted to the flattened ring called the ciliary ligament (Fig. 5, i) which connects it in front with the sclerotic. The iris arises from the anterior margin of this ring, and is extended, as we have seen, across the aqueous humour in the form of a thin partition with a round aperture, or *pupil*, of variable size in the centre, or a little nearer the inner side, the function of which, we need hardly repeat, is to regulate the quantity of light admitted into the eye, by contracting when it is in excess, and dilating when it falls short of the due amount.

Fig. 9.

Magnified view of a vertical section of the globe, showing the ciliary body and processes with the uvea, as seen from behind when the lens is removed.

a, Pupil; b, uvea, or back part of the iris; c, processes of the ciliary body; d, ora serrata of the ciliary body, to which a few shreds of the vascular web of the retina remain attached.

The external appearance of the iris is too familiar to need a particular description. It is covered in front with a glistening polished membrane. The brilliancy of the eye depends in a great measure upon the light reflected by this surface, and is lost when its smoothness and transparency are impaired by inflammation. The posterior surface of the iris is called the *uvea*. (Fig. 9, b.) It is thickly coated with pigment, which is prevented from diffusing itself in the aqueous humour by a membrane like that of Dalrymple on the choroid. Such a provision is particularly needed here on account of the quick movements of the part in a watery fluid. The colouring matter of the iris has much analogy with the pigment. Like that substance, it forms

no part of the texture it pervades, and when the outer membranes are removed by maceration in water, it may be washed away. Both have a relation in quantity as well as in depth of tint to the complexion and colour of the hair. In the negro the iris is of so dark a hue that it can scarcely be distinguished from the pupil; while in the white rabbit and other albinos, including the human variety, where the pigment is entirely wanting from some original malformation, the substance of the iris is transparent, and reflects only the pink colour of the circulating blood. Such eyes are dazzled by a strong light, and probably see better than others in the dusk. The iris, if minutely injected, appears, like the choroid, to be composed almost entirely of vessels. It is principally supplied by the two long ciliary arteries (Fig. 6)* which pierce the sclerotic about half an inch from the optic nerve on either side; and passing between that membrane and the choroid, divide near the edge and in the substance of the ciliary ligament, and are wholly distributed to the iris. Their branches are disposed in two conspicuous circles on the front surface, one near the outer or ciliary margin, the other not far from the pupil. But though the iris resembles the choroid in vascularity, it differs essentially from it in other respects. It is richly supplied with nerves, which proceed to the iris and are distributed upon it much in the same way as the arteries, and are the medium of its sympathy with the retina, and the source of its irritability. It also possesses a peculiar contractile power, thought by some to reside in fibres which they represent to be muscular, and to be disposed circularly in front and at the fore edge, and in a radiated form behind. (Fig. 9, b.) The former of these layers is supposed to contract and the latter to dilate the pupil. But this fibrous appearance may be deceptive, and is attributed by others to circular arrangements of the vessels and nerves, and to streaks and minute folds in the membrane itself.

Pupil. (Fig. 9, a.) The pupil in the human eye is bounded by a sharp well-defined circular edge. In other animals its shape is subject to many varieties which may often be explained by a reference to their habits and circumstances. In fish it is generally crescentic or imperfectly quadrangular. In herbivorous animals, which often continue to browse during the night, it is oblong and obliquely transverse, as in the horse and sheep. In most serpents and many rapacious quadrupeds, both aquatic and terrestrial, the pupil, though round and large at night, is a mere vertical slit when seen by day, especially in the smaller species of each genus, as in the common cat. It is curious that in the larger cats, as the lion and tiger, as well as in some of the larger four-footed reptiles, the pupil again becomes circular. In all birds, we believe, the pupil is round; and it may be observed that, with few exceptions, they all sleep after night-fall. In the few nocturnal species, as the owls, the pupil is very large though still round, and these birds always shun the day. The long narrow pupil is in fact a provision for a greater variation in size than the circular form permits, and is generally found in those animals which roam at night and also see well by day. When absent in such animals the bulk of the organ is commonly sufficient to secure the admission of a sufficient quantity of light after sunset without this provision. In the fœtus the pupil is closed by a vascular film called the *membrana pupillaris*, one function of which is precisely that of the centering of a bridge, to support and extend it during the process of its construction. A tubular film of the same kind has been lately discovered by Müller stretched between the margin of the pupil and the ciliary body. Both these films are absorbed before birth.

Ciliary body and processes. (Fig. 5, l; 9, d c.) Upon the compressed anterior surface of the vitreous humour where it curves inwards from the sclerotic towards the lens rests the ciliary body, a thin, dark, annular band, about the fifth part of an inch in breadth, consisting of a frill of flat converging plaits, which encircle but do not reach the circumference of the lens. The posterior aspect is concave, and adheres loosely over the rounded vitreous humour; the front is convex, and is firmly attached to the whole breadth of the ciliary ligament, and to a small portion of the back of the iris near its junction with the ligament. It appears to be a continuation of the inner layer of the choroid, or tunic of Ruysch, but is rather thicker, and resembles it in extreme vascularity. The medullary matter of the retina

terminates, as we have seen, at the indented posterior margin (*ora serrata*) of this membranous band. The ciliary body is everywhere thickly coated and pervaded with pigment, except at the extremities of about seventy minute unattached points which fringe the inner margin, and radiate towards the lens like the florets of a marigold round its central disc. These are the *ciliary processes*. (Fig. 5, k; 9, c.) They are separated from the uvea by the fluid of the posterior chamber, and are received behind into corresponding depressions in the vitreous humour.

Zone of Zinn.—If the ciliary body be carefully peeled off, and the thick radiated masses of pigment it leaves behind be washed away, a thin, transparent, and puckered membranous surface is exposed, extending from the indented margin of the retina nearly to the capsule of the lens, which appears to be something more than the mere external surface of the hyaloid membrane. This is called the *zone of Zinn*, from the anatomist who first drew attention to it. Various opinions are entertained of the nature of this zone. By some it is supposed to be a continuation of the vascular web, which may be called the internal tunic of the retina, arching round from the *ora serrata*, just as the tunic of Ruysch is continued into the ciliary body which lies upon the zone and corresponds with it in extent. The question is more curious than important in the present state of our knowledge of the functions of both of these delicate and elaborately constructed parts of the eye. The same remark may be extended to the controversies that subsist with respect to the part we have next to describe.

Canal of Petit (Fig. 7, b; 5, m). If the transparent membrane between the zone of Zinn and the margin of the lens be slightly punctured, and the point of a small blow-pipe be gently introduced, a canal may be inflated extending all round the lens in close proximity with the capsule, resembling a string of small glass beads laid in a circle. This is the *canal of Petit*. Whether the hyaloid membrane here separates into two layers, or whether the membrane of the aqueous humour lies upon it in this situation for a certain space without adhering, or how otherwise this canal is formed, it is not easy to say. In the natural state of parts it is empty and flaccid. When it is inflated the fine white triangular tips of the ciliary processes are seen to be received between its minute protuberances. But the points are loose and floating, and are not attached, as was formerly supposed, to the capsule of the lens.

Dr. Brewster has stated an opinion that the ciliary body is a muscular organ calculated to effect certain changes of curvature in the surfaces of the lens, or in its position, which seem to be required by the laws of refraction to account for the adjustment of the eye to different distances. Dr. Thomas Young was no less confident that the true solution of this optical enigma was to be found in the imagined muscularity of the fibrous structure of the lens itself. Both are high authorities, but neither opinion appears to have gained any ground.

Appendages of the Globe.—The eye-ball, of which we have thus described the contents, is lodged in the cavity of the orbit, a little nearer the inner than the outer side. In front, where the protection of bone is wanting, the two moveable and muscular eye-lids supply a sufficient defence, and contribute, by their gentle and constant pressure, to keep the eye in that state of equilibrium between opposite forces upon which the steadiness and precision of its rapid motions in a great measure depend. The space in the socket not occupied by the globe and its appendages is completely filled by a cushion of soft fat contained in elastic membranous cells, which permits the free movement of the several parts, while it keeps them separate, and affords them all, as well as the globe itself, a suitable and uniform support. Varieties in the quantity of this substance, in the capacity of the orbit, and in the development of the lids, determine the different degrees of prominence and of apparent size observed in the eyes of different persons; for the globe itself is nearly of the same size in all.

Muscles of the Eye-ball.—The movements of the globe are effected by six muscles arising from the bony surface of the orbit, and inserted into different parts of the sclerotic. Four are called *recti*, that is straight or direct muscles; the fifth and sixth are the *obliqui superior* and *inferior*, so called from the obliquity of their insertion, and their respective positions above and below the globe. The fifth, or superior oblique, is also called the *trochlearis*, from the *trochlea* or pulley through which the tendon passes.

* One of the long ciliary arteries is represented in the figure by the middle white line: the narrower lines are the ciliary or iridian nerves.

Fig. 10. Lateral view of the right eye-ball, seen from the outer side, with its muscles. (This cut is to be considered only as a diagram, the proportions of the parts having been much altered to make them more distinct.)

The recti (Fig. 10, *a, b, c, d*) are four flat ribbon-like muscles, each about half an inch broad, which arise together round the edge of the foramen opticum, and embrace the nerve at its exit from the skull. They end in broad, thin, glistening tendons, attached to the sclerotic at four equidistant points, about a quarter of an inch from the edge of the cornea, above, below, and on either side. Hence they are designated as the superior, inferior, internal, and external straight muscles. We have already explained how the outer surfaces of their tendons are blended, and form the tunica albuginea. Each turns the pupil towards the side of its insertion; and it is easy to see how by their single actions, or by a proper combination of two that are contiguous, the pupil may be turned in any required direction. The rectus externus, from its position on the diverging side of the orbit, is necessarily the longest of these muscles. It has also a double origin, arising not only in common with the rest from the edge of the optic foramen, but also from the edge of the sphenoid fissure, and arches over several nerves which enter the orbit by that passage (*p*). The superior oblique or trochlearis (*e*) is a round tapering muscle, which arises near and on the nasal side of the rectus internus (*c*), and ends in a smooth round tendon. The pulley (*k*) through which this tendon passes is a small loop of cartilage fixed to the roof of the orbit towards the nasal side, just within the margin. In this situation the tendon is enveloped in a lubricated extensible sheath called *bursa mucosa*; thence spreading into a thin fan-like expansion, it is reflected obliquely backwards and outwards between the globe and the tendon of the rectus superior (*a*), and is inserted into the back part of the sclerotic at a point (*m*), intermediate between the optic nerve and the insertion (*h*) of the rectus externus, and nearer the former. Its separate action turns the pupil downwards and outwards. The inferior oblique (*f*) arises broad within the lower edge of the orbit towards the nasal or inner side, and passing obliquely backwards over the tendon of the rectus inferior (*b*), is attached to the sclerotic at the outer and back part opposite the insertion of the trochlearis. It directs the pupil upwards and outwards, supposing the eye to look originally straight forwards: if the pupil be inclined either way, to the nose or to the temple, the inferior oblique increases that inclination, being equiposed as to lateral action when the eye is slightly turned inwards, as in reading. But its tendency is always to turn the pupil upwards. To a certain extent the same remark is applicable (*mutatis mutandis*) to the action of the antagonist muscle, the superior oblique, which if exerted at the same time would counteract the tendency upwards, so that both taken together would keep the eye in that easy position so often assumed by man and animals in looking without much effort yet steadily at near objects, as in taking food, reading, and most other quiet occupations. The position we mean is that in which the axes of vision are directed slightly towards each other and a little downwards, and the eye-balls are gently pressed against the lids and by them, and thus are kept in a convenient and steady equilibrium. When the oblique muscles act together with force, they hold the eye-ball firmly against the lids and to the nasal side of the orbit. One or both of these muscles, as well as the rectus externus, are supposed to be endowed with certain automatic or involuntary actions, very useful in the economy of vision. Their functions in this and other respects have given occasion to much curious disquisition.

a, Rectus superior; *b*, Rectus inferior; *c*, Rectus internus; *d*, Rectus externus, arising by a double head. It is represented as cut off from *h*, its insertion into the eye-ball, and turned aside to show the parts behind it; *e*, Obliquus superior, a round and tapering muscle terminating in a round tendon, which passes through a pulley or loop (*k*), and is reflected under the flat tendon of the rectus superior, and, becoming flat, is inserted at (*m*) into the sclerotic; *f*, Obliquus inferior coming round over the tendon of the rectus inferior from the front and inner edge of the orbit, near the inner corner of the eye, and inserted into the sclerotic opposite the insertion of the superior oblique; *g*, Levator palpebræ superioris, ending in a flat tendon, which is inserted into (*l*) the crescentic tarsal cartilage of the upper lid; *h*, *i*, the optic nerve; *n*, the nerves of the 3rd, 5th, and 6th pair, which pass between the two heads of the rectus externus. The rest of their course is not shown.

Fig. 11.

View of the left eyebrow and lids, showing their tarsal margins.

a, Lower punctum lachrymale; *b*, tarsal edge of the upper lid; *c*, orifices of the ducts of the Meibomian glands (those on the upper lid are similar); *d*, canaliculus, situated at the inner canthus, or corner of the eye. The double line of points external to the Meibomian orifices marks the situation of the eye-lashes, which are removed.

The Eyelids or Palpebræ. (Figs. 11, 12, 13.) The textures which enter into the composition of the eyelids are included between a soft external skin and a moist smooth internal surface, called the *conjunctiva palpebralis* or *propria*. (Fig. 13, *a, a*.) The latter is a membrane of the mucous kind, which, as we have already mentioned, after lining the interior of the lids, passes across in a loose circular scroll or fold to the sclerotic, and is reflected back again over the front of the eye, where it is called the *adnata* or *conjunctiva reflexa*. The name is derived from the junction thus effected between the ocular and palpebral surfaces. The outer skin of the eyelids, which is extremely soft and delicate, yet capable to a considerable extent of adapting itself to different degrees of extension, is loosely connected to the subjacent parts, except at the margin (where it adheres more closely), by a moist and abundant cellular tissue, entirely devoid of fat. By means of this connection, when the upper lid is raised and these under-lying parts are retracted under the edge of the orbit, the superfluous skin is gently drawn after them, and is disposed of conveniently under the brow (*supercilium*). The eye-lids meet, when closed, by two narrow flat surfaces, accurately applied to each other, called their *ciliary* or *tarsal* margins. These epithets are respectively derived from the *tarsi* or thin concave and crescentic shells of smooth and elastic cartilage which give form to the lids, and firmness and outline to their opposed edges (Fig. 10, *l*); and from the lashes or *cilia*, which grow in several rows at the margins of both lids, from their extreme outward verge, and in the direction of the flat surfaces. The angles in which the margins of the eye-lids meet towards the nose and temple are called the *canthi*. The outer canthus is kept in its place during the motions of the part by a tendinous expansion or *aponeurosis*, which, adhering to the thin crescentic edges of both tarsi on their outer or convex surface, attaches them, and most closely on this (the temporal) side, to the margin of the orbit. It is called the broad ligament of the tarsi. The nasal extremities of the tarsi are confined to the side of the nose by two slips which are given off behind from the tendon of the orbicular muscle.

Muscles of the Eyelids.—Immediately beneath the subcutaneous cellular tissue there is a broad layer of muscular fibres arranged elliptically round the transverse

assure of the eyelids, the disposition of which is well shown in the annexed figure. (Fig. 12.) The office of

Fig. 12.

View of the orbicular muscle of the left eyelid, as it appears when denuded of the integuments.

Fig. 13.

View of the internal surface of the right eyelid and lachrymal gland.

a, Conjunctiva propria, or mucous lining of the lid. The edges of the fold which passes to the sclerotic are seen loose and floating; b, lachrymal gland; c, orifices of the lachrymal ducts; d, tendon of the elevator muscle of the upper lid; e, parallel rows or clusters of the Meibomian glands; f, the semilunar fold of the conjunctiva at the inner canthus, which is the rudiment of the third eyelid of birds and other animals. Near f, on the right, are seen the two puncta lachrymalia.

this muscle, which is called the *orbicularis*, is to close the lids; and it is capable of acting under certain circumstances with great force. It is collected at the inner angle or canthus of the eye into a round short tendon, which is attached in that situation to the bone. Elsewhere it is connected with the skin, and aponeurotic expansions of the face and forehead. It is also connected with the *occipito-frontalis muscle*, which elevates the eye-brows, and with the *corrugator supercilii*, which wrinkles and knits them in the act of frowning. A person acquainted with mechanics will have no difficulty in perceiving the advantage derived from the oblique, or, as it might almost be called, the *incidental* action of the orbicularis in closing the lids, to the edges of which its fibres are parallel. A more direct application of muscular force would have been more powerful; but the actual arrangement secures a rapidity incomparably more conducive to the function of the eyelids, which is to cleanse and moisten the surface of the eye.

Llevator Palpebræ superioris. Below the orbicularis, in the upper lid, is the broad tendon of the muscle which elevates the upper lid. (Figs. 13, d; 10, g.) This muscle arises from the edge of the optic foramen, just above the rectus superior, and passing over it along the roof of the orbit, forms the thin tendon we have mentioned, which is inserted into the inner surface, or rather the thin upper edge of the tarsal cartilage. There is no such provision for depressing the lower lid, which is rendered unnecessary by its inferior extent. Moreover the muscle we have just described sufficiently answers the purpose, by pressing down the globe and causing it to slide a little forwards; as may

be easily felt if a finger be placed against the lower lid when the eye is closed, and suffered to remain while the upper lid is slowly raised.

Meibomian Glands. (Fig. 13, e e.) Between the tarsus of either lid and the conjunctiva are disposed numerous vertical rows of minute whitish grains, which appear through the semi-transparent mucous membrane, and occupy an elliptic space, taking both lids together, of about half an inch in width, exactly in front of the globe. These are called the Meibomian glands, from their discoverer. They secrete an unctuous matter which passes into tubes centrally placed in each row, and exudes from as many minute orifices on the ciliary margin of the lid. (Fig. 11, c.) There are about forty of these parallel clusters in the upper lid; in the lower there are not so many, nor are they individually so long. We need not dilate upon the use of this secretion, which often collects in a sensible quantity upon the edges of the lids during sleep, especially when the glandular action is excited by slight inflammatory irritation of the part. The palpebral conjunctiva, already described, immediately covers these glandular corpuscles. The *caruncle*, a small red prominence at the inner angle of the eye (Fig. 11, d) consists of a number of similar bodies.

Fig. 14.

a, The two puncta leading into the lachrymal ducts; b, the common entrance of these ducts into the lachrymal sac; c, the head of the lachrymal sac; d, the narrow portion of the sac, or membranous lachrymal canal passing downwards to the nose; e, the lachrymal gland.

Lachrymal Apparatus. (Figs. 13, 14.) At the upper and outer part of the interior of the eyelid are several minute orifices (Fig. 13, c), generally seven in number, arranged in a half-circle, which lead into the secretory ducts of the lachrymal gland. (Fig. 13, b; 14, e.) This is a white flattened lobulated body, of the size of a large bean, lodged in a depression just within the margin of the orbit, and covered externally by the orbicular muscle. The function of this gland is to secrete the tears; and is probably always going on, although not in a degree sufficient to be remarked, except in weeping, or when some foreign body or acrid vapour stimulates the surface of the eye, and by sympathy excites the gland to unusual secretion.

The involuntary actions of the rectus externus and inferior oblique muscles, to which we have alluded, are supposed to have a relation to the lachrymal secretion. In the act of winking, the eye-ball is thrown up in an outward direction, as it would be by the action of these muscles, which not only brings the cornea into the vicinity of the ducts, but makes pressure upon the gland, while it relatively increases the rapidity with which the lids, drawn in winking towards the fixed nasal tendon are swept over the surface of the globe. That there is such a movement, however produced is certain: the motion of the prominent cornea may be felt by the finger gently pressed upon the half-shut lid if it be completely and suddenly closed. The approximation of the lids towards the nose in winking is one of several provisions by which offending particles or superfluous fluids are brought to the inner canthus of the eye to be protruded or absorbed. In this situation there is a vacant space partly occupied by the caruncle, called the *lacus lachrymalis* (Fig. 11, d); it is a sort of reservoir or rather sink for the tears. Above and below, at the entrance to this space where the ciliary margins terminate, there is a small prominence on the inner edge of both, (Fig. 11, a; 14, a,) centrally punctured by small orifices. These are the *puncta lachrymalia*. Their *inward* aspect is well shown in Fig. 13. They are the excretories of the

eye; and their function is to absorb the fluids presented to them, and convey them by two converging canals (Fig. 4, a) to the *lacrimal sac* (Fig. 14, c), which they enter by a common orifice, (Fig. 14, b). This is a membranous bag about as large as a kidney-bean lodged in a groove in the lacrymal bone, behind the tendon of the orbicular muscle. The lacrimal sac entering a vertical channel in the bone at the end of the groove is narrowed into the *lacrimal canal* (Fig. 14, d), and passes directly downwards into the inferior meatus or chamber of the nose which it enters on the outer side by a slit in the mucous lining. It is not exactly understood in what way the puncta absorb,—whether by capillary attraction or by some vital force of suction. The side of the lacrimal sac is connected with the tendon of the orbicularis, which may aid in producing the effect by suddenly drawing its membranous surfaces apart. We all know the effect of repeated winking when the eyes are filled with tears.

Nervous and vascular constitution of the Eye.—Enough has been already said, for general information, with respect to the blood-vessels distributed to the eyeball, and it is not necessary to mention those which supply the appendages. With respect therefore to vascular arrangements we have only to add, that although there are abundant proofs of the existence of an active absorption within the globe, no lymphatic vessels especially destined to that function have been hitherto found in it. The optic or second cerebral nerve has been already described. All the straight muscles, with the exception of the rectus externus, the inferior oblique, and the levator palpebræ, are supplied by the third nerve. The fourth is wholly distributed to the trochlearis, and the sixth to the rectus externus. The orbicular muscle is supplied, like most of those of the face, by the *portio dura* of the seventh pair. All these, except the optic, are muscular or motor nerves. The fifth nerve supplies the whole organ in common with many other parts with ordinary sensation. Any account of the intricate nervous constitution of the iris would be here quite out of place. The third and sixth nerves are mainly concerned in it. Thus of the ten cerebral nerves, the second, third, fourth, and sixth are wholly, and the fifth and seventh partially distributed to the organ of vision; a fact which may give some idea of the elaborate organization and varied exigencies of the parts which compose it.

Comparative Anatomy of the Eye.—The eyes of insects and many other articulated animals, often consist (as we have mentioned before) of myriads of simple eyes grouped in one compound organ. The eye of the lobster is said to contain at least 5,000. Such organs are commonly placed one on each side of the head. The horny, rounded, naked, and transparent part seen externally represents the cornea. Its surface when viewed by the microscope displays as many hexagonal *facettes* as the organ contains simple eyes. Beneath each facette is applied the base of a minute transparent cone which constitutes the lens. These cones are arranged side by side with their acute angles directed inwards to the terminations of as many fibrils of an optic nerve. A choroid pigment is spread beneath, and often separates the lenticular cones. Vestiges of the aqueous and vitreous humours are also frequently present. When the eyes are simple, as in the spiders, there are generally several, from two to twelve, placed on different parts of the head and thorax. The lens is of the usual spherical shape, hard and sparkling, and highly refractive. In fish and other aquatic animals the lens is dense, hard, and spherical, to make up in refractive power for the density of the medium through which light reaches the eye. On the other hand the cornea is flat, and there is little aqueous humour. Such provisions would be of no value; for as the refractive power of water is the same as that of aqueous humour, rays penetrating the surface, however shaped, would pass on in the direction of their entrance. Fish are unprovided with eyelids, and the eyeball has but little independent motion. There is a red gelatinous structure near the optic nerve between the layers of the choroid, the use of which is unknown. It is called the choroid gland. The ciliary body and processes are generally absent; but there is a rudiment in the eyes of fish of that part called the *pecten* in birds.

The eyeballs of quadrupeds and other mammalia resemble the human organ in structure, and differ from it, but not essentially, in form. This is not the case with the appendages. One of the most remarkable additions commonly found to the parts we have described is that of a strong retractor muscle in the shape of a hollow cone at-

tached at the apex to the bottom of the orbit, and by the marginal base to the sclerotic, which it embraces, lying under the recti muscles. Its use is to draw back the eye in the orbit; a gesture which gives a very peculiar expression of hollowiness to the organ in beasts of prey.

We subjoin the following account of the eye of the common owl (*strix bubo*), chiefly for the purpose of explaining the *pecten* and the curious mechanism of the third eyelid, or *nictitating membrane*, in birds.

Fig. 15.

Horizontal section of the eye of an owl (*strix bubo*).
a a, Bony plates in the sclerotic; b, ciliary body; c, pecten.

Fig. 16.

Head of the same bird. A portion of the bony margin of the orbit having been removed, the eyeball is turned forward so as to show the recti and other muscles.

The general shape of the organ represented in the annexed figures resembles a bell. This arises from the disposition of a series of quadrangular bony scales (fig. 15, a) within the substance of the sclerotic, concave on their outer aspect, and overlapping and accurately fitted to each other. The rigidity thus communicated to the external case which contains the fluid media prevents their pressure from distending the eye into a spherical shape. The ciliary body (fig. 15, b) extends over the whole of this portion of the surface. A curious membrane called the *pecten* or comb (fig. 15, c), from some resemblance to that implement, projects through the choroid into the vitreous humour, and in some birds is attached to the side of the lens. In the owl it is comparatively short. It resembles a quadrangular piece of choroid folded backwards and forwards upon itself like the paper of a lady's fan. Of its use little is known. The foramen of Soemmerring, described in the account of the human retina, is thought to be a rudiment of the pecten. In birds the retina has generally the yellow colour seen only partially in man round the central spot misnamed a *foramen*.

At the back of the globe there are two muscles which originate from the sclerotic, and are applied to its curved surface round the entrance of the optic nerve (fig. 17, a). The larger represents rather more than half of what if completed would be a broad circular ring (fig. 17, b). It is called the *Quadratus*. Attached by its wider edge near the margin of this part of the sclerotic, its fibres converge to the narrower edge, and terminate in a narrow tendon (fig. 17, c), perforated through its whole length like the hem of an apron. The second smaller muscle, called the *pyramidalis* from its shape (fig. 17, d), at an opposite part of the circumference. Its fibres converge, and are fixed into a long round tendon (figs. 17 and 18, e), which passes through the loop or *hem* (c) of the *Quadratus*, and hence turning over the edge of the broad part of the sclerotic, is continued along the

Fig. 17. Posterior view of the sclerotic of the same bird, showing the muscles of the nictitating membrane. a. Optic nerve; b, quadratus muscle; c, its looped tendon; d, pyramidalis muscle; e, its tendon—having passed through the loop in that of the quadratus—turning over the edge of the sclerotic.

Fig. 18. Lateral view of the same part. e, The tendon of the pyramidalis, attached to the concave part of the sclerotic by tendinous loops, and passing round a prominent bony tubercle, is seen inserted into the nictitating membrane at f.

surface of its bell-shaped portion, where it passes through several thread-like loops or pulleys which keep it applied to the concavity, and round a bony point which projects from the surface, and is attached near the edge of the cornea to the edge of an elastic fold (fig. 18, f) of the conjunctiva which is called the third eyelid or nictitating (i. e. *winking*) membrane. It will be easily seen by the help of the figures, from this description, that the effect of the simultaneous contraction of the two muscles will be to draw the membrane with great rapidity, making it sweep over the surface of the cornea. It returns by its own elasticity with nearly equal quickness. A bird may be seen to use this mechanism twenty times in a minute; in fact, as often as it may be necessary to cleanse the surface of the eye. The colour of the membrane is milky; and it is seen to pass from the upper and inner to the outer and lower corner of the eye with the speed for which the act of *winking* is proverbial. There is a rudiment of this third eyelid in the human organ. It is a small crescentic fold of conjunctiva situated at the inner canthus behind the caruncle. (Fig. 13, f.) The *haw* is also a rudiment of it, in the eyes of quadrupeds; it is occasionally forced out by the pressure of the globe against the nasal side of the orbit, being unprovided with muscles.

Seat of Vision.—The retina in one sense is not the seat of vision. It is necessary to the perception that the impression of light should be received on another part not endowed with sensibility, namely the surface of the choroid; and that the vibration or other effect thus impressed should be transferred to the retina in front of that surface; for where the choroid is deficient at the entrance of the nerve, there is no perception of light. This may be easily shown by a very common and conclusive experiment. If two discs of white paper be fixed upon a wall at the distance of two feet from each other, and an observer, having closed one eye (the left), continues to gaze attentively at the left-hand disc, at the same time slowly retreating from the wall, he will for a time continue to see them both; the rays from the right-hand object entering of course laterally, and impinging upon the retina nearer and nearer to the entrance of the nerve as he goes backward. At length when he has reached the distance of about 6½ feet from the wall, the right-hand object will suddenly disappear, and remain invisible (the observer still retreating) till he has gained a distance of about eight feet. During this period the spectrum has been passing over the circular aperture in the choroid through which the nerve enters. The insensible portion of the retina is found to extend horizontally over five degrees and a half of the angular range of vision. The eyes are generally unequal in power, and the experiment succeeds best in the weaker organ, in which the obscuration is more sudden and complete. In the experiment previously mentioned, showing the distribution of the central artery of the retina, the surface of the choroid is faintly illuminated through the transparent nervous expansion by what is called the *dispersion* of part of the light admitted through the pupil; but the rays thus scattered are locally intercepted by the opaque blood contained in the minute branches of the artery; hence, after several repetitions, when the eye has become accustomed to neglect the taper, and attend to the fainter internal illumination, the *shadow* of the vascular net-work upon the choroid becomes perceptible in dark lines.

Apparent direction of objects seen obliquely.—A body in motion, as a ball, striking the surface of another, impresses it in a line perpendicular to the surface at the point of impact. This rule appears to hold good with respect to the action of light upon the retina. Indeed if impressions of any kind be made upon it, the sensation is that of light, and the direction suggested is that of a line joining the centre of the sphere of which the retina forms a part with the point impressed,—in other words, a line perpendicular to it. This may be shown in several ways: if we excite the nerve by pressing far back upon the eyeball with the finger nail, especially if the eye be closed or light otherwise excluded, a bright ring appears to be seen in a diametrically opposite quarter.

Erect Vision.—If the sclerotic and choroid be carefully removed under water from the back of an eye, an inverted picture of any object held before the cornea is seen upon the now milky surface of the retina. Hence the celebrated question raised in the age of philosophical barbarism, how is it that we see objects erect when the image on the retina is inverted? The question is an idle one, which is perhaps hardly worth answering. The mind judges of the apparent place of objects or of parts of an object by the *direction* of the impressions made upon the retina, not by the part of it which may happen to be affected by these impressions. The shadow of the central artery is an example of an impression necessarily received always upon the same parts; yet the *apparent*, or in other words the *relative*, place of the shadow will be found to vary with every movement of the eye.

Single Vision.—Another question, not so trivial as the last, has been raised with respect to single vision with *two* eyes, as the impression must be twofold. But perhaps it will not require an answer if the reader will try to imagine double vision of the same object, or rather of the same *point*, for the question resolves itself into that. Let the two supposed images approach each other, still remaining double, till they are in contact. Another step in the imaginary approximation, and they are one. The truth is, that both eyes see the object in the same place; and as two images, no more than two material substances, can occupy the same place at the same time, the impressions coincide and are single.

Diseases of the Eye.—We shall content ourselves in speaking of the diseases of the eye, with a few remarks which may serve as an index to the separate articles upon the most important of those diseases.

Blindness may be produced in various degrees by injury or disease of the retina, as by lightning. Such affections are technically known as *amaurosis*, but will be mentioned under the more familiar title of *GUTTA SERENA*. The sight may also be lost by anything which destroys the transparency of any of the refracting media. [CATARACT; GLAUCOMA; LEUCOMA.] Closure of the pupil is of course attended with loss of vision. It arises from diseases of the iris and may sometimes be remedied by an operation. Information with respect to inflammations and other diseases of the iris, sclerotic, and choroid, will be found under *GOUT*; *IRITIS*; *PUPIL*, *ARTIFICIAL*; *RHEUMATISM*; *SYPHILIS*. Inflammatory and ulcerative affections of the conjunctiva, whether of the eye or lid, are called *OPHTHALMIA*. The diseases of the lachrymal organs, and a peculiar paralytic affection of the muscle which elevates the upper eyelid will be mentioned respectively under the heads of *FISTULA LACHRYMALIS* and *PTOSIS*. Almost all affections of the eye, whether they result from injury or spontaneously, are liable to be extended from one eye to the other, so close is the sympathy between these organs. When the contents of the eyeball have been by any means evacuated, which may arise either from accident or disease, or operations which disease sometimes renders necessary, the sclerotic shrinks into a tubercle at the bottom of the eye, which produces of course a very unsightly effect, as well as no little inconvenience. It is common in these cases to resort to the introduction of what is called an artificial eye, consisting of a smooth shell of glass or enamel, suited in size and shape to the circumstances of the case, and coloured in exact imitation of the remaining organ. It is difficult when this is well made to distinguish it from a natural eye, and the illusion is much more complete from the circumstance that the muscles, still attached to the shrunk sclerotic, are capable of moving the artificial eye in correspondence with the other to an extent which would hardly be believed.

EYE (in Optics). [LIGHT; OPTICS.]

EYE, in horticulture, the name technically given to the bud of a plant.

EYE. [SUFFOLK.]

EYEMOUTH. [BERWICKSHIRE.]

EYLAU, more properly **PREUSSISCH-EILAU** (Prussian Eilau), is a circle in the Prussian administrative circle of Königsberg, having an area of about 460 square miles, which is partially wooded, is well cultivated, and has good pasture land and productive fisheries on its western boundary, the Frische Haff. Population about 37,000.

Preussisch-Eilau, the chief town, built in 1336, is situated on the Pasmer, in 54° 25' N. lat. and 20° 35' E. long. It has an old castle, a church, about 200 houses, and about 2150 inhabitants, who manufacture woollen cloths, hats, leather, &c. The name it bears has been given to it in order to distinguish it from Deutsch-Eilau, a town in the Prussian administrative circle of Marienwerder. An obstinate engagement took place near Preussisch-Eilau between the French forces under Napoleon and the Russian under Bennigsen on the 7th and 8th February, 1807. After the combatants had lost 30,000 in killed and 50,000 in wounded, they withdrew their troops from the field.

EYRE (from the old French *eyre*, a journey), the court of the justices itinerant who were regularly established, if not first appointed by the parliament of Northampton, A.D. 1176—22 Hen. II.—with a delegated power from the king's great court, or Aula Regia, being looked upon as members thereof. They were first appointed to make their circuit round the kingdom once in seven years, but by Magna Charta, c. 12, it was provided that they should be sent into every county once a year. Their jurisdiction and mode of proceeding are laid down 4 Inst., 184. These judges itinerant have been long superseded by the modern justices of assize. There was also a court so called which was held before the chief justices of the several forests, under the old Forest Laws. These courts were instituted A.D. 1184 by Hen. II., and were formerly very regularly held; but the last of any note that was holden was in the reign of Charles I., before the Earl of Holland, the rigorous proceedings at which are reported by Sir William Jones (Jones, i. 266). Charles I. endeavoured to make these odious forest laws a source of revenue independent of the parliament; and though, after the Restoration, another Court of Eyre was held before the earl of Oxford (North's *Life of Lord Guildford*, 45), it was merely *pro forma*, and since the Revolution, 1688, they have fallen into total disuse. There are still two officers appointed by letters patent (4 Inst. 291), who are called Chief Justices in Eyre, the one south, the other north, of Trent, whose deputies perform some trifling and harmless functions connected with the royal forests in their respective districts:—the offices themselves are sinecures.

EZEKIEL, the Book of the Prophet, is a canonical book of the Old Testament, divided, in our English version, into 48 chapters, and placed next after Jeremiah's Book of Lamentations, and before the book of Daniel. Ezekiel was partially contemporaneous with Jeremiah, and is one of the prophets called 'The Greater,' a distinction which relates to the comparative magnitude and importance of their books. He was a priest, the son of Buzi (i. 3), and, according to the account of his life ascribed (erroneously) to Epiphanius, he was born at a place called Saresa. In the first Babylonian captivity he was carried away by Nebuchadnezzar into Mesopotamia, with the Kings Jeconiah and Jehoiachin, and all the principal inhabitants of Jerusalem, who were stationed at Tel-abib (iii. 15) and at other places on the river Chebar (i. 1, 3), the Chaboras of Ptolemy, which flows into the east side of the Euphrates at Carchemish, about 300 miles north-west of Babylon. He is stated to have commenced his prophesying in the fifth year of his captivity (i. 2), about B.C. 598, and to have continued it during more than 22 years, that is, until the fourteenth year after the destruction of Jerusalem by Nebuchadnezzar. The pseudo-Epiphanius says that Ezekiel, on account of his refusal to adopt the Chaldean idolatry, was put to death by the Jewish prince or commander of the captives. Rabbi Benjamin of Tudela states that his tomb is between the Euphrates and the Chebar, in a vault built by King Jehoiachin, and that within it the Jews keep a lamp perpetually burning. The same writer asserts, with equal appearance of traditional falsehood, that the Jews possess the book of Ezekiel in the original autograph, which they read every year on the great day of expiation. Greatly inconsistent with such venera-

P. C., No. 613.

tion is the fact related by Calmet, that the Jews speak of this prophet very contemptuously as having been Jeremiah's servant boy, and the object of popular ridicule and railery, whence his name 'son of Buzi' (בן בוז, contempt). Josephus speaks of two books of Ezekiel, but commentators understand him to mean the present book, divided at the end of chapter xxxix., for the nine remaining chapters are distinctly different with regard both to subject and style. The first 39 chapters are occupied with the prophet's highly poetic and impassioned announcement of God's wrath and vengeance against the rebellious idolatry, perverseness, and sensuality of the Jews, as well as against their enemies, the surrounding nations. All this portion is replete with dreadful pictures of the calamities of war—of ruin, desolation, death, and destruction—slaughter, pestilence, famine, and every imaginable state of misery; but in the nine chapters of the latter portion the prophet describes, in a more prosaic style, his visions of the new temple and city of Jerusalem. In visionary presence he walks about the holy metropolis of Judæa as raised from its ruins in which it was left by the Chaldean conqueror, and restored to the splendor which it displayed in the reign of Solomon. He measures and observes minutely all the dimensions of the Temple and city; gives directions for the celebration of sacrificial rites, feasts, and ceremonies; partitions the country among the several tribes; and enumerates the duties of priests, king, and people. Dr. A. Clarke, in his edition of the Bible, gives a plate of the Temple according to Ezekiel's description, and a map of Judæa as allotted by this prophet to the different tribes. A full and particular analysis of the contents of the whole 48 chapters is given in Mr. Horne's 'Introduction to the Bible.' The following is a brief and general survey. Chapters i. to iii. (and see chap. 10) describe the vision of the wheels and cherubim, called 'Jehovah's Chariot,' and the prophet's reception of the divine instructions and commission. Chapters iv. to xxiv. reiterate reproaches and denunciations against the Israelites and their prophets, announcing, in various visions and parables, the numerous calamities about to come upon them as a punishment of their rebellious idolatry and depravity. The species of idolatry adopted by the Jews in preference to the religious system of Moses appears, by the declarations of Ezekiel and the other prophets, to have been Sabism, or the worship of the sun on high places planted with trees. (See chapters viii. xiv. xvi. xvii. xx. xxviii. &c.) Dr. A. Clarke quotes Palladius 'De Re Rustica' to show that the 'tile' (iv. 1) on which the prophet portrayed the city of Jerusalem was a brick, two feet long and one foot broad, and he supposes that the mimic apparatus of war (v. 2) were made by the prophet with clay. The 390 years signified by the prophet's lying as many days (v. 4 and 5) on his left side, are said by biblical chronologists to be the period from B.C. 970 to 580; and the 40 years signified by his lying 40 days on his right side (v. 6) is the period from B.C. 580 to 540. Concerning the fact of baking bread with human and other excrement (v. 12 and 15), see Calmet's Dict. by Taylor, vol. iii.; Fragments, p. 9, &c., where the oriental custom of using dung for fuel is explained. Chapters xxiv. to xxxii. declare the dreadful judgments of God against the enemies of the Jews, namely, the surrounding nations of Ammonites, Moabites, Edomites, and Philistines; against the cities of Tyre and Zidon; and against all the land of Egypt. It may suffice to remark here that all these manifestations of the divine anger towards the nations of Palestine, Phœnicia, and Egypt, relate to the slaughter and devastation which attended the conquests of Nebuchadnezzar, king of Babylon; and that in order properly to understand the prophet's descriptions, it is necessary to consider particularly the circumstances and character of the Jews, and all the collateral history of the period. Of these an abstract is given by Bishop Newcome in the Introduction to his Translation of Ezekiel, and more particular and critical accounts are supplied in the scholia and prolegomena of the various commentators named at the end of the article.

Chapters xxxiii. to xxxvii. are occupied with declarations of the justice and forgiveness of God to the repentant—the fall of Jerusalem—a severe rebuke (chap. xxxiv.) of the avarice, idleness, and cruelty of the shepherds or priests of Israel—and consolatory promises of the people's restoration and return to Palestine. Chapters xxxviii. and xxxix. contain the Prophecy of Gog and Magog; and the nine concluding chapters, as already

stated, contain the prophet's visions of the temple and city of Jerusalem—their dimensions, structure, embellishments, &c.—the ceremonial arrangements of the hierarchy, and the allotment of the land of Judaea among the several tribes on their return from captivity. The subject matter of Ezekiel is, for the most part, identical with that of his contemporary Jeremiah, and much similarity is observable in their declarations. The conquests and devastations of Nebuchadnezzar form the principal theme of each; but Ezekiel views them chiefly as affecting Israel, while Jeremiah describes them with especial reference to Judah. Both declaim with vehement indignation against the depravity of the priests, and against the 'lying divinations' of the prophets who sought to induce the people to shake off their Babylonian slavery. (Compare Jeremiah, chapters xxiii., xxvii., xxviii., xxix. with Ezekiel, chapters xiii., xxxiv.) Parts of the book of Revelations may be compared with some portions of Ezekiel: Rev. iv. with Ezek. i. and x., respecting the cherubim with wings full of eyes; and Rev. xl, xxi, xxii, with Ezek. xl. to xliii., describing the New Jerusalem.

That Ezekiel is a very obscure writer is asserted by all who have attempted to explain his prophecies. The ancient Jews considered them as inexplicable, and the council of the Sanhedrim once deliberated long on the propriety of excluding them, on this account, from the canon (Calmet, præf. ad Ezech.); but to prevent this exclusion Rabbi Ananias undertook to explain completely the vision of Jehovah's chariot (i. and x.). His proposal was accepted by the council, and in order to enable him to accomplish his task without interruption they furnished him with 300 barrels of oil to supply his lamp during the course of his studies. Dr. Adam Clarke relates this marvellous anecdote in his Comment on the Bible, and in repeating it in his 'Succession of Sacred Literature,' he says the quantity of oil was 300 *tons*. It was also alleged as a reason for rejecting Ezekiel from the canon that he teaches, in direct contradiction to the Mosaic doctrine, that children shall not suffer punishment for the offences of their parents (xviii., 2-20). (See Hueti 'Demonstratio Evang.,' prop. 4, de Prophet. Ezech.) St. Jerome considers Ezekiel's visions and expressions very difficult to be understood, and says that no one under the age of 30 was permitted to read them. (Hieron. præf. in lib. Ezech.) It is astonishing, says Dr. Clarke, how difficult it is to settle the text by a collation of MSS.; and, in accordance with the opinion of many other interpreters, he adds, that much remains to be done to restore the original Hebrew text to a state of purity. Michaelis, Eichhorn, Newcome, and many other commentators, have written copiously on the peculiarities of Ezekiel's style. Grotius (Præf. ad Ezech.) speaks of it with the highest admiration, and compares the prophet to Homer. Michaelis admits its bold and striking originality, but denies that sublimity is any part of its character, though the passion of terror is highly excited. Bishop Lowth (Prælect. Heb. Poet.) regards Ezekiel as bold, vehement, tragical; wholly intent on exaggeration; in sentiment fervid, bitter, indignant; in imagery magnificent, harsh, and almost deformed; in diction grand, austere, rough, rude, uncultivated; abounding in repetitions from indignation and violence. This eminent judge of Hebrew literature assigns to the poetry of Ezekiel the same rank among the Jewish writers as that of Æschylus among the Greeks; and in speaking of the great obscurity of his visions, he believes it to consist not so much in the language as in the conception. Eichhorn (the peculiar character of whose criticism we have noticed under that article) regards the Book of Ezekiel as a series of highly-wrought and extremely artificial poetical pictures. No other prophet, he says, has given such freedom to imagination. 'Every thing is dressed in fables, allegories, and visionary poetry. He is so used to ecstasies and visionaries that he adopts their appropriate language when he has no vision to describe.' In accordance with the doctrines of the German rationalism he considers the prophecies as nothing more than the poetical fictions of a heated oriental imagination of a similar nature with the poetry of the book of Revelations. A remarkable characteristic of the poems of Ezekiel, observes the same critic, is the painful detail and minuteness of his descriptions. He considers the prophet as a great original poet, but from his turgid and hyperbolic style he assigns him to the *silver* age of Hebrew literature.

In rude indignation, violent energy, and disregard of de-

licacy and disguise, the denunciations and descriptions of Ezekiel are said by Dr. Clarke to resemble the satires of Juvenal. The same character of thought and expression is exhibited in the writings of the two other Greater Prophets, Isaiah and Jeremiah. (Compare Ezek. xvi. 4 to 37; xxiii. 17-21; Isaiah, xxviii. 7, 8; xxxvi. 12. Ezekiel's remarkable prophecy of Gog and Magog, xxxviii. and xxxix., has always been a subject of learned controversy, and the explanations are nearly as numerous as the expositors. However, only two appear to possess any considerable probability. Gog, according to the first, was Antiochus Epiphanes; according to the second, he was Cambyse, king of Persia. In modern times it has been elaborately shown by Mr. Granville Penn that Gog is to be recognized in the person of the Emperor Napoleon, and Magog in the people or nation of France. His treatise on the subject, entitled 'The Prophecy of Ezekiel, concerning Gog, the last tyrant of the church,' &c., published in 1815, is a production replete with curious learning and argumentative ingenuity.

The most learned and elaborate commentary on Ezekiel is by two Spanish Jesuits, Pradus and Villalpandus, in 3 vols., folio.)

EZEKIEL. [DRAMATIC ART AND LITERATURE.]

EZRA, the Book of, is a canonical book of the Old Testament, placed next after the second book of Chronicles and before the book of Nehemiah, and, in the English version is divided into ten chapters. By Jews and Christians it has generally been attributed to the priest whose name it bears, chiefly because throughout chapters viii. and ix. the actions of Ezra are related in the first person. He is supposed to have written the two books of Chronicles and the book of Esther. It is remarkable that the first two verses of Ezra and a part of the third form the conclusion of the second book of Chronicles. [CHRONICLES.] Ezra, Esdras, or Esdra in the Hebrew is עֶזְרָא, *azra*, signifying 'help' or 'succour.' His genealogy up to Aaron is given in chap. vi. 1-5. In verses 6 and 11 he is said to have been a priest and ready scribe of the words of the law of Moses; and he appears to have been an able and important agent in the principal events of his age and nation. The prophets Haggai and Zechariah were contemporary with Ezra. (Compare Hagg. i. 12, Zech. iii. 4, and Ezra v.) There are four books of Ezra so called; namely, the canonical one bearing his name, the book of Nehemiah, which by the ancient Jews and by the Greek and Roman churches is considered as the second book of Ezra, and two books of Ezra or Esdras in the Apocrypha. The first of the two apocryphal books contains the substance of the canonical one, with many circumstantial additions, and in the Greek church it is read as canonical; but the second exhibits a more decided appearance of fiction, and by no church is regarded as a work of inspiration, though it is cited by several of the ancient fathers. The first six chapters of the canonical book are regarded by some biblical critics as improperly ascribed to Ezra, for between the event with which the seventh chapter commences, that is, the commission from Artaxerxes Longimanus, in the seventh year of his reign, to Ezra to go up to Jerusalem, B.C. 458, and that which terminates the sixth chapter, namely, the completion of the second temple, in the sixth year of the reign of Darius Hystaspes, B.C. 516, there is a chasm of fifty-eight years. The events recorded in the whole ten chapters of the canonical book of Ezra embrace a period of ninety-one years, that is, from the edict of Cyrus issued in the first year of his reign, B.C. 536, for the return of the captive Jews to Jerusalem, to the termi-

nation of Ezra's government by the mission of Nehemiah to Jerusalem from Artaxerxes Longimanus, in the twentieth year of his reign, B.C. 445. As Daniel's seventy prophetic weeks commence at the going forth of the edict of Cyrus to Zerubbabel or of that of Artaxerxes to Ezra, these events have been the subject of much critical investigation among biblical critics.

The contents of the first six chapters are briefly as follow. Chap. i. gives an account of the proclamation of Cyrus concerning his release of the captive Jews, permitting them to go from Babylon to Jerusalem to rebuild the temple; of the restoration of their property, sacred vessels and utensils; and of presents made by the Chaldeans of money and various provisions. Chap. ii. states the numbers of each of the families composing the multitude which returned to Judæa with Zerubbabel, and the number of their beasts of burden. All this account, excepting some of the numbers, is repeated word for word in the seventh chapter of Nehemiah, beginning at ver. 6. In ver. 64 and 65 of Ezra, the total number of the people is said to have been 42,360, which appears not to agree with the preceding particulars, since the addition of these produces only 29,818, that is, a deficiency of 12,542. The numbers given in Nehemiah occasionally differ very widely from those in Ezra: for instance, the children of Azgad are said in Ezra (ii. 12) to have been 1222; but in Nehemiah (vii. 17) they are said to have been 2322, or 1100 more. Nehemiah repeats precisely the total given by Ezra, 42,360; but the addition of Nehemiah's particular numbers makes 31,089, or a deficiency of 11,271. The numbers of horses, 736, mules 245, camels 435, and asses 6,720, exactly agree in the two accounts; but in Ezra, ver. 69, the chief fathers give to the treasury 61,000 drams of gold; in Nehemiah, ver. 71, they give only 20,000. Chap. iii. records the events of setting up the altar at Jerusalem and re-establishing the Jewish sacrificial worship. An account of the interruption of the building of the Temple by the decree of Artaxerxes, and its completion by a subsequent decree of the same monarch, with transcripts of the documents written on these occasions, occupy chapters iv., v., and vi. Chapters vii. and viii. contain an account of Ezra's commission from Artaxerxes to undertake the government of Judæa, his preparations and reception of presents for his journey thither, with a multitude of Jews, who it appears still remained in Babylon after the return to Judæa of the multitude under Zerubbabel; an enumeration of the people and families who returned, and the weight of gold and silver contributed by the king, his councillors, and the Israelites, for the use of the Temple at Jerusalem (viii. 25-28). The value of these presents amounts to 803,600*l*. Chapters ix. and x. relate the proceedings of Ezra in separating from their wives and children all the Israelites who had married women from among the surrounding nations, and thus 'mingled the holy seed with the abominations of the Gentiles.' Ezra (x. 3, 5, 19, 44) made all the Israelites who had 'strange wives and children' swear, and give their hands, that they would put them away, which accordingly was done. The latter half of the last chapter contains a long list of the husbands and fathers who were the subjects of this national renovation. The part from iv. 8 to vii. 27 is written in the Chaldee idiom, the rest in Hebrew. The period to which the four last chapters relate, comprising the Jewish history from B.C. 458 to B.C. 445, is coeval with the age of Pericles. The subject matter of the book of Nehemiah being identical with that of Ezra, the collation of the two affords a mutual illustration. Chapter viii. of Nehemiah relates circumstantially the fact of Ezra's solemn reading and exposition of the law to the assembled Israelites, who, according to Dr. Prideaux, were taught the signification of the Hebrew words by means of Chaldaic interpreters (8); for, since their seventy years' captivity in Babylon, the Chaldee instead of the Hebrew had become their vernacular language. (Dean Prideaux's *Connection*, fol., p. 263.) The critical arguments adduced in opposition to the opinion that the Israelites lost the Hebrew language, and understood only the Chaldean, are well exhibited in Dr. Gill's learned '*Dissertation on the Antiquity of the Hebrew Language*,' 8vo., 1767. The two principal undertakings of Ezra were—1. The restoration of the Jewish law and ritual, according to the modes observed before the captivity; and 2. The collection and rectification of the Sacred Scriptures. On account of these important services the Jews regarded him as a second Moses. It was

commonly believed by the ancient fathers of the Christian church that all the Sacred Scriptures of the Jews were entirely destroyed in the conflagration of the temple and city of Jerusalem by the king of Babylon, and that, on the return of the Jews from the Chaldean captivity, these writings were wholly reproduced by a divine inspiration of Ezra. (See Irenæus, *Adversus Hæreses*, l. iii. c. 25; Tertullian, *De Habitu Mulierum*, c. iii.; Clemens Alexandrinus, *Strom.* i.; Basil, in *Epist. ad Chilonem*.) The following passages from the second Apocryphal book of Ezra, xiv. 26, 45, 46, 47, appear to sanction this opinion. 'Behold, Lord,' says Ezra, 'I will go as thou hast commanded me, and reprove the people. The world is set in darkness, and they that dwell therein are without light, for *thy law is burnt*; therefore no man knoweth the things that are done of thee; but if I have found grace before thee, send the Holy Ghost into me, and I shall write all things that have been done in the world since the beginning, which were written in the law; And God said, Go, prepare to write swiftly, and when thou hast done, some things shalt thou publish, and some things shalt thou show secretly to the wise.' The learned Dr. Prideaux (*Connection*, p. 260, fol.) remarks, that 'in the time of king Josiah (B.C. 640), through the impiety of the two preceding reigns of Manasseh and Ammon (a period of sixty years), the book of the law was so destroyed and lost; that, besides the copy of it which Hilkiah, the high-priest, accidentally found in the Temple (2 Kings xxii. 8, &c.; 2 Chron. xxxiv. 14, &c.), there was then no other to be had; for Hilkiah's surprise in finding it, and Josiah's grief in hearing it read, do plainly show that neither of them had ever seen it before; and if this pious king and the high-priest were without it, it cannot be thought that any one else had it.' If this were the authentic copy laid up before the Lord in the Temple, it was burned, as believed by all Jewish and Christian writers, in the burning of the Temple, fifty-two years afterwards, by Nebuchadnezzar. Dr. Prideaux takes it to be implied in several passages which he cites that, from the copy accidentally found by the high-priest Hilkiah, some transcriptions were made previous to the destruction of the Temple, and that from these scattered copies Ezra formed his improved edition of the sacred text. In common with most other modern divines, he rejects the opinion of the fathers respecting the restoration of the Scriptures by a new revelation to Ezra, observing (p. 261) that 'it would very much shock the faith of many should it be held that the sacred writings owe their present being to such a revival; it being obvious for sceptical persons to object that he who is said thus to have revived them forged the whole.' All, he continues, that Ezra did was—'he got together as many copies of the sacred writings as he could, and out of them all he set forth a corrected edition, in which he took care of the following particulars:—1. He corrected all the errors introduced into these copies by the negligence or mistakes of transcribers; for, by comparing them, he found out the true reading, and set all to rights. 2. He collected together all the books of which the sacred Scriptures did then consist, disposed them in proper order, and settled the canon of scripture up to that time.' The Jewish writers state that the canon was decided by a congress of 120 elders under the presidency of Ezra; but since they mention as members of it, not only the contemporaries of Ezra, as Daniel, Shadrach, Meshech, and Abednego, but the high-priest Simon the Just, who lived 250 years later, it is evident that they mean the number of those who successively arranged and rectified the canonical books. Ezra divided all the books he collected into three parts; the law, that is, the Pentateuch; the prophets, containing all the historical and prophetic books; and the hagiographa, which comprised all the writings not included in the two other divisions. (Josephus, *advers. Apion.*) He divided the Pentateuch into 54 sections, one of which was read every Sabbath; and, according to the Jewish authorities, he was also the author of the smaller divisions called Pesukim, or verses, and of the various readings and suggested corrections inserted in the margins of the Hebrew copies. These, called Keri Cetib (that which is read and that which is written), appear however in the books attributed to Ezra himself. (On these particulars see the remarks of Prideaux; Buxtorf, *Vindiciæ Veritatis Hebraicæ*, par. ii. c. 4; Walton's *Prolegom.*, viii. § 18; and Dr. Gill's *Dissertation on the Hebrew Language*.) Most biblical critics state that Ezra changed the ancient names of places for those by which these places were known

in his time, and some say that he wrote out all the Scriptures in the Chaldee character, which alone was used and understood by the Jews after the Chaldean captivity. Whether Ezra added the vowel-points, and whether they were invented by the Masorite grammarians at a period far posterior to the rise of Christianity, are subjects of great controversy among Hebrew critics. A concise and able view of this dispute is contained in Houbigant's 'Racines Hebraïques,' 1732. The Jewish commentators assert that all the rules and observances preserved by tradition from the time anterior to the captivity were carefully collected by Ezra, and that having reviewed them, those which he sanctioned by his authority henceforth constituted the oral law, in contradistinction to that which is written; the church of Jerusalem, like the church of Rome, regarding Scripture and

tradition of equal authority, and believing the latter to be highly necessary for clearing the obscurities, supplying the defects, and solving the difficulties of the former. (See the Rabbinical authorities cited by Dr. Prideaux.) It is a theory suggested by this learned divine, and since adopted by many others, that all the numerous passages of the Hebrew Scriptures which involve chronological inconsistencies were interpolations made by Ezra, and that this is the only possible way to solve the difficulties which arise from considering the several books as the productions of the persons to whom they are commonly ascribed. The Book of Ezra, with the two Books of Chronicles, Nehemiah, Esther, and Malachi, are supposed by Dr. Prideaux to have been added to the sacred canon by the high-priest Simon the Just, in the year B.C. 150.

F.

F is a labio-dental aspirate bearing the same relation to the other labio-dental aspirate V which the letters called *tenues*, *p*, *k*, *t*, bear to the *mediae*, *b*, *g*, *d*. It occupies the sixth place in the English as in the Latin alphabet, thus corresponding with the digamma of the old Greek alphabet, and the *vau* of the Hebrew. In power and form it is likewise closely related to those two letters. [ALPHABET.]

The letter F is interchangeable with the other aspirates *ch* or *h* and *th*, and also with the lip-letters *p* and *b*.

1. F in Latin corresponds to *h* in Spanish, as Latin *formoso*, beautiful; Spanish *hermoso*; Latin *femina*, female; Spanish *hembra*; Latin *fugere*, fly; Spanish *huir*. Other examples may readily be found in a Spanish Dictionary under the letter *h*. The same change prevailed between the Latin of Rome and the Sabine dialect of that language.

2. F in Latin corresponds to *th* in Greek, as Latin *fera*, a wild beast; Greek *θηρ*. Latin *fle*, weep; Greek *θρη*, as seen in *θρηνη*. Indeed this interchange prevailed among the dialects of the Greek language itself as in *οψαπ* and *οψαφ*; *θαπ* and *θλαπ*; *θαβ* and *θλαβ*. This however seems to depend on the proximity of the letters *l* and *r*. (See L.)

3. F in Latin corresponds to *b* in German and English, as *frangere*, *brech-en*, to break; *frater*, *bruder*, brother; *fago*, *buche*, beech, &c.

4. F in English and German to *p* in Latin, as *pell*, fell (comp. *fellmonger*); *ped*, *fuss*, foot; *pugna-re*, *fechten*, to fight, &c.

F, in Music, is the fourth note, or degree, of the diatonic scale, answering to the *fa* of the Italians and French. It was originally used as the base clef, to which it gives a name; but while serving as a sign, time has gradually altered its form into that which as a clef it now takes. This letter is also an abbreviation of the Italian word *Forte*, strong, or loud. The double F signifies the superlative of *Forte*,—*Fortissimo*.

FABA'CRÆ. [LEGUMINOSÆ.]

FABIIUS MAXIMUS and the FABII FAMILY. The Fabii were a numerous and powerful gens or patrician house of ancient Rome, which became subdivided into several families or branches distinguished by their respective cognomina, such as Fabii Maximi, Fabii Ambusti, Fabii Vibulani, &c. They were of Sabine origin, and settled on the Quirinal from the time of the earliest kings. After the expulsion of the Tarquinii, the Fabii as one of the older houses exercised considerable influence in the senate. Cæso Fabius being Quæstor with L. Valerius, impeached Spurius Cassius in the year of Rome 268, 486 B.C., and had him executed. It has been noted as a remarkable fact, that for seven consecutive years from that time, one of the two annual consulships was filled by three brothers Fabii in rotation. Niebuhr has particularly investigated this period of Roman history, and speculated on the causes of this long retention of office by the Fabii as connected with the struggle then pending between the patricians and the plebeians, and the attempt of the former to monopolize the elections. (*History of Rome*, vol. ii., *The Seven Consulships of the Fabii*.) One of the three brothers, Quintus Fabius Vibulanus, fell in battle against the Veientes, in the year 274 of Rome. In the following year, under the consulship of Cæso Fabius and Titus Virginii, the whole house of the Fabii proposed to leave Rome and settle on the borders of the territory of Veii, in order to take the war against the Veientes entirely into their hands. After performing solemn sacrifices, they left Rome in a body, mustering 306 patricians, besides their families, clients, and freedmen, and encamped on the banks of the Cremera in sight of Veii. There they fortified themselves, and maintained for nearly two years a harassing warfare against the Veientes and other people of Etruria. At last in one of their predatory incursions they fell into an ambuscade, and fighting desperately, were all exterminated. (Livy, ii. 48. 50; and Niebuhr's *History*, on the *Veientine War*.) One only of the house, Quintus Fabius Vibulanus, who had remained at Rome, escaped, and became the parent stock of all the subsequent Fabii. He was repeatedly consul, and was afterwards one of the de-

cemviri with Appius Claudius for two consecutive years, in which office he disgraced himself by his connivance at the oppressions of his colleague, which caused the fall of the decemvirate. In subsequent years we find several Fabii filling the consulship, until we come to M. Fabius Ambustus, who was consul in the year 393 of Rome, and again several times after. He fought against the Hernici and the Tarquinians, and left several sons, one of whom, known by the name of Quintus Fabius Maximus Rullianus, attacked and defeated the Samnites (429 of Rome) in the absence and against the orders of his commanding officer, the Dictator Papirius, who would have brought him to punishment for disobedience, but was prevented by the intercession of the soldiers and the people. This Fabius was five times consul, and dictator twice. He triumphed over the Samnites, Marsi, Gauls, and Tuscans. His son, Quintus Fabius Gurges, was thrice consul, and was the grandfather of QUINTUS FABIIUS MAXIMUS VERRUCOSUS, one of the most celebrated generals of Rome. In his first consulate he triumphed over the Ligurians. After the Thrasymenian defeat he was named Prodictator by the unanimous voice of the people, and was intrusted with the salvation of the Republic. The system which he adopted to check the advance of Hannibal is well known. By a succession of skilful movements, marches, and counter-marches, always choosing good defensive positions, he harassed his antagonist, who could never draw him into ground favourable for his attack, while Fabius watched every opportunity of availing himself of any error or neglect on the part of the Carthaginians.

This mode of warfare, which was new to the Romans, acquired for Fabius the name of Cunctator, or 'temporizer,' and was censured by the young, the rash, and the ignorant; but it probably was the means of saving Rome from ruin. Minucius, who shared with Fabius the command of the army, having imprudently engaged Hannibal, was saved from total destruction by the timely assistance of the dictator. In the following year however, 536 of Rome, Fabius being recalled to Rome, the command of the army was intrusted to the consul T. Varro, who rushed imprudently to battle, when the defeat of Cannæ made manifest the wisdom of the dictator's previous caution. Fabius was made consul in the next year, and was again employed in keeping Hannibal in check. In 543 of Rome, being consul for the fifth time, he re-took Tarentum by stratagem, after which he narrowly escaped being caught himself in a snare by Hannibal near Metapontum. (Livy, xxvii. 15, 16.) When some years after the question was discussed in the senate of sending P. Scipio with an army into Africa, Fabius opposed it, saying that Italy ought first to be rid of Hannibal. Fabius died some time after at a very advanced age. His son, called likewise Quintus Fabius Maximus, who had also been consul, died before him. His grandson Quintus Fabius Maximus Servilianus, being proconsul, fought against Viriatus in Spain, and concluded with him an honourable peace. (Livy, *Epitome*, 54.) He was afterwards consul repeatedly, and also censor. He wrote Annals, which are quoted by Macrobius. (*Saturn*. i. 16.) His brother by adoption Quintus Fabius Maximus Æmilianus, the son of Paulus Æmilii (Livy, xlv. 41), was consul in 609 of Rome, and was the father of Fabius, called Allobrogicus, who subdued not only the Allobroges, but also the people of Southern Gaul, which he reduced into a Roman province, called from that time 'provincia,' or 'Gallia ulterior.' Quintus Fabius Maximus, a grandson of Fabius Maximus Servilianus, served in Spain under Julius Cæsar, and was made consul in the year 709 of Rome. Two of his sons or nephews, Paulus Fabius Maximus and Quintus Fabius Maximus were consuls in succession under Augustus. There was also a Fabius consul under Tiberius. Panvinius and others have reckoned that during a period of about five centuries, from the time of the first Fabius, who is mentioned as consul, to the reign of Tiberius, 48 consulships, 7 dictatorships, 8 censorships, 7 augurships, besides the offices of master of the horse and military tribune with consular power, were filled by individuals of the Fabian house. It also could boast of thirteen triumphs and two ovations. (Augustinus de *Familiis Romanorum*.)

FABIVS PICTOR, the historian, was descended from Marcus Fabius Ambustus, the consul. Caius Fabius, one of the sons of Ambustus, was called Pictor, because about B.C. 304 he painted the temple of the goddess of health, which painting existed till the reign of Claudius, when the temple was burnt. (Pliny, xxxv. c. 4.) The surname of Pictor was continued to his children, one of whom, Caius Fabius Pictor, was consul with Ogulnius Gallus B.C. 271, and was the father of the historian. Quintus Fabius Pictor, the historian, lived in the time of the second Punic war, according to the testimony of Livy (xxi.), who says, in speaking of the battle of the Thrasymene lake, that he followed in his narrative the authority of Fabius Pictor, who was contemporary with that memorable event. Fabius appears, from the testimony of Dionysius and Cicero, to have written both in Greek and in Latin. Of the extracts from or references to his 'Annals,' which have been transmitted to us, some concern the antiquities of Italy, and the beginning of Rome, others the subsequent fasti, or history of the Romans. He was the first who compiled a history of his country from the records of the pontiffs, and from popular tradition. He is spoken of with praise by Livy, who evidently borrowed largely from him, and by Cicero, Pliny, Appian, and others. Polybius however censures his obvious partiality for the Romans, and his unfairness towards the Carthaginians, in his account of the second Punic war. His Annals are lost, with the exception of some fragments, which have been preserved by subsequent writers, and are printed in the collections of Antonius Augustinus, Antwerp, 1595, Antonius Riccobonus, Venice, 1568, and others. The well-known impostor, Annio da Viterbo, published a small work on the origin of Rome, under the name of Fabius Pictor, but the fraud was discovered. Quintus Fabius Pictor was sent by the senate to Delphi after the battle of Cannæ, to consult the Oracle about the ultimate result of the war. He must not be confounded with Servius Fabius Pictor, who lived in the time of Cato the Elder, and who is praised by Cicero for his knowledge of jurisprudence, literature, and antiquity. (Vossius, *De Historicis Latinis*; Fabricius, *Bibliotheca Latina*.)

FABLE, *Fábula* in Latin, in its general sense means a fictitious narrative, but it also means more particularly a species of didactic composition, consisting of a short fictitious tale inculcating a moral truth or precept. As such it is divided into two sorts, the parable and the apologue. The former narrates some incident, which, although it may not have happened exactly as the narrator supposes, yet could have happened at any time, there being nothing impossible or improbable in it. Of this description are many of the parables contained in the Scriptures, and especially in the New Testament, it being a favourite mode with our Saviour of illustrating his precepts by similitudes. When, for instance, he spoke of the master who, before setting out on a long journey, intrusted certain talents or sums of money to each of his three servants, he did not mean that such a fact had occurred at any particular time, though it might have occurred, but he chose this figure as presenting the ways of God with regard to the mental or spiritual talents he has gifted men with, and which he expects them to cultivate and render useful in proportion to their capacities. The second species of moral fable, called apologue, relates facts which are evidently untrue, and cannot have happened; such as animals, or even inanimate things, speaking, but which serve as comparisons for the actions of men. Such was the well-known apologue of Menenius Agrippa, addressed to the plebs of Rome, who had revolted against the patricians, in which he told them of the various limbs of the human body having once revolted against the belly. (Livy, ii. 32.) Most of the fables which are called *Æsopian* are apologues, although some are of the parable kind; for example, that of *Æsop* and the villain who threw a stone at him. (Phædrus, iii. 5.)

The apologue is one of the oldest forms of composition, being well calculated to strike the minds of men in a rude state. Homer's War of the Mice and the Frogs is a composition of the nature of the apologue; only being extended to a considerable length, and including a succession of incidents, it is classed among the heroicomic poems, whilst the apologue, or fable properly so called, points out only one particular incident from which it draws a moral. In the same manner, in modern times, the 'Animali Parlanti,' or 'Court and Parliament of Beasts' of Casti must be classed among the mock epic poems, although it

may be said to consist of a series of apologues, each pointing to some particular error, or abuse, in the state of society, and in the conduct of men. It is probable that the older and simpler mythological fables of the gods and heroes among the ancients were originally intended by the early patriarchs or priests to illustrate, by allegory the attributes of the Creator, the phenomena of nature, and the progress of social life; but that in course of time people lost sight of the moral, and believed the fiction in its literal sense.

The oldest collection of fables in any European language is in Greek prose: the fables are attributed to *Æsop*, but much doubt exists as to the real author or authors of them. [*ÆSOP*.] Babrius wrote a metrical version of *Æsopian* fables, only a few of which have come down to us. [*BABRIUS*.] The fables called the fables of Bidpai [*BIDPAI*] are derived from a collection in the Sanscrit language, and Lokman is said to have written fables in Arabic; but several of the fables attributed to the latter appear to be the same as some of those attributed to *Æsop*, and it has been supposed that Lokman and *Æsop* were one and the same personage. [*LOKMAN*.]

Among the Latins, Phædrus, who lived under Tiberius, is the most celebrated. he professes to have taken his subjects from *Æsop*. The MS. of Phædrus was not discovered before the end of the sixteenth century. Avianus, or Avienus, who (supposing the two names to mean the same individual) lived under the elder Theodosius, wrote a collection of fables in Latin verse. (*Edition of Avienus*, Leyden, 1731, with a *Dissertation on the Identity of Avianus and Avienus*.) Faerno of Cremona, who lived about the middle of the sixteenth century, made a collection of *Æsopian* fables, which he turned into Latin verse, and which were published at Rome after his death in 1564. He was accused of plagiarism, as having found a MS. of Phædrus in some library, and borrowed his subjects from it.

In the modern languages, among the original writers of fables or apologues, La Fontaine has been generally considered as rivaling or surpassing Phædrus in this kind of composition; and indeed he may be fairly placed above all writers of this class. Among the English, Gay and Moore have written fables. The Germans have had Lessing, Gellert, and others; and the Spaniards have Yriarte and Samaniego. Among the Italians, Firenzuola, Crudeli, Baldi, Capaccio, in the sixteenth and seventeenth centuries, wrote chiefly translations or paraphrases from the Greek and Latin fabulists. In the eighteenth century Pignotti, a native of Tuscany, wrote original fables in verse, which were published at Pisa in 1782, and have been often reprinted since. Bertola also wrote fables (Pavia, 1788), with an essay on fables. Luigi Fiacchi published, under the name of 'Clasio,' a collection of fables (Florence, 1807).

FABRETTI, RAFFAËLE, born at Urbino in 1619, was secretary of Pope Alexander VIII., and prefect of the papal archives in the castle St. Angelo under Innocent XII. Fabretti spent most of his time in searching the ruins which are scattered about Rome and its neighbourhood, and digging for those which were under ground. He explored catacombs, columbaria, sepulchres, and other subterraneous receptacles; and he gathered an abundant harvest of antiquities, and chiefly of inscriptions, which he ranged in a collection at his house at Urbino, which collection has been since transferred to the ducal palace of the same town. It is related that the horse upon which he rode for many years in his perambulations through the Campagna, and which his friends had nicknamed Marco Polo, became so accustomed to his master's hunting after inscriptions that he used to stop of himself whenever he met with any. Fabretti wrote, 1°, 'Inscriptionum Antiquarum Explicatio,' fol., 1699; 2°, 'De Columnæ Trajani,' fol., 1683, an elaborate work, in which he illustrated with much erudition and judgment the sculptures of that celebrated monument. He added to it an explanation of the Iliac table which is in the Capitoline Museum. 3°, 'De Aquis et Aqueductibus Veteris Romæ,' 4to., 1680, reprinted with notes and additions in 1788. Fabretti rendered great services to archaeology by his system of illustrating one monument by the help of another. He had a controversy with James Gronovius about the interpretation of some passages of classical writers, in which both resorted to discreditable scurrilities. Fabretti died at Rome in January, 1700, at the age of eighty. He may be considered as the predecessor of Bianchini, Bottari, and other archaeologists who illustrated the antiquities of Rome during the eighteenth century.

FABRIANO. [MACERATA.]

FABRICIUS, CAIUS, surnamed *Luscinus*, was consul for the first time in the year 471 of Rome, 283 B.C., when he triumphed over the Boii and the Etruscans. After the defeat of the Romans under the consul *Lævinus* by *Pyrrhus* (B.C. 281), Fabricius was sent by the senate as legate to the king to treat for the ransom of the prisoners, or, according to others, to propose terms of peace. *Pyrrhus* is said to have endeavoured to bribe him by large offers, which Fabricius, poor as he was, rejected with scorn, to the great admiration of the king. Fabricius being again consul (B.C. 279) was sent against *Pyrrhus*, who was then encamped near *Tarentum*. The physician to the king is said to have come secretly to the Roman camp, and to have proposed to Fabricius to poison his master for a bribe, at which the consul, indignant, had him put in fetters and sent back to *Pyrrhus*, upon whom this instance of Roman integrity made a great impression. *Pyrrhus* soon after sailed for *Sicily*, where he was called by the *Syracusans*, then hard pressed by the *Carthaginians*. Fabricius having defeated the *Samnites*, *Lucanians*, and *Bruttii*, who had joined *Pyrrhus* against Rome, triumphed over those people. *Pyrrhus*, afterwards returning to Italy, was finally defeated and driven away by *M. Curius Dentatus* (B.C. 276). Two years after, Fabricius being consul for the third time, with *Claudius Cinna* for his colleague, legates came from king *Ptolemy of Egypt* to contract an alliance with Rome. Several instances are related of the extreme frugality and simplicity of the manners of Fabricius, which are conformable to what is recorded of the austerity of Roman life previous to the Punic wars. When censor, he dismissed from the senate *P. Cornelius Rufinus* because he had in his possession ten pounds' weight of silver plate. Fabricius died poor, and the senate was obliged to make provision for his daughters. (*Plutarch, Life of Pyrrhus*; *Livy, Epitome* xiii., xiv.; *Eutropius*; *Justinus*.)

FABRICIUS, JOANNES ALBERTUS, born at *Leipzig* in 1667, early distinguished himself by his proficiency in classical literature, and his penetration and judgment, assisted by an excellent memory. Having finished his studies at *Leipzig*, he went to *Hamburg*, where *I. F. Meyer* appointed him his librarian. He was afterwards appointed professor in the college of *Hamburg*, where he remained to the end of his life, having refused several advantageous offers made to him by the landgrave of *Hesse Cassel* and others. He was the author of many elaborate works, the principal of which are:—I. '*Bibliotheca Græca*,' 14 vols. 4to., *Hamburg*, 1705-28. A new edition, with considerable improvements, was published by *Harles*, *Hamburg*, 1790-1809. The '*Bibliotheca Græca*' is a most valuable work; it contains notices of all the Greek authors, from the oldest known down to those who flourished in the last period of the Byzantine empire, with lists of their works and remarks on them. II. '*Bibliotheca Latina*,' 3 vols. 4to., 1708-21. *Ernesti* published a new and much improved edition of the same at *Leipzig*, 1773. The '*Bibliotheca Latina*' is inferior in research and copiousness to the '*Bibliotheca Græca*,' but is still a useful work, especially in the new form given to it by *Ernesti*. III. '*Bibliotheca Latina Ecclesiastica*,' fol., *Hamburg*, 1718. IV. '*Bibliotheca Latina mediæ et infimæ Ætatis, cum Supplemento C. Schoettgenii, ex recensione Dominici Mansi*,' *Padua*, 6 vols. 4to., 1754. V. '*Memoriæ Hamburgenses*,' 7 vols. 8vo.; to which *Reimar*, the son-in-law of Fabricius, added an eighth volume in 1745. VI. '*Codex Apocryphus Novi Testamenti*,' 2 vols. 8vo., 1719; being a Collection of the false Gospels, Acts of the Apostles, and other apocryphal books which appeared in the early ages of Christianity. VII. '*Bibliographia Antiquaria*,' 4to., 1760; being notices of the authors who have written upon Hebrew, Greek, Roman, and ecclesiastical antiquities. VIII. '*Delectus Argumentorum et Syllabus Scriptorum qui veritatem Religionis Christianæ lucubrationibus suis asseruerunt*,' 4to., 1725. IX. '*Hydrotheologia*,' written in German, and translated into French under the title '*Théologie de l'Eau, ou Essai sur la Bonté, la Sagesse, et la Puissance de Dieu, manifestées dans la Création de l'Eau*,' 8vo., *La Haye*, 1741. X. '*Codex pseudepigraphus Veteris Testamenti*,' being a counterpart of his work on the Apocrypha of the New Testament. XI. '*Conspectus Thesauri Litterarii Italici*,' 8vo., 1749, or notices of the principal collections of the Historians of Italy, as well as of other writers who have illustrated the antiquities, geography, &c., of that

P. C., No. 614.

country, including the great works of *Burmamnus* and *Grævius*, with an account of the Italian literary journals existing or which had existed before the time of Fabricius, of the Italian academies, and a catalogue of Italian bibliographers and biographers classed according to the particular towns which they have illustrated. XII. '*Imp. Cæs. Augusti Temporum Notatio, Genus et Scriptorum Fragmenta*,' with '*Nicolai Damasceni De Institutione Augusti*,' 4to., 1727. XIII. '*Salutaris Lux Evangelii, sive Notitia Propagatorum per Orbem totum Sacrorum: accedunt Epistolæ quædam ineditæ Juliani Imperatoris, Gregorii Habessinii Theologia Æthiopica, necnon Index geographicus Episcopatum Orbis Christiani*,' 4to., 1731; a work which contains useful information for students of ecclesiastical history. XIV. '*Centifolium Lutheranum, sive Notitia Literaria Scriptorum omnis generis de Martino Lutero, ejus Vita, Scriptis, et Reformatione Ecclesiæ editorum*,' two vols. 8vo. 1730. XV. '*Centuria Fabriciorum Scriptis clarorum qui jam diem suam obierunt collecta*,' 8vo., 1709, with a continuation in 1727. The author has included in his list not only the authors whose name or surname was Fabricius, but also those whose names may be turned into the Latin Fabricius; such as *Le Fevre*, *Fabri*, the German *Schmidts*, &c. Independently of the above and other minor works, Fabricius published editions of *Sextus Empiricus*, of the *Gallia Orientalis* of *Father Colomies*, of the works of *St. Hippolytus*, and many others. The catalogue of the works published by him exceeds 100. Fabricius died at *Hamburg* in April, 1736, in his 69th year. His private character was as praiseworthy as his learning was great. He was modest, hospitable to strangers who came to visit him, indefatigable in the duties of his professorship and rectorship, and yet he found time for the compilation of the numerous works already mentioned. *Reimar*, his son-in-law, wrote his biography in Latin, 8vo. 1732.

FABRICIUS, JOHANN CHRIST, was born in the year 1742, at *Tundern*, in the duchy of *Sleswick*. He was brought up to the medical profession, and at the age of twenty-three was made professor of natural history and rural economy at *Kiel*.

Fabricius studied under *Linnæus*, and afterwards enjoyed perhaps a more brilliant reputation than any other pupil of that great naturalist. Having been filled with emulation by the circumstance of *Linnæus* quoting him in his '*Systema Naturæ*,' he resolved to make an especial study of entomology, a science at that time in its infancy. The first results of his investigations were shortly after (1775) made known in his '*Systema Entomologiæ*,' where he proposed a new arrangement of the insect tribe, the novelty of which consisted in choosing for his divisions the modifications observable in the parts of the mouth. The two methods previously adopted were founded, the one upon the metamorphoses of the various tribes, the other upon their organs of motion. The latter was first pointed out by *Aristotle*, and was that adopted by *Linnæus*.

Fabricius subsequently published numerous other works of still greater importance, a list of which is given at the end of this article. Possessing a great knowledge of languages, Fabricius travelled through the northern and middle states of Europe, collecting new materials, and frequenting the various museums, from which he described all such insects as had hitherto been unpublished. Accounts of his travels in *Norway*, *Russia*, and *England*, were published by him. He visited *England* seven times, and received great assistance from inspecting the collections of *Sir Joseph Banks**, *John Hunter*, *Drury*, *Francillon*, and others.

Far from being jealous of those naturalists who, in his day, enjoyed reputation in the same branches which he more particularly attended to, Fabricius, upon seeing the beautiful work of *Walckenaer* on spiders, expressed great delight; and although no request had been made, he hastened to convey to that author all the specimens which he possessed of the spider tribe. Fabricius was of an amiable disposition; and is said to have been reproached by a fellow professor for his extreme modesty, which his friend urged would retard his advancement. Although so well versed in entomology, Fabricius was not a stranger to other branches of zoology; he was also versed in botany and mineralogy. He died of dropsy, in his sixty-fifth year,

* Numerous insects in the collection of *Sir Joseph Banks* (which is now the property of the *Linnæan Society*) still have names attached to them in the handwriting of Fabricius.

much regretted by all naturalists. His principal works are as follows:—

1, 'Systema Entomologiæ, sistens Insectorum Classes,' &c., 1 vol., 8vo., Flensburgi et Lipsiæ, 1775; 2, 'Philosophia Entomologica,' 8vo., Hamburgi et Kilonii, 1778; 3, 'Reise nach Norwegen, mit Bemerkungen aus der Natur Historie und Oekonomie,' 8vo., Hamburg, 1779; 4, 'Species Insectorum, sistens eorum differentias specificas, synonymia auctorum, loca natalia, metamorphosis,' &c., 2 vols., 8vo., Hamburg et Kilonii, 1781; 5, 'Mantissa Insectorum; sistens species nuper detectas,' &c., 2 vols., 8vo., Hafniæ, 1787; 6, 'Genera Insectorum,' 1 vol., 8vo. (Chilonii), Kiel, 1776; 7, 'Entomologia Systematica, emendata et aucta,' 4 vols., 8vo., Hafniæ, 1792, 93, 94; 8, 'Index Alphabeticus,' 1796; 9, 'Supplementum Entomologiæ Systematicæ,' 1 vol., 8vo., Hafniæ, 1798; 10, 'Systema Eleutheratorum,' 2 vols., 8vo., Kiliæ, 1801; 11, 'Index,' 8vo., Kiliæ, 1802; 12, 'Systema Rhyngotorum,' 8vo., Brunsvigæ, 1801; 13, 'Index Alphabeticus Rhyngotorum, genera et species continens,' 4to., Brunsvigæ, 1803; 14, 'Systema Piezatorum,' 8vo., Brunsvigæ, 1804; 15, 'Systema Antliatorum,' 8vo., Brunsvigæ, 1805.

FABRIZIO, GERO-NIMO, commonly called FABRICIUS AB AQUAPENDENTE, was born in 1537 at Acquapendente in Italy, a city near Orvieto, in the States of the Church. His parents, although poor, contrived to furnish him with the means of obtaining an excellent education at Padua, which was then rapidly approaching the eminence it long held, especially as a school of medicine, among the universities of Europe. It appears to have been a favourite object with the Venetian government to encourage the study of the medical sciences. Vesalius and Fallopius had been successively invited to fill the chair of anatomy and surgery, then conjoined, and reaped a rich harvest of public emolument and honour; and Fabricius himself, who did much to extend the reputation of the school formed by these leaders in the restoration of anatomy, was afterwards still more munificently rewarded, though equal to neither in merit or posthumous fame. He became a pupil of Fallopius at an early age, and speedily attracted the attention and good-will of his instructor. He thus secured many peculiar advantages, of which he availed himself so well, that having taken his degrees in medicine with much credit, he was appointed on the death of Fallopius in 1562 to succeed him in the direction of the anatomical studies of the university, and three years later to the full emoluments of the professorship. The growing perception of the importance of anatomical knowledge led, in 1584, to the institution of a separate chair for the teaching of that branch of medicine, which, however, Fabricius appears to have still held in conjunction with that of surgery up to a late period of his life, with the able assistance of Casserius.

His reputation as a teacher drew students from all parts of Europe; till at length the theatre of anatomy, built originally by himself, became so crowded, that the Venetian senate provided him, in 1593, with another of ample dimensions at the public expense; and at the same time added largely to his salary, and granted him many exclusive privileges and titles of honour. The fame and wealth he derived from his practice as a surgeon was even more than equal to that which he enjoyed as an anatomist; and after upwards of fifty years of uninterrupted and well-deserved prosperity, he retired from public life the possessor of an enormous fortune and the object of universal esteem. Yet he does not appear to have found the contentment he sought in his retirement. His latter years were embittered by domestic dissensions and the unfeeling conduct of those who expected to become his heirs; and he died in 1619, at the age of eighty-two, not without the suspicion of poison, at his country-seat on the banks of the Brenta, still known as the Montagnuola d'Acquapendente.

The name of Fabricius is endeared to the cultivators of his science by the circumstance of his having been the tutor of William Harvey, whose discovery of the circulation of the blood (by far the most important yet achieved in physiology) was suggested, according to his own statement, by the remarks of Fabricius on the valvular structure of the veins. The title of Fabricius to the minor discovery has been disputed, though strongly asserted by some anatomists. The truth is, that his merit did not so much consist in original discovery as in the systematic arrangement and dissemination of the knowledge acquired by

his predecessors. We have mentioned that he had more contemporary reputation as a practical surgeon than as an anatomist; and it is as a surgeon that he is still chiefly remembered. The observations recorded in his works having, however, been since wrought up in the general body of surgical knowledge, are now seldom consulted or quoted specifically as derived from himself.

He published many tracts on both departments. Those on anatomy and physiology, often referred to, but not with unmixed praise, by Harvey and the writers of the period immediately subsequent to his own, were collected in one volume folio, and republished, with a biographical memoir of the author, by Albinus at Leyden in 1738. The best edition of his surgical works, the twenty-fifth, was printed, also in one folio volume, at Padua in 1666. His writings are all in Latin, and display a considerable knowledge of the literature, general and medical, of that language and of the Greek.

FABYAN, ROBERT, the historian, was descended of a respectable family of Essex. Bishop Tanner says he was born in London. We have no dates of his early life, but he is known to have belonged, as a citizen, to the Company of Drapers. From records in the city archives, it appears that he was alderman of the ward of Farringdon Without, and in 1493 served the office of sheriff. In 1496, in the mayoralty of Sir Henry Colet, we find him 'assigned and chosen,' with Mr. Recorder and certain commoners, to ride to the king 'for redress of the new impositions raised and levied upon English cloths in the archduke's land,' (that is, the Low Countries) an exaction which was desisted from in the following year. In 1502, on the plea of poverty, he resigned the alderman's gown, not willing to take the mayoralty, and probably retired to the mansion in Essex, mentioned in his will, at Theydon Gernon. That he was opulent at this period cannot be doubted, but he seems to have considered that the expenses of the chief magistracy, even at that time, were too great to be sustained by a man who had a numerous family. He ordered the figures, as may be seen in his will, of sixteen children, in brass, to be placed upon his monument. Stowe, in his 'Survey of London' (edit. 1603, p. 198), gives the English part of the epitaph on Fabyan's tomb, from the church of St. Michael Cornhill, and says he died in 1511, adding that his monument was gone. Bale, who places Fabyan's death on February 28th, 1512, is probably nearest to the truth, as his will, though dated July 11, 1511, was not proved till July 12, 1513. Fabyan's will, printed with the last edition of his 'Chronicle,' affords a curious comment on the manners of the time of Henry VIII.

There have been printed five editions of Fabyan's 'Chronicle.' The first was printed by Pynson in 1516, and is of great rarity, in a perfect state. Bale says that Wolsey ordered many copies of it ('exemplaria nonnulla') to be burnt. The second was printed by Rastell in 1533. The third in 1542, by Reynes. The fourth in 1559, by Kyngeston. The changes of religion gave rise to many alterations and omissions in the third and fourth editions; but all the editions, as well as a manuscript of the second part of the book, were collated by Sir H. Ellis for the fifth edition, 4to., London, 1811, from the preface to which the present account of the historian has been principally taken. Fabyan, whose object it was to reconcile the discordant testimonies of historians, named his book 'The Concordance of Histories,' adding the fruits of personal observation in the latter part of his Chronicle. The first edition had no regular title; the latest is called 'The New Chronicles of England and France, in two parts, by Robert Fabyan, named by himself the Concordance of Histories.' The first edition, which may be considered as Fabyan's genuine work, extends from the time when 'Brute entryd firste the Ile of Albion,' to 1485; the second continued the history to 1509; the third to 1541; and the fourth to the month of May, 1559. The names of the several authors who were the continuators are unknown.

FAÇADE, a French term of modern introduction into the English language. It expresses the face, or front view of an edifice, and is often used in speaking of architectural buildings, as the façade of the Louvre, or the façade of St. Peter's at Rome. Façade was applied originally to denote the principal front of a building: the term Facciata, used by the Italians, is, for the most part, applied to such fronts as have a principal entrance.

FACCIOLATI, JACOPO, was born at Torriglia on the

Euganean hills, in the province of Padua, in 1682. He studied first in the college of Este, and was afterwards placed by Cardinal Barbarigo, bishop of Padua, in the clerical seminary of that city, where he completed his studies and was admitted into holy orders. He was then appointed teacher and afterwards prefect or chief superior of the same establishment. The seminary of Padua had and still has a high reputation as a place for the study of Latin and for the numerous and generally accurate editions of the classics and other school books which have come from its press. Faccioliati contributed to support this reputation by his labours. Among other works, he published improved editions of the Lexicon of Schrevelius, of the Thesaurus Ciceronianus of Nizolius, and of the vocabulary of seven languages known by the name of 'Calepino,' 2 vols. fol., 1731. In this last undertaking he was greatly assisted by his pupil, Egidio Forcellini, although he was not willing to acknowledge the obligation. The work however being still incomplete, J. B. Gallizioli made a new edition of the 'Calepino,' 2 vols. fol., Venice, 1778, and added many oriental and other words. It was in the course of his joint labours with Faccioliati that Forcellini conceived the plan of a totally new Latin Dictionary, which, after more than 30 years' assiduous application, he brought to light under the title of 'Totius Latinitatis Lexicon,' 4 vols. fol., Padua, 1771. This work has superseded all other Latin Dictionaries. Forcellini, more generous than Faccioliati, acknowledged in the title-page of his work that its production was in great measure due to the advice and instruction of his deceased master. In the introductory address to the pupils of the seminary of Padua, he tells them with a touching simplicity that when he undertook his work he was in the prime of youth, but that in the course of its compilation he had grown old and infirm as they then beheld him. The MS. of his 'Lexicon,' in 12 vols. fol., is preserved in the library of the seminary. A new edition of Forcellini's Lexicon has been lately published by the Abate Furlanetto of the same institution.

In 1722, Faccioliati being appointed professor of logic in the university of Padua, delivered a series of introductory Latin discourses to the students of his class, which were received with considerable applause. In 1739 he began to write in Latin the 'Fasti of the University of Padua,' the introductory part, in which he describes the origin, the laws and regulations, and the object of that celebrated institution, is very well written, but the Fasti themselves contain little more than dry lists of the successive professors with few and unimportant remarks. His Latin epistles, as well as his Orationes or discourses, have been admired for the purity of their diction. Indeed Faccioliati's latinity was much praised by competent judges, such as Roberti and others of his countrymen, as well as by Brucker, the historian of philosophy, and other learned foreigners. The king of Portugal sent him a flattering invitation to Lisbon to take the direction of the public studies in his kingdom, but Faccioliati declined the offer on account of his advanced age. He however wrote instructions for the re-organization of the scholastic establishments of that country, which had become necessary after the expulsion of the Jesuits. Faccioliati died at Padua in 1769, in his 88th year. He left numerous works, mostly in Latin, besides those already mentioned; among others, some allegorical and satirical dialogues on the occasion of a funeral oration which he had written for the late Doge Pisani, being suppressed by the Padua Riformatori, or Censors.

FACIA. [CIVIL ARCHITECTURE; COLUMN.]

FACTOR, a name given to any algebraical expression considered as part of a product. Thus, a and $a+x$ are the factors of the product $a(a+x)$, or $a^2 + ax$.

The term *factorial expression* has been in some instances applied to an expression of which the factors are in arithmetical progression; such as—

$$(x+1)(x+2)(x+3)(x+4).$$

See Herschel, *Examples of the Calculus of Finite Differences*.

FACTOR is a mercantile agent, who buys and sells the goods of others, and transacts their ordinary business on commission. He is entrusted with the possession, management, and disposal of the goods, and buys and sells in his own name, in which particulars consists the main difference between factors and brokers. [BROKER.]

The chief part of the foreign trade of every country is

carried on through the medium of factors, who generally reside in a foreign country, or in a mercantile town at a distance from the merchants or manufacturers who employ them; and they differ from mere agents in being entrusted with a general authority to transact the affairs of their employers. The common duty of a factor is to receive consignments of goods and make sales and remittances either in money, bills, or purchased goods in return; and he is paid by means of a per-centage or commission upon the money passing through his hands. It is usual for a factor to make advances upon the goods consigned to him, for which, and also for his commission, he has a general lien upon all the property of his employer which may at any time be in his hands.

It is the duty of a factor to keep the goods with which he is entrusted free from injury, to keep a clear account of his dealings in the affairs of his employer, and at proper times to transmit it to him, together with information of all the transactions and liabilities which he has entered into and incurred in the course of his employment, and by which his principal can be affected; also to send him advice of all bills accepted or drawn upon his credit, and generally to act with fidelity to him, strictly observing the letter or the spirit of his instructions, and where they are silent, following the ordinary prudent course of other merchants dealing in like commodities as to time and mode of sale, credit, &c. A factor is not answerable against all events for the safety of the goods in his care: it is sufficient if he does all that a man of average prudence would do in the care of his own goods. He is not answerable in cases of robbery, fire, or other accidental damage happening without his default. He is bound, upon receiving notice from his principal, to insure the goods consigned to him (provided he has effects of his principal in his hands of sufficient amount to defray the premium), to discharge the duties payable upon the exportation or importation of the goods, or to cause the regular and necessary entries to be made at the custom-house, and do all other things necessary for the safety and preservation of the goods. His liability in this respect is ably explained by Sir William Jones in his *Treatise on Bailments*; and see BAILMENTS, fifth division, 'Locatum,' second subdivision.

Where general and unlimited orders are given to a factor, he is left to buy and sell on the best conditions he can; and if detriment arise to the principal, he has no redress, unless he can show that the factor acted fraudulently or with gross negligence.

In accordance with the general rule that a principal can only be bound by the acts of his agent while acting within the scope of his authority, it was held, previously to the passing of the recent stat. 6 George IV., c. 94, that a factor had only authority to sell the goods of his principal, and that if he pledged them, the principal might recover them from the pledgee. This was productive of considerable hardship in many cases; for, besides that by the mercantile law of every other country except England and America, the pledgee might retain the goods as security for his advances to the factor, it was urged, and with great reason, that, as between the principal and the pledgee of the factor, the principal ought to bear the loss. He it was who placed confidence in the factor, and who enabled him to appear the actual owner of the goods: he might have controlled the authority and limited the operations of his factor; but the pledgee knew nothing of his employment; he saw only the factor in the possession of the goods, and advanced his money on what appeared a sufficient security for repayment. In accordance with views like these, that statute was passed, and now the pledgee of a factor, when he lends his money without notice that the factor is not the actual owner of the goods, is enabled to retain them for his security; and even when he has such notice, the lender has a lien upon the goods to the same amount as the factor was entitled to.

A sale by a factor creates a contract between the principal and the buyer, and the principal may maintain an action against the buyer for the price, and may by notice direct him not to pay the money to the factor, which notice the buyer is bound to attend to. So a purchase by a factor for his principal renders the latter liable to the vendor, though a payment to the factor is a sufficient discharge, unless notice to the contrary has been given by the principal. And this holds good in both cases, even when the

name of the principal is not disclosed at the time of the contract, but is afterwards discovered; though, where a factor conceals the name of his principal and buys or sells apparently on his own account, the buyer or seller may treat the factor as the principal so far as any other liability of the factor may exist to him; as where a factor sells goods in his own name, being indebted to the purchaser, the latter may set off the amount of debt due to him from the factor against the price of the goods.

There is another description of factor, who acts under what is called a *del credere* commission, where, for an additional per-centage he engages for the solvency of the purchasers of the goods consigned to him. This contract, it is evident, arises on the supposition that the factor being resident among the purchasers, must be better able to judge of their solvency than the principal, residing in a foreign country. For a long time it was considered that under this arrangement those who dealt with the factor were liable to him alone, and that he was liable, in the first instance, to his employer; it has, however, been decided that the factor stands in the relation of a surety for the persons with whom he deals on account of the employer, and that he is liable to his employer only in case of their default. *Del credere* is an Italian mercantile phrase, of the same signification as the English word guarantee, and the Scotch warrandice.

When goods are consigned to joint factors they are answerable for one another for the whole, and by the law of merchants, as factors, are oftentimes dispersed, one may account without his companion.

The principal may recover against his factor by action for the neglect of his duty, or disobedience to his instructions if loss occur thereby, as if he purchases goods at a limited price, and fraudulently sells them again for his own profit. If a factor, without the orders of his principal, exports goods prohibited by the Customs' laws, and the same are seized, the loss is the factor's; and so, if he pay money without the direction of his employer, or sells his goods at an under-value, or exports goods of an improper quality, he is answerable for the damage. And if a factor exports goods of a different quality or kind from those he was directed to purchase, or sends them to a place other than that to which he was ordered to send them, the merchant may refuse to accept them, and may recover any damage he has sustained, in consequence of his neglect, from the factor. The rights and liabilities of merchants and factors are governed by the laws of the place in which they are domiciled, and any contract which may be made by either of them must be governed by the law of the place where it is made, and these rules are acted upon by the courts of justice of every civilized nation. Thus, since the passing of the above-mentioned statute, a foreign merchant cannot recover his goods from the pledgee of his factor in England, though he may be totally ignorant of the change which has taken place in the law. And again, if a bill be accepted in Leghorn by an Englishman, and the drawer fails, and the acceptor has not sufficient effects of the drawer in his hands at the time of acceptance, the acceptance becomes void by the law of Leghorn, and the acceptor is discharged from all liability, though by the law of England he would be bound. (See 2 *Strange's Reports*, 733; *Beawe's Lex Merc.*; *Bell's Commentaries*; *Paley, Principal and Agent*; *McCulloch's Commercial Dict.*)

FACTORY. FACTORY SYSTEM. The name of factory was formerly given only to establishments of merchants and factors resident in foreign countries, who were governed by certain regulations adopted for their mutual support and assistance against the undue encroachments or interference of the governments of the countries in which they resided. In modern times these factories have, in a great measure, ceased to exist, because of the greater degree of security which merchants feel as regards both the justice of those governments and the protection, when needed, of their own country. In its usual acceptation, the word factory is now employed to denote an establishment in which a considerable number of workmen or artisans are employed together for the production of some article of manufacture, most commonly with the assistance of machinery. The factory-system of England owes its origin to the invention and skill of Arkwright. It is true the name of factory is equally applied to various establishments for the operations of which those inventions are inapplicable, but it is probable that but for the invention of spinning-machinery, and the consequent necessary aggregation of large numbers

of workmen in cotton-mills, the name would never have been thus applied. It is in these cotton-mills that the factory system has been brought to its highest state of perfection, and it cannot therefore be necessary to extend our description to the operations of any other branch of manufacture.

The first cotton-factory was established by Arkwright in connection with Messrs. Need and Strutt, of Derby, and was situated at Cromford, on the river Derwent. It was built in 1771, and continues still in operation, with the original spinning-frames of the great inventor. It is not the least among the merits of that extraordinary man, that being the first to employ the combined labour of numerous workmen for the production of that which had previously resulted from individual employment, he was able to arrange and establish the details of the processes with so great a regard to order, economy, and simplicity of action, that with but few and unimportant modifications, his plans are continued to the present day. [ARKWRIGHT.] The operations of Arkwright and his partners were for many years met by a spirit of opposition on the part of other manufacturers, who foresaw that the success of the new machinery would speedily destroy the value of the hand spinning implements which they employed. Their combinations to destroy his patent rights have already been described. Taking advantage of the prejudices of the workmen, they had no difficulty in producing the belief that the new machines would soon entirely supersede manual labour, and the consequence of this delusion was a general crusade of the workmen against all spinning-machinery set in motion by horse or water-power. The principal effect of the riots thus occasioned was the removal of establishments to other and more peaceable parts of the country. For a considerable time Arkwright and his partners had an interest in the greater part of the cotton factories that were erected. The first of these establishments brought to use in Manchester was built in 1780, and had its machinery impelled by an hydraulic wheel, the water for which was furnished by a single-stroke atmospheric pumping steam-engine. The progress of these new establishments was so rapid that in 1787 there were 145 cotton-spinning factories in England and Wales, containing nearly two millions of spindles, and estimated to produce as much yarn as could have been spun by a million of persons using the old domestic wheel.

A return called for by the House of Commons in the last session states the number of factories which, in the month of February, 1837, were under the regulations imposed by the 'Factory Act.' From this return, it appears that the establishments at that time subject to the visits of the parliamentary inspectors amounted to 4160, showing an increase of 1000 factories upon the numbers given above. This great increase may be owing in part to the circumstance of some establishments existing in 1835 having since been brought under the regulations. The return does not apporportion the different manufactures to which those 4160 establishments are applied. In a report made by Dr. Kay, one of the assistant Poor Law Commissioners, in July, 1835, it is stated that in the cotton manufacturing districts of Lancashire and their immediate vicinity steam power equivalent to 7507 horses was then either erected or in the course of being erected, but the establishments for the use of which that additional machinery was destined were not yet supplied with hands. At the ordinary ascertained rate this amount of mechanical power would call for the employment of 45,042 hands, exclusive of mechanics, labourers, handicraftsmen, and others employed out of the factories. The activity that up to the close of 1836 was experienced in this branch of national industry must have occasioned even a still greater extension than is mentioned by Dr. Kay, and we shall probably be within the mark if we estimate the number of hands employed in cotton factories in the autumn of 1836 at considerably more than 300,000. The check to commercial operations then experienced has probably prevented any fresh extension of the manufacture, but at this time (October, 1837) the cotton factories throughout the kingdom are in full operation in order to answer the demand for goods in almost every market in the civilized world.

The number of cotton, wool, silk, and flax-spinning factories worked by steam or water-power in the United Kingdom, with the number and ages of persons employed therein in the year 1835, was stated in the Statistical Tables published by the Board of Trade to be as follows:—

NUMBER AND AGES OF PERSONS EMPLOYED.

| DIVISIONS OF THE KINGDOM. | Number of Factories. | | NUMBER AND AGES OF PERSONS EMPLOYED. | | | | | | | | | | | | | | |

| Total of the four branches of manufacture . | 3,160 | 76 | 10,067 | 10,501 | 20,568 | 17,687 | 18,180 | 35,867 | 43,482 | 64,726 | 106,208 | 87,299 | 103,411 | 190,710 | 156,655 | 196,819 | 355,373 |

It will be seen from the foregoing table, that a very large proportion of the hands employed in factories consist of children and young persons. The large sums invested in machinery make it a matter of great importance to the owners to keep their works in motion as constantly as possible, and, unless prevented by legislative interference, there is too much reason to believe that children may be tasked beyond their strength, to the permanent injury of their constitutions. This abuse was the more to be apprehended, because a large proportion of the children engaged in cotton-spinning are not directly employed by the masters, but are under the control of the spinners, a highly-paid class of workmen, whose earnings depend greatly upon the length of time during which they can keep their young assistants at work. Although the recitals of cruelties alleged to exist were shown upon investigation to have been very greatly exaggerated, it cannot be denied that enough of misery was produced to render it imperative upon the legislature to interfere. A parliamentary committee sat for the investigation of this subject in 1832, and subsequently a commission was issued by the crown for ascertaining, by examinations at the factories themselves, the kind and degree of abuses that prevailed, and for suggesting the proper remedies. In consequence of these inquiries an act was passed in 1833, (2 and 3 Wm. IV., c. 103,) the provisions of which, it is generally believed, have effected all the good which it is in the power of the legislature to do, consistently with the prosecution of the branches of industry to which the provisions of the act apply: the principal of those provisions are as follows:—

After the 1st January, 1834, no person under the age of 18 years is allowed to work in any cotton, woollen, flax, or silk factory worked by the aid of steam or water-power, between the hours of half-past eight in the evening and half-past five in the morning.

No person under 18 years of age is allowed to work more than 12 hours in any one day, nor more than 69 hours in the week. In factories worked by the aid of water-power, time lost through the deficiency of water may be made up at the rate of three hours additional labour in the week. In factories where the steam-engine is employed, lost time occurring through any accident happening to the machinery may be made up at the rate of one hour per day. One hour and a half to be allowed in each day for meals.

Except in silk-mills, no children under nine years of age are allowed to be employed.

Children under 11 years old are not to be worked more than nine hours in any one day, nor more than 48 hours in one week. This clause came into operation six months after the passing of the act. At the expiration of another 12 months its restriction was applied to children under 12 years old, and when 30 months from the passing of the act had elapsed the restriction was applied to all children under 13 years old. As the act was passed on the 30th August, 1833, this clause came fully into operation on the 1st of March, 1836. In silk-mills, children under 13 years of age are allowed to work 10 hours per day. The children whose hours of work are regulated by the act are entitled as holidays to the whole day on Christmas-day and Good-Friday, and besides to eight half days in the year. It is made illegal for any mill-owner to have in his employ any child who has not completed 11 years of age without a certificate by a surgeon or physician, 'that such child is of the ordinary strength and appearance of children of or exceeding the age of nine years.' In 18 months from the passing of the act this provision was made to apply to all children under 12 years of age, and upon the first March, 1836, the provision was made to include all children under the age of 13. Four persons were appointed under the act to be Inspectors of Factories, in order to carry into effect the various provisions which it contains, with power to make such rules and orders for the purpose as they should see necessary; and in order to assist the inspectors in the performance of their duties, an adequate number of superintendents were appointed to act under their directions.

After the expiration of six months from the passing of the act, it was declared unlawful to employ in any factory any child under the ages restricted to forty-eight hours' labour in the week, unless on every Monday the employer should receive a ticket from some schoolmaster, certifying that such child has 'for two hours at least for six out of seven days of the week next preceding attended his school. The school to be chosen by the parents or guardians of the child; but in case of their omitting to appoint any school, or in case of the child being without parent or guardian, the inspector may appoint some school in which the child may be taught, and the employer may be allowed to deduct from its weekly earnings any sum not exceeding one penny in every shilling, to pay for the schooling of such child.'

The full and perfect carrying out of the intention of the legislature in passing this act is provided for as far as possible by various penalties, which it is not necessary further

to particularise. One half of the penalties are, as is usual, awarded to the informers, and the remainder is to be applied towards the support of schools in which children employed in factories are educated.

The faithful discharge of their duties on the part of the inspectors is provided for, by requiring them twice in every year, and oftener, if called upon, to deliver in a report to the secretary of state, detailing the condition of the factories, and of the children employed therein.

FACULTIES. [UNIVERSITY.]

FÆCULA. [STARCH.]

FAENZA (formerly Faventia), a town and bishop's see of the papal state north of the Apennines, in the delegazione or province of Ravenna. It is situated in a well-cultivated plain watered by the river Lamone, which rises in the Apennines of Tuscany and runs to the Adriatic. A naviglio or navigable canal communicates between Faenza and the Po di Primaro, or southernmost branch of the Po. Faenza is a well-built, modern-looking town, with about 15,000 inhabitants. The streets are regular; there is a fine market-place surrounded by arcades, many palaces, churches rich in paintings, convents, a fine bridge on the Lamone, a theatre, and a Lyceum. There are several manufactories of a kind of coloured and glazed earthenware, which is called Majolica in Italy, and Faience in France, where it was introduced from Faenza, and which, before the manufacture of china or porcelain became established in Europe, was in greater repute than it is at present. There are also manufactories for spinning and weaving silk, and some paper-mills. Faventia was antiently a town of the Boii, and afterwards a municipium under the Romans. It was near Faventia that Sulla defeated the consul Carbo and drove him out of Italy. (Livy, *Epitome*, 88.) It was afterwards ruined by the Goths, was restored under the Exarchs, but its walls were not raised until A.D. 1286. It was then for some time subject to the Bolognese, but was afterwards ruled by the house of Manfredi to the end of the fifteenth century. Galeotto Manfredi being murdered by his wife left two infant sons, Astorre and Evangelista, the elder of whom, a remarkably handsome youth, was proclaimed by the inhabitants lord of Faenza; but a few years after, Cesare Borgia, as captain-general of his father, Pope Alexander VI., besieged the town, and the inhabitants surrendered on condition that Astorre and his brother should be free. He however sent them prisoners to Rome, where they were cruelly put to death in the Castle Sant' Angelo, and their bodies thrown into the Tiber, in the year 1501. This was one of the most atrocious transactions in the life of Borgia. Since that time Faenza has been annexed to the papal state. Faenza lies on the Via Emilia, 30 miles south-east of Bologna, 40 north-west of Rimini, and 20 south-west of Ravenna. In the Roman times, a road led from Faventia to the south, which ascending the valley of the Anemo, now Lamone, and crossing the ridge of the Apennines, descended to Fossulæ. By this road some have supposed that Hannibal crossed the Apennines into Etruria. A new carriage-road in a parallel direction, but more to the eastward, has been completed by the present grand-duke of Tuscany: it leads from Dicomano, in the valley of the Sieve, north of Florence, crosses the Apennines of San Benedetto, 4000 feet above the sea, and then following the course of the river Montone, joins the Via Emilia near Forlì.

FA'GUS, the beech, is a genus of Corylaceous exogens, having triangular nuts enclosed within a spiny capsule or husk. There are several species, some of which are mere bushes; the only one known in Europe of any importance is the *Fagus sylvatica*, or common beech, a native of various parts of the world in temperate climates. In Europe it is found as far north as 58° in Norway: it is met with in Palestine and Armenia, all over the south of Europe, and in the United States of America. It is one of the most handsome of our trees on dry sandy or chalky situations; its meat or nuts not only furnish food for swine, but yield by pressure after pounding a useful oil; and its timber, although not of good quality where strength and durability are required, is very extensively used for a variety of purposes, particularly for boat-building, work under water, carving and chair-making; it is also one of the best kinds of wood for fuel. Several varieties are propagated by the nurserymen, the *purple* and the *fern-leaved* being beautiful, and the *crested* very much the contrary. (See Loudon's *Arboretum and Fruticetum Britannicum*, p. 1949, for copious account of this tree.)

The common beech is multiplied by sowing its mast; the varieties by grafting upon the wild sort. To effect this successfully, it is necessary that the scions should be of at least two years' old wood, and the grafts must be clayed first and then earthed up. If one year old wood is used the scions rarely take.

There is no doubt that the beech is the plant called *Fagus* by Virgil; but the *Fegus* (φῆγος) of Theophrastus seems to have been some sort of oak with sweet acorns, and is by most botanical commentators referred to the *Quercus Esculus* of Linnæus.

FAHLORE, *Fahlerz*, grey copper ore. Of this there are two varieties, the *arsenical* and the *antimonial*; the former occurs crystallized and massive; the primary form of the crystal is a cube, but the regular tetrahedron is the predominating crystal. Colour steel-grey. Opaque. Lustre metallic. Sp. gr. 4.8, 5.1. Hardness 3.0, 4.0. Brittle. Cleavage parallel to the planes of the tetrahedron, very indistinct. Fracture conchoidal.

Massive Variety.—Amorphous. Structure, granular to compact.

It occurs in Cornwall, Hungary, Saxony, &c. A specimen from Freiberg, analyzed by Klaproth, yielded—

| | |
|---------|-------|
| Arsenic | 24.10 |
| Copper | 41. |
| Iron | 22.50 |
| Sulphur | 10. |
| Silver | 40 |
| Loss | 2. |

100.

It frequently contains a much larger quantity of silver, and not uncommonly zinc.

Antimonial Fahlore.—Occurs crystallized in modified tetrahedrons. Colour dark lead-grey, approaching to iron-black, both externally and internally; not very brittle.

Analysis of a specimen from Kapnic by Klaproth:—

| | |
|---------------------------------|-------|
| Antimony | 22. |
| Copper | 37.75 |
| Iron | 3.25 |
| Sulphur | 28. |
| Silver and a trace of manganese | 25. |
| Zinc | 5. |
| Loss | 3.75 |

100.

FAHLUNITE, *Tricklasite*. Occurs crystallized and massive. Primary form of the crystal a right rhombic prism, but it usually occurs in imbedded, regular, hexagonal prisms. Colour yellowish, greenish, and blackish-brown. Nearly or quite opaque. Lustre resinous. Sp. gr. 2.66. Hardness 5.0, 5.5. Streak greyish-white. Cleavage perpendicular to the axis of the prism.

It is found at Fahlun, in Sweden.

Before the blow-pipe alone it becomes grey, and fuses on its thinnest edges; with borax it melts slowly into a coloured glass.

According to Hissinger it consists of—

| | |
|--------------------|-------|
| Silica | 46.74 |
| Alumina | 26.73 |
| Magnesia | 2.97 |
| Oxide of iron | 5.11 |
| Oxide of manganese | 0.43 |
| Water | 13.50 |

95.48

FAHRENHEIT. [THERMOMETER.]

FAINTING. [SYNCOPE.]

FAIOM, a province of Egypt to the west of the Libyan ridge which bounds the valley of the Nile on the west. About 12 miles north-west of Benisouef there is a depression in the ridge about six miles in length, which leads to the plain of the Faioum. This plain is of a circular form, about 40 miles from east to west and about 30 from north to south. The northern and north-western part of this plain is occupied by the lake called Birket el Keroun, which spreads in the form of a crescent about 30 miles in length and about five miles broad towards the middle. A range of naked rocks bounds the lake to the north and joins towards the east the Libyan ridge which skirts the valley of the Nile. To the west and south the plain is bounded by lower hills which

divide it from the Libyan desert. It forms in fact a basin with only one opening or outlet to the east towards the Nile. The Bahr Yussouf, or great canal, which runs parallel to the Nile and skirts the Libyan ridge, on arriving at the gap above mentioned, at a village called Howarah Illahoun, turns to the west, passing under a bridge of three arches through which the water flows and forms a fall of about three feet at low water. It then runs along the valley, and, on reaching the entrance of the Faioum, at the village of Howarah el Soghair, a wide cut branches off from it to the right, running first north and then north-west, and passing by Tamieh meets the north-east extremity of the lake. About two miles below Howarah el Soghair another deep ravine opens to the south, and then turning south-west, passes by Nezeleh, and enters the south-west part of the lake. Between these two branches the cultivated part of the Faioum is contained. But these two cuts have been long dyked across at their beginning, in order to economize the water of the Nile, which, owing to the rising of the bed of the Bahr Yussouf, flows less copiously than formerly. Only a small part of the water finds its way to the lake by the Tamieh and Nezeleh cuts. The main stream continues its course westwards towards the middle of the plain and the town of Medinet el Faioum, the capital of the province. Here the water becomes distributed into a multitude of small canals for irrigation, which spread in every direction through the central part of the plain, and which are the cause of its extraordinary fertility, for the Bahr Yussouf contains water all the year round. But that fertility exists only within the range of the canals. All the part west of Nezeleh is arid and sandy, and only inhabited by a few nomade Arabs, though it bears the traces of former cultivation. The strip of land which borders the lake Keroun is low and marshy, marking the original basin of the lake which is separated from the cultivated lands by a considerable rise all along, reckoned by Jomard to be about 20 feet above the level of the lake. The village of Senhour, which is now some miles distant from the lake, was, in 1673, when Vansleb visited it, close to the water. Jomard reckons that when the water covered the whole of the low land below the rise above mentioned, its circumference must have been above 100 miles. [BRACKET EL KEROUN.] It is calculated that the land susceptible of cultivation in the Faioum is about 450 square miles, of which hardly one-half is now cultivated. The villages, which are said to have been at one time above 300, are now reduced to less than 70. Still the cultivated part is superior in fertility to every other province of Egypt, from which it differs in the greater variety of its products, and the better appearance of its villages. In addition to corn, cotton, and the other cultivated plants, it produces in abundance apricots, figs, grapes, and olives, and other fruit-trees, which thrive here better than in the valley of the Nile. This was also the case in antient times, for Strabo says that 'the Arsinoite nome (the antient name of the Faioum) excelled all others in appearance and condition, and that it alone produced olive trees, which were not found, elsewhere in Egypt except in the gardens of Alexandria. A vast quantity of roses also grow in the Faioum, and this district is celebrated for making rose-water, which is sold at Cairo and all over Egypt for the use of the wealthy.

The remains of antiquities in the Faioum are few. Two pyramids of some baked bricks about 70 feet high stand at the entrance of the valley, one near Howarah Illahoun, and the other near Howarah el Soghair. There is an obelisk of red granite 43 feet high, with two sides narrower than the others and a circular top, sculptured with numerous hieroglyphics, near the village of Bijige, a few miles south of Medinet el Faioum. In Burton's *Excursions* there is a drawing of it. Pococke i., 59, also gives a description of it. It is said to be of the same age as that of Heliopolis, bearing the name of Osirtesen I. (See an account of this obelisk in the *Library of Entertaining Knowledge, British Museum, Egyptian Antiquities*, vol. i., pp. 318—21.) Near Medinet el Faioum are some remains of the antient Arsinoe or Crocodilopolis, consisting of fragments of granite columns and statues, described by Belzoni. At Kasr Keroun, near the south-west extremity of the lake, is a temple 94 feet by 63 and about 40 feet high, which contains 14 chambers, and appears to be of the Roman period. On the north-west bank of the lake, at a place called Denay, a raised pavement or dromos, about 1300 feet in length, leads to a building, partly of stone and partly of brick, 199 feet by 67, divided

into several apartments and surrounded by an outer wall of crude brick 370 feet by 270. This is supposed to be the site of the antient Dionysias. Further to the east, but on the same bank of the lake, at a place called Kom Wassem el Hogar, are the ruins of Bacchis. The direction of the principal streets and the plans of many of the houses may be distinctly traced. The site of the antient labyrinth has not yet been ascertained; Wilkinson thinks it was near Howarah el Soghair, at the entrance of the plain. At Fedmain el Kunois, or 'the place of churches' in Coptic, near the south-east bank of the lake, are some remains of early Christian monuments: the village is now occupied one half by Copts and the other half by Mohammedans, who seem to live in harmony together.

The mountains along the north bank of the lake Keroun, on which the rains fall annually, are said to contain salt, and to this circumstance the saltiness of the waters of the lake is attributed by some. As the lake now receives but little of the waters of the Nile, the bitterness of its waters must have increased. No fish is said to be found in it, and Belzoni, at the time of his visit, saw nothing upon it except a crazy kind of ferry-boat.

South of the Faioum there is an opening through the ridge of low hills leading into a smaller circular plain or basin, with a small lake called Birket el Garaq, which has one or two hamlets on its banks. A small stream from the Bahr Yussouf runs into it. The road-track of the caravans to the smaller oasis passes through this place. (*Description of Egypt and Map* in the French work; Browne; Belzoni; and Wilkinson's *Topography of Thebes*.)

FAIR, an annual or fixed meeting of buyers and sellers; from the Latin *feria*, a holiday. Fairs in antient times were chiefly held on holidays.

Antiently before many flourishing towns were established, and the necessities or ornaments of life, from the convenience of communication and the increase of provincial civility, could be procured in various places, goods and commodities of every kind were chiefly sold at fairs; to which as to one universal mart, the people resorted periodically and supplied most of their wants for the ensuing year. The display of merchandise, and the conflux of customers at these principal and almost only emporia of domestic commerce, was prodigious; and they were therefore often held on open and extensive plains. Warton, in his 'History of English Poetry,' has given us a curious account of that of St. Giles's hill or down, near Winchester. It was instituted and given as a kind of revenue to the bishop of Winchester by William the Conqueror, who, by his charter, permitted it to continue for three days. But in consequence of new royal grants, Henry the Third prolonged its continuance to sixteen days. Its jurisdiction extended seven miles round, and comprehended even Southampton, then a capital trading town; and all merchants who sold wares within that circuit, unless at the fair, forfeited them to the bishop. Officers were placed at a considerable distance, at bridges, and other avenues of access to it, to exact toll of all merchandize passing that way. In the mean time, all shops in the city of Winchester were shut. In the fair was a court called the pavilion, at which the bishop's justiciaries and other officers assisted, with power to try causes of various sorts for seven miles round. Nor could any lord of a manor hold a court-baron within the said circuit without license from the pavilion. During this time the bishop was empowered to take toll of every load or parcel of goods passing through the gates of the city. On Saint Giles's eve, the mayor, bailiffs, and citizens of the city of Winchester delivered the keys of the four city gates to the bishop's officers; who, during the said sixteen days, appointed a mayor and bailiff of their own to govern the city, and also a coroner to act within it. Numerous foreign merchants frequented this fair; and it appears that the justiciaries of the pavilion and the treasurer of the bishop's palace of Wolvesey received annually for a fee, according to antient custom, four basons and ewers of those foreign merchants who sold brazen vessels in the fair, and were called *mercatores dianteres*. In the fair several streets were formed, assigned to the sale of different commodities, and called the *Drapery*, the *Pottery*, the *Spicery*, &c. Many monasteries in and about Winchester had shops or houses in these streets used only at the fair, which they held under the bishop, and often let by lease for a term of years. As late as 1512, as we learn from the Northumberland Household-book, fairs still continued to be the principal marts for pur-

chasing necessities in large quantities, which are now supplied by the numerous trading towns.

Philip, king of France, complained in very strong terms to Edward II. A.D. 1314, that the merchants of England had desisted from frequenting the fairs in his dominions with their wood and other goods, to the great loss of his subjects; and entreated him to persuade, and, if necessary, to compel them to frequent the fairs of France as formerly, promising them all possible security and encouragement. (See *Rym. Fœd.*, tom. iii., p. 482.)

When a town or village had been consumed, by way of assisting to re-establish it, a fair, among other privileges, was sometimes granted. This was the case at Burley, in Rutlandshire, 49th Edw. III. (*Abbrev. Rot. Orig.*, vol. ii., p. 338.)

The different abridgments of Stowe and Grafton's Chronicles, published by themselves in Queen Elizabeth's time, contain lists of the fairs of England according to the months. There is also 'An authentic Account published by the king's authority of all the Fairs in England and Wales, as they have been settled to be held since the alteration of the style; noting likewise the Commodities which each of the said Fairs is remarkable for furnishing;' by William Owen, 12mo. Lond. 1756.

No fair or market can be held but by a grant from the crown, or by prescription supposed to take its rise from some ancient grant, of which no record can be found. (2 *Inst.* 220.)

(See Dugdale's *Hist. Warw.*, pp. 514, 515; Warton's *Hist. Engl. Poet.*, vol. i., p. 279; Henry, *Hist. Brit.*, 8vo. edit., vol. viii., p. 325; Brand's *Popular Antiq.*, 4to. edit., vol. ii., p. 215.)

The fairs of Frankfurt on the Mayn and Leipzig are still pre-eminent in Europe; the former held at Easter and in the months of August and September; the latter at Easter, Michaelmas, and the New Year. Leipzig at these times is the mart and exchange of Central Europe, and is visited by merchants and foreigners, from the most distant parts of the globe, sometimes to the number of thirty or forty thousand. The whole book-trade of Germany is centred in the Easter fair at Leipzig.

FAIRFAX, EDWARD, was the second son of Sir Thomas Fairfax, of Denton in Yorkshire*. The date of his birth is unknown; but as his translation of Tasso's 'Jerusalem Delivered' was published in 1600, we may suppose that it fell some time in the reign of Queen Elizabeth.

Contrary to the habits of his family, who were of a military turn, he led a life of complete retirement at his native place, where his time was spent in literary pursuits and in the education, as is said, of his own children and those of his brother, one of whom became the celebrated Lord Fairfax. We learn from his own writings that he was neither 'a superstitious Papist nor a fantastic Puritan;' but farther particulars of his life there are none. He is supposed to have died about the year 1632.

Fairfax is now known only for his translation of Tasso's 'Jerusalem Delivered,' which is executed in a manner which makes it wonderful how the frigid, jingling, and affected version by Hoole ever survived its birth. The measure which he chose for his work (that of the original Italian) is one less stately perhaps than the Spenserian stanza, but not less fitted for heroic subjects. It consists of eight-line stanzas, of which the first six lines are in *terza rima* and the last two rhyme with each other. It has this great superiority over the common heroic couplet, that all jingle is avoided by the occasional introduction of a different species of rhyme. Moreover, the verses are much more harmonious than those of Hoole; the diction is more simple, and the English more pure. As the time is now gone by when Johnson gave the law in criticism, and Pope's method of versifying was the only one in repute, we may hope to see Fairfax's translation regain its ascendancy. We may now smile at the critic who asserts that Fairfax's translation 'is in stanzas that cannot be read with pleasure by the generality of those who have a taste for English poetry†;' but we must at the same time regret that a literary school like that of the followers of Pope should have usurped for so long a time such entire dominion as to enable one of its humblest members to make assertions so sweeping and insolent as those contained in the preface from which we have just quoted. (*Biographia*

Britannica; Preface to Fairfax's *Tasso*, edition 1749; Preface to Hoole's *Tasso*.)

FAIRFAX, SIR THOMAS, afterwards Lord Fairfax the son of Ferdinando Lord Fairfax and his wife, Mary, daughter of Edmund Sheffield, Lord Mulgrave, was born in the parish of Otley, at Denton, which is situated about 12 miles north-west of Leeds. He was sent from school to St. John's College, Cambridge; but we do not find that he was eminent as a scholar, for his disposition was inclined to military employment rather than to study. Accordingly, as soon as he left college, he enlisted in the army of Lord Vere, and served under his command in Holland. The connexion of Fairfax with Lord Vere afterwards became more close. When he returned to England, he married Anne, the fourth daughter of that peer, who, like her father, was a zealous Presbyterian, and disaffected to the king. If Fairfax did not already possess the same religious and political feelings, he soon imbibed the principles of his wife. When the king began to raise troops, as it was said, for the defence of his person, Fairfax, who foresaw that it was intended to collect an army, in the presence of nearly 100,000 people assembled on Heyworth Moor, presented a petition to the king in person, praying that he would listen to his parliament and refrain from raising forces. In 1642, when the civil wars broke out, he accepted a commission of general of the horse under his father, who was general of the parliamentary forces in the north. His first employment was in the county of York, where at first the greater number of actions between the parliamentary and royalist troops were in favour of the king, whose army was under the conduct of the earl of Newcastle. Sir Thomas Fairfax, somewhat dispirited, was despatched from Lincoln, where he was in quarters, to raise the siege of Nantwich, in Cheshire. In this expedition he was successful, not only in the main object, but he also took several garrisons, and on his return defeated the troops under Colonel Bellasis, the governor of York, and effected a junction with his father's forces (April, 1644). Thus Fairfax became master of the field, and, in obedience to his orders, proceeded towards Northumberland, to enable the Scots to march southwards, in spite of the king's forces, which were quartered at Durham. A junction took place between the Scots and Fairfax, who acted in concert during the spring (1644), and fought together in the memorable battle of Marston Moor (July 2, 1644), where the king's troops experienced such a signal defeat that the whole north, excepting a few garrisons, submitted to the parliament. Before Helmsley Castle, one of these fortresses, which Sir Thomas Fairfax was afterwards (September) sent to besiege, he received a wound in his shoulder that caused his life to be despaired of. When the earl of Essex ceased to be parliamentary general [Essex], it was unanimously voted that Fairfax should be his successor (January, 1644-5), and Cromwell by whom his actions were afterwards so greatly influenced, was appointed his lieutenant-general. Fairfax hastened to London, where, upon the receipt of his commission, the speaker paid him the highest compliments. After having been nominated governor of Hull, he marched to the succour of Taunton, in which place the parliamentary troops were closely besieged; but upon the king's leaving Oxford and taking the field with Prince Rupert, he was recalled before he had proceeded farther than Blandford, and received orders to join Cromwell and watchfully attend upon the movements of the king. On the 14th of June the decisive battle of Naseby was fought; and when the king had fled into Wales, Fairfax, marching through Gloucestershire, possessed himself of Bath, Bristol, and other important posts in Somersetshire. From thence, by the way of Dorsetshire, he carried his arms into Cornwall, and entirely dispersed the forces of the king.

After the surrender of Exeter, which was the last event of this western campaign, Fairfax returned to Oxford, which, as well as Wallingford, surrendered upon articles. In the autumn, after further active and successful employment, he was seized with a fit of illness, under which he laboured for some weeks. In November, when he returned to London, he was welcomed by crowds who came out to meet him on his road, was publicly thanked for his services, and received from the parliament a jewel of great value set with diamonds, together with a considerable grant of money. The payment of the 200,000*l.* to the Scottish army, in consideration of which they delivered up the king, was entrusted to Fairfax, who marched northward for this pur-

* He is said to have been illegitimate, but without sufficient proof.

† Hoole, Preface to his Translation of Tasso p. xviii.

pose. The discontent of the army, who were fearful either that they should be disbanded or sent to Ireland, now rose to a great height. Their complaints were encouraged by Cromwell and Ireton; a council was formed in the army by selecting two soldiers from each troop, and the Independents showed an evident desire to form a party distinct from the Presbyterians and the parliament, and to usurp for themselves a greater authority. Although Fairfax was in his heart opposed to these violent proceedings, and saw them with regret, yet he had not the resolution to resign his command. He remained the tool of Cromwell, following his counsels, until the army had become master both of the parliament and the kingdom.

In 1647 he was made Constable of the Tower; and in the following year, at his father's death, he inherited his titles, appointments, and estates. The difference of his condition made no alteration in his life; he continued to attack or besiege the royalist troops wherever they were mustered or entrenched. Many towns in the east, and among them Colchester, which he treated with great severity, yielded to his arms. In December he marched to London, menaced the parliament, and quartered himself in the palace at Whitehall. He was named one of the king's judges, but refused to act; and he was voted one of the new council of state (February, 1648-9), but refused to subscribe the test. In May he marched against the Levellers, who were numerous in Oxfordshire. He continued in command of the army until June, 1650, when, upon the Scots declaring for the king, he declined marching against them, and consequently resigned his commission. He now retired to his house at Nun Appleton, in Yorkshire, which for some years he made his principal residence. He left it (in 1659) to assist General Monk against Lambert's forces. In January, 1659-60, he made himself master of York. In the same month and in the February following he was chosen one of the council of state by the Rump Parliament, was elected one of the members for the county of York, and formed one of the committee appointed to promote the return and restoration of Charles II. In November, 1671, while residing privately at his country-house, he was seized with an illness, which terminated in his death. He was buried at Bilburch, near York. He left issue two daughters, Mary and Elizabeth. Mary married the duke of Buckingham; of Elizabeth we have no account.

The character of Fairfax was not distinguished for many vigorous qualities; the key to it may be found in the words of Clarendon: 'Fairfax wished nothing that Cromwell did, and yet contributed to bring it all to pass. He was courageous in battle, and sincere in his professions. He had an impediment in his speech: as an orator was not eloquent; as an author was indifferent: his love of literature was of no further benefit than as it served for the encouragement of others.' (Clarendon's *Hist.*; Whitelock's *Memorials*; Rushworth's *Coll.*; *Biog. Brit.*)

FAIRIES, a small sort of imaginary spirits of both sexes in human shape, who are fabled to haunt houses in companies, to reward cleanliness, to dance and revel in meadows in the night-time, and to play a thousand freakish pranks. Both sexes are represented generally as clothed in green, and the traces of their tiny feet are supposed to remain visible on the grass for a long time after their dances: these are still called fairy rings or circles. They are also fabled to be in the practice of stealing unbaptized infants and leaving their own progeny in their stead. Besides these terrestrial fairies there was a species who dwelt in the mines, where they were often heard to imitate the actions of the workmen, to whom they were thought to be inclined to do service. In Wales this kind of fairies were called 'knockers,' and were said to point out the rich veins of silver and lead. Some fairies are fabled to have resided in wells. It was also believed that there was a sort of domestic fairies, called, from their sun-burnt complexions, *Brownies*, who were extremely useful and who performed all sorts of domestic drudgery. The words fairy and brownie seem at once to point out their own etymologies.

Bourne, in his '*Antiquitates Vulgares*,' supposes the superstition relating to fairies to have been conveyed down to us by tradition from the *Lamiae*, or ancient sorceresses; others have deduced them from the lares and larvæ of the Romans. Dr. Percy tells us, on the assurance of a learned friend in Wales, that the existence of fairies is alluded to by the most ancient British bards, among whom their commonest

name was that of the Spirits of the Mountains. The most general conjecture, however, is, that these imaginary people are of oriental origin, and that the notion of them was first entertained by the Persians and Arabs, whose traditions and stories abound with the adventures of these imaginary beings. The Persians called them *Peris*, the Arabs *Ginn*; and the Arabs assigned them a peculiar country to inhabit, which they called *Ginnistan*, or fairy-land.

Shakspeare has been singularly happy in his dramatic exhibition of fairies. The belief in these fabled beings has still a fast hold upon the minds of many of our rustics, which may perhaps be considered as a remnant of that ignorant credulity which was once almost universal. Poole, in his '*English Parnassus*,' has given the names of the fairy court: Oberon the emperor; Mab the empress; Perriwiggan, Perriwinckle, Puck, Hobgoblin, Tomalin, Tom Thumb, courtiers; Hop, Mop, Drop, Pip, Trip, Skip, Tub, Tib, Tick, Pink, Pin, Quick, Gill, Im, Tit, Wap, Win, Nit, the maids of honour; Nymphidia, the mother of the maids. Dr. Grey, in his Notes on Shakspeare, vol. i. p. 50, gives us a description, from other writers, of fairy-land, a fairy entertainment, and fairy hunting. Dr. King's description of Orpheus' fairy entertainment (*Works*, edit. 1776, vol. iii. p. 112), and 'Oberon's clothing' and 'Oberon's diet,' in Poole's '*English Parnassus*,' almost exhaust the subject of fairy economy. A charm against fairies was *turning the cloak*. See Bishop Corbet's *Iter Boreale*. Anquetil du Perron's *Zend-Avesta*; Brand's *Popular Antiquities*, vol. ii. p. 327-350; Percy's *Reliques of Antient English Poetry*, 8vo. Lond. 1794, vol. iii. p. 207-215. The reader who would look further into fairy mythology may consult Sir Walter Scott's *Essay on the Fairy Superstition*, in the *Minstrelsy of the Scottish Border*; and more especially Keightley's *Fairy Mythology*, 2 vols. 8vo. 1828, in which the legends of different countries are collected.

FAITH (*fides*, in Latin), means belief or trust in a fact or doctrine, and is more especially used to express the belief of Christians in the tenets of their religion, and also by figure to mean that religion itself. The great divisions of Christianity, the Roman, the Greek, the Jacobite, the Reformed, or Calvinist, the Episcopal English, and the Protestant or Lutheran churches, have each separate confessions of faith, but they all acknowledge the great fundamental points of the Christian faith or religion, namely, the inspiration of the Scriptures, and the divinity of Jesus Christ. [CONFESSION.] In the earlier ages of the church the chief controversies of theologians, especially in the East, ran upon metaphysical questions concerning the mysteries of the Trinity, the Incarnation, and the divine nature of the Saviour. In modern times controversy has run more frequently upon moral questions concerning the conduct of men, the requisites of salvation, and the discipline of the Church. Faith, the necessity of which is acknowledged by all Christians, has been viewed in various lights with respect to its efficacy. From the earliest ages the Church has taught that faith, or belief in the Redeemer, joined with good works, was necessary for the justification of man; that good works, that is, works acceptable to God, could only be produced by the Spirit of God influencing the heart, but that the human will must co-operate with grace in producing them, though the human will alone is powerless to good unless assisted by divine grace. Still, man being a free agent, the will can call on God, through the merits of the Saviour, for a measure of his grace to assist its own efforts. Thus the co-operation of God and man was held as the means of the justification and salvation of the latter. Luther however and Calvin denied the power of the will to call on God for his grace; they substituted faith, and faith alone, in the merits of the Redeemer, as the means of salvation, by which faith man firmly believes that his sins are at once remitted. But this faith must be sincere, absolute, without a shadow of doubt or distrust; and as man cannot of himself obtain this, it can only be given to him by inspiration of the Spirit of God. Here the question of faith becomes involved with those of grace and predestination. As for our works, both Luther and Calvin look upon them as absolutely worthless for our salvation. Some fanatics, and the Anabaptists among the rest, drew from these premises of the leading reformers some very dangerous consequences, which Luther and Calvin had not anticipated, such as that men might live as profligately as they pleased, and yet, by the inspiration of divine grace, might obtain the faith requisite for their salvation.

The opinions of Luther and Calvin on the subject of faith and predestination have been since considerably modified by many Protestant divines, who have admitted that the will of man must co-operate in order to obtain the grace necessary for justification. The Roman Catholic church admits the merit of good works and repentance, united with faith, for the purpose of salvation. But then, it requires an absolute faith in all the decisions of its General Councils in matters of dogma, without the least liberty of investigation on the part of the laity, and without any doubt, for doubt itself is held to be sinful. The Reformed and Protestant churches, generally speaking, hold faith in the fundamental dogmas of Christianity as an essential requisite for salvation.

FAKENHAM. [NORFOLK.]

FAKIR, an Arabic word meaning poor, which is applied to the ascetics of several parts of the eastern world. In this sense it is synonymous with the Persian and Turkish *derwish*. The word *fakir* is chiefly used in India. There are *fakirs* who live in communities like the monks of the western world, and others who live singly as hermits, or wander about exhibiting strange displays of self-penance and mortification. Many of them are considered as hypocrites, and others are fanatics or idiots. [DERWISH.]

FALAISE, a town in France, the capital of an arrondissement, in the department of Calvados, near the source of the river *Anté*, which flows into the Dives: it is 127 miles from Paris, through Versailles, Dreux, Verneuil, and Argentan; in 43° 53' N. lat. and in 0° 14' W. long. The ancient castle of Falaise was one of the residences and strong-holds of the dukes of Normandie, and here William the Conqueror was born: it sustained fourteen sieges at different times, in the early troubles of the duchy of Normandie; in the wars of Henry I. of England with his brother Duke Robert and the Norman lords; in the invasion of France by Henry V. (A.D. 1417); in the expulsion of the English from France (A.D. 1450); and in the war of the League, in which Falaise was taken by Henri IV. in person (A.D. 1589). The fortifications, which were much injured in these attacks, are at present in a very dilapidated state: the donjon of the castle, situated on a bold and lofty rock, in the suburb of Guibray, is one of the proudest relics of Norman antiquity: its walls are in some parts eight or nine feet thick.

The town stretches along the top of a rocky ridge which rises abruptly from a fertile and well-wooded valley. The streets are wide, and the public fountains impart a freshness to the appearance of the place. Before the Revolution, there were twelve churches: there are now only four; two in the town, and two in the suburbs.

The population in 1832 was 9419 for the town, or 9581 for the whole commune. The inhabitants carry on a considerable manufacture of cotton yarn and hosiery. There is a large fair held in the suburb of Guibray, which is much frequented: it continues from the 15th to the 30th of August: many Norman horses are sold. This town has a tribunal de commerce, or court for commercial affairs, a high school, an agricultural society, and a theatre.

The arrondissement of Falaise contained, in 1832, a population of 62,349. The chief manufactures carried on in it are leather and paper: there are also many oil-mills.

FALAJAS. [ABYSSINIA, p. 58.]

FALCO. [FALCONIDÆ.]

FALCON. [FALCONIDÆ.]

FALCONER, WILLIAM, was born about the year 1730, being one of a large family, all of whom, except himself, were deaf and dumb. When very young, he served his apprenticeship on board a merchantman, and was afterwards second mate of a vessel in the Levant trade, which was shipwrecked on the coast of Attica, himself with two others being the only survivors. This event laid the foundation of Falconer's fame, by forming the groundwork of 'The Shipwreck,' which poem he published in 1762. The notice which the poem received enabled him to enter the navy, during the ensuing year, as midshipman in the Royal George. After some other appointments, he became purser to the Aurora frigate, and was lost in her somewhere in the Mozambique Channel, during the outward voyage to India, in the winter of 1769.

Falconer was the author of a 'Nautical Dictionary' of considerable merit, as well as of some minor poems; but his chief claim to reputation consists in 'The Shipwreck,' the merit of which is owing to the vividness and power of de-

scription which pervade the work, and to the facility the author has shown in introducing nautical language. His style is formed on a model which may now be thought erroneous, and is certainly the most artificial imaginable—that of Pope; and the mixture of phrases, such as 'weather back-stays,' 'parrels, lifts, and clew-lines,' with the affectations of 'nymph,' 'swain,' 'Paphian graces,' &c., form rather a ludicrous contrast. To call 'The Shipwreck' a first-rate poem, or to compare it with the *Æneid* of Virgil, would not now enter into many men's thoughts, although this was done at the time when it first appeared. Some might even assert that where there is no imagination, there is no poetry; but with all these limitations we must allow that Falconer has done what no one else ever attempted, and we must give him a high place among the writers of didactic poems.

(See Clarke's and Pickering's editions of *The Shipwreck*; Irving's *Life of Falconer*; Chalmers's *Biog. Dict.*)

FALCONET, ETIENNE, was born at Paris in 1716, of poor parents, of a family originally from Savoy. He studied sculpture under Lemoyne, whom he soon surpassed. He executed several groups and statues, which are at Paris, in the church of St. Roch, in the Musée des Monuments Français, and in several private collections. In 1766 he accepted the invitation of Catherine II. to repair to Petersburg, in order to execute the colossal statue of Peter the Great. He remained in that capital twelve years, during which he completed his work, which is now in the square called the Square of the Senate, and is perhaps the finest specimen of an equestrian statue existing. As he and the Russian founder appointed to cast the statue could not agree, Falconet cast it himself. He placed it upon an enormous block of granite, weighing about 1700 tons, which was found in some marshy ground at a considerable distance from Petersburg, and was brought to the capital by machinery. Catherine, who had shown him the greatest attention during the first years of his residence in the Russian capital, grew cool towards him at last, owing to the misrepresentations of some of her courtiers. Falconet returned to Paris in 1778. In May, 1783, as he was going to set off for Italy, a country which he had never visited, he had a paralytic stroke. He survived this misfortune several years, and died in January, 1791. In temper he was eccentric and blunt, but generous and warm-hearted. While at Petersburg he kept up a correspondence with Diderot, which is printed in Diderot's works. He wrote strictures and commentaries on the books of Pliny which treat of the sculpture and painting of the antients: he also wrote 'Observations sur la statue de Marc Aurèle,' in which he does not share in the admiration expressed by many for that work. In general, Falconet had no great veneration for ancient art. All his writings were published under the title, 'Œuvres Complètes de Falconet,' 3 vols., 8vo., Paris, 1808, to which is prefixed an account of his life.

FALCONIDÆ, Leach's name for a family of *Raptorial Birds*, or birds of prey. (*Raptures* of Illiger.) In this family the destructive power is considered by all zoologists to be most perfectly developed; and we find in the birds composing it natural instruments for striking, trussing, and dissecting their prey, combined with a power of flight and strength of limbs equivalent to the necessities of the case, whether the prey be aerial, that is, whether it be the habit of the raptorial bird in question to strike down its quarry while the latter is in the act of flight, or whether the prey be terrestrial, or, in other words, captured on the ground. Of these natural weapons some idea may be formed from the cuts here given.—

Bill of the Peregrine Falcon.

Foot of the Peregrine Falcon.

and they are rendered still more formidable by the organization of the whole animal, which is calculated to give them the greatest possible effect. The nails or claws, to be available, must be sharp; and in order that they may be kept in this state and fit for duty, there is a provision to enable the bird to prevent them from coming in contact with the ground or other foreign hard bodies: for the claws are retractile, not indeed in the same manner as those of the cats [*Felis*], which have the power of withdrawing or sheathing theirs within the integuments, but by a conformation which gives the bird of prey the power of elevating its claws at pleasure. The claws of falcons when sitting on stones or large branches of trees have often a cramped appearance; but this arises in most instances from the care of the bird so to arrange its talons that their points may not be blunted against the perch.

ANATOMY.

The power of flight, as Mr. Yarrell observes in his memoir *On the Anatomy of Birds of Prey* (Zool. Journ. vol. iii. p. 181), is one of the decided marks of the distinct organization of birds; and, as one division of the first genus, *Falco*, appears to possess this power in the highest degree of perfection, he proceeds to consider the conditions necessary to produce such a degree. These, he observes, are large and powerful pectoral muscles; great extent of surface, as well as peculiarity of form in the wing; and feathers of firm texture, strong in the shaft, with the filaments of the plume arranged and connected to resist pressure from below. 'A certain degree of specific gravity,' continues Mr. Yarrell, 'is necessarily imparted by large pectoral muscles, and the power of these muscles may be estimated by the breadth of the sternum and the depth of its keel, as affording extent of surface for the attachment of the large muscle by which the wing is depressed. As an illustration of this form the breast-bone of the peregrine falcon (*Falco peregrinus*) is represented, which ex-

Breast-bone of the Peregrine Falcon (Yarrell) reduced. a, the sternum; b, the keel; c, the furcula, or os furcatorius; d d, the clavicles; e, the scapula broken off.

hibits the breadth of the sternum, the depth of the keel, as well as the strength of the clavicles; and the power of flight peculiar to all the species of true falcons is still further illustrated by the form and substance of the *os furcatorius*, which is circular, broad, and strong, affording a permanent support to the shoulders. That the long and acuminated form of the wing in the true falcons, with

each feather narrow, firm in consistence, the second the longest, and all gradually tapering to a point, is also best adapted for rapidity of motion, may be inferred from the example in the various species of the genera *Hirundo*, *Scolopax*, *Tringa*, *Charadrius*, *Procellaria*, *Sterna*, &c.; out that extent of surface and this peculiarity of form in the wing are not in themselves sufficient alone to afford rapid flight, is proved in the genus *Larus*, the species of which, though capable of exercising their immense pinions with graceful ease for hours in succession, without any apparent lassitude, are still incapable of rapid flight, for want of strong pectoral muscles. The numerous examples also furnished by the *Gallinaceous* tribe sufficiently evince that immense pectoral muscles are insufficient when coupled with a small round wing, and afford but a short flight, sustained with great labour, rapid in a small proportion only to the strength and repetition of the impulse, and accompanied by a vibration too well known to need further remark. So material also is the perfection of the feather in the genus *Falco*, that when any of those of the wing or tail are broken, the flight of the bird is so injured that falconers find it necessary to repair them. For this purpose they are always provided with pinion and tail feathers accurately numbered, and the mode of uniting the more perfect feather to the injured stump is described in Sir John Sebright's excellent observations on hawking. The reader who is disposed to go farther back will find in the 'Booke of Falconrie or Hawking,' &c., &c., 'heretofore published by George Turberville, Gentleman,' (London, small 4to., 1611,) the following chapters:—'Of Accidents that happen and light uppon a hawks feathers, and first how to use the matter when a feather cannot be ymped.' 'The way and manner how to ympe a hawks feather, howsoever it be broken or bruised;' and four methods of operating, according to the circumstances, are detailed. 'How to ympe the traine of a hawks beeing all broken, and never a feather whole or sound.' Mr. Yarrell proceeds to observe that it is difficult to estimate the comparative rapidity of flight in different birds, and that our pigeons may appear to possess this advantage in a degree little inferior to the true falcons; but, he adds, the fact is that these birds are deficient in natural courage, and are unable, under circumstances, to avail themselves of those powers with which they are gifted.

'The bodies of all the species of true falcons,' writes Mr. Yarrell in continuation, 'when denuded of their feathers, are triangular in form, broad at the shoulders and tapering gradually to the tail, the muscles of the thighs and legs of great size; but these characters are less prominent in the hawks, the bodies of which are more lengthened, the legs long and slender, the pectoral muscles smaller, the wing rounded in form, the fourth feather the longest, the wing primaries broad in the middle, the inner webs overlapping the feather next in succession, and emarginated towards the end. These two divisions of the genus *Falco*, although the latter are unequal to the former in powers, are remarkable for their bold character and rapid flight, their invariable mode of striking their prey on the wing, as well as the instinctive knowledge by which they are directed to destroy life, attacking the most vital part, and penetrating the brain with their sharp hooked beak, either by one of the orbits where the bone is very thin, or at the junction of the cervical vertebrae with the occiput.

'On comparing the bones of our two British eagles, the greater power of flight appears to belong to the *Albicilla*, that of prehension to the golden eagle, but both exhibit various indications of great strength.

'By an extended examination of the different species of buzzards and harriers, it will be found that the characters described as necessary to produce rapid motion decline gradually. The sternum decreases in size, the keel loses part of its depth, the clavicles and furcula become more slight, while the form of the cranium, the loose ruffled feathers of the neck, as well as the general downy texture of the plumage, indicate the approach to the genus next in succession. Of the bones of the different species of the genus *Falco* generally, it may be added, that they are remarkable for their strength, such as are cylindrical being furnished with numerous transverse bony processes within the tubes, and the distribution of air throughout their internal cavities. The humerus is supplied with air through several orifices upon its inner and upper surface, and some difference will be found in the angle at which this bone is articulated with the clavicle to accomplish the ascending flight of the sky-

lark, in contradistinction to the precipitous horizontal direction of the falcons. The thigh bone is also supplied with air by an orifice at the situation which answers to the front of the great trochanter; the large bones forming the pelvis, the vertebrae, sternum, furcula, clavicles, scapulae, and even the ribs, are all furnished with apertures for the admission of air, supplied from the various cells of the abdomen, sides, and thorax. This distribution of air to the bones does not seem however to be absolutely necessary for flight, since the young birds of our summer visitors appear to perform their first autumnal migration with perfect ease and celerity, at an age when the cavities of their bones are filled with marrow.

'The various characters of the feet are too obvious to require particular notice.'

The reader is referred to the article BIRDS for the details of the rest of the skeleton of the *Falconidae*, as exemplified in the *Sparrow Hawk* (vol. iv., pp. 424, 425); and we shall now endeavour to give a sketch of the other internal parts worthy of notice, and especially of the organs of the senses.

Organs of Digestion.—In the Museum of the Royal College of Surgeons in London (Physiological Series), the reader will find a preparation (Gallery, 522 A.) of the stomach of the golden eagle. It is laid open, so as to show the orifices of the numerous gastric glands of the proventriculus, the smooth lining membrane of the gizzard, and the valvular structure of the pylorus. The oesophagus is very wide, so that externally it appears to form one continued cavity with the proventriculus and stomach. On the outer surface of the latter may be observed the two shining tendons from which the muscular fibres radiate; these however form a very thin layer in this and other carnivorous birds. A small quill is passed through the pylorus, which is guarded within by three cuticular tubercles, two on the upper side of the orifice and one below which fits into the interspace of the preceding. The crop has not been preserved in this preparation. (*Cat., Physiol. Series*, vol. i.) John Hunter, in his 'Observations on Digestion' (*Animal Economy*), says, 'There are few animals that do not eat flesh in some form or other, while there are many who do not eat vegetables at all; and therefore the difficulty to make the herbivorous eat meat is not so great as to make the carnivorous eat vegetables. Where there is an instinctive principle in an animal, directing it either to the one species of food or the other, the animal will certainly die rather than break through of its own accord that natural law; but it may be made to violate every natural principle by artificial means. That the hawk tribe can be made to feed upon bread I have known these thirty years; for to a tame kite I first gave fat, which it ate very readily; then tallow and butter; and afterwards small balls of bread rolled in fat or butter; and by decreasing the fat gradually, it at last ate bread alone, and seemed to thrive as well as when fed with meat. This, however, produced a difference in the consistence of the excrements; for when it ate meat, they were thin, and it had the power of throwing them to some distance; but when it ate bread, they became firmer in texture, and dropped like the excrement of a common fowl. Spallanzani attempted in vain to make an eagle eat bread by itself; but by inclosing the bread in meat, so as to deceive the eagle, the bread was swallowed and digested in the stomach.'

Mr. Yarrell observes, that the oesophagus offers nothing peculiar beyond that of other birds not possessing the power of minutely dividing their food. It is plicated lengthways, allowing great extension, and its separation from the stomach is marked by a zone of gastric rings. The same author notices an opportunity which occurred to him of observing the castings or pellets of some eagles, which had been occasionally fed with dead pigeons. These castings showed that the vegetable food, such as pease, wheat, and barley, which had been swallowed by the eagles in the crops of the pigeons, remained entire, but somewhat enlarged and softened by heat and moisture. In these cases no part of the bones remained.

The intestines of the *Falconidae* are in general short and large, but Mr. Yarrell remarks that the Osprey is an exception to this rule, and that to the thin membranous stomach of this bird there is attached an intestinal canal measuring 10 feet 8 inches in length, and in some parts scarcely exceeding a crow-quill in size. The canal in most of the species, he adds, is in length, compared with that of the bird itself, as three to one; but in the Osprey it is as eight to one: and he observes that in the other the intes-

tinal canal is very long, equal in size, and without caecal appendage; the seal, too, has long intestines with a small caecum. Mr. Yarrell inquires therefore if it may not be concluded that the small quantity of nutriment which fish, as an article of food, is known to afford, renders this extent of canal necessary in order that every portion may be extracted. The caeca of the *Falconidae* amount to no more than minute rudiments.

Organs of Respiration.—There is nothing very remarkable in these organs among the *Falconidae*. The trachea is composed of two membranes, inclosing between them numerous bony rings, forming a more or less perfect tube. The rings are strong and compressed. The point of divarication, the cross-bone and bronchiae constituting together the inferior larynx, are of the most common form, having but one pair of muscles attached; and the voice, though powerful, possesses, as might be expected, but little variation. (Yarrell.) *Falco musicus* seems, however, to be an exception, and it would be desirable to examine its trachea for the purpose of ascertaining whether it is not organized more after the fashion of that of the singing birds.

Organs of Sense.—Touch.—It might be expected that in the *Falconidae* the soles of the feet and lower surfaces of the toes which come so closely into contact with the living prey would be endowed somewhat more largely with the sense of touch than those of birds which have no such habits; accordingly, we find in the Museum of the College of Surgeons (Physiological Series) a preparation (No. 1400) of one of the feet of an eagle, with the cuticle removed, showing the papillae and cushions of the cutis on the under surface of the foot.

Taste.—In the same Museum (same series, No. 1482) will be found the tongue, larynx, and lower jaw of the Golden Eagle (*Aquila chrysaetos*). The tongue is fleshy and large, divided into two lateral portions by a deep longitudinal furrow; at its base is a series of small retroverted spines, arranged in the form of a chevron, between which and the larynx the surface is studded with the orifices of numerous glandular follicles: two rows of retroverted spines again occur behind the larynx. There is a row of glandular follicles on either side of the frænum linguae, and a large cluster of similar orifices immediately anterior to it. The preparations No. 1483 and 1484 exhibit respectively the tongue and fauces of an Erne (*Haliaetus albicilla*), and the tongue and larynx of an Osprey (*Pandion haliaetus*).

Smell.—A longitudinal section of the anterior part of the head of the Golden Eagle will be found in the same Museum and series (No. 1538). The preparation shows the turbinated cartilages and cavity of the nose, together with part of the orbit and the air-cell continued from it anteriorly, and situated below the nose. The parts are minutely injected, and the vascularity of the pituitary membrane covering the middle turbinated cartilage is well displayed. No. 1539 is a transverse section of the head of an Erne (*Haliaetus albicilla*), showing the convolutions of the middle turbinated cartilages, and the disposition of the pituitary membrane, which is thickest on the convex or mesial side of the convolutions. The air-cells in the superior maxillary bones, and their communications with those which are situated in front of the eye-ball, are well seen in this preparation. Bristles have been inserted into the lachrymal ducts, and into the common termination of the Eustachian tubes, the respective conduits of the eye and ear for conducting their superfluous moisture to the nasal passages. An anterior transverse section of the head of the same eagle is shown in No. 1540, which exhibits the external nostrils, the anterior terminations of the middle turbinated cartilages, and of the lachrymal ducts, in which bristles are placed; together with the communications of the maxillary air-cells with the cancellous structure of the upper mandible. (*Cat. Gallery*, vol. iii.)

Hearing.—Nothing remarkable.

Sight.—'The extraordinary powers of vision' says Mr. Yarrell, 'which birds are known to exercise beyond any other class of animals are in no genus more conspicuous than in that of *Falco*. Their destination, elevating themselves as they occasionally do into the highest regions, and the power required of perceiving objects at very different distances and in various directions, as well as the rapidity of their flight, seem to render such a provision necessary. The eyes of birds are much larger in proportion than those of quadrupeds, and exhibit also two other peculiarities. The one is the marsupium, a delicate membrane arising at

the bottom of the eye, and terminating at or near the edge of the crystalline lens: the other is a ring of thin bony plates, enveloped by the sclerotic coat. Comparative anatomists do not seem to be agreed as to the means by which birds obtain their power of vision, whether by an alteration in the form or situation of the crystalline lens, or by both, either or both of which, the greater quantity of aqueous humour which birds are known to possess would seem to facilitate. The existence of muscle attached to the inner surface of the bony hoop of the sclerotica, and inserted by a tendinous ring into the internal surface of the cornea, as shown by Mr. Crampton,* by which the convexity of the cornea may be altered, gives a still greater scope of action, since with two or at the utmost three varieties of powers, the sphere of distinct vision may be indefinitely extended. Whether the five species called the True Falcons possess, with their exclusive rapidity of flight, any power of vision beyond their generic companions, would be difficult to ascertain; but it may, while on this subject, be worthy of remark, that the irides of the *Gyr Falcon*, *Peregrine*, *Hobby*, *Martin*, and *Kestrel*, are hazel-brown, or still darker, while those of all the hawks, buzzards, harriers, and kites, are of various shades of yellow. I refer only to adult birds, and do not remember a single exception.

1, bony ring of a Golden Eagle; 2, crystalline lens of the same bird; 3, the anterior surface, somewhat less convex than the posterior one (Yarrell).

Mr. Yarrell observes, that the number of bony plates forming this circle in the Golden Eagle is fifteen; in the White-tailed Eagle there are but fourteen: and he adds, that the external convex form of the bony ring in the Golden Eagle will be found to extend through all the species of every genus of British birds, except the owls, in all of which it is concave.

In the Museum of the College of Surgeons (*Physiological Series, Gallery*) are the following preparations illustrative of this part of the subject. No. 1741. The head of an eagle, with the eyes *in situ*. In the left eye the anterior part of the tunics and the humours have been removed to show the retina expanding from the oblique line by which the optic nerve terminates, and the vascular processes of the *marcupium* extending forwards from the centre of the optic fissure. In the right eye a lateral section of the coats has been removed, together with the humours and a great part of the retina, showing the uniformly dark-coloured choroid, the thin but dense texture of the *sclerotica*, and the zone of osseous plates which supports the projecting *cornea*. The *marcupium* is preserved *in situ*. It is of an unequal quadrilateral figure, broadest below, and extending upwards and inclined a little backwards, with a slight convexity towards the nasal side of the eye-ball. The large size of the eyes is worthy of notice. No. 1742 exhibits a longitudinal section of the eye of an eagle, showing the oblique manner in which the optic nerve perforates the *sclerotica* and its extended termination, from which the *retina* expands in a plicated manner: only the folds at its origin are here preserved. The parts being minutely injected, the vascularity of the choroid is shown; also the breadth of the ciliary zone, the breadth and thickness of the bony imbricated hoop surrounding the base of the *cornea*, the thickness of the *cornea* itself, and the large size of the anterior chamber of the eye. No. 1743 is the eye of an eagle, with a portion of the coats removed from one side, showing the folds of the marsupial membrane, from which the colouring matter has been removed. In No. 1538 above alluded to portions of the eye and eye-lids with the nictitating membrane are preserved, showing the situation of the two *puncta lachrymalia*, through which bristles are passed along the ducts to the nose; and in No. 1539, at the back part of the preparation, the left eye-ball is laid open, showing the marsupial membrane. The right eye-ball is entire, and the *abductor*, *attollens*, and *deprimens oculi*, together with the *quadratus* and *pyramidalis* muscles of the *membrana nictitans*, are well displayed. See also No. 1540, as referrible to the organs

of vision. No. 1796 exhibits the eye-ball, with portions of the horizontal eye-lids, the vertical eye-lid, or *membrana nictitans*, of an eagle. The *quadratus nictitans* may be observed to have a more extensive origin than in the ostrich, and both muscles of the third eye-lid are relatively larger. The *cornea* is cut away, and the nictitating membrane raised. To show the termination of the duct of the Harderian gland, in which a bristle is placed. Bristles are also placed through the two *puncta lachrymalia*. The round and slightly concave tarsal cartilage of the lower eye-lid may be observed. The upper lid has no tarsal cartilage. In No. 1797 the three eye-lids of an eagle are exhibited, and the tarsal cartilage, which is raised as in the act of closing the eyes, is shown (*Cat. Gallery, Physiol. Series, vol. iii.*)

NATURAL HISTORY.

Aristotle divided the *Falconidae* into 'Aerol or Aleri' (Eagles), 'Iipaxec' (Hawks), and 'Ierivov' (Kites), with many subdivisions. Mr. Vigors is of opinion that the division 'Iipa' (Hierax) of Aristotle comprises all the *Falconidae* of Vigors which belong to the stirpes or sub-families of *Hawks*, *Falcons*, and *Buzzards*. Pliny separates the group into *Aquila* (Eagles) and *Accipitres*, a general term comprising, as used by him, the rest of the *Falconidae*. The subdivisions of both Aristotle and Pliny do not differ much from the subdivisions of some of the modern zoologists.

Belon, beginning with the Vultures, proceeds from them to the Eagles; thence to the *Gersault*, which he gives as the *Morphos*, *Morphna*, *Nittophonos*, *Plangos*, *Plancus*, *Plangus*, and *Clangus* of the Greeks, and *Anataria* of the Latins; next he places the *Orfraye*, which he makes the *Hakæstus* of the Greeks, the *Aguista piombina* of the modern Italians, and gives *Aquila marina* as the Latin name. He then treats of the *Ossifragus* as the *Phiris* of the Greeks, *Aquila barbata* in Latin, recording it provisionally as a species of *Vulture* (*Petit vautour*), and next describes the *Buzzard* (Buse ou Busard) as a kind of *bastard Eagle*, and as the *Gypætos*, *Pernopteris*, or *Oripolargus* of the Greeks. Then comes the *Goulan* or *Boudree*, which he describes as living upon rats, mice, frogs, lizards, &c., caterpillars, and sometimes slugs and serpents, asserting that it becomes very fat, and that it is taken frequently in winter for the sake of its flesh, which is good for food. This he supposes to be the *Hierax*, called *Phrynolochos* by the Greeks, and gives *Rubetarius* *Accipiter* as the Latin name. *Jean le Blanc*, or *Oyseau Saint Martin*, which he considers to be the *Pygargus* of the Greeks, follows, and is succeeded by another *Oyseau Saint Martin*, or *Blanche-queue*. Belon then gives an account of the birds of prey employed in falconry. The *Sacre* and her *Sacret*, the *Autour* and her *Tiercelet*, the *Fau-perdrieux* (Circus?), and the *Falcons* generally, with their *Tiercelets*.* He then describes the *Hobbeau* (Hobby?), the *Emerillon* (Merlin?), the *Espervier* (Sparrowhawk?), the *Lanier* and *Laneret*, and the *Cresserelle* (Kestrel?). Next follow the *Butcher-birds*, then come the *Kites* (Milan Royal, Milan Noir—Milvus), and (the *Cuckoo* intervening from a supposed similitude to the Birds of Prey) the *Owls*.

Passing by Gesner, Aldrovandus, and Jonston, we pause to notice Willughby's arrangement. He separates the carnivorous and rapacious birds, called *Birds of Prey*, into the *Diurnal* (those that prey in the day-time) and the *Nocturnal* (those that fly and prey by night). The following is his table of the *Diurnal* section.

| | | | |
|---------|---|--|--|
| Diurnal | The Greater, and these either . | The more generous, called <i>Eagles</i> : the Golden Eagle, the Sea-Eagle, the Black Eagle, &c. | |
| | | The more cowardly and sluggish, called <i>Vultures</i> . | |
| | The Lesser, called in Latin <i>Accipitres</i> . | The more generous, that are wont to be reclaimed and trained for fowling, called <i>Hawks</i> , which our falconers distinguish into . | |
| | | Long-winged, whose wings reach almost as far as the end of their train, as the <i>Falcons</i> , <i>Lanner</i> , &c. | |
| | | Short-winged, whose wings when closed fall much short of the end of their trains, as the <i>Goshawk</i> and <i>Sparrowhawk</i> . | |
| | | The more cowardly and sluggish, or else indolent, and therefore by our falconers neglected, and permitted to live at large . | |
| | | The Greater.—The Common Buzzard, Bald Buzzard, &c. | |
| | | The Lesser . | |
| | | European; BUTCHER-BIRDS OF SWITZERLAND. | |
| | | Kentic; BIRDS OF PARADISE. | |

* It is a general rule that, in the *Falconidae*, especially among the birds of prey, the female is larger than the male.

Ray, in his 'Synopsis,' follows Willughby, and both Ray and Willughby place the Cuckoo after their Diurnal Birds of Prey and immediately before the Nocturnal.

Brisson's third order consists of birds with a short and crooked beak, and the first section contains the genera *Epervier* (Hawk), *Aigle* (Eagle), and *Vautour* (Vulture).

Linnæus makes his first order, *Accipitres*, consist of the genera *Vultur*, *Falco*, *Strix*, and *Lanius*. The genus *Falco* contains the elements of the different branches of the family of *Falconidae*.

Without entering into the methods of Buffon, Schœffer, and Scopoli, we proceed to that of Latham, who made the *Accipitres* his first order of Terrestrial Birds, containing the genera *Vulture*, *Falcon*, and *Owl*.

Pennant makes the *Rapacious Birds* (his first section) consist of two genera only, viz. *Falcon* and *Owl*.

M. de Lacépède placed the *Birds of Prey* (his seventh order) at the head of his second Division of Birds. His genera are *Vultur*, *Gypætos* (Griffon), *Aquila*, *Astur*, *Nisus*, *Buteo*, *Circus*, *Milvus*, *Falco*, and *Strix* (Owl).

M. Duméril divided his first order, *Rapaces*, into three families; the first *Nudicolles* or *Philodères*, consisting of the genera *Sarcoramphus* and *Vultur*; the second *Plumicolles* or *Cruphodères*, containing the genera *Griffon*, *Messenger*, *Aigle*, *Buse*, *Autour*, and *Faucon*; and the third the *Nocturnes* or *Nycterins* (Owls).

Blumenbach's first order, *Accipitres* (Birds of Prey, with strong hooked bills and large curved talons, a membranous stomach, and short cæca) consists of the genera *Vultur*, *Falco*, *Strix*, and *Lanius*.

Meyer's first order, *Rapaces*, is divided into two suborders: first, the *Scleroptères*, or *Diurnal Birds of Prey*; second, the *Malacoptères*, the *Nocturnal Birds of Prey*.

The third order of Illiger, *Raptatores*, is composed of the *Nocturni* (*Strix*), the *Accipitrini* (*Falco*, *Gypogeranus*, *Gypætos*), and the *Vulturini* (*Vultur*, *Cathartes*).

Cuvier divides his first order (the Birds of Prey) into *Diurnal* and *Nocturnal*. The first are subdivided into the *Vultures* and the *Falcons* (*Falco*, Linn.), which last are separated into the *Noble Birds of Prey*, or *Falcons properly so called* (*Falco* of Bechstein), comprising the genera *Faucon* (*Falco*) and the *Gersfautes* (*Gyr-falcons*, *Hierofalco* of Cuvier); and the *Ignoble Birds of Prey*, consisting of the *Eagles* (*Aquila* of Brisson), which are subdivided into the *Eagles properly so called* (*Aquila* of Cuvier), the *Aigles-Pêcheurs* (Fishing Eagles, with comparatively long wings, *Haliaeetus* of Savigny), the *Balbusards* (*Pandion* of Savigny), the *Circætes* (*Circætes*, Vieillot, *Jean le Blanc*, &c.), the *Caracaras* (*Polyborus*, Vieillot, and *Ibycter*, Vieillot), and the *Harpies* or Fishing Eagles, with short wings, (*Harpyia* of Cuvier; the tribe *Cymindis* of Cuvier; the *Aigles-Autours* (*Morphnus* of Cuvier, *Spizaetos* of Vieillot); the *Autours* (*Astur* of Bechstein, *Dædalion* of Savigny); the *Milans* (*Milvus* of Bechstein, *Elanus* of Savigny); the *Bondrées* (*Pernis* of Cuvier, *Honey Buzzard*); the *Buses*, *Buteo* of Bechstein; the *Busards* (*Circus* of Bechstein); and the *Messenger* or *Secrétaire* (*Serpentarius* of Cuvier, *Gypogeranus* of Illiger).

Vieillot divides his first order, *Accipitres*, into the *Diurnal* and *Nocturnal* tribes, making the first tribe to consist of three families; 1st. *Vautourins*, among which he places the *Caracara*; 2nd. *Gypætes*; 3rd. *Accipitrins*, consisting of the genera *Aigle*, *Pygargue*, *Balbusard*, *Circæte*, *Busard*, *Buse*, *Milan*, *Elanus*, *Ictinie*, *Faucon*, *Physète*, *Harpie*, *Spizaète*, *Asturine*, *Epervier*.

Temminck's first order, *Rapaces*, comprises the genera *Vautour*, *Catharte*, *Gypæte*, *Messenger*, *Faucon*, *Chouette*.

Mr. Vigors thus arranges the *Falconidae*.

| TYPICAL GROUPS. | | | |
|--|---|----------------------------------|----------|
| Beaks short, strongly toothed. Prey aerial. | Wings short. | Sub-family, <i>Accipitrina</i> . | HAWKS. |
| | Wings long. | Sub-family, <i>Falconina</i> . | FALCONS. |
| ABERRANT GROUPS. | | | |
| Beaks long, or sublong, not toothed. Prey terrestrial. | Beaks hooked (advance) from the base. Wings long. | Sub-family, <i>Buteonina</i> . | BUSARDS. |
| | Beaks hooked from the base; Tail forked. Wings very long. | Sub-family, <i>Milvina</i> . | KITES. |
| | Beaks hooked at the apex only. | Sub-family, <i>Aquilina</i> . | EAGLES. |
| | Long-winged. | | |
| | Short-winged. | | |

De Blainville divides the *Raptatores* into the *Diurnas* and the *Nocturnal*. The former he divides into the *Anomalous* (the Secretary, *Serpentarius*); and the *Normal* (*Falco*, Linn.).

M. Latreille separates his first order of terrestrial birds (*Rapaces*) into two tribes—the diurnal and the nocturnal. The first contains two families: 1st, The *Vautourins* (*Vultures*); 2nd, The *Accipitrins*. The latter consists of the genera *Aigle*, *Pygargue*, *Balbusard*, *Harpie*, *Aigle-Autour*, *Asturine*, *Messenger*, *Autour*, *Epervier*, *Élane*, *Milan*, *Bondrée*, *Buse*, *Busard*, *Faucon*, *Gersfaute*.

C. L. Bonaparte (Prince of Musignano), in his 'Tabella Analitica,' divides his 'Ordine' *Accipitres* into the 'Famiglia *Vulturina*,' and the 'Famiglia *Rapaces*.' These last he separates into the *Diurni*, with eyes on the sides of the head, 'Occhi nei lati,' and the *Nocturni*, with eyes in the face, 'Occhi sulla faccia.' His diurnal rapacious birds consist of two genera, viz., *Gypætos* and *Falco*. The latter comprises the following sub-genera:—*Aquila*, *Haliaeetus*, *Pandion*, *Falco*, *Astur*, *Milvus*, *Elanus*, *Buteo*, *Circus*.

M. Lesson, in common with other zoologists, separates his first order, the *Birds of Prey*, *Accipitres*, or *Rapaces*, into the diurnal and nocturnal. The first embraces three families:—1st, The Vultures; 2nd, The Falcons, or *Falconidae*, which he subdivides into the *Noble Birds of Prey*, viz. the genera *Falco*, *Hiero-Falco*, *Physeta*, and *Gampsonyx*; and the *Ignoble Birds of Prey*, viz. the genera *Aquila*, *Haliaeetus*, *Pandion*, *Circætes*, *Caracara*, *Harpyia*, *Morphnus*, *Cymindis*, *Astur*, *Nisus*, *Milvus*, *Ictinia*, *Elanus*, *Nauclerus*, *Pernis*, *Buteo*, *Circus*. 3rd, The *Messengers*, or *Serpentarii*, consisting of one genus only, *Serpentarius*, the Secretary Falcon.

Mr. Swainson (*Fauna Boreali-Americana*) remarks that in contemplating the diurnal birds of prey, arranged by Linnæus under the genus *Falco*, we can be at no loss to discover the two typical forms in the *Toothed-billed Falcons* and the *Sparrow-hawks*. Their peculiarities, he adds, did not escape the notice even of the earliest systematic writers, and the moderns, he observes, have only confirmed the justness of the distinction. But with regard to the remaining groups, he states that much diversity of opinion still exists; not, indeed, as regards the leading divisions, for here likewise the antients had long ago anticipated our distinctions between the *Eagles*, *Kites*, and *Buzzards*. It is not, therefore, to these groups, taken *per se*, that any doubts can attach on their respective peculiarities, but rather as to their relative rank with those that are considered typical. These doubts, in Mr. Swainson's opinion, can only be solved by analysis; and from an attentive consideration of the difficulties arising from the want of materials in our museums, and other causes, he has been induced to dissent from several modern writers upon this family. He admits that it has been sufficiently proved that the various forms of which it is composed exhibit, as a whole, a circular succession of affinities; but the true series of the secondary groups, among themselves, has not, he asserts, yet been made out: he adds however, that the inability to state in what way the falcons or hawks form their own respective circles cannot militate against the belief that such is their true distribution. 'It remains, therefore,' continues Mr. Swainson, 'to be considered whether there is presumptive evidence to believe that the three remaining divisions, namely the *Buzzards*, *Kites*, and *Eagles*, form one circular group, independent of their affinity to the two former. The true *Buzzards*, of which the *Vulgaris* and the *Lagopus* may probably be types, are slender long-winged birds; the bill is small, short, and considerably curved: in this structure they agree with the true falcons, yet they are well known to be distinguished from them by wanting the toothed-bill, and by the shortness and graduated abbreviation of the exterior quill-feathers. Now, if Nature had proceeded in a simple course from the buzzards to the falcons, we should have had birds uniting the distinctions of both variously modified. Both these groups being composed, in their typical examples, of slender long-winged birds, with short bills, any species exhibiting the reverse of such characters, and intervening between the two forms, would certainly appear anomalous, on the supposition of a simple series of affinities being aimed at. Yet, that such birds are to be found, even among the few that we are subsequently to notice, is unquestionable. Let us then take the *Buteo borealis*, which, as being more allied to the falcons than to the kites, may be considered an intervening

form between the *Buteo vulgaris* and *Falco*. We here see a large-sized, heavy bird with shortened wings, not reaching to more than half the length of the tail; while the elongated bill, unlike either that of *Buteo* or *Falco*, obviously assimilates to that lengthened form which belongs to the eagles. Now, upon the supposition that a bird so constructed is intended to fill up the interval between *Buteo* and *Falco*, and at the same time to unite the former with the *Eagles*, the singularity of its structure is no longer surprising: but if we consider it with a simple reference to the passage between *Buteo* and *Falco*, we are almost tempted to suspect that, in this instance, a real *saltus* has been made. While upon this subject we may cite an acute observation made by Prince C. Bonaparte, that 'the *Borealis* is almost as much an *Astur* of the first section as a *Buteo*;' a proof, at least, that its affinities to *Astur* and to the aberrant eagles adjoining that group have not escaped observation. Our idea that the buzzards are truly united to the eagles is still further strengthened by the *Buteo pterocles*, Temm.***. In this species the wings, as in *Buteo*, are remarkably long, but the bill is so considerably lengthened, that were we to judge alone from this member, we should have no scruple in placing the bird among the *Aquila*. On the other hand, it must be remembered that, as every group, from the highest to the lowest denomination, when perfect, contains a representation of the other four, united to a form peculiar to itself, so we might naturally expect that one division of the buzzards would represent the true eagles. To ascertain, therefore, whether the resemblances above stated are those of analogy or of real affinity, recourse must be had to strict analysis. Now this, in our present state of knowledge, cannot be done, at least from the resources to be found in this country. We have thought it advisable to cite the above facts, drawn from the structure of the birds themselves, as likely to awaken the attention of ornithologists to a further investigation of the subject; they will, at least, show that our opinion on the unity of the three aberrant groups is not entirely without foundation. Mr. Swainson considers the relative value of the whole group equivalent to that of *Vultur* or *Strix* in its own order, and to the families composing the *Rasores*, *Grallatores*, and *Natatores*, and he contemplates the five principal divisions as *genera*, arranging the subordinate forms as *sub-genera*; but in considering the five forms of the *Falconidae* as *genera*, rather than sub-families, he guards himself against the supposition that he may mean to insinuate that the minor distinctions which have been dwelt upon by several able ornithologists who have investigated this family, are either trivial, or that they deserve not to be brought immediately before us. On the contrary he recommends to others the plan adopted by himself, viz. the minute examination of every change of structure, and the assembling together in minor groups such species as agree in certain peculiarities. Further, he would proceed, in certain cases, even to impose a name upon such groups. but in a family already so crowded by generic names he considers it essential to preserve a distinction between groups of unequal value; and not to elevate sub-genera, or forms of transition, to a rank they do not hold. *Milvago*, *Polyborus*, *Daptrius*, and *Ibycter*, are, unquestionably, in his opinion, of the latter description, each confined but to one species, and he says that he has another of the same natural group in his cabinet, equally deserving a patronymic name. By regarding these as *genera*, each, as he thinks, is made equivalent to the whole genus of typical falcons; whereas, by representing them as lesser variations, which he considers them in truth to be, the student immediately perceives that their station is subordinate.

The genera into which Mr. Swainson divides the *Falconidae* are *Falco*, *Accipiter*, *Buteo*, *Cymindis*, and *Aquila*; and he gives the following table as the concentration of his remarks in reference to the sub-genera of *Falco*.*

1. Typical group.

Sub-genera
of *Falco*.

Genera of the
Falconidae.

Falco. { Pre-eminently typical; bill
acutely toothed; wings
pointed, rather long. } **FALCO.**

2. Sub-typical group.

Harpagus. { Wings shorter, rounded;
tarsi with entire transverse
scales. } **ACCIPITER.**

3. Aberrant group.

| | | |
|--------------------|---|------------------|
| <i>Lophotes</i> . | Feet short; head crested. | AQUILA. |
| <i>Aviceda</i> . | { Feet small, very short; soles broad and flattened; outer toe and claw shortest. } | CYMINDIS. |
| <i>Gampsonyx</i> . | { Bill neither notched or (nor) festooned; head small; feet strong. } | BUTEO. |

By throwing each of these columns into their respective circles, and then bringing them into juxtaposition (which he does in the work quoted) the same results, he remarks, will follow. Into the accipitrine circle he admits *Ictinia*, provisionally, *Accipiter* (type), *Astur* (Goshawks), *Haliaeetus* (*H. Pondicerianus*), and no more. In the Aquiline circle he retains four 'types,' viz. *Fundion*, *Harpyia*, *Aquila*, and *Ibycter*. In the Cymindian or Milvine circle he places *Polyborus*, *Cymindis*, *Elanus*, *Nauclerus*, and *Circetus*, the last with a query, and in the cut of the circle it is not mentioned. In the Buteonine circle *Milvus*, *Circus*, and *Buteo*.

Mr. Vigors who, as we have seen, first proposed the application of the Quinary System to the *Falconidae*, and indeed to the birds in general, thus defines the family which is the subject of our inquiry, and thus follows out his arrangement

FALCONIDÆ. (Leach.)

Head plumose. *Beak* strong, hooked, with a cere at the base. *Nostrils* lateral, more or less rounded, open and situated in the cere. *External toes* especially connected with the middle toes. *Clares* or *nails* strong, very sharp, very much incurved, and retractile.*

1st. Sub-family, *Aquilina*.

Beak long, hooked at the apex only. Fourth quill the longest.

Long-winged Eagles.

Genera. *Ibycter*. (Vieillot.)

Beak convex above. *Lower mandible* notched at the apex, and subacute. *Cere* naked. *Cheeks*, *throat* (gula) and *crop* (jugulum) featherless. *Clares* acute.

Mr. Vigors remarks that the type of this genus is *Falco aquilinus* of Gmelin, *Petit Aigle d'Amerique* of Buffon, and that he believes it still stands single in the genus.

Description. *Beak* caerulean; *cere* and *feet* yellow; *orbis* yellow; *irides* orange; *body*, above, caerulean; below red going into white; *neck* purplish to rufous; *claws* black. Gmelin gives it as the *Red-throated Falcon* of Latham

Locality, South America.

Head and Foot of *Ibycter Aquilina*.

* The characters of the sub-families and genera are from those given by Mr. Vigors.

* Natural History and Classification of Birds. London, 1836.

Daptrius. (Vieillot.)

Beak convex above. Lower *mandible* angular beneath, notched at the apex, obtuse. *Cere* with scattered hairs. *Orbits*, *throat*, and *crop*, featherless. *Claws* acute.

'How far,' writes Mr. Vigors, 'the two preceding genera of M. Vieillot are sufficiently distinct from each other, or from the remainder of the naked-cheeked *Eagles*, it is not for me to hazard an opinion, without the opportunity of more accurate examination of the birds than is at present within our power, and a more accurate knowledge of them than a mere description affords us. It would appear, however, that one group at least, that of *Ibycter*, is sufficiently distinguished from the other *Falconidae* with the naked cheeks, by the difference of its food and habits. The accounts which have reached Europe of its mild and gentle manners and vegetable food have even induced some naturalists to refer it to the Gallinaceous Birds. I have strong doubts indeed whether the birds that compose this genus may not belong to quite a distinct station from the present, and be referrible to one of those groups which I have elsewhere observed to be wanting among the Birds of Prey, to perfect that chain of affinities which is to be found complete in all the other orders. It is impossible, however, at present, to come to any decision on the subject. While our materials for classification are so scanty, the most that is in our power is to conjecture the place which more perfect information will enable us to assign any group hereafter. For the present we may leave the genus before us in that situation, between the *Vulturidae* and the *Falconidae*, which they have hitherto been generally supposed to fill.'

Example, *Daptrius ater*.

Description.—Black with bluish reflections; *tail* white at its base above, and rounded; *beak* and *claws* black; *cere* blackish ash, space round the eyes naked and of a flesh-colour; *feet* yellow. Length from 14 to 15 inches French. This is the *Iribin noir* of Vieillot, and the *Caracara noir*, *Falco aterrimus*, of Temminck. *Locality*, Brazil and Guiana. M. Lesson notes it as probably a genus for suppression

Head and Foot of *Daptrius ater*.

Polyborus. (Vieillot.)

Beak compressed above. Lower *mandible* entire and obtuse; *cere* covered with hairs, large; *cheeks* and *throat* featherless; *crop* woolly. Example, *Polyborus Brasiliensis*,

Polyborus vulgaris. Vieillot. The Brazilian Caracara Eagle.

We select Mr. Bennett's *Description* and general history of this species as the most complete. After giving the generic characters, and observing that the wings nearly equal the tail in length, that they are of a rounded form with the third and fourth quills longest; that the legs are rather long, naked, and reticulated, and the claws of moderate length and curvature, but with little acuteness or power of grasping, the last-named author thus proceeds:—'In the Brazilian Caracara the whole upper surface of the head is black, with the feathers slightly elongated backwards, and capable of being partially elevated in the shape of a pointed crest. The entire neck is of a light brownish gray, which also forms the ground colour on the breast and shoulders, but with the addition on these parts of numerous transverse wavy bars of a deeper brown. Nearly all the rest of the plumage is of a tolerably uniform shade of blackish brown, with the exception of the tail, which is at the base of a dirty white, with numerous narrow, transverse, undulated bands of a dusky hue, and, in its terminal third, black without any appearance of banding. The beak is horn-coloured at the tip and bluish at the base; the iris hazel; the cere and naked cheeks of a dull red; the legs yellow, and the claws black. Such at least are the colours of the living specimen in the Society's garden. Several changes, however, take place in the plumage of the bird as it advances in age, and these are well illustrated by an extensive series of specimens in the Museum in Bruton-street, —now in Leicester Square. 'So great in fact is the variation of colours in this species that scarcely any two descriptions of it correspond throughout, and the figures by which it has been illustrated differ from each other even more remarkably than the descriptions by which they are accompanied.' (*The Gardens and Menagerie of the Zoological Society delineated*, vol. ii.)

The same author observes that Marcgrave was the first to introduce into Europe the name of Caracara, the vulgar appellation of the bird in Brazil, derived from its hoarse and peculiar cry. But although M. Cuvier regards Marcgrave's Caracara as identical with the species described by Mr. Bennett, the latter remarks that both the figure and description are so much at variance with it that he feels himself compelled to adopt in preference the opinion of Professor Lichtenstein, founded upon the original drawing, that they belong to a totally different bird. Mr. Bennett is consequently unable to trace the history of the true Caracara beyond the year 1784, when a figure and description were published at Vienna by the younger Jacquin, from his father's papers, under the name of *Falco cheriway*. These Mr. Bennett has no hesitation in referring to the present species. The principal differences between them consist, he states, in the markings on the breast and neck, which in the figure are more longitudinal than transverse; and in the very awkward foreshortening of the beak, which completely distorts its natural form. The former appears, from the specimens in the Society's Museum, to be one of the distinctive marks of the young bird. Cuvier, in the last edition of the *Règne Animal*, observes that the *Falco cheriway* of Jacquin may be nothing but a variety of age. Mr. Bennett then notices the very complete description of the adult Caracara in D'Azara. According to this author, the full-grown bird measures 21½ inches in length and 50 in the expanse of the wings. Its colours agree with the description above given, excepting that the first six quill-feathers of the wings are white, marked with rays and spots of brown, and become blackish towards the point; the back is transversely rayed with brown and white, the latter predominating on its upper half, and *vice versa*; the fore part of the neck and breast are traversed by dusky lines mixed with a larger proportion of white; the cere is of an orange hue; and the throat and sides of the head are almost white. This description, Mr. Bennett remarks, very nearly coincides with that of M. Cuvier, taken from specimens in the Paris Museum, and with the figure of one of these specimens given by M. Vieillot in his 'Galerie des Oiseaux'; and Mr. Bennett then refers to the figure given by M. Spix in his 'Birds of Brazil,' as the young of this species, which resembles M. Vieillot's in its form, except that the legs are longer and thicker, and the tips of the wings reach to the extremity of the tail. In colour it is rather of a darker brown, approaching more nearly to the Society's specimen alluded to by Mr. Bennett; the throat is light brown instead

of white; and the transverse waves of the breast and shoulders are replaced by longitudinal brown dashes upon a light ground. The cere and naked cheeks are in both of a bright yellow; indeed Mr. Bennett states that he has nowhere met with them of the same hue with those of the Society's living specimen, except in the figure and description of Jacquin.

Habits, Food, Reproduction. The *Caracara* is said to live either alone or in pairs. But D'Azara states that he has seen them join in companies of four or five to hunt down prey which a single caracara would find a difficulty in mastering, such as red buzzards, herons, and other large birds, and it is believed that they will even destroy the American ostrich, young fawns, and lambs, when so associated. In its food it seems to be content with any animal substance. Carrion (for if a caracara see a vulture devour a piece of flesh he is said to pursue him and compel him to disgorge it), toads, frogs, worms, snails, lizards, grubs, grasshoppers, winged ants, snakes, and flies, birds—in short the general prey of buzzards, hawks, falcons, and insectivorous birds,—all suit its appetite. Two of the specimens obtained by M. Spix were shot in the act of extracting insects from the hides of oxen. D'Azara will not allow that the caracara preys on the smaller birds, because, he says, that it is unable to catch them; but Prince Maximilian found in the stomachs of those which he opened the remains of small birds and insects, especially grasshoppers, which abound in its haunts. It is by no means shy, and advances like the vultures to inhabited places, perching on trees and house-tops and not caring to conceal itself. It is seldom attacked, for it rarely molests domestic poultry, but it is stated that it will sometimes carry off the sportsman's game. The nest, according to D'Azara, is built on the tops of trees, especially those round which the climbing plants are most luxuriant, or in a bushy thicket. It is large, and composed of sticks and twining branches laid nearly flat, and lined, inartificially, thickly with hairs. The eggs, which are laid in August, September, or October, are two in number, pointed at one end, and dotted and blotched with crimson on a brownish-red ground.

Head and foot of *Polyborus Brasiliensis*.

Locality. The bird extends over a considerable part of South America; the island of Aruba, on the coast of Venezuela (Jacquin); Brazil and Paraguay (Cuvier). most P. C., No. 616

abundant in the south and east of Brazil (Prince of Neuwied); Spix's specimens were from the northern provinces; less numerous on the Rio de la Plata than in Paraguay, where it is almost equal in number to all the other birds of prey put together (D'Azara); Straits of Magalhaens (Capt. Phillip Parker King, R.N.).

N.B.—There are now (1837) two fine specimens in the garden of the Zoological Society in the Regent's Park.

Mr. Bennett's provisional species *Polyborus* (?) (*hypoleucus*) was founded on the *Angola Vulture* of Pennant, *Vultur Angolensis* of Gmelin, in an immature state of plumage.

Dr. Smith proposed the genus *Polyboroides* on the *Falco Gymnogenys* of Temminck in the South African Journal, in April, 1830, and M. Lesson, in the November of that year, separated the same form under the generic title *Gymnogenys*.

From *Ibycter* and *Polyborus* Mr. Vigors passes to the *Fishing Eagles*, and particularizes as the first

Pandion (Savigny).

Beak rounded above. **Cere** hispid. **Nostrils** lunulated and membranaceous on the upper margin. **Tarsi** naked. **Acrotarsia** covered with rigid, reticulated scales. **Toes** free, the external toes versatile. **Claws** equal, rounded underneath. **2d. quill** longest.

Example, *Pandion Haliaetus*.

Head and foot of *Pandion Haliaetus*.

Mr. Vigors is of opinion that this group presents us with a decidedly characteristic difference from all the other species of the family, except those of *Elanus*, in the internal parts of the nails being rounded instead of grooved. The **culmen** of the bill, he observes, is also more broad than usual and much rounded; the toes are entirely separated, and the tarsi are covered with strong, prominent, and thickly reticulated scales. The same author remarks that the well-known *Osprey* of our coasts, *Falco Haliaetus* of Linnæus, is the type of the genus to which the valuable researches of Dr. Horsfield in Java have added a second species, *P. Ichthyæetus*. In this species, however, which agrees with *Pandion* in the more essential characters, Mr. Vigors finds a strong approximation to the following genus, *Haliaetus*.

its bill, he adds, is more compressed than that of *Pandion*, the *acrohuria* are scutellated, and the 4th quill feather, as in *Halietus*, is the longest. It thus stands, in the opinion of Mr. Vigors, osculant between the two groups. For the description and natural history of *Pandion Halietus* see BALD BUZZARD, vol. iii. p. 316.

The last group of the *Fishing Eagles*, according to Mr. Vigors, is comprised in the genus

Halietus (Savigny).

Beak convex above. *Nostrils* lunulated, transverse. *Cere* sub-hispid. *Tarsi* semiplumed. *Acrotarsia* scutellated. *Toes* free, the external toe versatile. *Clares* unequal.

Mr. Vigors notices the difference of this form from *Pandion* in the structure of the nails and the more compressed culmen of the bill; in the *tarsi*, also, which have the *acrotarsia* scutellated and are feathered half way below the knee. There are several species; for instance, *F. leucocephalus*, *F. albicilla*, *F. Pondicerianus*, *F. blagrus*, *F. vocifer*, &c., &c.

Example, *Halietus leucocephalus*.

Before we proceed to the description of our example, it may be necessary with Mr. Bennett's assistance to clear up the confusion which, as he observes, has existed in the synonymy of *Halietus albicilla*, the difference of the colours of the plumage in the various stages of its growth having induced authors to record it under several distinct names. Three of these were almost universally admitted till about 26 years ago, when the result of M. F. Cuvier's observations on the individuals kept in the Jardin des Plantes led him to unite *Falco ossifragus*, *albicaudus*, and *albicilla* of Gmelin under one name: subsequent inquiry has confirmed this conclusion. In the earlier stages of life the beak of *H. albicilla* is of a bluish horn-colour; its head and neck deep brown; the plumage above, brownish-black mixed with whitish or ash-coloured spots on the back and tail. In this state it is *Falco ossifragus* of systematists. About the third or fourth year the head and neck become ashy-brown; the beak gradually changes from bluish to pale-yellow, the white spots on the back vanish, and the tail becomes uniformly grayish-white. It is now *Falco albicaudus* of Gmelin, *Petit Pygargue* of Buffon, and the *Lesser White-tailed Eagle* of Latham. In its fifth year it is come to maturity, and the change is complete. The head and neck have little of the brown tinge left, the back is through out of a dusky-brown intermingled with ashy-gray, and the tail is quite white. In this its perfect state it is *Falco albicilla*, the *Grande Pygargue*, the *White-tailed or Cinereous Eagle*. In all the stages of this, *The Great Sea Eagle*, which inhabits nearly the whole of Europe and of Northern Asia, the cere and naked parts of the legs are yellow; the under part of the body is of a lighter hue than the upper, and more thickly interspersed with pale cinereous spots; the claws are completely black. (*Gardens and Menagerie of the Zool. Soc. delineated*, vol. ii.)

We now return to *Halietus leucocephalus*, the *Sea Eagle*, *Bald Eagle*, *White-headed Eagle*, the symbol of the United States of America.

Mr. Bennett, in the work last quoted, remarks, that in the earlier stages of its growth there is little to distinguish this species from the *Great Sea Eagle*. M. Vieillot, indeed, following the example of Daudin, has united the *White-headed Eagle* to the list of synonyms of the *Great Sea Eagle*. 'That such a union, writes Mr. Bennett, 'is founded upon insufficient data is proved by the gradual development in the bird under consideration of a character which, after a certain age, at once distinguishes it from the remainder of its tribe. This character consists in the pure whiteness of its head and neck, from whence it has derived the popular but inappropriate title of the *Bald Eagle*, by which it is most commonly known.' The young are clothed at first with a thick whitish or cream-coloured cotton-like down, and they become gradually gray as the development of the true plumage goes on. In the third year the white may be traced upon the head, neck, tail-coverts, and tail; and by the end of the fourth year these parts become completely white, or sometimes tinged slightly with cream-colour. The eye, which is at first hazel, changes to a brilliant straw-colour as the head whitens (Wilson). 'This account of the metamorphoses in colour of the white-headed sea eagle,' says Mr. Bennett, 'derived from the personal observations of the accurate author of the *American Ornithology*, has been in a great measure verified under

our own inspection in the specimen now before us, which remained for several years in the possession of Mr. Brookes, before it was presented by him to the Society.

'During a considerable part of the time it was regarded as the *Common Sea Eagle*; and it was not until its gradual change of plumage had at length rendered obvious its true character, that it was ascertained to be in reality a distinct species. The same error appears frequently to have existed with regard to it; and M. Temminck observes that the only mark of distinction that can be traced in it until it has assumed the adult colouring, consists in the somewhat greater length of its tail. He might however have added its smaller size, which is probably one-fourth less than that of the preceding bird, at the same age and under similar circumstances. From the observations which we have been enabled to make upon the subject, we should be led to conclude that the period in which it attains its full growth and perfect colouring is, in this country at least and in captivity, two or three years longer than that stated by Wilson. In its immature state, that is to say about the third year, the upper parts of the head and body exhibit a mixture of brown and dirty white, the separate feathers having a ground of the latter colour, and being deeply tipped and broadly barred along the centre with the former. The quill-feathers and primary wing-coverts are black, with their shafts of a pale brown; the secondary are considerably lighter; and the tail, which projects in a trifling degree beyond the extremities of the wings, is brown on the outer quills and of a mixed white and brown on the inner. The under surface, as far backwards as the middle of the belly, is of a much lighter shade than the upper, being of a dull white, with numerous broad streaks of pale brown. In the posterior part it is of a deep brown, the feathers being only slightly margined with white. A similar hue prevails on the upper parts of the legs, which are plumed somewhat below the knees. The beak is of a dusky brown; the cere and legs of a golden yellow; the iris somewhat lighter; and the talons deep blackish-brown. The latter are long, strongly curved, of considerable power, and extremely sharp at the points. The full-grown bird measures upwards of three feet in length from beak to tail, and more than seven in the expanse of its wings. Its beak is changed to a bright yellow; and its head, a greater or less proportion of the neck (according as the bird is more or less advanced in age), and the entire tail, are become perfectly white. An analogous change, as we have before seen, takes place in the plumage of the preceding species; but the head and neck of that bird always retain more or less of a brownish tinge, seldom changing fully into grey, and never turning completely white. These observations have been made upon numerous individuals, many of them placed for upwards of ten years under the eyes of various scientific observers: their accuracy may therefore be regarded as unquestionable. The remainder of the plumage in this state is of a deep brown, approaching to black, and strongly contrasted with the head and tail. The colour of the legs, feet, and talons remains nearly the same; but the iris generally continues to assume a lighter and a lighter hue. The eyes, it should be observed, are deeply sunk in the head, and instead of being placed in a line parallel with that of the cheeks, are directed forwards, so as to form with them a considerable angle.'

Habits, Food, Reproduction.—The reader will find in the article BALD BUZZARD an account of the robberies committed by the *Bald Eagle* on the latter: nor are its acts of plunder confined to that bird, for it will rob the vultures, and even, in hard times, make them disgorge their carrion to satiate its appetite. According to Audubon, it will strike down a swan and other aquatic birds, and now and then procure fish for itself by pursuing them in shallow creeks; it also devours young pigs, lambs, fawns, and putrid flesh of every description. Niagara is one of its favourite haunts, where it watches for the swollen carcasses that the cataract has precipitated down the falls. Wilson saw one seated on a dead horse, keeping a whole flock of vultures at a distance till it had satisfied itself; and, on another occasion, when many thousands of tree-squirrels had been drowned in their migration across the Ohio, and had collected hosts of vultures, the sudden appearance of a *Bald Eagle* sent them all off, and the eagle kept sole possession for many days.

Benjamin Franklin thus speaks of this emblem of the United States of America:—'For my part, I wish the Bald

Eagle has not been chosen as the representative of our country. He is a bird of bad moral character; he does not get his living honestly. You may have seen him perched on some dead tree, where, too lazy to fish for himself, he watches the labours of the fishing-hawk; and when that diligent bird has at length taken a fish, and is bearing it to his nest for the support of his mate and young ones, the Bald Eagle pursues him and takes it from him. With all this injustice, he is never in good case, but, like those among men who live by sharpening and robbing, he is generally poor, and often very lousy. Besides, he is a rank coward: the little King-Bird, not bigger than a sparrow, attacks him boldly, and drives him out of the district. He is therefore by no means a proper emblem for the brave and honest Cincinnati of America, who have driven all the *King Birds* from our country; though exactly fit for that order of knights which the French call *Chevaliers d'Industrie*.

With regard to the *Reproduction*, M. Audubon says that incubation commences in the beginning of January. He shot a female on the 17th of that month, as she sat on her eggs, in which the chicks had made great progress. 'The nest,' says that author, 'which in some instances is of great size, is usually placed on a very tall tree, destitute of branches to a considerable height, but by no means always a dead one. It is never seen on rocks. It is composed of sticks from three to five feet in length, large pieces of turf, rank weeds, and Spanish moss in abundance, whenever that substance happens to be near. When finished, it measures from five to six feet in diameter, and so great is the accumulation of materials, that it sometimes measures the same in depth, it being occupied for a great number of years in succession, and receiving some augmentation each season. When placed in a naked tree, between the forks of the branches, it is conspicuously seen at a great distance. The eggs, which are from two to four, more commonly two or three, are of a dull white colour, and equally rounded at both ends, some of them being occasionally granulated. Incubation lasts for more than three weeks, but I have not been able to ascertain its precise duration, as I have observed the female on different occasions sit for a few days in the nest before laying the first egg. Of this I assured myself by climbing to the nest every day in succession, during her temporary absence.' (*Ornithological Biography*, vol. i.)

Locality.—In every part of the United States of America, seldom appearing, according to Audubon, in very mountainous districts, but preferring the low lands of the seashores, those of the larger lakes, and the borders of rivers. Mr. Bennett remarks, that the *White-headed Eagle* is usually spoken of as inhabiting the northern parts both of the old and new continent; but that it appears to be only a rare and occasional visitant of the former. It is probable, he adds, that some of the varieties of the *Common Sea-Eagle* of this quarter of the globe have been frequently mistaken for it, and remarks, that throughout nearly the whole of North America, on the contrary, where the European species seems to be unknown, it is met with in great abundance. Dr. Richardson says that it is the earliest of the summer visitors to the fur countries, and the period of its arrival has given the name of *Meekesheew espeeshim*, or Eagle Moon, to the month of March. 'Temminck,' says Dr. Richardson (*Fauna Boreali-Americana*), 'assigns for its habitual residence the regions within the Arctic Circle; and Wilson observes, that it is found at all seasons in the countries it inhabits. Both these assertions however require, I apprehend, to be taken with considerable latitude. We did not, on the late expeditions, meet with it to the north of the Great Slave Lake (62° N. lat.), although it is common in the summer, in the country extending from thence to Lake Superior, and its breeding-places in the latter district are numerous. But in the month of October, when the rivers from which it draws its principal supply of food are frozen over, it entirely quits the Hudson's Bay lands; and if, after that period, it is to be seen in the northern regions, it can only be on the sea-coast, and for a limited time, while the sea continues unfrozen. . . . It is known to breed as far south as Virginia, but its nests do not appear to be so common within any part of the United States as they are in the fur countries.' The bird is not mentioned in the Supplement to Captain (now Sir W. E.) Parry's First Voyage, nor in that to Captain (now Sir John) Ross's Last Voyage.

This bird is the *Meekesheew* (name for the species), *Wapustquan-Meekesheew* (*White-headed Eagle*—mature bird),

Appish-Meekesheew (*Black-headed Eagle*—immature bird) and *Meekesheesh* (*Yearling birds*) of the Cree Indians.

Head and foot of *Haliaeetus leuccephalus*.

Colonel Sykes notes among the birds of Dukhun (Deccan) *Haliaeetus Ponticerianus*, *Falco Ponticerianus* of Latham, *Bruhmany Kite* of the Europeans in India. The Colonel says that it is seen constantly passing up and down rivers at a considerable height, but prepared to fall at an instant on its prey. Usually it seizes while on the wing, but occasionally dips entirely under water, appearing to rise again with difficulty. It is quite a mistake, he adds, to suppose it feeds on carrion. On the examination of the stomach and craw of many specimens, the contents were found to be fish, and fish only, excepting on one occasion, when a crab was met with. (*Zool. Proc.*, April, 1832.)

There is a beautiful specimen of *Haliaeetus Aquia*, *Chilian Sea-eagle*, now (1837) in the gardens of the Zoological Society, in the Regent's Park; and there is a specimen of *Haliaeetus vocifer*, the *Fishing Eagle* of the Cape colonists, in the South African Museum, now (1837) exhibiting in the Egyptian Hall, Piccadilly. The last bird is only met with in the neighbourhood of the sea, or upon the banks of large rivers. See the interesting Catalogue, where it is also stated that *Aquila vulturina*, also in the Museum, resorts exclusively to high rugged mountains, where it preys upon the *Hyrax Capensis*—the *Dassie* of the Cape colonists. Dr. Smith (*Zool. Proc.*, April, 1833) had previously stated that *Aquila Verrauxii* of Lesson is synonymous with *Aquila vulturina*, which had recently been described by M. Lesson as a *Haliaeetus*, but that it has however none of the habits of the *Fishing Eagles*, inhabiting the highest and most rocky mountains, preying principally upon the animal mentioned in the Catalogue. In the 'Proceedings' it is added that the error probably arose from the white back being concealed, in stuffed specimens, by the wings.

Leaving the *Fishing Eagles*, Mr. Vigors proceeds to

Circus. (Vieillot.)

Beak convex above. *Nostrils* lunulate, transverse. *Care* subhispid. *Tarsi* elongated, naked. *Acrotarsis* re-

insulated. *Toes* short, the external toe connected with the middle one at the base. *Clares* short, subequal. This genus is founded upon the well-known *Jean le Blanc* of the European continent, *Falco brachydactylus* of Wolff, *Falco Gallicus* of Gmelin, *Aquilotto* of the Italians. Here, Mr. Vigors observes, we find the exterior toe united to the middle by a short membrane, which is the case indeed in the greater portion of the family, while in the two latter genera the toes are all divided to the origin.

Description.—*Circæetus brachydactylus* is, according to Temminck, the *Falco brachydactylus* of Wolff; *Aquila brachydactyla* of Meyer; *Falco Gallicus* of Gmelin; *Falco leucopsis* of Bechstein; *Aquila leucamphoma*, Borkh. *Deut. Orn.*; *Le Jean le Blanc* of Buffon and the French generally; *Aigle Jean le Blanc* of Temminck; *Falco Terzo d'Aquila*, Stor. deg. Ucc.; and *Kurzzehiger-Adler* of Meyer.

Old Male.—*Head* very large; below the eyes a space clothed with white down; summit of the head, cheeks, throat, breast, and belly, white, but variegated with a few spots of bright brown; *back* and *coverts* of the wings brown, but the origin of all the feathers of a pure white; *tail* square, gray-brown, barred with deeper brown, white below; *tarsi* long and grayish-blue, as are the *toes*; *beak* black; *cere* bluish; *iris* yellow; length, two feet.

Female.—Less white than the male. The *head*, the *neck*, the *breast*, and the *belly*, are marked with numerous brown spots, which are very much approximated.

Young.—*Upper parts* darker, but the origin of the feathers pure white; *throat*, *breast*, and *belly*, of a red-brown, little or not at all spotted with white; bands on the *tail* nearly imperceptible; *beak* bluish; *feet* greyish-white.

Food and Reproduction.—Lizards and serpents, to which it gives the preference; rarely birds and domestic poultry. The *nest* is built on the highest trees, and the eggs are two or three in number, of a lustrous grey, and spotless.

Head and foot of *Circæetus brachydactylus*.

Locality.—The great fir forests of the eastern parts of the north of Europe; not common in Germany and Switzerland; rare in France; never seen in Holland. (Tem-

minck.) Prince Bonaparte notes it as rather rare near Rome. Colonel Sykes notes it among the birds of the Dukhun (Deccan).

Dr. Smith's *Circæetus pectoralis*, which undergoes many changes of plumage before it arrives at maturity (see South African Museum and Catalogue), is stated (*Zool. Proc.*, April, 1833) to be synonymous with *Circ. thoracicus* of Cuvier.

Mr. Vigors next proceeds to the true

Aquila (of Authors).

Beak subangular above. *Nostrils* rounded. *Cere* subhispid. *Tarsi* plumed to the toes.

Leg and foot of Golden Eagle.

Mr. Vigors observes that the predominant mark of distinction in this genus is the *tarsi* being feathered to the toes. The *culmen* of the bill appears also to differ from that of the other eagles in being more angular. The species *Aquila heliaca* of Savigny, *Falco chrysaetos*, and *Falco naevius* of Linnæus, *Falco bellicosus* of Daudin, with some others lately made known to us, belong to the group which contains the most powerful birds of the family.

Example, *Aquila chrysaetos*, the Golden Eagle. *Adler* of the Germans, *Eyrer Melyn* of the antient British.

Aquila chrysaetos

Description. *Old birds.*—Summit of the head and nape with acuminate feathers of a lively and golden-red; all the other parts of the body obscure brown, more or less blackish according to the age of the individual; inside of the thighs and feathers of the tarsus clear brown; never any white feathers among the scapulars; tail deep grey, barred with tolerable regularity with blackish-brown, and terminated at the end by a large band of that colour; beak horn-colour; iris always brown; cere and feet yellow. In this state Temminck considers it to be the *Aquila fulva* of Meyer; *Falco niger* of Gmelin; *Falco fulvus* and *Falco Canadensis* of Gmelin; *Falco chrysastor* of Linnæus; *L'Aigle Royal* of Buffon; *Le Grand Aigle*, Gerard, *Tab. Elem.*; *L'Aigle Commun* and *L'Aigle Royal* of Cuvier; *Ring-tail* and *Golden Eagle* of Latham; and *Aquila Reale* of Color *leonato* and *Aquila Rapace*, Stor. deg. Ucc.

Young birds of one and two years. (Ring-tail Eagle.) All the plumage of a ferruginous or clear reddish-brown, uniform on all parts of the body; lower tail-coverts whitish; inside of the thighs and feathers of the tarsus of a pure white; tail quite white from the base to three-fourths of its length, but afterwards brown to the end; internal barbs of the quills and of the caudal feathers pure white: this same colour occupies also the greatest part of all the feathers of the body from their base. In proportion as the young bird advances in age the colours of the plumage become brown, the white of the tail occupies less space, and traces of the transverse bars appear. In the third year the young bird puts on his adult plumage.

Varieties.—Partially or totally white. (*Falco albus* of Gmelin; *Falco cygneus* of Latham; *L'Aigle Blanc* of Brisson.)

Food and Reproduction.—The Golden Eagle preys on lambs, fawns, &c., and often on large birds. Extreme hunger will drive it to prey on carcases.

Locality.—The great forests in plains, and in a less degree those in the mountains of the north of Europe; very common in Sweden, in Scotland, in the Tyrol, Franconia, and Suabia; more rare in Italy and Switzerland; rather common in France, in the forest of Fontainebleau, in the mountains of Auvergne, and on the Pyrenees; rare in Holland; less common in the Oriental countries than the preceding species, i.e. *Aquila heliaca* of Savigny, *Aquila imperialis* of Temminck. (Temminck.) According to Wilson, the Golden Eagle inhabits America, and occurs from the temperate to the arctic regions, particularly in the latter, where it breeds on precipitous rocks, always preferring a mountainous country. Dr. Richardson (*Fauna Boreali-Americana*) mentions it with a query as breeding in the recesses of the sub-alpine country which skirts the Rocky Mountains, and as seldom seen farther to the eastward. 'It is,' says Dr. Richardson, 'held by the aborigines of America, as it is by almost every other people, to be an emblem of might and courage, and the young Indian warrior glories in his eagle plume as the most honourable ornament with which he can adorn himself. Its feathers are attached to the calumets, or smoking pipes, used by the Indians in the celebration of their solemn festivals, which has obtained for it the name of the Calumet Eagle. Indeed, so highly are these ornaments prized, that a warrior will often exchange a valuable horse for the tail feathers of a single eagle.' It is the *Kæoo* of the Cree Indians. Dr. Richardson observes that the mature British Golden Eagle has a darkish-brown tail and wings, blackish-brown back, clouded with brownish-black, and a paler and brighter-brown head. He had not seen an American one in this state, but we do not think that any reason for a doubt. Many other authors mention the eagle and ring-tails in such terms as to leave the identity of the bird almost unquestionable; and though Dr. Richardson says that it is seldom seen farther to the eastward than the Rocky Mountains, M. Audubon relates that he saw a Golden Eagle on the coast of Labrador, besides others in various parts of the United States. It inhabits Russia, Iceland, and Germany, and is said to occur in Northern Africa and Asia Minor. Mr. Yarrell, in his interesting History of British Birds, now in the course of publication, thus sums up its localities in our islands. 'The Golden Eagle, though occasionally seen, and sometimes obtained, in the southern counties of England, is more exclusively confined to Scotland, and its western and northern islands. Some years ago a specimen was killed at Baxhill, in Sussex it has also occurred, but very rarely, in

Suffolk, Norfolk, Derbyshire, Durham, and Northumberland. Mr. Mudie, in his 'Feathered Tribes of the British Islands,' has named 'the higher glens of the rivers that rise on the south-east of the Grampians, the high cliff called Wallace's Craig, on the northern side of Lochlee, and Craig Muskeldie on its south side,' as localities for the Golden Eagle. Mr. Selby and his party of naturalists observed this species in Sutherlandshire in the summer of 1834. Mr. Macgillivray, in his detailed descriptions of the rapacious birds of Great Britain, has recorded his own observations of this species in the Hebrides; and other observers have seen it in the Orkney and Shetland Islands, where it is said constantly to rear its young. In a direction west of London the Golden Eagle has been obtained or seen on the coasts of Devonshire and Cornwall. In Ireland, a Ring-tailed Eagle (the young of the Golden) was seen by a party of naturalists in Connamara in the autumn of 1835; and from William Thompson, Esq., vice-president of the Natural History Society of Belfast, to whom I am indebted for a catalogue and notes of the birds of Ireland, which will be constantly referred to throughout the work, I learn that specimens of the Golden Eagle are preserved in Belfast which were obtained in the counties of Donegal and Antrim. The age of the eagle is almost proverbial. One that died at Vienna is said to have lived in confinement 104 years. Colonel Sykes notes the Golden Eagle among the birds of the Dukhun (Deccan). His specimen differed so slightly from the European bird as not to justify its separation. (*Zool. Proc.*, April, 1832.)

In the catalogue of birds collected on the Ganges between Calcutta and Benares, and in the Vindhyan hills between the latter place and Gurrâh Mundela, on the Nerbudda, by Major James Franklin, F.R.S., &c., we find recorded an eagle, *Aquila Vindhiana*, with a query whether it is the *Cawnpore Eagle* of Latham (*Zool. Proc.*, August, 1831), and among the Dukhun birds, *Aquila bifasciata* of Hardwicke and Gray. (*Ind. Zool.*) A whole rat was found in the stomach of one bird. A second was shot by Colonel Sykes at the dead carcass of a royal tiger, but it had not fed, for the stomach was empty. Dr. Smith stated (*Zool. Proc.*, 1833) that the eagle from the Cape presented to the Society by the Hon. J. T. Leslie Melville, and in the Society's menagerie, was not the young of *Aquila vulturina* (Daudin), but of *Aquila Choka* (Smith), *Falco rapax* (Temminck). Specimens of *Aquila bellicosa* and *rapax* are in the South African Museum, as well as of *A. vulturina*. The first is only found in wooded districts, preys upon small quadrupeds, and has been known to pounce upon small antelopes, and carry them off entire to its nest. *A. rapax*, though it principally preys on living creatures, does not wholly reject carrion, being frequently one of the first birds that approaches a dead animal. (See Catalogue of South African Museum.) Mr. Keith Abbott (*Zool. Proc.*, June, 1834) notes among the Trebizond birds *Aquila pennata*, inhabiting Eastern Europe and the adjacent parts of Asia and Africa.

Hæmatornis. (Vigors.)

Mr. Vigors, at a meeting of the Zoological Society (December, 1831), characterized among the species comprising the 'Century of Birds from the Himalaya Mountains,' drawn and lithographed by Mr. and Mrs. Gould, the above-named genus, which Mr. Vigors considered as exhibiting a striking diversity of form among the *Eagles*.

Generic Character.—Beak rather strong, sufficiently elongated; upper mandible straight at the base, very much curved at the apex; nostrils oval, placed obliquely in the cere. Wings long, subrounded; the first quill rather short, the second and third longer, the fourth and fifth nearly equal and longest, the rest gradually decreasing. Feet rather weak, subelongated; tarsi rough, reticulated with scales; toes rather short, reticulated; claws strong. Tail sufficiently long, somewhat rounded. (Vigors.)

This group was observed to bear a near affinity to the genus *Pandion* in the shape of the bill, wings, and the rugose reticulated scales of the tarsi, but to differ from it in the comparative length and weakness of the legs and claws, as well as in having the nails grooved underneath, and not convex as in the latter group. To this genus belongs the *Falco Bacha* (Latham) of Africa, and the Manilla bird then lately described in the Proceedings (page 96), under the name of *Buteo holospilus*. These, from the ap-

parent weakness of their limbs, had hitherto generally been ranked among the buzzards; although from the description of the courageous habits of the *Bacha Falcon*, the only one well known of the group, doubts had been expressed of the propriety of ranking them with that tribe. Mr. Vigors suggested the subfamily of *Eagles* as a more appropriate station for them; where, united by many important characters to *Pandion*, they apparently led off by the length of their *tarsi* to the genus *Limnaëtus* ('Memoirs of Sir S. Raffles,' Append., p. 648) and others of the long-legged *Eagles*. The three species of the group were exhibited, their general similarity in colour and markings pointed out, and their specific differences explained. These consist chiefly in size. *Hæmat. holospilus* being one-third smaller than *H. Bacha*; while *H. undulatus* (which is 2 feet 7 inches in length) considerably exceeds the latter. The first is spotted all over the body, the second only on the abdomen, while the third is marked by spots on the wing-coverts, and by *ocelli* bearing an undulated appearance upon the abdomen, the breast also being crossed by undulating *fasciæ*. A specimen of *H. undulatus* was afterwards (January, 1832) exhibited from Mr. Hodgson's Nepaul collection. It agreed accurately with that which had been previously exhibited, except in size; the present specimen being about one-third longer. From this difference in size it was conjectured to be a female. Colonel Sykes identified a specimen shot in the Dukhun (Deccan) with *Hæmatornis Bacha*. (Zool. Proc.)

Description of *H. undulatus* (male and female probably). *Back* and *wings* intense brown; *head* crested, the feathers white at the base, of a dark brown, nearly approaching to black at the end, the hind ones being margined with a light rufous band at the apex. The *wing-coverts* near the carpal joint deep brown, marked with small white spots; *quill-feathers* fuscous, darker at the apex, and marked with white towards the base of the interior web; the *cere*, base of the *beak*, and *legs*, yellow; *claws* black. (Vigors, in Gould's 'Century of Birds from the Himalava Mountains.')

Hæmatornis undulatus, from the work above quoted, by permission.

Short-winged Eagles.
Harpyia. (Cuvier.)

Beak, above, convex. Upper *mandible* slightly toothed. *Nostrils* semilunar, transverse. *Tarsi* elongated, very strong, feathered at the base. *Acrotarsia* scutellated. *Claws* long, very strong, acute.

Mr. Vigors, in placing *Harpyia* next to *Aquila*, observes that the former equals the latter in size and powers of body. Its *tarsi*, he remarks, are strong, thick, partly plumed, with scutellated *acrotarsia*. The *nares* are elongated, apparently semilunar, and placed transversely on the

cere. The upper mandible, he adds, seems to have a notch somewhat analogous to that of the true *Falcons*. The type is *Falco imperialis* of Shaw.

This powerful bird is the *Grande Harpie d'Amérique* of the French, *Aquila coronada* of the Spanish, *Falco destructor* of Daudin, *Aigle destructeur* of Sonnini, *Grand Aigle de la Guiane* of Mauduyt, *Harpyia destructor* of Cuvier. Mr. Vigors states with truth that much confusion has arisen as to the synonyms of this bird, and even as to the characters of the genus. Mr. Bennett has, in our opinion, well cleared this confusion away, and we therefore select his synonymy.

'M. Temminck,' says the last-mentioned zoologist (*Gardens and Menagerie of the Zoological Society delineated*, vol. ii.), 'the latest writer on this magnificent bird, positively denies its identity with the *Vultur harpyia* of Linnæus, and the crowned eagle (*Vultur coronatus*) of Jacquin, on the singular ground that those names indicate a smaller bird with longer and more slender legs. Now Linnæus, who borrowed his original description of the harpy from Hernandez, asserts, on the authority of that writer, that it is equal in size to a common ram; and Jacquin states his bird to have measured full two feet and a half in height in its natural sitting posture, and almost two inches in the diameter of its legs. It is impossible to read the descriptions of Hernandez and Jacquin, making in the case of the former some little allowance for exaggeration, without feeling a conviction that they both refer to the bird now under consideration. That of the latter author in particular is admirably characteristic. Linnæus originally founded his species on the indication given by Hernandez in the tenth edition of his 'System' he suggested a comparison between it and a bird seen by a friend, probably a pupil, in the Royal Menagerie at Madrid, which there is every reason to believe, from the description given, to have been just. It was only in the twelfth edition of his immortal work that he introduced a slight confusion by adding to the citation from Hernandez, to the account furnished by his friend, and to some particulars extracted from Jacquin's then unpublished description of his supposed species, a synonym from Marcgrave, which can alone justify M. Temminck's criticism. We restore without hesitation both these synonyms of Linnæus and Jacquin, excluding only from the twelfth edition of the *Systema Naturæ* the references to Marcgrave and his copyists. With the *Vultur harpyia* of Linnæus and the *Vultur coronatus* of Jacquin are necessarily included among the synonyms of the Harpy eagle the *Falco harpyia* and the *Falco Jacquinii* of Gmelin, by whom the trivial name assigned by Jacquin to his bird was changed on account of its introduction into a genus in which that appellation was pre-occupied. In the year 1778, Mr. Dillon observed, in the Menagerie of Buen Retiro at Madrid, a species of eagle, which he imagined to be 'an undescribed kind not taken notice of by Linnæus.' This bird, which he figures in his Travels through Spain under the name of the *Crested Falcon*, is evidently of the same species with the harpy, although the representation is rudely executed, and in some respects, as for example the length of the beak, grossly caricatured. We might almost be tempted to suspect that the specimen seen by him was identical with that described by Linnæus from the same menagerie twenty years before, were it not that the latter bird is expressly called Mexican, while that of Mr. Dillon is stated to have come from the Caracas. For this reason Dr. Latham introduced it into his Synopsis under the name of the *Caracca Falcon*.

Gmelin, quoting from Latham, soon after latinized its former name into *Falco cristatus*, and this may therefore be added to the synonyms of our bird, of which Mr. Dillon's was the first published figure. The next original describer of the Harpy Eagle was Mauduyt, who also regarded his specimens as nondescript, and gave them the name of *Grand Aigle de la Guiane*, from the country whence they were obtained. To these birds, which formed part of the collection of the Paris Museum, Daudin, in his Ornithology, published in 1800, applied the scientific appellation of *Falco destructor*; and the names given by these two writers have been generally adopted on the continent of Europe as the only ones certainly applicable to the species. M. Sonnini seems doubtful whether or not to regard the two specimens described by him as distinct species, and names the one *Aigle destructeur*, and the

other *Grand Aigle de la Guane*; but there seems no sufficient reason for their separation. Dr. Shaw's *Falco imperialis* is founded on this indication of Sonnini. In all probability the *Crested Eagle* of Stedman's 'Expedition to Surinam,' spoken of as a very strong and fierce bird, belongs to the same species. Figures of the harpy are likewise given by M. Cuvier in his 'Règne Animal,' by M. Vieillot, in the second edition, of the 'Nouveau Dictionnaire des Sciences,' and by M. Temminck, in his 'Planches Coloriées.' Those of the two last-named works are strikingly characteristic. That of the 'Dictionnaire' exhibits the crest-feathers equally and stiffly elevated round the back part of the head, a state in which we have never seen them in our bird, and which, on account of their laxity, and the lower position of the middle ones, we doubt their power to assume. It is right however to remark, that the crest is stated by Linnæus and other authors to possess this power of elevation round the head in form of a crown, an ornament alluded to in the Spanish name of the bird, *Aquila coronada*, and in the trivial appellation, *coronatus*, affixed to the species by Jacquin. We believe that we have now restored to this bird all the original synonyms which unquestionably belong to it. The original descriptions of Hernandez, Linnæus, Jacquin, Mauduyt, Daudin, and Sonnini, and the figures of Dillon, Shaw, Cuvier, Vieillot, and Temminck, are such as leave no doubt upon our minds of the accuracy of the references to those authors. We have purposely abstained from mentioning others which have been occasionally quoted, but which either do not appear to us to be satisfactorily determined, or are evidently founded on mistake. Of the former class, the *Ouyra-Ouasou* of Lery, or Royal Bird of Prey of Brazil, may serve as an example; of the latter, the *Calquin* and *Tharu* of Molina.

Description (adult).—Head with thick downy plumage, of a light slaty-gray. **Crest** arising from the back part, of numerous broad feathers increasing in length towards the middle line of the head, and thus assuming a rounded form, of a dull black, with the exception of a slight margin of gray on the tips of the longer feathers, and a more extensive tinge of the same colour on those of the sides. This crest is slightly raised above the level of the feathers of the back of the neck when the bird is quiet, but is capable of being elevated at right angles with them upon any sudden excitement. In this state, to an observer placed in front of the bird, the middle feathers of the crest are rarely visible, on account of their being inserted much lower down than the lateral ones; while the latter, converging on either side, form, as it were, two lax ear-like processes. Below the crest, the whole of the *back* and *wings*, together with a *broad collar* round the fore part of the *neck* black, each of the feathers of the back terminating in a narrow transverse somewhat lighter streak. **Under surface**, from the breast backwards, pure white; plumage of the *legs* white with blackish transverse bars. **Tail** with four transverse black bands, of about equal breadth with the four alternating whitish or ash-coloured spaces; the tip light ash. (Bennett.)

Immature bird.—*Upper parts* mottled with brown gray and whitish; *cheeks*, *occiput*, *throat*, and *under parts* light gray, with a few black feathers in front of the *neck*, and some large irregular black spots on each side of the lower surface of the *tail-feathers* on a light ash-coloured ground. (*Falco imperialis*, Shaw); (Vieillot, young female?). *Back* and *wings* grayish fawn-colour, irregularly marbled and spotted with black; *collar* ashy-fawn, more or less spotted with black; bars crossing the *legs* fewer and more irregular; all the *lower parts* whitish-fawn sprinkled with darker spots; upper surface of *tail* ash-coloured, with small blackish spots; patches of black mark the places of the future bands which gradually increase at each change; under surface whitish, dotted with fawn. (Temminck.)

(Bird further advanced.) *Collar*, *crest*, *back*, and *wing-coverts* almost uniformly gray; *quill-feathers* of the wings black; *under surface* of body dirty white; each of the *tail-feathers* marked beneath by four large black patches crossing its shaft and occupying about half its width. (Bennett.)

Upper mandible very thick at the base, straight for some distance, and suddenly curving downwards with a strong arch towards the sharp point; *lower mandible* straight, short and blunt; *nostrils* transverse and oval; *wings* when closed not reaching beyond the middle of the *tail*, which is rounded at the extremity; *legs* feathered on the upper part

of their anterior surface only, the rest naked and reticulated; *talons* extremely strong, internal and posterior ones very long. Mr. Bennett observes that in some of these characters, as for instance the nakedness of the legs, the harpy approaches the sea-eagles; but it differs from them in many essential points, and in none more remarkably than in the shortness of its wings, and the robustness of its legs and talons; the former character rendering it, like the short-winged hawks, more adapted for preying near the surface of the ground on gallinaceous birds and quadrupeds, and the latter enabling it to carry off a prey of much greater magnitude.

Habits.—The harpy is stated to be a solitary bird, frequenting the thickest forests, where it feeds upon the *sloths* it also preys on fawns and other young quadrupeds. Sonnini observed it sitting motionless and uttering no cry, on a high tree on the banks of the Orapu. Hernandez does not seem inclined to detract from the powers of the bird, for he says that it will attack the most fierce beasts, and even man himself; and he further states that it may be trained like a hawk to pursue game. Linnæus gives the bird credit for strength sufficient to split a man's skull with a single blow (*unico ictu*). These accounts of its prowess must be taken with some grains of allowance, but that the bird is very powerful is without doubt. Jacquin's specimen was found dead in the ship that was conveying it to Europe, and its death was with some probability attributed to the sailors, whose monkeys the eagle had destroyed. When these animals gambolled too near its cage they were seized by its talons and devoured with almost all their bones, but not their skin, which the bird invariably stripped off. The harpy which was obtained by Mr. Hesketh, consul at Maranham, near the mouth of the river Amazon, and brought to England by Captain (now Major) Sabine, by whom it was presented to the Horticultural Society, which transferred it to the Zoological Society, in whose collection at the Regent's Park it now (1837) is, is said to have destroyed and eaten a king of the vultures (*Sarcocornophus Papa*) while on its passage to England. After its arrival a cat was put into its cage, and the eagle, with one blow of its immense foot, broke its back.

Localities.—Mexico (Hernandez, Linnæus, and others); neighbourhood of the river Magdalena, in New Granada (Jacquin); Caracas (Madrid specimen). Guiana (Sonnini)

Harpyia Destructor.

Morphnus (Cuvier.)

Beak convex above; *nostrils* elliptical; *tarsi* elevated, rather slender; *acro-tarsia* scutellated; *toes* rather short; *claws* acute.

Mr. Vigors observes, that this genus differs from *Harpyia* in its more slender, lengthened, and scutellated *tarsi*, and the comparative weakness of its toes. It is separated into two sections, as the *tarsi* are plumed or otherwise; among the former M. Cuvier arranges *Falcones occipitalis*, *ornatus*, and *albescens* of Daudin, and *F. maculosa* of Vieillot; among the latter, *F. Guianensis* of Daudin, and *F. Urubitinga* of Gmelin. *Spizaetus* of Vieillot corresponds with this group.

*

Tarsi naked.

Example, *Morphnus Urubitinga*, *Falco Urubitinga* of Gmelin, *Aquila Brasiliensis* of Brisson, *Brazilian Eagle* of Latham, *Urubitinga* of Maregrave, Willughby, Ray, and others. The following is Willughby's

Description.—This bird is like an eagle of the bigness of a goose of six months old. It hath a thick hooked black beak; a yellowish skin (cere) about the nostrils; great sparkling aquiline eyes; a great head; yellow legs and feet; four toes in each foot, disposed after the usual manner; crooked, long, black talons; large wings; a broad tail. It is all over covered with dusky and blackish feathers; yet the wings are waved with ash-colour. The tail is nine inches long, white for six, the end for three inches being black; howbeit in the very tip there is again a little white.

Young of the year.—Blackish yellow below; the centre of each feather marked with blackish brown tear-like spots; throat and cheeks with brown strise on a whitish ground. *Locality*, Brazil and Guiana, where it is said to seek its prey on inundated places

Head and foot of *Morphnus Urubitinga*.

* *

Tarsi feathered.

Example.—*Morphnus occipitalis*, *Falco occipitalis* of Daudin, *L'Aigle-autour noir huppé d'Afrique*, and *Huppart*.

Description.—Size of a crow; black, with a long crest or tuft dependant from the occiput; tarsi, edge of the wing, and bars on the tail, whitish. *Locality*, Africa.

Head and foot of *Morphnus occipitalis*.

Cymindis (Cuvier.)

Beak convex above; *nostrils* nearly closed, rimiform; *tarsi* short, semipalmated.

Distinguished by their short, half-plumed, and reticulated *tarsi*, and more particularly by their nostrils being nearly closed, and bearing the appearance of a narrow slit or channel.

*

Acrotarsia scutellated.

Example.—*Cymindis hamatus* *Falco hamatus* of Illiger.

Head and foot of *Cymindis hamatus*.

Description.—(Adult) upper *mandible* extremely hooked; *cere* and *feet* yellow; all the plumage uniform lead colour: Length 15 inches 8 lines French.

Young of the year.—Plumage sombre brown, each feather bordered and blotched with red; summit of the *head* and *cheeks* marked with yellowish elongated spots; a yellowish band below the eyes; front of the neck whitish. Locality, Brazil.

* *

Acrotarsia reticulata.

Example, *Cymindis Cayennensis*, *Falco Cayennensis* of Gmelin, *Petit autour de Cayenne*.

Description.—Summit of the *head* ash-coloured; *back* (manteau) brown, barred with deeper brown; *belly* white; *tail* grey, barred with white beneath; *feet* ash-coloured. Locality, Cayenne.

Head and foot of *Cymindis Cayennensis*.

Asturina (Vieillot).

Beak convex above; *nostrils* lunulate; *tarsi* short, somewhat slender; *claws* long, very acute.

Example, *Asturina cinerea*.

Description.—Bluish ash-colour; whitish bands on the under part of the body; *tail* traversed by two black stripes, white at the point; *beak* blue below; *cere* blue; *feet* yellow. Locality, Guiana.

Mr. Vigors observes, that it is among these *short-winged Eagles* that the greatest difficulty prevails in deciding on their immediate affinities. Being for the most part extra-European, and not within the reach of general examination, their manners also being but little noted, and the characters on which we depend for forming our decision respecting their affinities being for the most part passed over in the descriptions given of them, it is only by conjecture that we can assign them a place in the general arrangement. Of this nature, he remarks, is the genus last described. The same difficulty, he adds, extends to several other described species of the *Falconidae*, which appear to him to belong to the group of *short-winged Eagles*, although they have been assigned a different locality by the authors who have described them. Among these is the *Falco Bucha* of Daudin, which has been generally ranked with the *Buzzards*. Its short wings and lengthened bill, however, seem, according to Mr. Vigors, to bring it among the present group of the *Eagles*; and its habits, as described to him by Dr. Horsfield, who had an opportunity of closely observing them in the Island of Java, where the birds are by no means uncommon, do not in any respect correspond with the *Buzzard* tribe. Mr. Vigors would place it, together with *F. albidus* of Cuvier, near those species of the genus *Cymindis* which are distinguished by

P. C., No 617.

Head and foot of *Asturina cinerea*.

the reticulated *acrotarsia*, if not in that genus itself. He has, indeed, some doubts whether most of the short-winged *Falconidae* at present placed among the *Buzzards*, such as *F. buson* and *F. tachiro* of Daudin, *F. pæcilonotus* of Cuvier, &c., may not be more properly removed to a situation between the *short-winged Eagles* and the *Hawks*, with both of which they seem to have a considerable affinity. There is, continues Mr. Vigors, another group which also appears allied to the present, distinguished by a rather feeble and elongated bill, short wings, and slender, lengthened *tarsi*, feathered to the toes. It includes *F. limnæstus* of Horsfield (*Zool. Res.*, No. 6, Pl. Col. 134), *F. niveus* of Temminck (Pl. Col. 127), and *F. atricapillus* of Cuvier (Pl. Col. 79.) These appear to be strongly allied, in the opinion of Mr. Vigors, if not to appertain, to the before-mentioned genus *Morphnus*. *F. tyrannus* of Prince Maximilian (Pl. Col. 73) bears also, Mr. Vigors thinks, a strong similitude to the same group, though partially differing in external characters.

2. Sub-family *Accipitrina* (Hawks).

Beak short, hooked from the base; *wings* short, fourth *quill* longest.

'The short wings of the last groups,' writes Mr. Vigors, 'lead us to the present division of *Hawks*, all of which, a considerably extensive tribe, are characterized by their wings extending no further than two-thirds of the extent of their tail. The fourth quill-feather is the longest, the first, second, and third, gradually exceeding each other in length. In this division we may observe that the upper mandible, though not furnished with distinct teeth like the true *Falcons*, has the festoon or prominence that generally supplies its place more strong and angular than is usual among these tribes. In some of the *Accipitres* this is particularly distinguishable. The sub-family we have just quitted includes all the birds of the present family in which the *beak* is straight at the base, and hooked only at the apex. We now enter upon the first of those groups where the bill is curved from the base, a character that extends through the remainder of the *Falconidae*. It may be observed, that this character, which thus separates the family into two departments, was equally noticed as a mark of distinction between the species known to the ancients. Pliny, apparently referring to it as a line of demarcation between them, divides the group into his two departments of *Aquila* and *Accipitres*. It is from adopting the same views respecting

Vol. X.—2 A

the family, that M. Brisson instituted his two leading divisions, to which he assigned corresponding denominations.

Dædalion (Savigny).

Beak short; **tarsi** moderate; **acrotarsia** reticulated; type *F. cachinnans* of Linnæus, and *F. melanops* of Latham.

Mr. Vigors adopts the name which was conferred by M. Savigny on the whole of the sub-family, for the present division of it.

Example, *Dædalion melanops*.

Description.—(Adult male) white, flamed with black on the neck and breast; back, wings, and tail, deep black, the last with a white stripe, and terminated with white; there are dots of the same colour on the coverts of the wings; cere and tarsi reddish. **Locality**, Guiana. The form may be illustrated by the

Head and foot of *Dædalion cachinnans*.

Astur (Bechstein).

Beak short; **nostrils** suboval; **tarsi** moderate; **acrotarsia** scutellated.

Mr. Vigors observes, that *Astur* is a title which has been applied to the whole group, but which may be confined to those whose tarsi, moderate in length, have their *acrotarsia* scutellated or covered with broad and even scales. He considers our European species, *Falco palumbarius* of Linnæus, as the type; to which may be added *F. Novæ Hollandiæ* of Latham, and a considerable number of corresponding species from every quarter of the globe.

Example, *Astur palumbarius*.

Description.—This is the *Autour* and *Atour* of the French; *Astore* (Zinn.) and *Girfalco* (Bonaparte), *Sparviere da columbe* and *Sparviere Terzuolo* of the Italians; *Grosser gefeilter Falck* and *Hunerhabicht* of the Germans; *Goshawk* of the modern, and *Hebog Marthin* of the antient British.

A full-grown female measures from twenty-three to twenty-four inches in length; the males one-fourth, and sometimes one-third less; but when adult, the plumage is nearly similar. The beak is horn-colour or bluish-black; the cere and irides yellow; the top of the head, the whole of the back, upper surface of the wings, and tail-feathers, dark greyish-brown: in females the colour inclines to olive-brown; the upper surface of the tail-feathers barred with darker brown; a band passing

over the lore, eyes, cheeks and ear-coverts; the nape of the neck, throat, breast, belly, and thighs, nearly white, with spots, transverse bars, and undulating lines of dull black; under tail-coverts white; lore, cheeks, and ear-coverts, greyish-brown, forming an elongated dark patch on the side of the head; the legs and toes yellow; the claws black.

Young birds have the beak, cere, and eyes, nearly similar to those of the old birds; the top of the head, nape, and ear-coverts, ferruginous white, each feather darker in the middle; back, wings, and upper tail-coverts, brown, margined with buff; upper surface of the tail-feathers with five bands of dark-brown and four bands of lighter brown, the ends of all the feathers white; wing-primaries dark-brown, barred with two shades of brown on the inner webs; the chin, throat, breast, and belly, greyish-white, each feather with a central elongated patch of dark-brown; thighs and under tail-coverts with a dark-brown longitudinal streak instead of a brown patch; under surface of the wings greyish-white, with transverse dusky bars; under surface of the tail-feathers greyish-white, with five darker greyish-brown transverse bars, the tips of all the feathers white; legs and toes yellow-brown; the claws black; those of the inner toe considerably larger than those of the outer. (Yarrell.)

Habits, Food, Reproduction.—Flies low and pursues its prey in a line after it, or in the manner called 'raking,' by falconers. If the game takes refuge it will sit patiently on a tree or stone till it moves, or till some other prey is accessible. **Food**, hares, rabbits, pigeons, pheasants, grouse, and partridges. The female was generally flown by falconers at fur, and the male at feather, but the female was also trained to take the larger winged game, the male being principally flown at partridges. Turberville says, 'you shal not neede to shew any other game to a goshawke for her first entring than a partridge, because in learning to flee the partridge they prove most excellent; and the first yeare you shall doe best to flee them to the field, and not to the covert, for so will they learne to hold out and not to turne tayle) in the midst of their flight; and when they be mewed hawkes, you may make them doe what you will; and understand you, that you shall not neede to take such pain, nor to use such art in making of a goshawke which is taken a brancher as with a *Nyasse*, for she will alwayes know of her selfe what to doe. (*The Book of Falconrie*.) **Nest**, on a high tree in the outskirts of the forest; rarely found in the interior, except in those parts which are open and free from timber. Eggs three or four, frequently hatched in the middle of May. (Hewitson, *exrelatione* Hoy.) Mr. Yarrell says that the eggs are rare, and that the few which he has seen were uniform in size and colour, $2\frac{1}{4}$ ths inches in length by $1\frac{1}{4}$ th inch in breadth, of a pale bluish-white, without any spots or streaks.

Locality.—Denmark, Norway, Sweden, Siberia, Russia, and Chinese Tartary. (Müller, Linnæus, Pennant.) Very common in France, Germany, Russia, and Switzerland; more rare in Holland. (Temminck.) Rare in the south of England. Mr. Yarrell says 'the few that are used for hawking are obtained from the continent. Colonel Thornton, who kept them constantly in Yorkshire, procured some of his specimens from Scotland. Dr. Moore, in his catalogue of the birds of Devonshire, says that it is found occasionally in Dartmoor, but I can find no record of its appearance farther west in England, nor any notice of it in Ireland. A fine adult male was trapped by a game-keeper in Suffolk in March, 1833; and Mr. Doubleday, of Epping, has sent me word that he received a young bird from Norfolk in the spring of the same year. Mr. Scibv mentions that he had never seen a recent specimen south of the Tweed, but states that it is known to breed in the forest of Rothiemurcus, and on the wooded banks of the Dee. Mr. Low says that this species is pretty frequent in Orkney; but as he speaks of it in connexion with sea-beaten rocks without shelter or woods, is there not reason to suspect that Mr. Low was mistaken, and that the birds he saw were Peregrine Falcons?—the more so, as several recent visitors to these northern islands have observed peregrines but no goshawks.' (*British Birds*.) Prince Bonaparte has noted the goshawk as not common in the neighbourhood of Rome, and as rare in that of Philadelphia. Dr. Richardson (*Fauna Boreali-Americana*) describes one shot in company with the female at the nest on the plains of the Saskatchewan, and states that another specimen was

killed in the woody country three or four degrees of latitude farther north than the preceding. He records another killed near Jasper's House, on the Rocky Mountains, and a fourth killed at York Factory, supposed to be a young bird of the season (the specimen noticed by Mr. Sabine in 'Franklin's Journey').

The *Falcon-Gentil* is supposed to be the female and young of this species, which is the *Ash-coloured* or *Black-capped Hawk* of Wilson.

Colonel Sykes describes an *Astur* (*A. hyder*) among his birds of the Dukhun (Deccan), and there are specimens of *Astur musicus* and *A. melanoleucus* in the South African Museum.

Astur palumbarius.

Accipiter (of Ray, Brisson, and authors).

Beak short. **Nostrils** suboval. **Tarsi** elongated, smooth. **Acrotarsia** scutellated, the suture scarcely to be discerned. Type, the *Common Sparrow-hawk*, *Accipiter fringillarius* of Ray: to which, says Mr. Vigors, may be added many corresponding species which do not seem to have any limits to their geographical distribution.

Description.—The *Sparrow-hawk* is *L'Epervier* of the French; *Falco palombino* and *Sparviere da fringuelli* of the Italians; *Die sperber* of the Germans; *Sparshoek* of the Fauna Suecica; *Falco Nisus* of Linnæus; and *Goeppia* of the antient British.

Adult Male.—About twelve inches in length; **beak** blue, lightest at the base; **cere** greenish-yellow, the **irides** yellow; top of the head, nape of the neck, back, wings, and wing-coverts, rich dark-brown—in very old males with a tinge of bluish-grey; **tail-feathers** grayish-brown, with three conspicuous transverse bands of dark-brown; **chin, cheeks, throat, breast, belly, thighs, and under tail-coverts**, rufous, with numerous transverse bars of darker rufous brown; **legs and toes** long, slender, and yellow; the claws curved, sharp, and black.

Female.—Generally three inches longer than the male; **beak** bluish horn-colour; **cere** yellowish, the **irides** yellow; top of the head, upper part of the neck, back, wings, and **tail-coverts**, brown—the base of many of the feathers white, which, extending beyond the edge of the feather immediately above it, causes a white spot or mark; **primaries and tail-feathers** light-brown, barred transversely with darker brown; under surface of the neck, body, wing-coverts, and thighs, greyish-white, barred transversely with brown; under surface of the wing and tail-feathers of the same colour, but the light and dark bars much broader; the first six wing-primaries emarginated; the fourth and fifth tail-feathers equal and the longest, the first quill-feather

the shortest; **legs and toes** yellow; **claws** long, curved, sharp, and black.

Young Male.—Resembles the female; but the brown feathers of the back and the wing-coverts are edged with reddish-brown; feathers of the tail reddish-brown, particularly toward the base, with three conspicuous dark-brown transverse bands. In other particulars like the female: both have a collar formed by a mixture of white and brown, which extends from the sides of the neck to the nape. (Yarrell.)

Habits, Food, Reproduction.—Haunts, wooded districts. The great enemy of small quadrupeds and birds, and often very destructive to young chicks in poultry-yards in the breeding season. Used in falconry; the best of all hawks for landrails. (Sebright.) **Nest.** The *Sparrow-hawk* generally takes possession of some old or deserted nest in a tree, most frequently that of the crow, in which the female deposits four or five eggs, each about one inch seven lines long, by one inch four lines broad, of a pale bluish-white, blotched and spotted with dark-brown. The young are covered with a delicate and pure white down, and are abundantly supplied with food. Mr. Selby mentions having found a nest of five young sparrow-hawks, which contained besides, a lapwing, two blackbirds, one thrush, and two green linnets, recently killed, and partly divested of their feathers. (Yarrell.)

Locality.—Spread throughout Europe, Japan (Temminck), Smyrna (Mr. Strickland), Denmark, Sweden, Norway, Russia, and from thence southward over the European continent to Spain and Italy. Common in most of the counties of England, and has been observed in the west and north of Ireland; occurs also in Scotland and its northern islands. (Yarrell.) Very common, migratory, near Rome. (Bonaparte.)

Head and foot of *Accipiter fringillarius*

The form is widely spread. Col. Sykes records *Accipitres Dukhunensis* (resembling *A. fringillarius*, but differing in certain points), and *Dussumieri* among the birds of the Dukhun (Deccan). In the South African Museum will be found *Accipitres polyzonus*, *polyzonoides*, *niger*, *Gubar*, *Tachiro*, *minulus*, and *rufiventris*.

Mr. Vigors remarks that there are some species which seem to be allied to this sub-family and to be intermediate between it and the succeeding sub-family of *Falcons*, which, from some peculiarities of character, cannot well be appended

to any established genus. They possess, he observes, a shortness of wing which would incline us to refer them to some of the present groups: but their upper mandible, strongly and doubly dentated, presents a character that will not admit of their being included in any of the foregoing genera, in which the mandibles are entire, or where the place of the tooth is supplied by a rounded prominence. These species Mr. Vigors would have wished to arrange in one genus: but they are found to differ in essential points which bring them respectively within the pale of the two conterminous sub-families now under consideration; and he feels obliged, for the sake of perspicuity, to adopt the following genus of which the type is *Falco bidentatus* of Latham.

Harpagus. (Vigors. *Bidens** of Spix.)

Beak short. Upper *mandible* strongly bidentated, lower with a double notch. *Tarsi* moderate. *Acrotarsia* scutellated. Third and fourth *quills* longest, equal.

Mr. Vigors observes that the essential characteristic of this group is the double tooth on both the upper and lower mandible. The wings, which correspond with those of the other *Hawks*, in being one-third shorter than the tail, have the third and fourth quill feathers, which are the longest, of equal length. The *tarsi* are of moderate length and strength, and have the *acrotarsia* scutellated as in the latter groups of the present sub-family. The *nostrils* are of a semicircular form and the *cere* is naked.

Example, *Harpagus bidentatus*. Locality, Brazil, and Guiana.

Description.—Length, a foot and some lines (French). Slate-colour above; *throat* white; *breast* and *belly* red, undulated with yellowish; lower coverts of the *tail* white; *tail* nearly equal, brownish, barred with whitish.

Head and foot of *Harpagus bidentatus*.

Mr. Vigors remarks that *Falco Diodon* of Temminck is to be referred to this genus.*

Gampsonyx. (Vigors.)

Beak short, *mandibles* entire. *Nostrils* rounded. *Wings* short, second *quill* longest, third generally equal to the second, and internal web of the first and second strongly notched near the apex. *Tail* moderate, equal. *Feet* moderate; *tarsi* reticulated, *acrotarsia* feathered below the knee to the middle. (Vigors.)

'The genus is founded on a small and beautiful *Hawk*,' writes Mr. Vigors in 'The Zoological Journal,' vol. ii., 'which has been kindly submitted to my inspection by Mr. Swainson, one of the fruits of that gentleman's extensive researches in Brazil. This bird decidedly belongs to the *Accipitrine* sub-family of the *Falconidae*; but it is placed at that remote extremity of it, where the species, gradually approaching the *Falcons*, partially assume some of their leading characters. It possesses the bill of the *Hawks*, and also the shortness of wing which so strongly characterizes them: but the structure of the wing itself is the same as in *Falco*, the second quill-feather being the longest, and the first and second of these feathers being marked on the inner web by an abrupt emargination near the apex; while the *tarsi* also display the character of the same group in having the *acrotarsia* reticulated. The bird thus exhibits a striking modification of form, at once partaking of the chief of the respective characters of both the *Hawks* and *Falcons*; with the former of which it may in addition be

* Mr. Vigors observes that the term *Bidens* is appropriated to Botany, and is under Linnæan genus.

† For the description of Mr. Swainson's genus *Aviceda*, the reader is referred to the interesting work on the birds of Western Africa by that zoologist. *Naturalist's Library*, vol. vii. p. 104. *Aviceda cuculoides*, Cuckoo Falcon.

observed that it agrees in its general form, and with some of the latter, particularly the beautiful group of *Ierax cærulescens*, in its colours, and in the general distribution of them. To the latter group indeed it has a striking resemblance, and might perhaps be referred unconditionally to it, could we pass over the important character of the unnotched bill.'

Description of Gampsonyx Swainsonii. Above *caneraceous-black*, white beneath; *front*, *cheeks*, *sides* of the *abdomen*, and femoral feathers orange; a black spot on each side of the *breast*.

Beak black. Feathers of the *back* and *scapulars* ashy-black, spotted with ferruginous. Lower *side* and *nuchal collar* white, sparingly variegated with orange. *Primaries* blackish, internally margined with white at the apex; *secondaries*, sparingly sprinkled with ferruginous, beneath white. *Tail-feathers* ashy-black, internally (the middle excepted) margined with white, beneath white. *Feet* yellow, *claws* black. Length of the body 9½ inches. (Vigors.)

Locality, Brazil. Mr. Vigors says that the following MS. note was appended to this bird in Mr. Swainson's handwriting:—'The only individual of this species I ever met with was shot on the Table Land, about 10 leagues in the interior of Bahia, in a direction west-south-west from the bay of St. Salvador. It was perched on the trunk of a withered tree, apparently watching some small birds. The *tarsi* are bright and the *irides* hazel.'

3rd. Sub-family, *Falconina* (Falcon).

Beak short, hooked from the base. *Wings* long. Second *quill* longest.

Mr. Vigors observes that this, closely allied to *Harpagus* by the double tooth on its upper mandible, is another group for which he proposes the name of

*Ierax** (Vigors.)

Beak short, upper *mandible* strongly bidentated, lower simply notched. *Tarsi* moderate. *Acrotarsia* scutellated. *Wings* short. Second *quill* longest, slightly notched near the apex.

Ierax cærulescens.

'Whoever,' writes Mr. Vigors, 'has seen that beautiful species, the smallest of its race, *Falco cærulescens* of Linnæus, now rendered familiar to us by the accurate and splendid illustrations of Dr. Horsfield, will at once acknowledge its separation from every other established genus of the family. Its upper mandible is strongly and sharply bidentated, as in *Harpagus*, but the under mandible is simply notched as in the true *Falcons*. Its wings, shorter than the tail, differ also from those of *Harpagus*, in having the second quill-feather the longest, thus again establishing the affinity of the genus to the *Falcons*. The *tarsi* are moderate, and the *acrotarsia* scutellated as in the latter group of *Hawks*. From its thus possessing characters in common with both sub-families, it is difficult to say to which we should refer

* *Ierax*, *Agouti*.

it. But I prefer placing it in its present situation on account of the length of the second quill-feather, a peculiarity which distinguishes the true *Falcons*, and gives a striking character to their flight. Placed, however, at the extremity of the division, it preserves its affinity with those that went before.

Description.—*Hierax caerulescens* is, according to Dr. Horsfield, the *Allap*, or *Allap-allap* of the Javanese; *Falco caerulescens* of Linnaeus; *F. Bengalensis* of Brisson; *Falco parvus Indicus* Ger. Orn.; *Little black and orange Indian Hawk* of Edwards; and the *Bengal Falcon* of Latham. Entire length six inches and a half. Upper parts bluish-black and glossy. Throat, breast, axillæ, sides of the neck, forehead, and a line continued from the environs of the bill over the eye and along the neck, white, with a ferruginous tail. Lower part of the breast, abdomen, vent and thighs, ferruginous. Hypochondria, thighs posteriorly, and a broad patch extending from the eye along the side of the head, black; the plumes which cover the thighs behind are terminated by long silky filaments, or radii which are straggling and pendulous, and by their laxity and irregularity afford a peculiar character to the bird. (Horsfield.) The natives told Dr. Horsfield that this small but robust bird was uncommonly bold in the pursuit of little birds. Several individuals were brought to him from the range of the southern hills, which are covered with forests, during his abode at Suakarta. He obtained one in the eastern districts. In the other parts of the Island of Java he did not observe it. Bengal is also given as its locality.

Head and foot of *Hierax caerulescens*.

Mr. Vigers (Zool. Proc. 1831) describes another species, *Hierax erythrogenys*, the size of *H. caerulescens*, from the neighbourhood of Manilla.

Falco.

Beak short. Upper mandible strongly toothed; lower notched. *Acrotaria* reticulated. Second quill longest; first and second deeply notched internally near the apex.

This genus, which includes, as Mr. Vigers observes, the greater portion of the present sub-family, comprises the typical species. 'The upper mandible of this group,' writes that zoologist, 'is armed with a strong angular tooth; the lower is notched near the extremity. The *nares* are rounded. The wings are for the most part as long as the tail, the second quill-feathers being invariably the longest. The first and second quill-feathers are also distinguished by an abrupt emargination on the inner web near the extremity. In some species, as in *F. peregrinus*, the emargination of the second quill-feather is not so abrupt as in others. But in all the species of the true *Falcons* that have come under my examination, this emargination of the first quill-feather at least is strongly apparent. The *tarsi* are moderate in length and strength, and have the *acrotaria* reticulated. Our European species, *F. peregrinus*, Linn., *F. subbuteo*, Linn., *F. Asalon*, Linn., *F. rustipes*, Bechst., are readily distinguished as belonging to this typical genus. Some species belonging to the group have the wings somewhat shorter than the tail, which, in conjunction with *terax*, thus evince a gradual series of affinity between the short and long-winged tribes. Among these we may distinguish *F. tinnunculus*, Linn.: *F. rupicolus*, Daud.; with some corresponding species.' Example, *Falco peregrinus*.

Description.—The Peregrine Falcon is *Le Faucon pelerin* of the French; *Sparviere pellegrino* and *Falco reale* of the Italians; *Wander Falke* of the Germans; *Apetæ-kæoo* (Little Eagle) of the Cree Indians; *Hebog tramor* and *Cammin* of the antient British.

Adult.—Length from 15 to 18 inches, depending on the sex and age of the bird. **Beak** blue, approaching to black

at the point; *cere* and *eyelids* yellow, *irides* dark hazel-brown; top of the *head*, back of the *neck*, and a spot below the eye nearly black; *back* and upper surface bluish-slate or ash colour, becoming lighter at every succeeding moult; the males usually the most so; feathers of *back*, *wing-coverts*, and *tail* barred with a darker tint; *primaries* brownish black, inner webs barred and spotted with rufous white; front of *neck* white, with dark longitudinal lines; *breast* rufous white, with dark-brown transverse bars; *flanks*, under *tail-coverts*, and under surface of the *tail-feathers* barred transversely with dark-brown and greyish-white; *legs* and *toes* yellow, *claws* black.

Young.—**Head** and upper surface of *body* and *wing-coverts* brownish ash, the edge of each feather rufous; the dark longitudinal streaks on the white under-side of the body more conspicuous, but, gradually shortening and spreading laterally, they ultimately change their direction, and become transverse. This change is first observed on the belly and flanks. (Yarrell.)

Temminck considers the *Lanier* (Lanner) of Buffon the perfect state of the male *Peregrine*. He also adds *Falco Barbarus* of Latham as one of its synonyms.

Habits, Food, Reproduction.—The food of the Peregrine consists of land and water-fowl, rabbits, young hares, &c. It was highly prized in falconry. Turberville, in his chapter 'Of the Haggart Falcon, and why she is called the Peregrine or Haggart,' gives the following reasons for the name: 'First, because a man cannot find, nor ever yet did any man, Christian or Heathen, find their eyrie in any region; so as it may well be thought, that for that occasion they have achieved and gotten that name and terme of Peregrine or Haggart Falcons, as if a man would call them pilgrims or forainers. The second cause is, because these falcons do range and wander more then any other sort of falcons are wont to doe, seeking out more strange and uncouth countries, which indeed may give them that title of Haggart and Peregrine Hawks for their excellency, because they doe seeke so many strange and forraigne coasts, and doe range so farre abroad. The third and last cause, I doe thinke, may be their beauty and excellency, because this word (*Peregrino*), or Peregrine, doth many times import an honourable and choise matter had in great regard. . . . Wherefore I conclude that these Haggart Falcons are not of Italie, but transported and brought thither from forraigne places, as, namely, from Alexandria, Ciprus, and Candie. And yet this is for certain, that in Italie there are taken of these Haggart Falcons, as in the dominion of the renowned duke of Ferrara and in the countrie near Ravenna, being brought thither by force of weather and wind. And by that means there are none of those Haggarts found Eyesees, but they are al either soare Hawks or mewed Haggarts.'

'In the language of falconry,' writes Yarrell, 'the female Peregrine is exclusively called the Falcon, and on account of her greater size, power, and courage, is usually flown at herons and ducks; the male Peregrine, being smaller, sometimes one-third less than the female, is called the Tercel, Tiercel, and Tiercelet, and is more frequently flown at partridges, and sometimes at magpies. Young Peregrines of the year, on account of the red tinge of their plumage, are called, the female a red falcon, and the male a red tiercel, to distinguish them from older birds, which are called Haggards or intermewed Hawks. The Lanner of Pennant is a young female Peregrine, at which age it bears some resemblance to the true Lanner, *Falco lanarius* of authors—a true falcon also, but much more rare than the Peregrine, and which probably has never been killed in this country. Mr. Gould says he was unable to find a specimen in any collection here, either public or private, at the time he was desirous of figuring this species in his birds of Europe. The true Lanner is only found in the south and south-eastern parts of Europe. The king of France, Louis XVI., had Lanners sent annually from Malta; but they were brought from the eastern countries. It exceeds the Peregrine Falcon in size, being intermediate between that and the Gyr-falcon; was much esteemed for flying at the kite, with which the Peregrine is hardly able to contend.' The name of Lanner is confined to the female. The male is called a Lanneret, on account of his smaller size. (*British Birds*.) Our limits will not allow us to enter into any account of the mode of flying it at herons, &c., flying at the brook or at the river, as it was antiently called; and we must refer the reader to Turberville, among

the old writers, and to Sir John Sebright as the best of the modern authors on the subject. (See Sir John's *Observations on Hawking.*) *Nest.*—On high rocks. In Britain, Mr. Yarrell states that the Peregrine builds on various parts of the coast, more frequently in Scotland than in England. The eggs are from two to four in number, about two inches long by one inch and eight lines in breadth, mottled all over with pale reddish brown. Mr. Selby notices their eyrie at St. Abb's Head. It was from this locality that the late Mr. Baird of Newbyth usually obtained his cast of Hawks, for each of which he gave the persons who undertook the peril of climbing the rock one guinea. Other localities for the nest in Britain are the cliffs between Freshwater Gate and the lighthouse near the Needles. Devonshire and Cornwall, where it is called *Cliff Hawk*. Holyhead and the Great Orme's Head. (Yarrell.) Rocky coast of Caernarvonshire. (Pennant.) Rocky situations inland and marine in Ireland. (Thompson quoted by Yarrell.) Vale of Moffat in Dumfriesshire, the Bass Rock, and the Isle of May, in the Forth. (Sir Wm. Jardine.)

Localities.—All the mountainous countries of Europe, particularly on rocks; very rare in champaign countries; never found in marshy districts; abundant in Germany and France; sufficiently common in England and Holland; rare in Switzerland. (Temminck.) Shetland Isles, where it breeds; Denmark, Sweden, Norway, Lapland, and Greenland. (Yarrell.) Uralian and Siberian mountains. (Pennant.) Dr. Richardson, who describes an old male from Melville Peninsula, lat. 68° N., says (*Fauna Boreali-Americana*), 'The Peregrine being a rare bird in the wooded districts of the fur countries where the trading posts are established, I did not procure a specimen on the late expeditions; but I have frequently seen it whilst on the march across the Barren Grounds. Of the two specimens figured by Edwards, one was from Hudson's Bay and the other was caught off the entrance of Hudson's Straits. Captain Parry likewise brought home several male and female specimens from Melville Peninsula, some of which are preserved in the British Museum. It is a summer visitor of the northern parts of America, and frequents the coasts of Hudson's Bay and the Arctic Sea, with the Barren Grounds, but is very seldom seen in the interior. It preys habitually on the long-tailed ducks (*Anas glacialis*), which breed in great numbers in the Arctic regions, arriving in June and departing in September. Captain Parry observed it, in his second voyage, following flocks of the snow-bunting on the coast of Greenland, near Cape Farewell. It frequents the shores of New Jersey and Pennsylvania in the winter, and is celebrated there for the havoc it makes

among the water-fowl. Mr. Ord states that the ducks which are struck by it are lacerated from the neck to the rump; it gives the blow in passing, and returns to pick up its bird.' Port Famine, straits of Magalhaens. (Captain King.) New Holland. (Vigors and Horsfield.) Cape of Good Hope. (Dr. A. Smith.) Prince Bonaparte notes it as rare, and as seen only in winter near Rome, and as rare and casual near Philadelphia. Dr. Smith (*South African Museum*, No. 94) says that the bird so numbered, though it does not exhibit exactly the plumage of the Peregrine Hawk of Europe, yet approaches it so closely, that it might be considered as attempting too great a refinement to class it as a different species.

Mr. Vigors observes that Cuvier has separated the *Falco Islandicus* of Latham from the rest of the true *Falcons*, under the generic title of *Hierofalco*, which he characterizes as possessing no tooth on the upper mandible, but a rounded prominence in the centre, and in which he observes that the wings considerably fall short of the tail in length. In this opinion Mr. Vigors does not acquiesce. He cites examples of the Jerfalcon in its different stages of growth, and in none did he perceive any material difference between its bill and that of the true *Falcons*. He adds that he feels much hesitation in advancing the above opinion, not merely on account of the known accuracy of Cuvier, but on account of some facts that had then lately come to his knowledge. He mentions a specimen in the British Museum, in which the mandible accords exactly with Cuvier's description—'Il n'a qu'un feston comme celui des ignobles.' In several specimens from the arctic regions, however, in the same collection, he found the tooth. After referring to the figures quoted by Cuvier, and their discrepancies, he inquires whether it may not be possible that there are two species. He cannot think that the character itself is variable, or that Cuvier would have adopted one which must have been known to him as such, even from the plates. 'In no specimen of a true falcon,' says Mr. Vigors, 'have I seen the slightest alteration of the tooth, except by accident.'

Our limits will not permit us to do more than hint at the other species of *Falco*. *F. chicquera*, Himalaya Mountains (Gould), Deccan (Sykes), South Africa (Smith), seems to be the nearest in typical points to the Peregrine Falcon. The following *Falcons*, besides *F. peregrinus* and *F. chicquera*, are in the catalogue of the South African Museum; *biarmicus*, *rusticolus*, *rusticoloides*, *subbuteo*, and *Straussii*: *F. tinnunculus*, the *Kestrel*, inhabits Asia and Africa, as well as Europe, and is very abundant in the Dukhwa (Deccan). (Sykes, Abbott.)

4th. Sub-family, *Buteonina* (Buzzards).

Beak moderate, hooked from the base. *Tail* equal.

The sub-family of the *Buzzards* agrees, in the opinion of Mr. Vigors, with the last in the length of the wings, and the bill being bent from the base, and differs from it by a weaker and somewhat more elongated bill, by the third or fourth quill-feather being longest, and more particularly by the absence of a tooth on the upper mandible. A gradation seems, however, as Mr. Vigors observes, to soften down these differences, and there is an approximation to the teeth of the falcons in the first genus of the sub-family.

Ictinia (Vieillot).

Beak short. Upper mandible subdentated, lower notched. *Tarsi* short and weak. *Acrotarsia* scutellated. *Wings* long. Third quill longest.

Mr. Vigors states that this genus is founded upon the *Milan Cresserale* of M. Vieillot, and has a strong and short bill, the upper mandible of which is somewhat angularly festooned, and the under distinctly notched. The *nares* are rounded as in the *Falcons*; the *tarsi* are rather short and feathered below the knees, and the *acrotarsia* scutellated. The wings are of considerable length, extending far beyond the tail; a character which induced M. Vieillot and others to place the bird near the *Kites*. Its strong affinity however to the last sub-family, of which it possesses so many of the characteristics, inclines Mr. Vigors to assign it its present situation. In manners, he adds, it seems also to approach the falcons; and he remarks that if we consider the *Mississippi Kite* of Wilson to belong to the present group of Vieillot, of which Mr. Vigors has little doubt, we must attribute to the bird before us, judging from the interesting description in the *American Ornithology*, much of those

Falco peregrinus

spirited and generous qualities which we admire in the typical groups of the family.

Example, *Ictinia plumbea*. (*Falco plumbeus* of Latham.)

Description.—Back and wings slate-blue; head and belly whitish, spotted with brown. Iris fine red.

Habits.—Said to fly to a great height, where it remains a long time poised or stationary, and cleaves the air with rapidity in order to seize the great insects which are its prey, independently of reptiles and birds.

Locality, America.

Head and foot of *Ictinia plumbea*.

Circus (of Authors).

Beak moderate. **Nostrils** sub-oval. **Tarsi** elongated. **Acrotarsia** scutellated. **Toes** generally short. Third **quill** longest. Sides of the **head** furnished with a circle of feathers, very like the capital disk of the owls.

This genus, says Mr. Vigors, exhibits still a slight approximation to the last groups in the structure of the upper mandible, which has a rounded protuberance towards the middle, similar to that of the *Hawks*. They are distinguished from the rest of the buzzards by their elevated and slender **tarsi**, which are covered with feathers for some space below the knees, and of which the **acrotarsia** are scutellated. The **nares** are sub-oval and transverse on the cere, and the third quill-feathers are the longest. It includes, according to Mr. Vigors, the European species *F. æruginosus* of Aldrovandus, and *F. pygargus* of Linnæus, to which, he says, may be added, *F. acoli* and *F. melanoleucos* of Daudin, together with some newly described species.

Example, *Circus æruginosus*.

Description.—This is the Harpaye, Busard Harpaye, and *Husard de Marais* of the French; *Falco castagnolo* and *Falco con la testa bianca* (young birds), *Falco albonella con il collare* (old), of the Italians; *Schwartz-bräuner*, *Fisch Geyer mit dem gelben Kopf*, *Brauner rohr Geyer*, *Brandweihe*, *Wasserweihe*, and *Sumpfweihe*, of the Germans; *Moor-Buzzard*, *Marsh-Harrier*, *Duck-Hawk*, *Harpy*, and *White-headed Harpy* of the modern, and *Bod y gwerri*, of the antient British.

Adult Male (third moult).—**Beak** bluish black, with a slight festoon on the cutting edge; **cere** and **irides** yellow; top of the **head**, **cheeks**, and **nape** of the neck, yellowish white, tinged with rufous and streaked with dark brown; **back**, **wing-coverts**, and **tertials**, dark reddish brown with lighter margins; **primaries** brownish black; **secondaries** and **tail feathers** ash-grey.

After the third moult.—**Wing-coverts** and **tertials** become in addition, partially or entirely ash-grey; **wing primaries** slate grey; **chin** and **throat** nearly white; **breast** rufous, streaked longitudinally with dark brown; **belly**, **thighs**, and under **tail-coverts** reddish-brown, each feather streaked with dark brown; **legs** long, slender, and yellow; **toes** yellow; **claws** sharp and black.

Second year.—**Head**, **neck**, **chin**, and **throat** dull yellow, with an occasional patch of the same colour on the carpus, or anterior point of the wing. (Bewick's figure.)

Young of the year.—All the plumage chocolate brown; feathers tipped with lighter reddish brown; irides darker than in the adult; legs and feet as in old birds. Length from twenty-one to twenty-three inches, depending on the sex. (Yarrell.)

Habits.—**Food.**—**Reproduction.**—The moor-buzzard, when in pursuit of game, flies low, and will, so to speak, beat a moor, or other piece of ground, with the regularity almost of a well-trained pointer. Young rabbits, small quadrupeds, birds, especially water-birds, reptiles, and even fish, are its prey. Sometimes it will sit on the look-out on

a stone or low bush. **Nest.**—Generally on the ground, in a tuft of rushes, or coarse grass, or furze, and composed of rushes, or rank grass, and small sticks. Latham says that it will sometimes build its nest in the fork of a large tree, but that the instance is rare. Eggs, three or four, oval, rather pointed at one end, two inches and one line in length, one inch six lines in breadth (Yarrell).

Locality.—Denmark, Norway, Sweden, south of Russia, Germany, France, Holland, Spain, Italy, Turkey. In all countries where there are marshes, very abundant in Holland; rare in the south, migratory in the autumn (Temminck); common in the marshes near Rome, but only young birds, and migratory (Bonaparte); Trebizond (Abbott), Ganges, between Calcutta and Benares, &c. (James Franklin). Europe, India, Africa (Gould). Smyrna (Strickland).

The *Moor Buzzard* may be seen in most parts of England and Wales favourable to its habits. It occurs in Scotland and the Hebrides, and Mr. Thompson notes it as existing in several counties of Ireland from Cork to Antrim.

Mr. Vigors observes that the sub-family of *Buzzards* is that which of all the *Falconideæ* approaches nearest to the family of the owls (*Strigideæ*). In their dull and slothful habits, their heavy flight, and indeed their whole appearance, these contiguous groups evince, he remarks, a general resemblance indicating a corresponding inferiority in the qualities which distinguish the birds of prey. The soft and loose texture of the plumage of both presents a similar affinity, and he adds that *Circus*, in particular, furnishes us with a still further and more intimate point of resemblance. The feathers that cover the cheeks and ears form, as he says, a sort of rounded collar that rises on each side of the face; thus exhibiting a conformity to the disk, or circular erection of the face-feathers so conspicuous in the owls.

Circus æruginosus.
